Infoblox NIOS 8.6.x Documentation

07/11/2023

Contents

What's New

The NIOS 8.6 release includes the following new features and enhancements:

Bypassing Subscriber Secure Policy for Allowed Lists (RFE-11652)

NIOS 8.6.3 introduces the **Enable Subscriber Secure Policy Bypass for Allowed list** and the **Set Global Allow List RPZ index range (0 to 30)** options in which subscriber specific allow domains take priority over category based policies (content-filtering), security policies and blocklist entries. Subscriber specific block domains take priority only over category-based policies (content-filtering).

The **Enable Subscriber Secure Policy Bypass for Allowed list** checkbox enables NIOS to generate a normal response for all domains in a subscriber's allowed list. Allowed domains will override RPZ rules if any (for example, NXDOMAIN), and categorization policy rules for the subscriber. This enables subscribers to override all policies for a specific domain. The Set Global Allow List RPZ index range (0 to 30) checkbox adds a domain to an RPZ specified as a passthru RPZ rule, and that domain is also added as a global allowed list. NIOS 8.6.3 also introduces a new report called *Daily Report on Subscriber Information and DNS Queries matching with ABLs* that displays the overall subscriber information and DNS domain queries that match the queried domains in the allow and block lists. For more information about these options, see the *Scaling Subscriber Sites* topic in the NIOS 8.6 online documentation.

Validating Certificates (SPTYRFE-52)

NIOS 8.6.3 introduces the **Grid** > **Certificates** > **Validate Certificates** option that validates all certificate uploaded using the Manage Certificates option and also validates DNS Traffic Control HTTPS health monitor certificates. It displays the certificates to be either valid, invalid, or expired. It displays warning messages for expired certificates and for certificates with no SKI (Subject Key Identifier). For more information, see the *Validating Certificates* topic in the NIOS 8.6 online documentation.

ZVELO Category Database Update Failure Changes (RFE-12140)

If a ZVELO category database update failure occurs for three consecutive days:

- Grid Manager displays a yellow background with the "Please correct the download credentials or the proxy configuration to get the latest database updates" message and the member status is displayed as "Domain category db is not latest" in the **Grid Manager** > **Subscriber Collection** > **Services** > **Service Status** column.
- A new SNMP trap is sent with the message "Domain category db is not latest". Additionally, if email notifications are configured, an email is sent to the configured email address with the "Domain category db is not latest" message.
- Post this event, if the ZVELO download is successful, a new SNMP clear trap is sent, and an email with the "zvelo SNMP Clear Trap" message is also sent. The Service Status column has a green background and the "Subscriber service is working" message is displayed.

If a ZVELO category database update failure occurs for more than 60 days:

- Grid Manager displays a red background with the "zvelo database expired. Subscriber secure queries will be fail-open." message and the member status is displayed as "zvelo db has expired" in the **Grid Manager** > **Subscriber Collection** > **Services** > **Service Status** column.
- A new SNMP trap is sent with the "zvelo db has expired" message. Additionally, if email notifications are configured, an email is sent to the configured email address, with the "zvelo db has expired" message.
- Post this event, if the zvelo download is successful, a new SNMP clear trap is sent, and an email with the "zvelo SNMP Clear Trap" message is also sent. The Service Status column has green background and the "Subscriber service is working" message is displayed.

Support for Network Insight on the AWS and Microsoft Azure Public Cloud (RFE-10248)

Starting from NIOS 8.6.3, deployment of Network Insight appliances on Microsoft Azure and AWS public cloud is supported. You can use the discovery feature to detect devices in your network and manage device data from Grid Manager.

Filtering Options for vDiscovery

Starting from NIOS 8.6.3, you can configure vDiscovery jobs with CIDR-based filters to limit vDiscovery only to configured networks or to skip vDiscovery from excluded networks. For more information, see the *Configuring vDiscovery Jobs* topic in the the NIOS 8.6 online documentation.

Infoblox BloxConnect Changes

From NIOS 8.6.3 onwards, the Infoblox BloxConnect screen that appears when you first log in to Grid Manager will no longer be displayed. To better enhance the NIOS customer experience and for Infoblox to proactively respond to customer issues in a timely manner, BloxConnect data will be collected by default and the same data will be included in the support bundle. For information about the data collected, see *https://insights.infoblox.com/resources-datasheets/infoblox-datasheet-infoblox-bloxconnect*.

Synchronizing Amazon Route 53 Data from Multiple AWS Accounts (RFE-9382)

vNIOS for AWS is integrated with Amazon Route 53. You can now discover and synchronize Amazon Route 53 DNS data from multiple AWS accounts of an AWS organization to NIOS using a single NIOS admin account. For more information, see the Amazon Route 53 topic in the *Installation Guide for vNIOS for AWS* at *https://docs.infoblox.com*.

Support for Route 53 Integration on AWS GOV Cloud (RFE-11806)

Starting from NIOS 8.6.3, the vNIOS for AWS Route 53 integration is supported on AWS GOVCloud. For more information, see the Amazon Route 53 topic in the *Installation Guide for vNIOS for AWS* at *https://docs.infoblox.com*.

Support for Amazon EC2 R6i Instance Type (RFE-12312)

vNIOS for AWS instances running on NIOS 8.6.3 or later can be deployed on Amazon EC2 R6i instance types. For information about supported EC2 shapes and models, see the Infoblox vNIOS for AWS AMI Shapes and Regions topic in the *Installation Guide for vNIOS for AWS* at *https://docs.infoblox.com*.

Connecting to the Serial Console of an Amazon EC2 Instance (RFE-11803)

You can now connect to the serial console of a vNIOS for AWS EC2 instance that is deployed on an R6i instance type for troubleshooting purposes. For more information, see the Provisioning vNIOS for AWS Using the BYOL Model topic in the *Installation Guide for vNIOS* for AWS at *https://docs.infoblox.com*.

Support for EBS Encryption (RFE-11931)

vNIOS for AWS instances running on NIOS 8.6.3 or later versions of 8.6.x, support encryption of Amazon Elastic Block Storage volumes. For more information, see the For more information, see the Provisioning vNIOS for AWS Using the BYOL Model topic in the *Installation Guide for vNIOS for AWS* at *https://docs.infoblox.com*.

Enabling the SHA1 Encryption Algorithm for the NTP Key (RFE-8178)

In NIOS 8.6.3, you can add the SHA1 NTP authentication key before enabling the NTP service on the Grid. The key is a 40 character hexadecimal string and it uses a hash-based symmetric encryption algorithm. For more information, see the *Using NTP for Time Settings* topic in the NIOS 8.6 online documentation.

Exporting to CSV Before Deleting a Network (RFE-11846)

NIOS 8.6.3 introduces the **Export & Delete** button that allows you to export the network data into a CSV file before deleting a network. For more information, see the Exporting and Deleting Networks section in the *Configuring IPv4 Networks* topic in the NIOS 8.6 online documentation.

Reconnecting Groups After a Grid Master Candidate Promotion (RFE-4753)

In NIOS 8.6.3, you can reconnect groups after a Grid Master Candidate promotion thus giving you more control over the promotion and minimizing service outages by allowing you to group Grid members and schedule a time for the groups to reconnect to the newly promoted Grid Master. As soon as the scheduled time arrives, members of Grid Master Candidate groups reconnect to the newly promoted master. You can do this by using the **Activate GMC Group Promotion Schedule** option in the *GMC Group Promotion Schedule* editor. For more information, see the *Managing a Grid* topic in the NIOS 8.6 online documentation.

Device Handling Performance Optimization for NIOS Subscriber Cache (RFE-12397)

Device handling performance optimization optimizes the use of NIOS subscriber cache by updating only the provisioned devices to NIOS thereby reducing the number of devices delivered to the NIOS cache. For more information, see the **Device Handling Performance Optimization for NIOS Subscriber Cache** section in the *Infoblox Subscriber Insight and Subscriber Policy Enforcement* topic in the NIOS 8.6 online documentation.

Improvements in Internal Cache Handling (RFE-12003)

Fast replication now does not take place for all subscriber site members; instead, it takes place from a single member with a full cache thus greatly improving cache handling.

Discovering Juniper Mist Devices

You can now discover Juniper Mist devices using Network Insight. For more information, see the *Configuring Discovery for SDN and SD-WAN* topic in the NIOS 8.6 online documentation.

SHA-512 and SHA-256 Support in Network Insight (RFE-12053)

Network Insight now supports the SHA-512 and SHA-256 algorithms for SNMP polling.

AES-256 Support for SNMPv3 Authentication (RFE-10304)

From NIOS 8.6.3 onwards, the AES-256 encryption is supported for SNMPv3 authentication in Network Insight.

Converting Real-Time Alerts to Scheduled Alerts (RFE-12594)

In NIOS 8.6.3, alert types in NIOS Reporting for the new device discovery alert, security alert, and category alert have been converted from *Real-time" to "Scheduled*.

Enhancements in the DNS Object Count Trend and FLEX Grid Licensing Features Enabled Reports (RFE-11909)

In NIOS 8.6.3, certain changes have been implemented to the following reports:

- Managed DDI features enabled
- SPLA Grid Licensing Features Enabled
- Managed DDI Peak IP Usage Trend
- Managed Trend DNS Peak Usage
- DNS Effective Peak Usage Trend for SPLA Grid License

Changes to these reports include:

- All of these reports now also support non -IB-FLEX appliances.
- All of these reports have the **Members" and the "Reporting SPLA** filters.
- If you want to include a Grid member that does not have an extensible attribute in these reports, you must set the Reporting SPLA extensible attribute to **Managed IB-FLEX' or 'Managed HW/SW** depending on the Grid member type, and the Grid license must be **flex_grid_ms**.

Support for Microsoft Server 2022 (RFE-12246)

NIOS 8.6.3 supports Microsoft Server 2022.

Support for VMware ESXi 7.0.x (RFE-12555)

vNIOS for VMware is now supported on VMware ESX or ESXi versions 7.0.2 and 7.0.3.

Support for Nutanix AOS 6.x LTS (RFE-12650)

vNIOS for Nutanix™ AHV is now supported on NIOS 8.6.3, NIOS 8.6.2, and NIOS 8.5.5. For more information, see the *Infoblox Installation Guide vNIOS for Nutanix AHV* at *https://docs.infoblox.com*.

IB-FLEX Support for Nutanix AHV (RFE-12601)

vNIOS for Nutanix™ AHV is now supported on IB-FLEX appliances. For more information, see the *Infoblox Installation Guide vNIOS for Nutanix AHV* at *https://docs.infoblox.com*.

Virtual Advanced DNS Protection Software and Virtual DNS Cache Acceleration Support in vNIOS for Nutanix (RFE-12615)

vNIOS for Nutanix now supports virtual Advanced DNS Protection Software (vADP).

DHCP, IPv6, and HA Support in vNIOS for Red Hat OpenShift (RFE-12835)

vNIOS for Red Hat OpenShift can now manage DHCP, IPv6, and HA configurations. For more information, see the *Infoblox Installation Guide vNIOS for Red Hat OpenShift* at *https://docs.infoblox.com*.

Support for Upgraded Splunk Version 8.2.10

NIOS 8.6.3 supports Splunk version 8.2.10.

NIOS Enhancements to Support Consolidated Hotfixes

NIOS 8.6.3 introduces new enhancements to the implementation of hotfixes. NIOS 8.6.3 introduces the manifest file that is generated after the hotfix is successfully applied. The manifest file contains key details such as affected files, RPMs installed, and the best suggested action to activate changes. NIOS 8.6.3 also introduces CLI support to view the best suggested action to activate hotfix changes in the Grid member and to support the download of manifest files using WAPI and support bundles.

Enabling and Disabling DNS Traffic Control Objects (RFE-7088)

NIOS 8.6.2 introduces the *Enable Traffic Management Objects* and the *Disable Traffic Management Objects* screens using which you can enable or disable individual DNS Traffic Control objects. You can also disable the health monitoring of a particular object to stop performing health checks. You can access the new screens from the **Traffic Control** panel on the **Data Management** > **DNS** > **Traffic Control** tab. For more information about enabling and disabling DNS Traffic Control objects, see the *Managing DNS Traffic Control Objects*.

Multi-Master DNS Failover for DDNS (RFE-5514)

In NIOS 8.6.2, if you have configured more than one Grid DNS primary server for DDNS updates for multi-master zones, DHCP servers use the first available DNS primary server that is configured. If the first DNS primary server is not reachable or is offline, then the DHCP servers reach for the next DNS primary server in the preferred multi-domain DDNS list and so on. You can add upto a maximum of three DNS primary nameservers for each zone.

Configuring Microsoft Servers and Delegated Name Servers (RFE-10168)

From NIOS 8.6.2 onwards, you will not be able to add a delegated name server group only if DNS synchronization is enabled on any Microsoft server configured in NIOS. You also cannot enable DNS synchronization for Microsoft servers in NIOS if delegated name servers are configured on them.

Support for Upgraded Splunk Version 8.2.4

NIOS 8.6.2 supports Splunk version 8.2.4.

vNIOS for Azure and vNIOS for AWS Support in IB-V5005 (RFE-7962)

IB-V5005 support is now extended to vNIOS for Azure and vNIOS for AWS. For detailed information see the *Infoblox Installation Guide for vNIOS for AWS* and the *Installation Guide for vNIOS for Microsoft Azure* available at *docs.infoblox.com*.

vNIOS for GCP Support in IB-V4015 and IB-V4025 (RFE-11349)

IB-V015 and IB-V4025 now support vNIOS for GCP. For detailed information see the *Infoblox Installation Guide for vNIOS for GCP at docs.infoblox.com*.

DHCP Support on vNIOS for GCP (RFE-9945)

vNIOS for GCP instances running on NIOS 8.6.2 offer DHCP services for on-premise networks. For more information see the *Infoblox Installation Guide for vNIOS for GCP at docs.infoblox.com*.

vNIOS for Nutanix AHV 5.20.3 (RFE-11997)

NIOS 8.6.2 supports the deployment of vNIOS on Nutanix AHV 5.20.3. For more details, see the *Infoblox Installation Guide vNIOS for Nutanix AHV at docs.infoblox.com*.

Enabling and Disabling BFD Internal DNS Monitoring (SPTYRFE-49)

NIOS 8.6.2 introduces a new checkbox called **BFD Internal DNS Monitoring** in the *Grid Member Properties* editor > **Anycast** tab. Selecting this checkbox enables the internal DNS monitor to send and receive DNS responses and to retract the OSPF or BGP route if it does not receive a DNS response.

You can enable or disable the **BFD Internal DNS Monitoring** checkbox only if you select the **Enable BFD** checkbox. When you enable the **BFD Internal DNS Monitoring** checkbox, you have the option to toggle between enabling or disabling the internal DNS monitor. When you select this checkbox, Infoblox recommends that you also select the **Enable DNS Health Check** checkbox in the *Grid Properties Editor* or the *Member Properties Editor*. The **BFD Internal DNS Monitoring** checkbox is enabled by default. For more information see the *About BFD*.

Support for Cisco ISE Integration Through Outbound Endpoint

NIOS 8.6.2 supports Cisco ISE versions 3.0 and 3.1. Infoblox recommends that you configure Cisco ISE 3.0 and 3.1 using the **Outbound Endpoint** tab. Cisco ISE version 3.1 (pxGrid 2.0) is supported only through the Cisco outbound endpoint. For more information see the *Configuring Outbound Endpoints*.

Enforcing the Global Proxy List

In NIOS 8.6.2, if you want to proxy the traffic through the MSP (Multi-Services Proxy) server and have categorized the queried domains in the incoming traffic to the global proxy list, then the query resolves to an MSP virtual IP address and NIOS generates a synthetic resolution. For more information, see the *Scaling Subscriber Sites*.

New DNSKEY Algorithm (RFE-6068 and RFE-9845)

You can now add the ECDSAP/SHA-256 and ECDSAP/SHA-384 cryptographic algorithms which the Grid Master can use when it generates the Key-Signing Key Rollover (KSK) and Zone-Signing Key Rollover (ZSK).

Extensible Attribute-based Topology Rulesets (RFE-9107 and RFE-11133)

You can now specify IPAM objects types, network containers, networks, ranges, and hosts and their External Attribute (EA) values in the **Extensible Attributes Source Types for Topology Rules** field to be used as source types when defining DNS Traffic Control topology rules. For more information, see the *Configuring DNS Traffic Control Properties*.

vNIOS Support for Microsoft Azure Stack Hub (RFE-8303)

You can now deploy the NIOS virtual appliance on Microsoft Azure Stack Hub. vNIOS for Microsoft Azure Stack Hub which is a hybrid cloud platform that enables a vNIOS appliance to deliver Azure services in an on-prem environment. You can deploy vNIOS for Azure Stack Hub instances from the Azure CLI or the Azure Stack Hub portal. For more information, see the vNIOS Infoblox Installation Guide for Microsoft Azure at *docs.infoblox.com*.

Health Status of DNS Traffic Control Objects in API Responses (RFE-9893)

The Grid Master Candidate now provides the health status of DNS Traffic Control objects such as servers, pools, and LBDNs through WAPI requests.

Regenerating the Anycast Password (RFE-11117)

This release of NIOS introduces the s `et regenerate_anycast_password` command that regenerates the anycast service password. The regenerated 8-character alphanumeric password is saved to the NIOS database and is used across all anycast configuration files (ospf.conf/bgp.conf/bfd.conf) for the following CLI commands: `show ospf, show bgp, show ipv6_ospf, show ipv6_bgp, show bfd`.

This command is a maintenance mode command and has no arguments. Only superusers can execute this command. The value of password and enable password in the output of the configuration file commands such as `show bfd` are encrypted when you run the command. For more information, see the *set regenerate_anycast_password*.

Viewing Lightweight Access Point Details in Network Insight (RFE-9556)

You can now view the discovered lightweight access points on the **Data Management > Devices** page. The table displays the following information about the discovered lightweight access points: their name, IP address, device type, model, vendor, and device version. You can also view the discovery statuses and other information in the **Discovery Status** table (**Data Management > Devices > Discovery Status**).

Displaying the Lead Secondary Column in Name Server Group (RFE-2804)

You can now determine which member is configured as a lead secondary by adding in a column to the **Authoritative Zone > Name Servers** tab.

Support for creation_time for Host Records (RFE-8509)

NIOS 8.6.1 introduces the option of adding, updating, listing tthe creation timestamp value of DNS and non-DNS host records using Grid Manager and WAPI.

Support for IB-V4015 on Red Hat OpenShift (RFE-11545)

Red Hat OpenShift is now supported on IB-V4015 virtual appliance. For more information, see the Infoblox Installation Guide vNIOS for Red Hat OpenShift at *docs.infoblox.com*.

New Port Placements for the Infoblox 2205 and Infoblox 4005 Series Appliances

The front panels of the Infoblox 2205 Series and the Infoblox 4005 Series have been modified to have slots for the four ports (LAN2, HA, LAN1, MGMT) at the right. However, the Infoblox 2205 and Infoblox 4005 Series models that have the ports located at the center are also being shipped. There is no difference in software functionality between the models that have ports on the right and those that have ports in the center. Both the models will support NIOS versions prior to 8.5.4 and earlier.

For a visual representation of these models, see the Infoblox Installation Guide for 2205 Series Appliances and the Infoblox Installation Guide for 4005 Series Appliances documentation at *https://docs.infoblox.com*

ACL Support for the Last Queried Time in DNS Scavenging (RFE-7933)

You can now create an ACL or ACE for the **Last Queried Time** field in DNS scavenging and thus prevent a specified set of ACLs or ACEs from updating the last queried timestamp. A new GUI field called **Prevent the following ACLs or ACEs from updating the last queried timestamp** in the **Grid DNS Properties** > **DNS Scavenging** > **Basic** tab has been introduced. The set of ACL or ACEs can include IPv4 and IPv6 addresses and networks. For more information, see *DNS Record Scavenging*.

New Load Balancer to Add Persistence (RFE-6827)

You now have a new load balancing method called Source IP Hash to configure DNS Traffic Control pools. In this method, requests are distributed based on the hash value of an IP address from an incoming query and the health status of the pool or server. Here, clients have their own pool or server and are always associated with the same pool or server for the same query as long as the pool or server is green. If the health status of the pool or server turns red, NIOS switches the clients to the working pool or server and switches back when the health restores to green. For more information, see *Load Balancing Methods for DNS Traffic Control*.

New DNS Responses When No DNS Traffic Control Responses are Available (RFE-10212)

You now have the option to allow NIOS to either drop LBDN queries, or return DNS responses, or not return DNS responses when DNS Traffic Control responses are not available. Two new options have been introduced in the **Data Management** > **DNS** > **Grid DNS Properties/Member DNS Properties** > **Traffic Control** tab:

- Drop LBDN matched DNS queries during full health update: this option drops all LBDN queries when the DNS service is waiting to receive a full health status update.
- No specific behavior: this option does not return DNS responses when DNS Traffic Control responses are not available.

These options are in addition to the existing **Return DNS response if there are no DNS Traffic Control responses available** option which is selected by default. For more information, see the *Configuring DNS Traffic Control Properties*.

Consolidated Health Checking for DNS Traffic Control Grid Members (RFE-9427)

You can now choose the Grid members that must monitor health and share the health status. You can also select with which other members the health status is to be shared. You can do this by enabling or disabling the new **Full Health Communication** checkbox on the **Data Management** > **DNS** > **Traffic Control** > **Health Monitors** > **Advanced** tab. For more information, see the *Configuring DTC Monitors for Health Check*.

Notification Rule Enhancements

NIOS now includes the Delete operation type in the Outbound notification rules. The Delete operation type has been included for the DB Change DNS Record, DB Change DNS Zone, and Object Change Discovery Data event types. For more information, see the *Configuring Notification Rules*.

IP Address in DHCP address conflict notification (RFE-5170)

NIOS now displays the conflicting IP address along with the conflict category when an email notification is sent in case of an IPAM IP address conflict.

The content of the IB-TRAP-MIB::ibTrapDesc.0 SNMP trap is updated to STRING: DHCP address conflicts with an existing host address. [IP address].

New Cluster Logout Event in the Syslog File (RFE-9840)

The syslog file now contains a cluster logout message to easily identify between network-related disconnects and distribution-related logouts in real time. The message is in the following format: <date:time> daemon infoblox.localdomain INFOBLOX-Grid[]: notice Cluster logout for node <node_name>, for node clean restart.

WAPI Performance Optimization (RFE-9986)

The performance of the WAPI GET method has been optimized for SRV, CNAME, and DNAME records.

Grid Backup Details in the Audit Log (RFE-9614)

The audit log file now logs information about who started the database backup and where the database backup file is stored. For more information, see the *Audit Log*.

New CLI Command to Set DNS and Anycast Start and Restart (RFE-10176)

This release of NIOS introduces the following commands:

- `set restart_anycast_with_dns_restart` : sets DNS and anycast start and restart sequences. This command brings down the anycast service during the DNS restart or stops and redirects the traffic on the IP address of anycast to another site. You can use this command only on Grid Master.
- `show restart_anycast_with_dns_restart` : displays the status of the set restart_anycast_with_dns_restart command.

For more information about these commands, see the *set restart_anycast_with_dns_restart* and *show restart_anycast_with_dns_restart* topics.

Hybrid HA Support

In NIOS 8.6, an HA setup can comprise a physical appliance and a virtual appliance. This setup is called a hybrid HA setup. For information about hybrid HA and its limitations, see the *About HA Pairs*.

Single Network Interface of vNIOS for GCP (RFE-9995 and RFE-9807)

This release of NIOS introduces an option to deploy vNIOS for GCP as a single network interface instance using VPC (Virtual Private Cloud) and shared VPC networks on GCP. This instance provides core network services such as DNS and IPAM services on a modular Infoblox solution. For more information, see the online Installation Guide for vNIOS for GCP at *https://infoblox-docs.atlassian.net/wiki/display/ILP/Appliances*.

Resolving CNAME and DNAME Chains in A and AAAA Alias Records (RFE-9129)

NIOS now follows CNAME and DNAME chains if they appear as a target of an A or AAAA alias record and returns the RDATA in the final link of the CNAME and DNAME chain as the answer. The chain itself will not be present as part of the answer.

Resetting SNMP and CLI Credentials in Network Insight (SPTYRFE-97)

If SNMP or CLI credentials become obsolete for devices polled by Network Insight, this release of NIOS introduces the following new CLI commands to reset the credentials for all affected devices at once:

- `reset snmp` : clears obsolete SNMP credentials (community strings) of devices polled by Network Insight.
- `reset cli:` clears obsolete CLI credentials (community strings) of devices polled by Network Insight.

After clearing obsolete credentials, Network Insight reguesses the credentials for each device. For information about these commands, see the *reset snmp* and *reset cli* topics.

Credential Grouping for Discovery Devices in Network Insight

In Network Insight, you can now group credentials and assign them to devices based on their group. You can do this for devices globally, for probe members, or for individual devices.

Credentials apply to devices at the following levels:

- Grid Manager: settings apply across the Grid and all probe appliances licensed for discovery.

- Discovery probe appliances: you can use inherited Grid settings or override them.
- Individual devices: you can use inherited Grid or probe settings or override them with device-specific settings.

For more information, see the *Configuring Discovery Properties*.

Microsoft Server 2022 Support (RFE-12246)

NIOS 8.6 is supported on Microsoft Server 2022.

Discovery of Cisco Viptela SDN and SD-WAN devices

You can now discover SDN and SD-WAN devices from Cisco Viptela on-premise or cloud infrastructure using Network Insight. For more information, see the *Configuring Discovery Properties*.

Adjustable Support Bundle Download Timeout

You can override the default timeout value for support bundle download by a custom value. For more information, see the *Downloading Support Bundles*.

Support for New Vendors Using Advisor

A few more new vendors can use the Advisor service to monitor their device lifecycle and vulnerabilities. For more information, see the *Monitoring Device Lifecycle and Vulnerabilities Using Advisor*.

Display of Source Device for Discovered Networks

You can now view the device on which a network is discovered by Network Insight. For more information, see the *Viewing Network Inventory*.

Unbound Upgrade

The Unbound version has been upgraded to 1.10.1.

Enabling DDNS Updates from IPv6-Only DHCP Members (RFE-5118)

You can now enable DDNS updates from IPv6-only DHCP members.

DHCP Fingerprint Updates

NIOS now contains new and updated DHCP fingerprints and the fingerprint configuration file has been upgraded to version 10. For details about the fingerprint format, see the *DHCP Fingerprint Detection*.

Support Matrix

This section lists requirements for the management system you use to access the NIOS appliance. The management system is the computer from which you configure and manage the NIOS appliance. The management system must meet the requirements listed in this topic.

Hardware Requirements

- (Minimum) 1.4 GHz CPU with 1 GB RAM available to the product GUI, and 256 Kbps connectivity to NIOS appliance
- (Recommended) 2.0 GHz (or higher) dual core CPU with 2 GB RAM
- Monitor Resolution:
    - 1280 x 768 (minimum)
    - 1280 x 1024 or better (recommended)

Software Requirements

For CLI access:

- Secure Socket Shell (SSH) client that supports SSHv2
- Terminal emulation program, such as minicom or Hilgraeve Hyperterminal®

For Grid Manager:

- JavaScript
- SSL version 3
- TLS version 1 connection

Supported Browsers

For information about supported browsers, see the NIOS Release Notes on the Infoblox Support Site.

Getting Started

This section helps you to get started using NIOS and familiarize yourself with NIOS terminology and UI conventions.

To...	See...
Understand NIOS and Infoblox terminology	*Glossary of Terms*
Understand the underlying architecture of various NIOS features and components	*SSL and TLS Protocols*
Know the NIOS system requirements	*Support Matrix*
Get familiar with the Grid Manager interface	*About the Grid Manager Interface*
Use NIOS through the CLI	*Using the NIOS CLI*
Create and manage administrator, users, roles, and groups	*Managing Administrators*
Learn about different types of licenses and how to add and manage licenses	*Managing Licenses*
Create NIOS reports	*Infoblox Reporting and Analytics*

Grid Manager Icons

This section contains the following information about icons used in Grid Manager, System Manager, and Orchestration Server Manager:

- **Icon**: The graphical display of an icon.
- **Icon Name**: The icon name.
- **Description**: The task that Grid Manager performs after you click the icon.
- **Tab/Table/Panel**: Lists the tab, table, or panel in which the icon appears.

The following are common icons that appear in most of the tabs, tables, panels, and in the Toolbar:

Icon	Icon Name	Description
	Active User	Indicates a user is active on the Microsoft server
	Add	Adds an object
	Add Bookmark	Adds a bookmark for an object and displays it in the Bookmarks panel
	Arrow (Down)	Moves an object down in a list
	Arrow (Up)	Moves an object up in a list

Icon	Icon Name	Description
	Clear	Clears specific data
	Clock	Displays a drop-down list for time
	Configure/Manage	Configures or manages a specific function
	Delete	Deletes an object
	Disabled	Indicates a disabled object
	Download/Import	Downloads/imports a file or data
	Edit	Displays the corresponding editor for modifying object configurations
	Execute Now	Executes a scheduled task immediately
	Export	Exports data displayed in the current panel
	Extensible Attribute	Configures extensible attributes for the selected object
	Flat View	Displays a list of objects in a flat view
	Hierarchical view	Displays objects in a hierarchical view
	Help	Displays information about an object
	Indexer	Indicates that the reporting member functions as an indexer
	Information	Displays informational data about an object
	Locked	Indicates a locked object
	Microsoft Server	Indicates a Microsoft server
	Pause	Pauses a process
	Print	Prints the information in the current panel

Icon	Icon Name	Description
	Restart	Restarts services on appliances
	Refresh	Refreshes the current page or table
	Report	Displays a report, such as the capacity report
	Search	Searches for specific objects
	Search Head	Indicates that the reporting member functions as a search head
	Start	Starts a process
	Stop	Stops a process
	Unlocked	Indicates an unlocked object
	User	Indicates a user has logged out of the Microsoft server
	User Profile	Configures a user profile
	View	Lists data in the current panel or lists detailed status about an object
	Warning	Indicates a warning message

The following icons appear in the **Data Management** tab:

Icon	Icon Name	Description	Tab/Table/Panel
	Configure	• Configures DHCP properties • Configures File Distribution properties • Configures Licenses	• **Data Management** tab -> **DHCP** tab -> Toolbar • Data Management tab -> DHCP tab -> Toolbar • Grid tab-> Grid Manager tab -> Toolbar

Icon	Icon Name	Description	Tab/Table/Panel
	Conflict	Indicates an IP address conflict	**Data Management** tab -> **IPAM** tab -> Net Map
	Convert	Converts an object	**Data Management** tab -> **IPAM** tab -> *network* -> IP Map -> Toolbar
	Discovery	Performs a network discovery	**Data Management** tab -> **IPAM** tab -> Toolbar
	Force HA Failover	Forces an HA failover	**Data Management** tab -> **DHCP** tab -> Toolbar
	Force Recovery	Forces a recovery	**Data Management** tab -> **DHCP** tab -> **Members** tab -> **Failover Associations** tab -> Toolbar
	Grid Manager	Indicates the Grid Master	**Data Management** tab -> **DHCP** tab -> **Members** tab -> **Data Management** tab -> **IPAM** tab
	Grid Manager Candidate	Indicates the Grid Master candidate	**Data Management** tab -> **DHCP** tab -> **Members** tab -> **Data Management** tab -> **IPAM** tab
	Grid Member	Indicates the Grid member	**Data Management** tab -> **DHCP** tab -> **Members** tab -> **Data Management** tab -> **IPAM** tab
	Join	Joins networks	**Data Management** tab -> **IPAM** tab -> *network* -> Toolbar
	Key-signing Key Rollover	Indicates the key-signing key that is due to rollover	**Data Management** tab -> **DNS** tab
	Microsoft Server	Indicates a Microsoft server	**Data Management** tab -> **DHCP** tab -> **Members** tab -> **Data Management** tab -> **IPAM** tab
	Multi-Ping	Pings all the addresses in a network	**Data Management** tab -> **IPAM** tab -> IP Map -> Toolbar
	Network Container	Indicates a non-cloud network container	**Data Management** tab -> **IPAM** tab or **DHCP** tab

Icon	Icon Name	Description	Tab/Table/Panel
	Network	Indicates a non-cloud network or a leaf network in a network container	**Data Management** tab -> **IPAM** tab or **DHCP** tab
	Network Container (for **Cloud** platform appliance)	Indicates a **cloud** network container	**Cloud** tab -> **Networks** tab or **Data Management** tab -> **IPAM** tab or **DHCP** tab
	Network (for **Cloud** platform appliance)	Indicates a **cloud** network	**Cloud** tab -> **Networks** tab or **Data Management** tab -> **IPAM** tab or **DHCP** tab
	Network (Disabled)	Indicates a disabled network	**Data Management** tab -> **IPAM** tab or **DHCP** tab
	Microsoft Network	Indicates a network with Microsoft servers	**Data Management** tab -> **IPAM** tab or **DHCP** tab
	Infoblox Network	Indicates a network with Infoblox appliances	**Data Management** tab -> **IPAM** tab or **DHCP** tab
	Ping	Pings an IP address	**Data Management** tab -> **IPAM** tab -> IP Map -> Toolbar
	Properties	Configures Grid DNS properties	**Data Management** tab -> **DNS** tab -> Toolbar
	Reclaim	Reclaims an IP address	**Data Management** tab -> **IPAM** tab -> IP Map -> Toolbar
	Resize	Resizes a network	**Data Management** tab -> **IPAM** tab -> *network* -> Toolbar
	Resolve Conflict	Resolves an IP address conflict	**Data Management** tab -> **IPAM** tab -> IP Map -> Toolbar
	Set Partner Down	Sets partner down	**Data Management** tab -> **DHCP** tab -> **Members** tab -> **Failover Associations** tab -> Toolbar
	Split Network	Splits a network	**Data Management** tab -> **IPAM** tab -> *network* -> Toolbar
	DNSSEC status	Displays status for DNSSEC	**Data Management** tab -> **DNS** tab -> Toolbar

Icon	Icon Name	Description	Tab/Table/Panel
FEED ZONE	Secondary Zone Status	Displays status for the secondary zone	**Data Management** tab -> **DNS** tab
	Zoom In	Zooms in to the selected network	**Data Management** tab -> **IPAM** tab -> Net Map
	Zoom Out	Zooms out from the selected network	**Data Management** tab -> **IPAM** tab -> Net Map
	Directory	Indicates a directory	**Data Management** tab -> **File Distribution** tab

The following icons appear in the **Smart Folders** tab:

Icon	Icon Name	Description	Tab/Table/Panel
	Smart Folder	Lists a smart folder	**Smart Folders** tab
	Smart Folder (Group By)	Lists smart folders in a group-by list	**Smart Folders** tab
	Smart Folder (Link)	Indicates a link to the smart folder	**Smart Folders** tab and other selectors

The following icons appear in the **Grid** tab:

Icon	Icon Name	Description	Tab/Table/Panel
	Backup	Backs up the configuration file and database	**Grid** tab-> **Grid Manager** tab -> Toolbar
	Restore	Restores the configuration file and database	**Grid** tab-> **Grid Manager** tab -> Toolbar
	bloxTools	Performs bloxTools services	**Grid** tab-> **Grid Manager** tab -> Toolbar
	Certificate	Creates, generates, uploads, or downloads an HTTPS certificate	**Grid** tab-> **Grid Manager** tab -> **Members** tab -> *member* -> Toolbar
	Control	Restarts, reboots, or shuts down a member	**Grid** tab-> **Grid Manager** tab -> **Members** tab -> *member* -> Toolbar

Icon	Icon Name	Description	Tab/Table/Panel
	Manage Services	Manages member services	**Grid** tab-> **Grid Manager** tab -> **Members** tab -> *member*
	Syslog	Displays the syslog file	**Grid** tab-> **Grid Manager** tab -> **Members** tab -> *member* -> Toolbar
	Traffic Capture	Captures the traffic report on a member	**Grid** tab-> **Grid Manager** tab -> Members tab -> *member* -> Toolbar

The following icons appear in the **Administration** tab:

Icon	Icon Name	Description	Tab/Table/Panel
	Execute Now	Executes a scheduled task immediately	**Administration** tab -> Toolbar
	Overlap	Shows overlapping permissions	**Administration** tab -> **Permissions** tab
	Reschedule	Reschedules a task	Reschedules a task **Administration** tab -> Toolbar

The following icons appear in the **Finder** panel:

Icon	Icon Name	Description
	Bookmarks	Lists all bookmarked objects
	Recycle Bin	Lists all deleted objects
	Smart Folders	Lists all smart folders
	URL Links	Adds URL links

The following icons appear in the **Load Balancer** related panels:

Icon	Icon Name	Description
	Traffic Management Visualizer	Views GLB object map
	DNS View Mapping	Maps NIOS DNS view to GLB DNS view

The following icons appear in Multi-Grid Manager:

Icon	Icon Name	Description
	Apply Template	Applies templates
	Delta Viewer	Views snapshots
	External Storage	Access external storage

Glossary of Terms

The following table provides descriptions of some key terminology used in the Infoblox products. Some terms, such as Grids and high availability, are used in different ways by other networking product vendors. The alphabetically arranged table can help you understand the terms and concepts as Infoblox uses them and as they are used in this guide.

Active Node	The NIOS appliance in an HA (high availability) pair that receives, processes, and responds to all service requests. When an HA failover occurs, the active node becomes the passive node in the HA pair.
API (Application Programming Interface)	A set of rules and specifications that software programs follow to communicate with each other. It serves as an interface between different software programs and facilitates their interaction. Infoblox provides a Perl API to help facilitate the integration of Infoblox NIOS appliances into network environments. It is an alternate method to the GUI (graphical user interface) in which you use a mouse pointer to click and select options and items to perform tasks.
Authenticated DHCP	The process of authenticating a network device before a DHCP server assigns a lease. On Infoblox appliances, you can divide a network into segments for unauthenticated, authenticated, and guest users. The Infoblox DHCP server assigns clients to the appropriate segment based on their MAC addresses and authentication credentials.
BIND (Berkeley Internet Name Domain)	The most commonly used DNS server on the Internet. It allows a standard way to name objects and resource records in distributed UNIX environments. It also provides operations to store and retrieve information of these objects and records.
bloxSYNC	An Infoblox proprietary mechanism for secure, real-time synchronization of the database that maintains the data, system configuration, and protocol service configuration between the active and passive nodes of an HA pair. With bloxSYNC, the nodes continuously synchronize changes of their configurations and states. When a failover occurs, the passive node can quickly take over services from the active node.
bloxTools	An Infoblox pre-installed environment provides tools to create custom applications that facilitate administrative tasks for an organization.
Bucket	A bucket contains indexed data.
Bulk Host	If you need to add a large number of A and PTR records, you can have the NIOS appliance add them as a group and automatically assign host names based on a range of IP addresses and the host name format you specify. Such a group of records is called a bulk host, which the appliance manages and displays as a single bulk host record.

Captive Portal	An Infoblox service that you enable on Grid members to register users, guest users, or both types of users for authentication purposes on network segments that you define using the authenticated DHCP feature.
CIDR (Classless Inter-Domain Routing) Notation	A compact specification of an IPv4 or IPv6 address and its associated routing prefix. For example, the CIDR notation of 192.168.100.1/24 represents the IPv4 address of 192.168.100.1 and its routing prefix of 192.168.100.0, or its subnet mask of 255.255.255.0. The CIDR notation of 2001:DB8::/48 represents the IPv6 addresses from 2001:DB8:0:0:0:0:0:0 to 2001:DB8:0:FFFF:FFFF:FFFF:FFFF:FFFF.
CLI (Command-line Interface)	A way to interact with Infoblox products by typing text-only commands to perform specific tasks.
Cluster Grouping	Grouping reporting appliances as a disaster recovery measure.
Dashboard	Your home page on Infoblox Multi-Grid Manager, Grid Manager, and System Manager. It provides easy access to tasks and to the status of your Grids and networks. It also provides various widgets for viewing and managing data.
DDNS (Dynamic DNS)	The automatic updating of real-time DNS configuration changes and other information on a DNS server when a network device is assigned a new IP address.
DHCP (Dynamic Host Configuration Protocol)	A configuration protocol that provides address assignments to network devices within a network. It keeps track of network configuration for each network device.
DHCP Failover Association	The pairing of two DHCP servers that establish a TCP connection for their communications. The servers form a pair of DHCP failover peers and provide DHCP protocol redundancy to minimize DHCP service outages.
DHCP Filter	A set of criteria and rules used to screen requesting hosts by matching MAC addresses, relay agent identifiers, DHCP options, or RADIUS authentication results.
DHCP Template	A set of predefined properties that you use to create IPv4 and IPv6 DHCP objects, such as networks and DHCP ranges, on the Infoblox appliance.
DIW (Data Import Wizard)	An Infoblox software tool that facilitates the import of DNS, DHCP, and TFTP data from legacy servers to Infoblox NIOS appliances. DIW supports DNS data import in the following formats: BIND 9, BIND 8, BIND 4, Microsoft DNS, Lucent VitalQIP, and Nortel NetID. It supports DHCP data import in the following formats: ISC DHCP, Microsoft DHCP, Lucent VitalQIP, and Nortel NetID.
DNS (Domain Name System)	A hierarchical naming system that translates domain names of any network devices into IP addresses for the purpose of locating and addressing these devices worldwide.
DNS View	On Infoblox appliances, a DNS view provides the ability to serve one version of DNS data to one set of clients and another version to another set of clients. With DNS views, the Infoblox appliance can provide a different answer to the same DNS query, depending on the source and match destinations of the query.
DNSSEC (Domain Name System Security Extensions)	A suite of IETF (Internet Engineering Task Force) specifications to secure certain kinds of information provided by DNS for use on IP networks. It is a set of extensions to DNS, which provide DNS resolvers with the original authentication of DNS data, authenticated denial of existence, and data integrity.
DNSone™	The software package that enables Infoblox appliances to provide DNS, DHCP and TFTP services. You can add the Grid upgrade to Infoblox appliances running DNSone.

Endpoint	An IP device such as a personal computer, laptop, or mobile handheld device. This term is often used in a security context.
Extensible Attribute	Metadata you define to capture additional information about an object managed by the Infoblox NIOS appliance. You can use predefined attributes or create your own. You can also specify required attributes and restrict the values that users can enter for each attribute.
Filters	Criteria the Infoblox NIOS appliance uses to request specific information in the database. You can use filters to control the amount and the kind of data displayed in a panel or table in Infoblox Multi-Grid Manager, Grid Manager, and System Manager.
FQDN (fully qualified domain name)	A complete domain name that specifies its exact location in the hierarchy of the DNS. It specifies all the domain levels, including the top-level domain and the root domain.
FTP (File Transfer Protocol)	A standard network protocol used to transfer files from one network device to another over a TCP-based network, such as the Internet. FTP is built on a client-server architecture and utilizes separate control and data connections between the client and server.
Gateway	The default router for the immediate network segment of an interface.
Grid™ Technology	Infoblox's unique and patented high availability Grid technology ensures network reliability. The Infoblox Grid provides resilient network services, failover, recovery, and seamless maintenance for an Infoblox deployment inside a single building, across a networked campus, or between remote locations. The Infoblox Grid establishes a distributed relationship between individual or paired appliances to remove single points of failure and other operational risks inherent in legacy DNS, DHCP, and IP address management infrastructure.
Grid Manager	The NIOS web interface that provides access to your Grid for performing IPAM, DNS, and DHCP management and other administration tasks.
Grid Master	The Grid member in an Infoblox Grid that maintains the NIOS database that is distributed among all members of the Grid. You connect to the Grid Master to configure and monitor the entire Grid.
Grid Member	Any single Infoblox NIOS appliance or HA pair that belongs to a Grid. Each member can use the data and services of the Grid. You can also modify settings so that a Grid member can use unique data and member-specific services.
HA Pair	Two physical Infoblox NIOS appliances that are linked to perform as a single virtual appliance in an HA (high availability) configuration. The HA configuration provides hardware redundancy to minimize service outages. In this configuration, one appliance is the active node and the other is the passive node.
Host Record	On Infoblox appliances, host records provide a unique approach that enables you to manage multiple DNS records and DHCP and IPAM data collectively, as one object on the appliance.
IBOS (Infoblox Orchestration Server)	IBOS is the Infoblox IF-MAP (Interface to Metadata Access Points) server that contains a searchable database for storing state information about network resources. It is the central point with which IF-MAP clients communicate to send and retrieve real-time information defined in the IF-MAP data format.
IF-MAP (Interface for Metadata Access Points)	An open standard client-server protocol developed by the Trusted Computing Group as one of the core protocols of the TNC (Trusted Network Connect) open architecture. IF-MAP allows network resources to share real-time information.

IP Map	In Infoblox Grid Manager or System Manager, this is a graphical representation of all IPv4 addresses in a given subnet.
IPAM (IP Address Management)	Infoblox IPAM provides a means of planning, tracking, and managing IP address space in a network. It glues DNS and DHCP services together so that each service is aware of changes in the other. The Infoblox IPAM implementation offers an IP address-centric approach so you can manage your networks and IP addresses through a centralized GUI.
Leaf Network	On Infoblox appliances, a network that does not contain any subnets. Lease Logging Member An Infoblox Grid member that is designated to collect DHCP lease events.
License Pool	A license pool is a container associated with the Grid and holds dynamic licenses for a specific feature. Licenses in the pool can be dynamically allocated to and deallocated from Grid members. When not in use, dynamic licenses are released back to the pool for future allocation. There is no expiration for dynamic licenses.
Limited-Access User	An admin user account that has specific roles and permissions assigned. Limited-access users have restricted access to Infoblox Multi-Grid Manager, Grid Manager, and System Manager, and can only perform certain tasks based on their assigned roles and permissions.
Lite Upgrade	On Infoblox appliances, a lite upgrade occurs when there are incremental changes to the NIOS software that do not require any change to the database. The appliance can perform a lite upgrade only if the format of the database between the existing NIOS version and the upgrade version is the same. In general, when you upgrade from a major release to a patch release or a patch release to another patch release, you are performing a lite upgrade.
Loopback Interface	On Infoblox appliances, the virtual network interface on which you can consolidate DNS servers for migration purposes, add anycast addresses to improve the performance of the DNS service, and separate DNS traffic.
Managing Member	An Infoblox Grid member that is configured to manage Microsoft DNS and DHCP servers.
Master Candidate	An Infoblox Grid member that is designated to assume the role of the Grid Master as a disaster recovery measure.
Master Grid	A group of Infoblox appliances that are connected to provide a single point of administration for multiple Grids and network management of these Grids.
Master Grid Member	Any single Infoblox appliance or HA pair that belongs to the Master Grid. All Master Grid members serve as Master Candidates.
Multi-Grid Manager	The NIOS web interface that provides access to the Master Grid, from which you can manage multiple Grids and their networks.
Multi-Grid Master	The Infoblox Master Grid member that maintains the NIOS database that is distributed among all Master Grid members. You connect to Multi-Grid Manager to configure and monitor the Master Grid.
Multi-Grid Master Candidate	An Infoblox Master Grid member that is designated to assume the role of the Multi-Grid Master as a disaster recovery measure.
Name Server Group	On Infoblox appliances, a server group that contains one primary DNS server and/or one or more secondary DNS servers. Specifying a single name server group can simplify DNS zone creation.

NAT (Network Address Translation) Group	A group of Infoblox Grid members that are configured on the same side of a NAT appliance. In a Grid configuration where the Grid Master is configured behind a NAT appliance and there are Grid members on both sides of the NAT appliance, it is necessary to create a NAT group to ensure that the Grid Master and Grid members use the correct NAT and interface addresses for Grid communications.
Network Block	On Infoblox appliances, an IP address space that is defined in the Master Grid. A network block can consist of other network blocks, network containers, and leaf networks.
Network Container	On Infoblox appliances, an automatically created container of multiple networks that are subnets of the IP address space configured for the network container. A network container cannot be assigned to a Grid member or be directly created.
Network Discovery	A set of tools provided by the Infoblox NIOS appliance for detecting active hosts on specified networks and specified VMware vSphere servers.
Network Map	In Infoblox Grid Manager and System Manager, Network Map presents a complete view of your network space, including the different types of networks that are in it and its unused address space. You can use Network Map to design and plan your network infrastructure, configure and manage individual networks, and evaluate their utilization.
Network Mask or Netmask	A numeric representation of the bits that are used to split an IP address into the network portion and the host portion. In Infoblox products, this is represented by either quad-dotted decimal representation or CIDR notation for IPv4 network masks, or by CIDR notation for IPv6 network masks.
Network View	On Infoblox appliances, a single routing domain with its own networks and shared networks. A network view can contain both IPv4 and IPv6 networks. All networks must belong to a network view on the Infoblox appliance.
NIOS	An Infoblox proprietary system that powers Infoblox solutions with an embedded processor that delivers core network services. It is the operating system that runs on the NIOS appliances—a security-hardened, real-time set of appliances built to ensure the non-stop operation of network infrastructure. NIOS automates the error-prone and time-consuming manual tasks associated with deploying and managing IPAM, DNS, and DHCP required for continuous IP network availability and business uptime.
NIOS Virtual Appliance	Any Infoblox supported platform, such as AWS, VMWare, Azure appliances that runs the vNIOS software. These appliances are also known as the vNIOS appliances.
Node	A single Infoblox appliance of an HA (high availability) pair. An HA pair consists of an active node and a passive node.
NTP (Network Time Protocol)	A protocol for synchronizing the clocks of computer systems over packet-switched, variable latency data networks; it essentially keeps network devices on a common clock by resisting the effects of variable latency by means of a jitter buffer.
Passive Node	The Infoblox NIOS appliance in an HA pair that constantly keeps its database synchronized with that of the active node, so it can take over core network services when an HA failover occurs. When an HA failover occurs, the passive node becomes the active node in the HA pair.
PortIQ	An Infoblox switch port appliance that enables quick discovery of the Ethernet switch ports. PortIQ identifies ports that are not fully utilized and those that exceed their capacity. You can use PortIQ to troubleshoot LAN environments.

Quick Filter	A filter that stores specific filter criteria for requesting information displayed in a specific panel in Infoblox Multi-Grid Manager, Grid Manager, and System Manager. For more information, see "Filter."
Overlapping Network	On Infoblox appliances, a network that exists in multiple locations, which can be multiple Grids in the Master Grid or within various network views in a Grid.
Replication	Database distribution among the Infoblox Grid Master and Grid members as well as among the Multi-Grid Master and Master Grid members.
Replication Factor (Reporting - Multi-Site Cluster)	The number of copies of reporting data in each bucket that the cluster maintains.
Reservation	On Infoblox appliances, a static IP address that you create for future use. A reservation is a pre-provisioned fixed address. You can reserve this static IP address on the NIOS appliance and assign it to a client in the future.
Resource Records	A collection of data in the DNS server database. Each resource record specifies information about a DNS object. For example, an A (address mapping) record maps a host name to an IP address, and a PTR (reverse-lookup pointer) record maps an IP address to a host name. The DNS server uses these records to answer queries.
Roaming Host	On Infoblox appliances, a host with a dynamically assigned IP address and a specific set of properties and DHCP options. When you create a roaming host for a network device, the device can receive any dynamically assigned address from the network to which it belongs.
Scope	A DHCP address range on a Microsoft server. Microsoft scope information is converted to equivalent DHCP range information after Microsoft data is synchronized with the NIOS appliance.
Search Factor	The number of searchable copies of reporting data in each bucket that the cluster maintains.
Shared Network	On Infoblox appliances, a network segment to which you assign two or more subnets. When subnets in a shared network contain IP addresses that are available for dynamic allocation, the addresses are put into a common pool for allocation when client requests arise.
Shared Record Group	On Infoblox appliances, a set of resource records that you add to multiple DNS zones. You can create resource records in a group and share the group among multiple zones. The zones handle the shared resource records as any other resource record.
SSO (Single Sign On)	An Infoblox feature that allows you to automatically sign in to selected Grids from the Master Grid, without having to log in to each individual Grid each time you sign on.
Smart Folder	On Infoblox appliances, a virtual folder in which you place the results of filter criteria that you select to request specific data in the NIOS database. Once you set up a smart folder, the appliance displays up-to-date information based on your filter and grouping criteria each time you access the folder.
Subnet (or network)	A logical division of an IP network. A subnet of network may also be called a network. For example, 10.1.0.0/16 is a subnet of 10.0.0.0/8, and fc80:8:8:16::/64 is a subnet of fc80:8:8::/48.
Superscope	On a Microsoft server, superscope comprises multiple scopes or DHCP address ranges created on a single physical network segment. Microsoft superscope information is converted to equivalent network information after Microsoft data is synchronized with the NIOS appliance.

Superuser	An admin user account that has unrestricted access to Infoblox Multi-Grid Manager, Grid Manager, or System Manager.
Support Bundle	A tar.gz file that contains configuration files and system files of the Infoblox NIOS appliance. You can download a support bundle for an independent appliance and for each member in a Grid.
System Manager	The NIOS web interface that provides access to an independent appliance (single or HA) for performing IPAM, DNS, and DHCP management and other administration tasks.
TFTP (Trivial File Transfer Protocol)	A data transfer service that provides devices—such as phones, RFID readers, IP cameras, and other devices—with up-to-date software and configuration data.
Traffic Capture	An Infoblox tools that captures the traffic on one or all of the ports on a NIOS appliance. The NIOS appliance saves all captured traffic in a .cap file and compresses it into a .tar.gz file.
Upgrade Group	On Infoblox appliances, a group of Grid members that you put together so you can perform software distribution and upgrade at the same time.
VIP (Virtual IP)	On Infoblox appliances, the shared IP address of an HA pair. A VIP address links to the HA port on the active node of an HA pair.
VRID (Virtual Router ID)	VRID identifies the VRRP (Virtual Router Redundancy Protocol) HA pair to which the Infoblox appliance belongs. Through VRID, two HA nodes identify each other as belonging to the same HA pair, and they obtain a virtual MAC address to share with a VIP. A VRID can be any number between 1 and 255, and it must be unique on the local LAN so that it does not conflict with any other Infoblox appliances using VRRP on the same subnet.
vNIOS	The virtual version of NIOS. You can install Infoblox vNIOS software on any supported virtual platform and configure the system as a vNIOS virtual appliance.
VRRP (Virtual Router Redundancy Protocol)	An industry standard MAC address level HA failover mechanism.

Installing NIOS

NIOS comes with its own hardware box (appliance) on which NIOS will be installed. Ensure that you verify the hardware that you receive.

Verifying the Hardware

To verify the secure delivery of the hardware:

- Use the tracking number of the order to review the status of the shipment.
- Inspect the tamper-evident seals for any signs of tampering.
- Verify the product by comparing the shipping slip with the invoice.

Prerequisites

Before you begin the configuration, ensure that you have all the necessary components. The following are needed and must be acquired before continuing with this guidance:

- Supported NIOS appliances
- A management station or computer from which you configure and manage the NIOS appliance. See *Support Matrix* for the system and browser requirements.
- The IP address of the appliance on your network.

Supported Appliances

For the list of supported physical appliances and virtual appliances that NIOS is supported on, see the Release Notes.

Downloading the NIOS Software

You can download NIOS from the Infoblox Support web site at *https://support.infoblox.com/*. You must be a registered user to access this web site.

To download the software:

1. Log on to the Infoblox Support web site at *https://support.infoblox.com/*
2. Click the **Downloads** tab.
3. Select **NIOS/vNIOS** from the **Infoblox Software** drop-down list.
4. Select the **General maintenance products with full engineering support for routine patches and bug fixes on all significant issues** option.
5. Select **NIOS 8.6.1** from the **Select version** drop-down list.

The NIOS installer files are available for download. The installer files are of two sizes:

- Files of size 250 GB
- Files of size 70 GB

Infoblox recommends using a minimum size of 70 GB for any of these files that has resizable as part of the file name and you can resize them depending on your requirement and deployment.

If you download the resizable files, a default disk size is defined on the VM. You then change the default disk size using the VMware UI. When you start the VM for the first time, NIOS detects how much disk space has been reserved for the virtual disk and allocates partitions within that space. You can increase the disk size upto a maximum of 2.5 terabytes.

If you want to resize the disk space from the current 250 GB to a lower size, remove the member from the Grid and add a replacement member with the required disk size. If you want to resize a smaller disk to a higher size, back up the Grid database, and deploy the new instance with the required disk size. After the deployment, restore the backed up

database. Infoblox recommends configuring a scheduled backup so that if the disk limit is reached and the system is unresponsive, the earlier backup can be restored.

Infoblox recommends configuring instances of only 250 GB and higher as Grid Master and Grid Master Candidate.

Note

- Images of types .vhd and .raw comprise only one file each and can be resized. The minimum size of the .vhd image is 250 GB and that of the .raw image is 43 GB.
- Infoblox recommends that you provision 70 GB or more disk space for the NIOS instance while deploying resizable images.
- If you add members to a FIPS mode -enabled Grid Master, ensure that the members have the same NIOS build version. That is, the same NIOS build must be installed on Grid Master and members before joining. You can perform upgrades and install hotfixes in FIPS mode.

Limitations of Using the Scalable Image File

The following are the limitations of using the scalable NIOS image:

- You can use the scalable image only on the following appliances: IB-V805, IB-V1405, IB-V2205, IB-V4005, IB-V815, IB-V825, IB-V1415, IB-V1425, IB-V2215, IB-V2225, IB-V4015, IB-V4025, IB-FLEX, CP-V805, CP-V1405, CP-V2205.
- If you use ovftool to deploy the OVA image, there is no command line option to increase the disk-size. As a workaround, you can use ovftool to upload the image but before powering on the VM, you will need to use the UI to change the disk size based on your requirement.
- The Parental Control feature fails to start because of no space left on the device when downloading Zvelo data.
- The primary disk size is full if you enable the bloxTools service on the member provisioned with the lower disk size.
- Infoblox recommends to not run DNS/DHCP/updates on the member provisioned with the lower disk size.
- Do not try to join a resizable disk image to a Grid running an NIOS version earlier than 8.5.
- Infoblox does not recommend auto-synchronizing or downgrading resizable disk images to NIOS versions earlier than 8.5.
- If you have resizable members whose provisioned disk space is lower than 85 GB, disable the rsync-batch mode by running the `set upgrade_dist rsync_batch disable` command on Grid Master.
- If you have a reporting member as part of your Grid, then you must have a minimum disk space of 250 GB by default.

Upgrading NIOS

This topic explains how to manage upgrade groups and perform software upgrades and downgrades for NIOS appliances. It also describes how to back up and restore configuration files.

It includes the following sections:

Upgrading NIOS Software

Infoblox frequently releases updated NIOS software. Contact Infoblox Technical Support to learn which file name to use when downloading a new upgrade file, or watch your email for periodic notifications that a new software upgrade is available. To get the latest upgrade, your local network must be capable of downloading a file from the Internet.
After you download and store the new upgrade file on your local network, complete the following tasks to upgrade an Infoblox independent appliance or a Grid.

- Upload the new software to the Grid Master, as described in Uploading NIOS Software below.
- Distribute the software upgrade files, as described in Distributing Software Upgrade Files below.
- Optionally, test the upgrade, as described in Testing Software Upgrades below.
- Perform the software upgrade, as described in Performing Software Upgrades below.

Before upgrading, Infoblox recommends that all members in the Grid be connected to the network and operating normally. If one or more members are offline when you upgrade the Grid, they automatically receive the distributed software and upgrade when they join the Grid or come back online.

⚠ Note

- You cannot upgrade directly to NIOS 5.x from NIOS releases earlier than 4.2r4. Refer to the release notes for the appropriate upgrade and revert paths.
- In a Grid that is configured with an HA pair, Infoblox does not recommend that you disconnect any node of the HA Grid Master and then join it back after installing a NIOS version that does not match with the current running version of NIOS on the other node. If an upgrade operation is performed this way, the Grid displays an unexpected behavior and will need a manual intervention of the Support team to recover the Grid.
- The shared secret that you enter when adding a RADIUS authentication server in the *Add RADIUS Authentication Service* wizard > **RADIUS Servers** > **Shared Secret** field must be between 4 and 64 characters (inclusive) in length. Otherwise, the upgrade will fail.

⚠ Caution
Do not attempt to add or remove a member, or convert an HA pair to single members or vice versa during a distribution or upgrade.

When you upgrade from NIOS 6.4.0 to a later release, you can start, stop, or restart DNS and DHCP services, or only the DHCP service on a member that has not been upgraded. When you start, stop, or restart other services, such as reporting or file distribution, the operation is put in queue for execution until after the targeted member has been upgraded.

Uploading NIOS Software

After you download the NIOS software upgrade to your management station, upload it to the Grid Master, as follows:

1. From the **Grid** tab, select the **Upgrade** tab, and then click **Upload** in the panel or from the Toolbar.
2. Navigate to the directory where you have stored the NIOS software upgrade, and then click **Open** or **Upload**.

The appliance uploads the file and displays the status of the upload in the status bar. You can click the Stop icon in the status bar to stop the upload. Ensure that you do not navigate away from the **Upgrade** tab until after the upload is complete. Otherwise, the upload process stops.

> ⚠ Note
> When you upload the NIOS software upgrade to an HA Grid Master, only the active node receives the software. The passive node does not. Therefore, if the Grid Master fails over before a distribution starts, you must upload the software again. If you do not, the distribution fails because the new active node does not have the uploaded software.

Distributing Software Upgrade Files

Distributing the software upgrade files involves unpacking the software files and loading the new software. When you perform a distribution, the NIOS appliance loads the new software code into an alternate disk partition, which overwrites any previously saved version of code that is already there. Therefore, starting the distribution disables the appliance from reverting to a release prior to the current version.
The time this process takes depends on the number of appliances to which the software is distributed; the more appliances, the longer it takes. Therefore, you might want to schedule the Grid distribution during times when your network is less busy. You can distribute the software immediately or schedule the distribution of any software upgrade file, even if it is not Upgrade Lite compatible.

Distributing Software Immediately

The Grid Master distributes the software upgrade to each member in the Grid, including itself. As an alternative to scheduling the Grid distribution (see Scheduling Distributions below), you can distribute the software upgrade throughout the Grid immediately, as follows:

1. From the **Grid** tab, select the **Upgrade** tab, and then click **Distribute** -> **Distribute Now** from the Toolbar.
2. In the confirmation dialog box, click **Yes** to start the distribution.

The distribution starts and if there is an active distribution scheduled, the appliance changes its status to inactive. The appliance distributes the upgrade files and displays the status of the distribution in the status bar. You can pause, resume, or stop the distribution by clicking the corresponding icon in the status bar.
Note that starting a manual distribution cancels a scheduled distribution.

Scheduling Distributions

When you schedule a distribution, you schedule the distribution of the Grid Master as well as the upgrade groups, including the Default group. The Grid Master distribution must always occur before the distribution of the upgrade groups. To schedule a software distribution:

1. From the **Grid** tab, select the **Upgrade** tab, and then click **Distribute** -> **Schedule Distribution** from the Toolbar.
2. In the *Schedule Distribution* editor, complete the following:

- **Activate Distribution Schedule:** Select this to enable the distribution schedule. Clear this if you are creating a distribution schedule you plan to activate at a later date. You can configure and save information in this editor even when you deactivate a scheduled distribution.
- **Grid Master Distribution Start Information:** Enter a Grid Master distribution date, time, and time zone. The distribution date and time must be before those of the upgrade groups.
    - **Date:** Enter a start date of the Grid Master distribution in YYYY-MM-DD (year-month-day) format. You can click the calendar icon to select a date from the calendar widget.
    - **Time:** Enter a start time of the Grid Master distribution in hh:mm:ss AM/PM (hour:minute:second in AM or PM) format. You can also select a time from the drop-down list.
    - **Time Zone**: Select a time zone that applies to the start time you enter. If this time zone is different from the Grid time zone, the appliance converts the time you enter here based on the Grid time zone, after you save this schedule. When you display this schedule again, it displays the converted time. Selecting the time zone here does not affect any time zone settings in the Grid. (For information about selecting the Grid and member time zones, see *Managing Time settings*.)
    - **Admin Local Time:** Displays the Grid Master distribution start date and time in the time zone of the administrator, as explained in *Creating Local Admins*.
- In the upgrade group table, specify the following for each upgrade group by clicking the corresponding field in each row:
    - **Start Distribution:** Specify when the distribution occurs. Select one of the following from the drop-down list:
        - **Date/Time:** Select this to configure the distribution start date, time, and time zone.
        - **After *<group>*** : Select **After Grid Master** to start the distribution immediately after the completion of the Grid Master distribution. Select an upgrade group that must complete its distribution before the group you are configuring. When you select this option, you cannot enter a date, time, and time zone.
          Date, **Time**, **and Time Zone** are enabled only when you select **Date/Time** for **Start Distribution**.
        - **Date:** Enter a distribution start date in YYYY-MM-DD (year-month-day) format. You can click the calendar icon to select a date from the calendar widget.
        - **Time:** Enter a distribution start time in hh:mm:ss AM/PM (hour:minute:second in AM or PM) format. You can select a time from the drop-down list.
        - **Time Zone:** By default, the appliance displays the time zone of the first Grid member in the Upgrade Group. You can change this time zone if you want to enter the time using a different time zone. After you save the schedule though, the appliance converts the time you entered to the time zone of the upgrade group, if it is different. (For information about setting the Grid and member time zones, see *Managing Time Settings*.) To change the default time zone of the upgrade group, change the time zone of the first group member, as explained in Adding Upgrade Groups, see *Managing Upgrade Groups*.
        - **Admin Local Time:** Displays the start date and time in the time zone of the administrator, as explained in *Creating Local Admins*.
        - **Distribute to Members:** Indicates whether the distribution within the group occurs simultaneously or sequentially. You cannot edit this field here. You define this when you create the upgrade group. To change this setting, see Modifying Upgrade Groups in *Managing Upgrade Groups*.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Grid Manager confirms that the schedule is saved and indicates whether the distribution schedule is active. You can click the Refresh icon to refresh the information in this panel.
Note that the appliance does not save the schedule and displays an error message if the schedule contains the following:

- Circular dependencies between upgrade groups. For example, the distribution of Group A is scheduled after Group B, and the distribution of Group B Is scheduled after Group A.
- The distribution time is in the past.

Software Distribution Process

The following series of events occur after a Grid distribution starts:

- The appliance checks if a NIOS software upgrade was uploaded.
    - If the upgrade files are not uploaded, the distribution stops. The appliance displays an error message and if the distribution is scheduled, the appliance deactivates the distribution schedule.
    - If the upgrade files are uploaded, the distribution proceeds.
- A single Grid Master uploads the file to a backup partition and unpacks the contents, which overwrites any existing backup software that might have been there. For an HA Grid Master, it is the active node that uploads the file to a backup partition and unpacks the contents.
    - The Grid Master (or active node of the HA Grid Master) sends a command to all nodes that are online to copy their database and software to a backup software partition.
    - For an HA Grid Master, the active node sends the command to the passive node as well.
    - The nodes perform resynchronization on their backup partition, retrieving only the changed files from the Grid Master.
    - After the active node of an HA member receives the software, it then distributes it to the passive node.

When the distribution successfully completes, the appliance updates the distribution status and sets the schedule, if configured, to inactive. The new software is now staged on all member appliances and is ready for use. Grid Manager displays the software version in the **Distribution** field in the Grid Version Information section.

Managing Distributions

After you start a distribution, you can pause, resume, or stop it. For information, see Pausing and Resuming Distributions and Stopping Distributions below. Grid Manager displays the status of the overall distribution as well as the status of individual members. You can view this information in the **Upgrade** tab.

Pausing and Resuming Distributions

The following are some operational guidelines for performing a distribution:

- You cannot create new upgrade groups, add members to a group, or remove members from a group after a distribution starts.
- You can skip a member that is currently offline from a distribution. When both nodes of an HA pair are online, the skip member function is not available.

To pause a distribution:

1. From the Grid Distribution Status bar, click the Pause icon.
2. When the appliance displays a confirmation dialog box, click **Yes** to pause the distribution.

The Grid Distribution Status bar indicates the distribution is paused. For information about the distribution status of each member, see Monitoring Distribution and Upgrade Status below.
To skip a member from a distribution:

1. From the **Grid** tab, click the **Upgrade** tab, and then click **Toggle Member List View**.
2. Select a member checkbox, and then click **Skip Member** from the Toolbar. Grid Manager automatically skips the distribution of software to the members that are offline.

To resume a distribution:

1. From the Grid Distribution Status bar, click the Resume icon.
2. When the appliance displays a dialog box confirming that you want to resume the distribution, click **Yes** to continue.

Members that have not completed or started distributions that were scheduled at an earlier time resume the distribution.

Stopping Distributions

You can stop a distribution immediately, for example, if there are offline members and you do not want to wait for them to come back online, or if you realize that you have uploaded the wrong software version. When you stop a distribution, you can do the following:

- If the Grid Master has completed its distribution, you can upgrade the Grid immediately. This forces members that do not have a complete distribution to synchronize their releases with the Grid Master.
- If the Grid Master does not have a valid distribution, you can restart the distribution.
- Upload another software upgrade.

Ending a distribution does not affect the upgrade schedule, if configured. The Grid upgrade starts as scheduled, as long as the Grid Master completes its distribution.
To stop a distribution:

1. From the Grid Distribution Status bar, click the Stop icon.
2. When the appliance displays a dialog box confirming that you want to stop the distribution, click **Yes** to continue.

Testing Software Upgrades

After you successfully distribute a software upgrade to the Grid Master, you can test an upgrade on the Grid Master before actually implementing it. This allows you to resolve potential data migration issues before the actual upgrade. The length of time the upgrade test takes depends on the amount of data and the difference between the current NIOS version and the software upgrade. The test does not affect NIOS services and you can perform other administrative tasks during the upgrade test.
To start an upgrade test:

- From the **Grid** tab, select the **Upgrade** tab, and then click **Test Upgrade** from the Toolbar. Test upgrade is enabled only for a major upgrade (not an Upgrade Lite compatible upgrade).

After you start an upgrade test, you can view its status in the status bar. You can also stop it at any time. To stop an upgrade test:

- From the *Grid Upgrade Test Status* bar, click the Stop icon.

Note that if an admin restarts the Grid services or reboots the Grid Master, or if an HA failover occurs on the Grid Master during the upgrade test, the appliance automatically stops the test. The appliance always resets the status of the Grid to "Distributed" when it stops the upgrade test.
If the appliance encounters an error during the test, it stops the test and displays a message in the *Upgrade Status* panel indicating that the upgrade test failed and the reason for the failure, such as a data translation error or data import error. You can review the syslog for specific error messages before downloading the Support Bundle and contacting Infoblox Technical Support.
After the test successfully finishes, the appliance displays a message confirming that the test upgrade is complete.

Performing Software Upgrades

Performing a software upgrade involves rebooting the appliances and then running the new software. Essentially, each appliance switches between the two software partitions on its system, activating the staged software and saving the previously active software and database as backup.

> ⚠ Note
> Before you upgrade the software, Infoblox recommends that you back up the current configuration and database. For information, see *Backing Up and Restoring Configuration Files*.

Depending on your upgrade paths, you can upgrade to a new release immediately or you can schedule the upgrade. For information about how to upgrade immediately, see Upgrading the Grid Immediately below. Before you schedule an upgrade, ensure that you understand the limitations, as described in *Managing Upgrade Groups*. For information about how to schedule an upgrade, see Scheduling Upgrades below.

Upgrading the Grid Immediately

For unschedulable full upgrades, all the Grid members in the Grid must upgrade at the same time. For lite upgrades and schedulable full upgrades, you can schedule the upgrades as described in *Scheduling Upgrades*, or you can upgrade all the Grid members at the same time.
To upgrade a Grid immediately:

- From the **Grid** tab, select the **Upgrade** tab, and then click **Upgrade** -> **Upgrade Now** from the Toolbar.

> ⚠ Note
> The Grid upgrades immediately and if there is an active upgrade schedule, it becomes inactive.

Scheduling upgrades

You can schedule lite upgrades and full upgrades for certain NIOS versions. For limitations about scheduling a full upgrade, see *Managing Upgrade Groups*. When you schedule an upgrade, you schedule the upgrade for the Grid Master and the upgrade groups, including the Default group. The Grid Master must always upgrade before the upgrade groups. Depending on your upgrade paths, you can schedule the upgrade for the Grid Master and upgrade groups at different times over a period of nine days. If you schedule an upgrade that takes more than nine days, the appliance displays a warning.
To schedule an upgrade:

1. From the **Grid** tab, select the **Upgrade** tab, and then click **Upgrade** -> **Schedule Upgrade** from the Toolbar.
2. In the *Upgrade Schedule* editor, complete the following:
    - **Activate Upgrade Schedule:** Select this to enable the upgrade schedule. Clear it if you are creating an upgrade schedule that you plan to activate at a later date. You can configure and save information in this editor even when you deactivate a distribution.
    - **Grid Master Upgrade Start Information:** Enter a Grid Master upgrade date, time, and time zone. The date and time must be before those of the upgrade groups.
        - **Date:** Enter a start date of the Grid Master upgrade in YYYY-MM-DD (year-month-day) format. You can click the calendar icon to select a date from the calendar widget.
        - **Time:** Enter a start time of the Grid Master upgrade in hh:mm:ss AM/PM (hour:minute:second in AM or PM) format. You can select a time from the drop-down list.
        - **Time Zone**: Select a time zone that applies to the start time you enter. If this time zone is different from the Grid time zone, the appliance converts the time you enter here based on the Grid time zone, after you save this schedule. When you display this schedule again, it displays the converted time. Selecting the time zone here does not affect any time zone settings in the Grid. (For information about setting the Grid and member time zones, see *Managing Time Settings*.)
        - **Admin Local Time:** Displays the Grid Master upgrade date and start time in the time zone of the administrator, as explained in *Creating Local Admins*.
    - In the upgrade member table, specify the following by clicking the corresponding field in each row:
        - **Group**: The name of the upgrade group. You can assign a different upgrade group by selecting the group from the drop-down list.
        - **Group Members**: When you expand an upgrade group, this field displays the group members.
        - **Warning**: This field turns yellow when there is a conflict among the upgrade groups. Hover your mouse over the field and the tooltip displays the member that contains the conflict. It also displays recommended upgrade groups in the **Group** column so you can change the group assignment to resolve the conflict. The tooltip can display one of the following: **GMC**, **DNS Primary**, **DHCP Logging Member**, or **DHCP Failover**. For information about how to resolve a conflict, see Resolving Upgrade Warnings below. Select an upgrade group from the drop-down list in the Group column to assign a different upgrade group. Click **Validate and Refresh** to validate the new group assignment.
        - **Start Upgrade:** Specify when the upgrade occurs. Select one of the following from the drop-down list:
            - **Date/Time:** Select this to configure the upgrade start date, time, and time zone.

- **After *<group>*** : Select **After Grid Master** to start the distribution immediately after the completion of the Grid Master distribution. Select an upgrade group that must complete its distribution before the group you are configuring. If you select this option, you cannot enter a date, time, and time zone.
  Date, **Time**, and **Time Zone** are enabled only when you select **Date/Time** for **Start Upgrade**.
- **Date:** Enter an upgrade start date in YYYY-MM-DD (year-month-day) format. You can click the calendar icon to select a date from the calendar widget.
- **Time:** Enter an upgrade start time in hh:mm:ss AM/PM (hour:minute:second in AM or PM) format. You can select a time from the drop-down list.
- **Time Zone:** By default, the appliance displays the time zone of the first Grid member in the Upgrade Group. You can change this time zone, if you want to enter the time using a different time zone. After you save the schedule though, the appliance converts the time you entered to the time zone of the upgrade group, if it is different. (For information about setting the Grid and member time zones, see *Managing Time Settings*.) To change the default time zone of an upgrade group, change the first group member in the Upgrade Group list, as explained in Adding Upgrade Groups, see *Modifying Upgrade Groups*.
- **Admin Local Time:** Displays the data and time in the time zone of the administrator, as explained in *Modifying Upgrade Groups*.
- **Upgrade Members:** Indicates whether the upgrade within the group occurs simultaneously or sequentially. You cannot edit this field here. You define this when you create the upgrade group. To change this setting see as described in Modifying Upgrade Groups, see *Modifying Upgrade Groups*.

3. Save the configuration.

The appliance does not save the schedule and displays an error message if the schedule contains the following:

- Circular dependencies between upgrade groups; for example, the upgrade of Group A is scheduled after Group B, and the upgrade of Group B is scheduled after Group A.
- The upgrade time is in the past.

The appliance also does not save the schedule and displays a warning when there is a group assignment conflict. Otherwise, the appliance confirms that the schedule is saved and indicates whether the upgrade schedule is active.

Resolving Upgrade Warnings

The appliance can generate the following warnings when you schedule an upgrade:

- **GMC**: To resolve this warning, put all Grid Master candidates in the first upgrade group.
- **DNS Primary**: To resolve this warning, put all the members that are serving as DNS primaries in the first upgrade group.
- **DHCP Logging Member**: To resolve this warning, put the DHCP logging member in the first upgrade group.
- **DHCP Failover**: To resolve this warning, place the peers of a DHCP failover association in separate upgrade groups. Ensure that you schedule upgrades of the failover peers close to each other to minimize configuration rules. NIOS does not allow DHCP configuration changes that affect the communication between the peers until both peers are upgraded.

Upgrading Groups Immediately

After you schedule an upgrade with multiple upgrade groups, you can choose to immediately upgrade an upgrade group that has not been upgraded yet. This function is available only for scheduled upgrades.
To upgrade an upgrade group now:

1. From the **Grid** tab, select the **Upgrade** tab, and then click **Toggle Group List View**.
2. In the Group List view, click the Upgrade Group Now icon in the upgrade group row. Grid Manager immediately upgrades the selected group.

Upgrading a Single Member Immediately

After the Grid Master has been upgraded, you can choose to immediately upgrade a specific member that has not been upgraded yet. This function is available only for scheduled Grid upgrades from NIOS 6.4.0 to a later release. You can upgrade a single member only when the Grid upgrade is paused, and you cannot upgrade the Grid Master, reporting appliance, and an offline member. Once the member has been manually upgraded, the appliance skips this member when its scheduled upgrade time is reached.
To upgrade a specific member now:

1. From the **Grid** tab, select the **Upgrade** tab.
2. Pause the upgrade.
3. Click **Toggle Member List View**, and select the member checkbox from the table.
4. From the Toolbar, click **Upgrade** -> **Upgrade Single Member**. Grid Manager immediately upgrades the selected member.

Reverting a Single Member

During an upgrade from NIOS 6.4.0 to a later release, you can revert a specific member that has already been upgraded and is within its revert time window. The revert single member feature is useful when you want to troubleshoot issues, such as service outages, on a specific member after it has been upgraded. You can revert a member only when the Grid upgrade is paused, and you cannot revert the Grid Master, reporting appliance, and an offline member. If the upgrade is paused and you have reverted a member in an upgrade group that has already completed the upgrade, you must move the member to another upgrade group that has not been upgraded before you can proceed with the upgrade.

Once a member is upgraded, the appliance starts counting down and displays the time that is left for you to revert this member. You can revert the member before the revert time window expires. The default time window to revert a member is 24 hours. You can view the time that is left to revert the member in the Member List view, as described in Grid and Member Status below. You can also use the CLI commands *set default_revert_window* to configure the default revert time window for the Grid. For information about this command, refer to the *Infoblox CLI Guide*. Once a member exits the revert time window, you must revert the entire Grid in order to revert the member.

> ⚠ Note
> You may potentially lose some data when you revert a member. The appliance keeps information about DHCP leases and DNS records intact.

To revert a specific Grid member during a scheduled Grid upgrade:

1. From the **Grid** tab, select the **Upgrade** tab.
2. Pause the upgrade.
3. Click **Toggle Member List View**, and then select the member checkbox.
4. From the Toolbar, click **Revert** -> **Revert Single Member**.
   Grid Manager displays a message indicating that the revert process disrupts Grid services. Read the message carefully, and then click **Yes** to confirm your decision to revert the member. Be aware that when you revert a member, some changes made since the member was last upgraded may get lost.

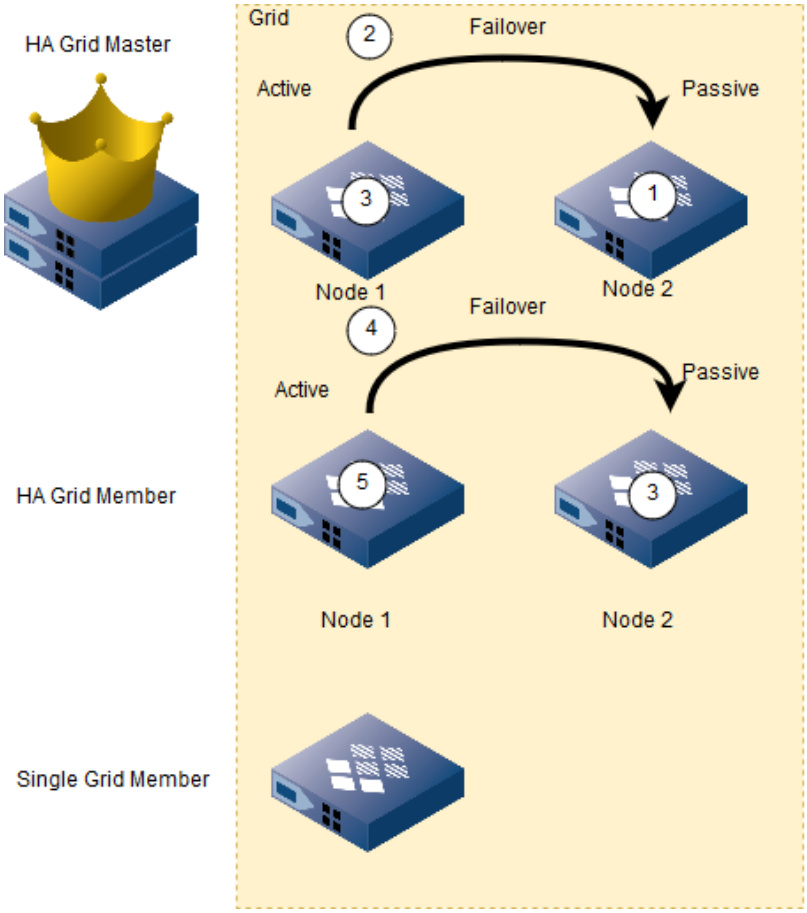
Upgrade Process

When an upgrade starts, Grid Manager checks if the nodes of an HA Grid Master have the same NIOS software version on their alternate partitions. If they do not have the same software version, the upgrade process stops. Grid Manager displays an error message and if it is a scheduled upgrade, Grid Manager deactivates the schedule as well. Otherwise, the upgrade process continues.

> ⚠ Note
> During the upgrade, you can view the status of the Grid Master in the serial console.

During the upgrade, if a Grid member has not completed its distribution, it automatically resynchronizes with the Grid Master after the Grid Master upgrade is complete.
Due to the nature of the upgrade sequence, HA pairs fail over during the upgrade. Therefore, be aware that the active and passive nodes reverse roles. The order in which Grid members upgrade, including when HA pairs fail over, is shown in the below figures Upgrade Sequence for an HA Grid Master and Grid Members and Upgrade Sequence for a Single Grid Master and Grid Members.

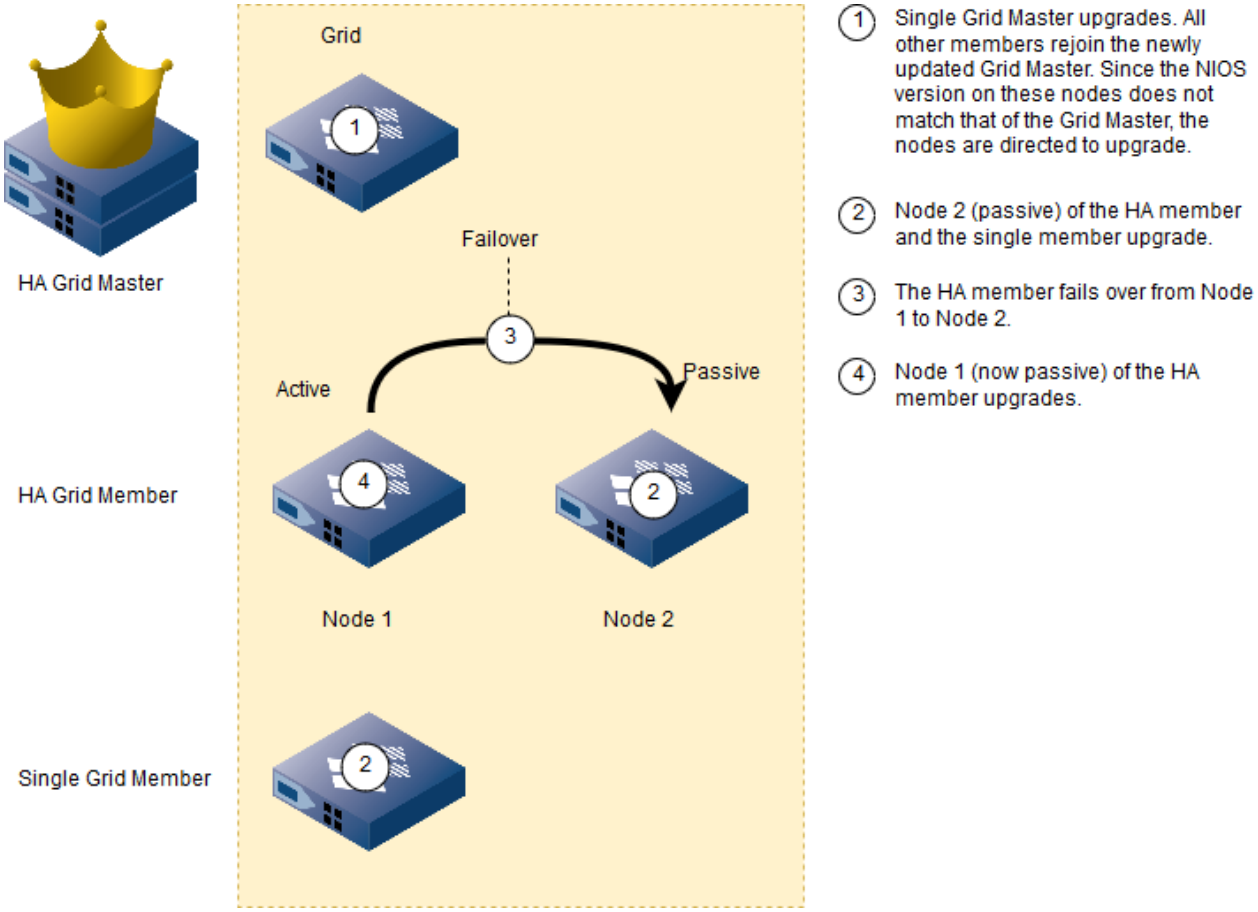
Upgrade Sequence for an HA Grid Master and Grid Members



1. The passive node (Node 2) of the Grid Master upgrades.
2. The Grid Master fails over from Node 1 to Node 2. At this point, the active Grid Master (Node 2) is using the upgraded code. All other nodes, including the passive node (Node 1) and all Grid members, rejoin the newly updated active node (Node 2). Since the NIOS version on these nodes does not match that of the active Grid Master, the nodes are directed to upgrade.
3. Node 1 (now passive) of the Grid Master upgrades. The passive node (Node 2) of the HA member and the single Grid member upgrade.
4. The HA Grid member fail overs from Node 1 to Node 2.
5. Node 1 (now passive) of the HA member upgrades.

> **Note**
> Grid members that do not have the correct NIOS version on their alternate partitions due to an incomplete distribution automatically resynchronize the NIOS version with the Grid Master, and then upgrade.

Upgrade Sequence for a Single Grid Master and Grid Members



The Grid Manager session terminates when the HA Grid Master fails over from Node 1 to Node 2, or when the single Grid Master reboots and goes offline.
During a scheduled upgrade, the Grid members that have not upgraded yet can join the Grid and function normally until their scheduled upgrade time. When the upgrade finishes, the upgrade schedule is set to inactive.

Managing Upgrades

During an upgrade, Grid Manager displays a system message at the top of the screen indicating the Grid is being upgraded. After you start an upgrade, you can pause or resume it. For information, see Pausing and Resuming Upgrades and Monitoring Distribution and Upgrade Status below.

Pausing and Resuming Upgrades

The following are some operational guidelines for performing an upgrade:

- You may not be able to perform certain administrative tasks during an upgrade.
- The Grid Manager session terminates when an HA Grid Master fails over from Node 1 to Node 2, or when a single Grid Master reboots and goes offline. You can log back in to the appliance after the upgrade.
- When you pause an upgrade, you can do the following
    - Change the sequence of the upgrade groups
    - Change the scheduled upgrade time for an upgrade group

To pause an upgrade, from the Grid Upgrade Status bar, click the Pause icon. When you pause an upgrade, Grid Manager displays a system message at the top of the screen indicating the upgrade is paused, until you resume the

upgrade. For information about the upgrade status of each member, see Monitoring Distribution and Upgrade Status below.

To resume an upgrade:

1. From the Grid Upgrade Status bar, click the Resume icon.
2. When the appliance displays a dialog box confirming that you want to resume the upgrade, click **Yes** to continue.

Members that have not completed or started upgrades that were scheduled at an earlier time resume the upgrade.

Monitoring Distribution and Upgrade Status

During a distribution or an upgrade, Grid Manager displays the status of the distribution or upgrade in the status bar. It also displays the process status for each member. You can view the status in either the Member List view or Group List view from the **Grid** tab -> **Upgrade** tab.
When you perform a distribution or an upgrade, the status bar displays the overall Grid distribution status with a progress bar that describes the process being performed. The status bar also displays the number of members that have completed the distribution or upgrade.
A difference between a distribution and an upgrade process is that during an upgrade, the Grid Manager session terminates when an HA Grid Master fails over from Node 1 to Node 2, or when a single Grid Master reboots and goes offline. You can log back in to the appliance after the upgrade.

Grid and Member Status

You can view the distribution and upgrade process status at the Grid and member level. To view the process status, from the **Grid** tab, select the **Upgrade** tab, and then click **Toggle Member List View**.
The status bar displays the status of the overall Grid process. It contains a progress bar that indicates the percentage of completion. It also shows the number of members that have completed the process.
Grid Manager displays the following information for each member:

- **Member**: The name of the Grid member.
- **Group**: The upgrade group to which the member belongs.
- **HA**: Indicates whether the member is an HA pair or not.
- **Status**: The current distribution or upgrade status. This can be Running (green) or Offline (red).
- **IPv4 Address**: The IPv4 address of the member.
- **IPv6 Address**: The IPv6 address of the member.
- **Running Version**: The NIOS software version that is currently running on the member.
- **Alternate Version**: Displays the NIOS software version to which the appliance can revert.
- **Distribution/Upgrade Status**: The current distribution or upgrade status. When the distribution or upgrade is in progress, Grid Manager displays a progress bar in this field to indicate the percentage of completion.
- **Hotfix**: The name of the hotfix that was last run on the member.
- **Status Time**: The date, time, and time zone of the status displayed.
- **Member Revert**: Indicates whether the member has been reverted or not. This appears only when the member has been upgraded from NIOS 6.4.0 to a later NIOS release.
- **Time to Revert**: The time (in HH:MM:SS format) left to revert a member. This appears only when the member has been upgraded from NIOS 6.4.0 to a later NIOS release.
- **Site**: The location to which the member belongs. This is one of the predefined extensible attributes. The appliance automatically refreshes the information in this panel.

Upgrade Group Status

You can view the distribution or upgrade status of an upgrade group in the group list view. In this view, the distribution or upgrade status rolls up to the group level. You can expand an upgrade group to view the status of individual member. However, you cannot view detailed status of a selected member from this view.
To view the process status of an upgrade group, from the **Grid** tab, select the **Upgrade** tab, and then click **Toggle Group List View**. Grid Manager displays the following information for each member in an upgrade group:

- **Group**: The upgrade group to which the member belongs.

- **Member**: The name of the Grid member.
- **Status**: The current member status. This can be Running (green) or Offline (red).
- **IPv4 Address**: The IPv4 address of the member appliance.
- **IPv6 Address**: The IPv6 address of the member appliance.
- **Running Version**: The NIOS software version that is currently running on the member.
- **Distribution Status**: The current distribution status. For an upgrade group, Grid Manager displays a progress bar to indicate the overall percentage of completion. For a member, Grid Manager displays the state of the distribution process.
- **Timestamp**: The date, time, and time zone of the status displayed.

Detailed Status

You can view detailed process information of a member during a distribution or an upgrade. To view detailed process information:

1. From the **Grid** tab, select the **Upgrade** tab, and then click **Toggle Member List View**.
2. Select a member and then click the Detailed Status icon.

Grid Manager displays a panel that shows the required steps during a distribution or an upgrade. It also displays a color indicator, next to each step, to indicate the current status of each step. The color indicator can be one of the following:

- Grey: The process has not started yet.
- Green: The process is complete.
- Blue: The distribution or upgrade that is in progress.
- Red: There is an error; Grid Manager displays a description of the problem.
- Yellow: A warning message.

When the selected member is an HA pair, Grid Manager displays the status information for both nodes. The panel remains open until you close it or select a different member.

Lite Upgrades

A lite upgrade occurs when there are incremental changes to the software that do not require any upgrade to the database. The appliance can perform a lite upgrade only if the format of the database between the existing NIOS version and the upgrade version is the same.
In general, when you upgrade from a patch release to another patch release, you are performing a lite upgrade. In a lite upgrade, members can be running a different software version than the Grid Master. You can add objects, such as zones, networks, and resource records to the members that are running an older NIOS version. Replication of zones, networks, resource records, and DHCP leases is supported between the Grid Master and members. When you want to revert a member however, you must revert the entire Grid.
Whenever possible, the appliance uses the lite upgrade mode to speed up the upgrade process. You can always schedule a lite upgrade. Note that the appliance disables the testing function for lite upgrades because you do not need to test a lite upgrade for any database translation. For information about how to schedule an upgrade, see Scheduling Upgrades in *Upgrading NIOS Software*.

Viewing Software Versions

Before you upgrade, downgrade, or revert to a different NIOS software version, you can view the current software version that is running on the Grid, the NIOS image you have uploaded, and the available version to which you can revert. Grid Manager displays the software information in the **Upgrade** tab.
To view software information:

1. From the **Grid** tab, select the **Upgrade** tab.
2. Grid Manager displays the following in the Grid Version Information section:
    - **Running**: The NIOS software version that is currently running on the Grid.
    - **Uploaded**: The latest NIOS image file you have uploaded and is available for distribution.
    - **Distribution**: The NIOS software version used for distribution or is available for distribution.

- **Revert**: The NIOS software version to which the appliance can revert.
- **DistributionSchedule**: Displays the date and time of the next scheduled distribution.
- **UpgradeSchedule**: Displays the date and time of the next scheduled upgrade.

> **Note**
>
> Grid Manager leaves a field empty when there is no available software for the specific function.

Grid Manager automatically refreshes the **Upgrade** tab with the latest information and displays the timestamp in the **Last Updated** field below the Grid Version Information section.

Downgrading Software

Each Infoblox appliance model has a minimum required release of Infoblox software. Before downgrading an appliance, refer to the document, *Minimum Required Release Software for Hardware Platforms*, that shipped with your product. The downgrade procedure is for single independent appliances only. Infoblox does not support software downgrades for Grid members, but you can revert to the previous NIOS release (see the next section) on a Grid Master.

> **Note**
>
> Although the downgrade process preserves license information and basic network settings, it does not preserve data. After you complete the downgrade procedure, all data in the database is lost.

To downgrade software on a single independent appliance running NIOS 4.0 or later:

1. From the **Grid** tab, select the **Upgrade** tab, and then click **Downgrade** from the Toolbar.
   Grid Manager displays a warning indicating that reverting to the current release is not possible once you start the downgrade. Read the warning carefully, and then click **Yes** to confirm your decision to downgrade.
2. In the *Choose file* dialog box, navigate to the downgrade image file, and then click **Open** to upload the file. The appliance uploads the file to the Grid Master. You cannot stop the downgrade process once you start it. Grid Manager displays the downgrade status in the status bar.

Reverting the Grid to the Previously Running Software

You can revert the Grid to a version of software that was previously running on your NIOS appliance. The NIOS appliance stores the previous software version in its backup software partition. You can see if there is a software version to which you can revert and its version number in the Alternate Version column in the Grid Version Information section of the **Upgrade** tab. To view the software version, from the **Grid** tab, select the **Upgrade** tab. Note that once you start distributing a new NIOS version after an upgrade, you cannot revert to a previous NIOS version.
Be aware that when you revert to this software, changes made since the Grid was last upgraded are lost, including the new DHCP leases and other DNS changes.
To revert to a version of software previously running on a Grid or on an independent appliance or HA pair:

- From the **Grid** tab, select the **Upgrade** tab, and then click **Revert** -> **Revert Grid** from the Toolbar.

Grid Manager displays a warning indicating that the revert process disrupts Grid services. Read the warning carefully, and then click **Yes** to confirm your decision to revert.

Applying Hotfixes

Infoblox periodically releases hotfixes that contain resolved issues. Only superusers can apply hotfixes through Grid Manager. When you install hotfixes through Grid Manager, you can apply them to the Grid Master and All Grid members, the Grid Master only, the Grid Master and Grid Master Candidates, or selected Grid members. This feature is supported on appliances running NIOS version 7.1 or later. Note that each hotfix addresses specific issues.
Infoblox recommends that you verify the hotfix before you apply it to ensure that it is the correct version.

After you apply a hotfix, Grid manager displays the hotfix status in the **Upload Status** bar. In addition, you can view the history of the most recent list of applied hotfixes in the *Hotfix History* dialog box.

> **Note**
>
> A hotfix installation may fail if there is a mismatch in the NIOS software versions or if a hotfix image fails to meet the software or hardware restrictions.

To apply a hotfix:

1. From the **Grid** tab, select the **Upgrade** tab, and then click **ApplyHotfix** from the Toolbar and select one of the following:
    - **ToGridMasterandallGridMembers**: Click this to apply hotfix to the Grid Master and all Grid members.
    - **ToGridMaster**: Click this to apply hotfix to the Grid Master only.
    - **ToGridMasterandGridMasterCandidates**: Click this to apply hotfix only to the Grid Master and Grid Master candidates.
    - **ToselectedGridMembers**: Click this to apply hotfix to the selected Grid member. This option is available only after you have selected a Grid member or members.
2. In the *ApplyHotfix* dialog box, click **Select** and navigate to the hotfix image file you want to upload. Click **Open** to select the file, and click **Upload**.

> **Note**
>
> If you have already installed a hotfix and subsequently try to upgrade or downgrade NIOS, the appliance displays a warning message because resolved issues in the hotfix will no longer be valid if the upgrade or downgrade version does not contain the original hotfix.

The appliance applies the hotfix to the targeted appliance(s). You cannot stop the hotfix process once you start it. Grid Manager displays the hotfix status in the **Upload Status** bar.

Viewing Hotfix History

You can view hotfix history on selected members. To view the hotfix history:

1. From the **Grid** tab, select the **Upgrade** tab, click the Show Hotfix History icon in the **Hotfix** column.
2. The *Hotfix History* dialog box displays the following information:
    - **Date**: The timestamp when the hotfix was applied.
    - **Hotfix**: The name of the hotfix that was last run on the member. The name of the hotfix image file that was applied to the member.
3. Click **Close** to close the *Hotfix History* dialog box.

Using Database Snapshots

Infoblox recommends that you regularly create database snapshots that helps in mitigating the impact of any user errors in the NIOS configuration. Whenever there is an error in the NIOS configuration, you can roll back the database (onedb) to the snapshot that you have created earlier. This is potentially faster than restoring the database using the backup file. The following sections describe how to create snapshots and roll back snapshots:

Creating Database Snapshots

You can create a database snapshot periodically and save it locally on the appliance. You can create only one copy of the database snapshot at any given time. Each time you create a new snapshot, it overrides the previous snapshot. When you create a database snapshot, only data that is currently saved in the database is included in the snapshot. Only

superusers are allowed to create a database snapshot. Creating database snapshots does not have any impact on the scheduled local backup. The snapshot saved locally on the appliance will not be affected if an HA failover occurs, but the snapshot is deleted during a Grid Master Candidate promotion, upgrade, downgrade, or if you restore the appliance using the backup file. Note that creating a database snapshot fails when any of the following operations are in progress:

- Rolling back database snapshot.
- When another database snapshot is being created.
- Restoring backup files. To create a snapshot:

1. From the **Grid** tab -> **Grid Manager** tab, click **Snapshot** -> **Create** from the Toolbar.
2. In the *Create Snapshot* dialog box, enter information about the snapshot in the **Comment** field and click **OK**.
3. In the *Create Snapshot* confirmation dialog box, click **Yes**.

Rolling Back Database Snapshots

If you have already created a snapshot, you can roll back the database to the snapshot to recover from any user errors in the NIOS configuration. Rolling back the database (onedb) to the snapshot is potentially faster than restoring the database from a backup file. Rolling back to the snapshot changes only the database, not any other transient data, such as file distribution, reporting splunk, discovery data, etc. Note that you might lose the data that you have saved after creating the snapshot. Only superusers can perform the rollback operation.

> When reporting cluster is enabled, rolling the database back to the snapshot that was created when reporting was in the single-indexer mode might cause some data loss. The database settings will reset reporting to the single-indexer mode, and the indexer might not have all the data indexed since reporting cluster was enabled.

To roll back the database to the snapshot:

1. From the **Grid** tab -> **Grid Manager** tab, click **Snapshot** -> **Rollback** from the Toolbar.
2. The *Rollback Snapshot* dialog box displays the following information:
    - **Snapshot Time**: The date and timestamp when the snapshot was created.
    - **Comment**: Information about the snapshot.
3. Click **OK**.

Downloading Support Bundles

When you need assistance troubleshooting a NIOS appliance, you can log in to the appliance as a superuser, download the support bundle of the appliance, and then send it to Infoblox Technical Support for analysis. A support bundle is a tar.gz file that contains configuration files and the appliance system files. You can download a support bundle for an independent appliance and for each member in a Grid. When you download a support bundle for an HA pair, it includes the files of both nodes in the HA pair.

By default, the appliance includes the following files in the support bundle: core files, current logs, and rotated logs. Because core files can be quite large and take a significant amount of time to download, Infoblox recommends that you include core files in the support bundle only when requested by Infoblox Technical Support. You can include all the core files or specific core files in the support bundle when Infoblox Support requests them. Note that the option of downloading only specific core files is supported on appliances running NIOS version 8.0 or later. If your appliance supports multiple primary servers for DNS authoritative zones, you can select to include cached zone data in the support bundle. This data is not included in the bundle by default.

You can override the default support bundle download time which is 1200 seconds. To do so, go to **Grid** -> **Grid Manager** -> **Grid Properties** -> **Edit** -> **Advanced**, and set a custom value for **Support Bundle Download Timeout**. You can also use the *set support_timeout* command from the Administative Shell.

To download a support bundle:

1. From the **Grid** tab, select a *member* checkbox, and then click **Download** -> **Support Bundle** from the Toolbar.
2. In the *Download Support Bundle* dialog box, select the files you want to include in the support bundle, and then click **OK**.

- **Core Files:** Infoblox recommends that you include these files only when requested by Infoblox Technical Support.
- **Current Logs:** Infoblox recommends that you always include these files in the support bundle.
- **Rotated Logs**: These are rotated logs that contain historical information.
- **Cached DNS Recursive Data:** Select this to include cached DNS recursive data in the support bundle. This is deselected by default.
- **Cached Zone Data**: Select this to include cached DNS zone data in the support bundle. This is deselected by default.
- **Subscriber Services Data**: If you have configured Infoblox Subscriber Services, you can select this to include subscriber services data in the support bundle. This is deselected by default. For information about Infoblox Subscriber Services, see *Infoblox Subscriber Services*.
- **Cloud Discovery Data**: Select this to include cloud discovery data in the support bundle. This is deselected by default.
- **Files from the previously installed NIOS version**: Select this to include files from the previously installed NIOS version in the support bundle. This is deselected by default.
- **Discovery SNMP Logs**: Event logs related to device discovery SNMP probes of routers, switches and other network infrastructure devices.
- **Core Files:** Infoblox recommends that you include these files only when requested by Infoblox Technical Support.
    - **All Core Files**: Select this to include all core files in the support bundle.
    - **Select Core Files**: Select this to include only specific core files in the support bundle. Click the Add icon in the table. Grid Manager displays the *Core Files Selector* dialog box from which you can select specific core files. You can delete a core file by selecting its checkbox and clicking the Delete icon. Note that on an HA pair, you can select the core files of the active node only.

3. Navigate to the location you want to save the file and change the file name. Do not change the .tar.gz file extension in the file name.
4. Send this file to Infoblox Technical Support.

Guidelines for Upgrading, Backing Up, and Restoring Data

You should take into consideration the impact on scheduled and approval tasks when you perform any of the following:

- When you upgrade from previous releases to NIOS 6.7 and later, the appliance converts all valid punycode data to IDNs for DNS resource records and DNS zones. When you have a fresh installation of NIOS 6.7 and later, the appliance converts all valid punycode data to IDNs for DNS zones only. It retains punycode data for resource records.
- Upgrade the NIOS software: In a full upgrade, all scheduled and approval tasks are deleted. In a lite upgrade, scheduled and approval tasks are not deleted.
- Back up the NIOS database: All scheduled and approval tasks are backed up for troubleshooting purpose.
- Restore the database: Scheduled and approval tasks are not restored.
- Promote a Grid member to a Grid Master: After the promotion, all scheduled and approval tasks that are past due are executed immediately.
- Revert the NIOS software image: After the revert, all scheduled and approval tasks that are past due are executed immediately.
- Restore data from the Recycle Bin: To restore a deleted parent object (such as a network) that contains a child object (such as a DHCP range) associated with a scheduled or approval task, you must first delete the scheduled or approval task for the child object.

Scheduling Tasks

Guidelines for Upgrading the Reporting and Analytics Solution

When you upgrade from a previous NIOS release to NIOS 7.3.x and later releases, you will notice that some of the reporting features and terminologies have changed. For example, searches and reports in previous NIOS releases are now reports and dashboards respectively in the new reporting solution. In addition, your custom reports might be affected. Infoblox recommends that you take some time to explore the new user interface and get familiar with the terminologies.
You can continue to use the Infoblox predefined reports from previous releases in the new interface and customize them to meet your specific requirements, or you can create new custom reports from the ground up using a powerful search pattern.

> ⚠
>
> **Note**
>
> Infoblox Reporting and Analytics integrates with Splunk to deliver an enhanced reporting interface so you can create dashboards, reports, and alerts. This chapter attempts to explain all reporting functionality you can perform through the enhanced interface. However, you may need to refer to the Splunk documentation for certain functionality as indicated in specific sections of this chapter. In addition, some functions and capabilities referenced in the Splunk documentation, such as setting up custom Python scripts, are not available or applicable to the Infoblox Reporting and Analytics as some Splunk functionality in the Infoblox product may be limited or modified by Infoblox. Infoblox does not represent or warrant that Infoblox Reporting and Analytics will function in accordance with the Splunk documentation. Infoblox is also not responsible for the accuracy of the Splunk documentation. For Infoblox Reporting and Analytics technical support, contact Infoblox Technical Support. DO NOT contact Splunk.

When you upgrade from a previous NIOS release to NIOS 7.3.x and later, there are some significant changes to the Reporting and Analytics solution. Some of the important changes are as follows:

- **Terminology**: The following table lists the terminology differences when you upgrade:

Reporting Terminology Changes

Pre-NIOS 7.3.0 Release	NIOS 7.3.0 and later
Searches	Reports
Reports	Dashboards

- **Object Management**: NIOS no longer manages reporting objects such as searches, smart folders, alerts, and reports. You will not be able to perform operations such as global search, quick filtering, bookmarking, and others for these objects. You can now manage these objects through the new user interface.
  Smart folders are migrated after an upgrade. However, data in the smart folders is not migrated, and all filters for the smart folders are reset to default.
- **Permissions**: Permissions for all reporting objects are migrated to the new Reporting and Analytics solution and managed through the new user interface after an upgrade. You may see the new built-in role, **Everyone**, when configuring Reporting permissions. For best practices, do not alter permissions for this new built-in role. Note that the **Reporting Dashboard** and **Reporting Search** global permissions have been removed. If an admin group or admin role was granted these permissions before an upgrade, the permissions will still be displayed after an upgrade. However, they won't take any effect. The **Grid Reporting Properties** permission is retained. In addition, reporting object permissions for dashboards and searches (including global dashboards and searches) are migrated. These object permissions are retained for applicable migrated users. If permissions were granted to a specific admin group for a dashboard or search before an upgrade, only these admin users and superusers have permissions to access the migrated dashboard and report after an upgrade. If a limited-access user group is created through the new interface after the upgrade, users in this admin group will not be able to access the dashboard and report even if they are granted access to the **Infoblox Reporting and Analytics App**. Superusers

must explicitly grant permissions to this limited-access admin group for users in this group to access the dashboard and report. For more information, see *Administrative Permissions*.

- **Navigation and Visualization**: Navigations for some reporting functions, such as searches, alerts, email and page settings, and email PDF delivery, have changed. You can navigate through the new user interface to get familiar with the changes in this release. In addition, all predefined reports might look different than the traditional ones depending on your filtering configuration. The *Grid Reporting Properties* editor and **Groups** tab are moved under the **Administration** tab –> **Reporting** tab.
  Note that the Bookmarked groups are migrated after an upgrade. The bookmarked group navigates to the **Administration** tab –> **Reporting** tab –> **Groups** tab.
- **Extensible Attributes**: The reports that supported filtering and grouping by multiple extensible attributes are migrated to the new interface with filtering and grouping only by the extensible attribute **Site**. You must clone the dashboard, add filter inputs and modify the view XML to support additional extensible attributes. For information about Editing the XML Source Code of a Dashboard, see *About Dashboards*.
- **Searches and Reports**: Only NIOS system and global reports and searches are migrated to NIOS 7.3.0 and later versions as dashboards and reports respectively. All user private reports and searches are dropped. In addition, bookmarked reports and searches are not migrated to 7.3.x release. If you want to keep any customization for the user private dashboards and reports, do one of the following:
  - Create global dashboards and reports using the same settings.
  - After an upgrade, you can clone the corresponding migrated system or global dashboards and reports, and then reconfigure the original settings, such as filters and scheduling in the new user interface.
- **Custom Search**: You can create your own search pattern and save it as a dashboard or report. For information about About Searches, see *Home Dashboards*.

After completing the NIOS upgrade successfully, you configure the *Grid Reporting* properties and remote server (FTP, SCP, or TFTP) to export search results. For information, see *Grid Reporting Properties* and *Configuring an External Server for Search Result Exports*.

Infoblox Reporting and Analytics

Guidelines for Scheduling Full Upgrades

When scheduling a full upgrade in NIOS, the Grid Master replicates the following features to the Grid members, including to those members that have not been upgraded:

- DNS resource records
- DNS zones
- DNS views
- Name server groups
- Shared record groups
- IPv4 and IPv6 host addresses
- Roaming hosts
- IPv4 and IPv6 networks
- IPv4 and IPv6 shared networks
- Fixed addresses
- DHCP ranges
- DHCP failover association
- DHCP option spaces
- DHCP options
- DHCP filters
- MAC filter items
- Blacklist & NXDOMAIN rules
- DNSSEC key pairs
- DNSSEC import keyset operation
- Signed and unsigned zones

- DNSSEC rollover KSK and ZSK operations.

You can perform the following tasks during an upgrade:

- Upgrade a specific member during the scheduled Grid upgrade. For information about how to upgrade a single member during a scheduled Grid upgrade, see Upgrading a Single Member Immediately in *Upgrading NIOS Software*.
- Revert a single member that has already been upgraded to troubleshoot issues, such as service outages, on that specific member. The upgrade of that member can then be rescheduled. For more information, see Reverting a Single Member in *Upgrading NIOS Software*.
- Clear authentication cache and authentication records.
- Perform AD (Active Directory) configurations. Note that the keytab file must be uploaded before the upgrade starts.

Note the below restrictions when scheduling a full upgrade:

- Any action that requires a service restart for configuration changes to take effect are not recommended and can result in upgrade issues.
- Do not add, modify, or delete an NS group.
- Do not add, modify, or delete manually created NS records.
- Do not add, modify, or delete a zone.
- Do not assign or unassign an NS group to a zone.
- Do not change the NS group assigned to a zone.
- Do not change the host name of the Grid members that are assigned to a zone if the members have not been upgraded, have been reverted, or are in the revert time window.
- Do not restart DNS and DHCP services or schedule a restart for these services on Grid members that have not been upgraded. For more information about Restarting Groups, see *Restarting Services*.
- Do not add, delete, or modify a DHCP range, a filter, or a fixed address.
- Do not modify the settings for automated mitigation of phantom domain attacks using the CLI commands on a Grid member until the member has completed the upgrade.

The Grid Master and Upgrade Groups can be scheduled to upgrade at different times in order to limit service impact. However, upgrades needs to be performed within a limited window of time (i.e. within a couple of days). If an upgrade spans nine or more days, a warning is displayed in the NIOS UI.

NIOS does contain checks and rules to ensure data integrity that can cause undesirable results during the upgrade process. However, when scheduling a full upgrade, the following rules and behavior has to be noted and followed to ensure a seamless upgrade:

- Do not modify member properties for the following: DNS, DHCP, TFTP/HTTP/FTP, bloxTools, Captive Portal, Reporting, and load balancing until the member has completed the upgrade and exited its revert time window.
- Do not delete DNS views until the entire Grid upgrade is complete.
- Do not delete DNS zones and IPv4 and IPv6 networks that are under Microsoft Management until the managing member of the Microsoft servers has completed its upgrade and exited its revert time window.
- Synchronization between load balancers and the appliance is disabled until the load balancer managing member has completed its upgrade. Do not change the managing member during the upgrade.
- Do not add, modify, or delete network views, rulesets, and DNS64 synthesis groups until the entire Grid upgrade is complete.
- Replication of Grid and member DNS and DHCP properties is not supported.
- Do not create additional named Access Control Lists (ACLs) until after the entire Grid has been upgraded. For information about named ACLs, see *Configuring Access Control*.

During a scheduled full upgrade, the Grid Master skips Grid members that do not complete their NIOS upgrade within 10 minutes, the default upgrade policy time, and moves to the next Grid member within the upgrade schedule.

During a scheduled full upgrade, do not perform the following tasks on a Grid member that has not been upgraded yet:

- Import the DHCP lease history file
- Use the DHCP expert mode configuration feature
- Clear the NAC authentication cache of a DHCP member
- Set the time zone for a Grid member
- View the capacity report of a Grid member

- Test the email configuration settings of a Grid member
- Check whether an IPv6 address is already configured on a Grid member

When scheduling a full upgrade from a previous NIOS release to a release that includes the DHCP fingerprint detection feature, the following rules apply until the entire Grid has been upgraded:

- DHCP fingerprint detection is disabled
- Do not add DHCP fingerprint filters
- Do not apply DHCP fingerprint filters to any DHCP address range

When scheduling a full upgrade from a previous NIOS release to a release that includes the multi-primary zone feature, the following rules apply until the entire Grid has been upgraded:

- Do not configure multiple primary servers for an authoritative zone or configure a name server group that contains multiple primary servers.
- Do not assign or unassign a Grid member to an authoritative zone or name server group.
- Do not change the stealth state of an authoritative zone or name server group.

When scheduling a full upgrade from a previous NIOS release to a release that includes the Infoblox Threat Protection feature, do not perform the following on a Grid member until the member has completed the upgrade:

- Start or stop the Threat Protection and DNS services.
- Activate a ruleset.
- Perform any threat protection related tasks such as adding custom rules and activating rulesets.

Before scheduling a full upgrade from a previous NIOS release to a release that includes the IPv6 Grid feature, the following rules apply:

- If the Grid has an HA Master or HA member and if it is configured with IPv6 VIP address, IPv6 addresses must be configured for both node 1 and node 2.
- Both the Grid Master and the Grid Master Candidate must have the same type of network connectivity.
- The current configuration and database must be backed up.
- If the subscriber site has HA and the HA passive node is the first to upgrade, the data repository connectivity uses the IPv4 protocol for the site members. If you want the data repository to be connected over the IPv6 protocol, you must stop and restart the subscriber service in the upgraded Grid. The subscriber data is lost when the service is stopped and restarted. It is recommended to stop/start the service of each member at a time to synchronize the subscriber cache with the next active member on the same site.

When scheduling a full upgrade from a previous NIOS release to a release that includes the Secure Dynamic Updates feature, the following rules apply until the Grid has completed the upgrade:

- All dynamic updated records are labelled as static records. Infoblox suggests to enable this feature only after all records are changed to Dynamic.
- NIOS tags the RRsets that are not auto-generated as static records. For information about Secure Dynamic Updates, see *Secure Dynamic Updates.*

When scheduling a full upgrade that includes the DNS Traffic Control feature, the following rules apply until the entire Grid has been upgraded:

- Do not add an SNMP health monitor.
- Do not configure the All available load balancing method for a DTC pool.
- The record types are reset to default record types (A and AAAA records) and do not modify the record types for an LBDN.

Upgrading Parental Control at DNS Cache Acceleration

Upgrading Infoblox subscriber services parental control at DNS Cache Acceleration using cached domain and subscriber data has the following restrictions:

- Upgrade subscriber services using a staged upgrade. This does not affect subscriber data.
- You must update parental control category data download credentials after the upgrade.
- When you upgrade, designate a few members per site to run garbage collection as subscriber services does not perform garbage collection.

- Restrictions when upgrading subscriber sites:
    - You cannot add or remove members from a site during an upgrade.
    - You cannot stop or start a subscriber secure service during an upgrade.
    - You cannot change any subscriber service configuration during an upgrade.

Microsoft Management Rules

On a member that synchronizes data with Microsoft DNS and DHCP servers, the following functions are deactivated during an upgrade:

- Synchronization of Microsoft DNS and DHCP data
- Rotation of Microsoft logs
- Start and stop of Microsoft servers
- Releases of DHCP leases from a Microsoft DHCP server

Deactivation of these functions does not affect data on the Microsoft servers. After the upgrade, the member automatically restarts the synchronization of Microsoft data.

On a member that synchronizes data with Microsoft DNS and DHCP servers, the following rules apply:

- Do not modify the managing member if the old and new members have not been upgraded and have not exited their revert time windows.
- Do not add, modify, or delete zones, IPv4 DHCP ranges, and IPv4 networks until the managing member has been upgraded and exits the revert time window.
- Do not add, modify, or delete DNS resource records if the associated zone is managed by a Microsoft server and the managing member is still in its revert time window.
- Do not add, modify, or delete fixed addresses that are assigned to a Microsoft server and the managing member is still in its revert time window.
- Wait until the new managing member is upgraded to configure it as a DNS primary or secondary.

DHCP Expert Mode Upgrade

Enabling DHCP expert mode allows administrators to directly manipulate sections of the DHCP configuration file. In this mode, all built-in protections and error checking normally provided by Infoblox are bypassed.

Because these protections are removed, Infoblox is unable to provide support for DHCP while in the DHCP expert mode except to confirm that administrator changes to the configuration file were written. The integrity of the configuration file when the DHCP expert mode is enabled is entirely the responsibility of the administrator. If Infoblox support for DHCP is required, first disable the DHCP expert mode and then reproduce the issue.

Infoblox strongly discourages the use of DHCP expert mode. Consider using it only after discussing the situation with Infoblox Support.

Backing Up and Restoring Configuration Files

Infoblox recommends that you regularly back up your configuration files and/or discovery database files. You can back up your system files locally on the appliance or to your management system, or use TFTP (Trivial File Transfer Protocol), FTP (File Transfer Protocol), or SCP (Secure Copy) to back them up to a remote server. Backing up and restoring the configuration files using TFTP, FTP, or SCP is supported on both IPv4 and IPv6 communication protocols. You can select to back up files manually or schedule automatic backups for a later date.
To avoid missing a backup when a remote server is unavailable during a scheduled automatic backup, you can choose to save files locally on your appliance while backing up to the remote server. Both the local and remote backup files share the same date because NIOS saves these files from the same backup. The backup file is a .tar.gz file that contains the configuration settings, data set, and TFTP files. Note that the local backup contains only the Grid backup. It does not contain backups for reporting or NetMRI.

> **Note**
>
> While the content of the backup file in plaintext it does not contain any plaintext representation of any passwords. These are either encrypted with AES-256 or salted hashed with SHA-128.

You may also schedule automatic backups of the discovery database, which consists of the complete discovery data for networks and network devices such as core, distribution and edge routers, enterprise switches, security devices, and end host devices. NIOS backs up the discovery database in a .tar.gz file, with the raw discovery data formatted as an XML file.

> **Note**
>
> Infoblox recommends that you backup the configuration after you convert a Grid to a different mode. Restoring the old backup by performing a forced restore, may prevent the Grid members from rejoining the Grid Master after the restore.

The following sections describe how to use the backup and restore functions:

- Backing Up Files
- Automatically Backing Up Data Files
- Manually Backing Up Data Files
- Restoring Backup Files
- Downloading Backup Files from a Different Appliance

> **Note**
>
> Infoblox highly recommends that you always back up the current configuration file before upgrading, restoring, or reverting the software on the appliance. If you are performing these operations on appliances licensed for Discovery and that perform discovery, the discovery database can be backed up and restored using the same mechanisms.

Backing Up Files

You can back up system files and discovery databases periodically and on demand. You can then restore the files on the same appliance or on a different appliance. For information about restoring files, see Restoring Backup Files below. You can configure the appliance to automatically back up the files on a weekly, daily, or hourly basis.
Infoblox recommends that you back up the system files during off-hours to minimize the impact on network services. By default, the automatic backup function is turned off. You must log in with a superuser account to back up files.
You can back up system configuration and/or discovery database files to the following:

- A local directory
- The management system that you use to operate the appliance
- A TFTP server
- An FTP server. This option requires that you have a valid username and password on the server prior to backing up files.
- An SSH server that supports SCP. This option requires that you have a valid username and password on the server prior to backing up files.

Local Backup

You can store a backup file on the appliance itself. However, Infoblox recommends that you store backup files in an alternate location. When you back up the system files locally, the appliance uses the following format to name the file: BACKUP_YYYY_MM_DD_MM.tar.gz. For example, a file name of BACKUP_2013_11_30_23_00 means that the file is backed up on November 30th, 2013 at 11:00 PM.
The appliance can save up to 20 configuration files, regardless of how often the files are saved (weekly, hourly, or daily). Ensure that you take the size of the configuration file into consideration when backing up files because the storage limit on an appliance is 5 Gb (gigabytes). If your configuration file is 500 Mb (megabytes), then the appliance can store 10 configuration files. When uploading configuration files on to a TFTP, FTP, or SCP server, you must consider the file size on that server as well.

Using TFTP

TFTP is a client-server protocol that uses UDP as its transport protocol. It does not provide authentication or encryption, therefore it does not require a username or password.
When you back up the system files to a TFTP server, you select the backup file you want to download, enter the name in which the file is stored on the TFTP server and the server IP address.

Using FTP

FTP is a client-server protocol used to exchange files over TCP-based networks. The appliance, as the FTP client, connects to a remote FTP server that you identify. When you use FTP to back up the system files, the password and file contents are transmitted in clear text and may be intercepted by other users.
When you back up the system files to an FTP server, the appliance, as the FTP client, logs on to the FTP server. You must specify the username and password the appliance uses to log on to the FTP server. The user account must have write permission to the directory to which the appliance uploads the backup file.

Using SCP

SCP is more secure than TFTP and FTP. It uses the SSH protocol to provide authentication and security. You can use SCP to back up the NIOS system files to a server running SSHv2.
When you use SCP to back up the system files to an SSH server, you must specify the username and password the appliance uses to log on to the server. Note that you must use either "password" or "Password" in the SCP password prompt because the appliance does not recognize "PASSWORD" in the prompt. Therefore, ensure that you customize the SCP password prompt to say "Enter your password" or "Enter your Password." Otherwise, the SCP backup will fail. The user account must have write permission to the directory to which the appliance uploads the backup file. In addition, make sure that you enter the correct IP address of the SSH server; the appliance does not check the credentials of the SSH server to which it connects.

Note

The SCP protocol uses SSH for data transfer and thus provides the same authentication and security as SSH. SCP uses LAN1 regardless of whether the MGMT port is enabled or not.

Automatically Backing Up Data Files

Infoblox recommends that you regularly back up your configuration files and/or discovery database files. The easiest way to accomplish this task is to configure the appliance for scheduled automatic backups of the NIOS configuration files. When you automatically back up a configuration file on the appliance, the file is named in the format

<GRIDNAME>_YYYY_MM_DD_HH.MM.tar.gz. The default time for an automatic backup is 3:00 AM. Infoblox recommends scheduling configuration file backups to take place during the slowest period of network activity. You can choose a schedule for when and how often files are backed up: weekly, daily, or hourly.
If a Grid has a discovery member, you may also schedule automatic backups of the Discovery database, which consists of the complete discovery data for networks and network devices such as core, distribution and edge routers, enterprise switches, security devices, and end host devices. NIOS backs up the Discovery database in a .tar.gz file, with the raw Discovery data formatted as an XML file. For information on discovery features and requirements, see the chapter *Infoblox Network Insight*.
To automatically back up a database file on an independent appliance or Grid Master:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Backup** -> **Schedule Backup** from the Toolbar.
2. In the *Schedule Backup* dialog box, select the destination of the backup file from the **Backup to** drop-down list**:**
    - **TFTP**: Back up system files to a TFTP server.
    - **Keep local copy**: Select this to also save a local copy of the backup file on your appliance. This is disabled by default. The local backup contains only the Grid backup, it does not contain backups for reporting and NetMRI. Note that when you select this, the total backup time will increase.
        - **IP Address of TFTP Server**: Enter the IP address of the TFTP server to which you want to back up the system files.
        - **Directory Path**: Enter the directory path of the file. For example, you can enter **/archive/backups**. The directory path cannot contain spaces and backslash (\). The folder or directory you enter here must already exist on the specified server. Do not include the file name in the directory path.
        - **Recurrence**: Select how often you want to back up the files. You can select **Weekly**, **Daily**, or **Hourly** from the drop-down list. When you select **Weekly**, complete the following:
            - **Every:** Choose a day of the week from the drop-down list.
            - **Time**: Enter a time in the hh:mm:ss AM/PM format. You can also click the clock icon and select a time from the drop-down list. The Grid Master creates a backup file on the selected day and time every week.
              When you select **Daily**, enter a time in the hh:mm:ss AM/PM format. You can also select a time from the drop-down list.
              When you select **Hourly**, complete the following:
            - **Minutes after the Hour**: Enter the minute after the hour when the Grid Master creates a backup file. For example, enter 5 if you want the Grid Master to create a backup file five minutes after the hour every hour.
        - **Disable Scheduled Backup:** Select this if you want to disable automatic backups from occurring now.
          You can still save the settings for future use.
    - **FTP**: Back up system files to an FTP server.
    - **Keep local copy**: Select this to also save a local copy of the backup file on your appliance. This is disabled by default. The local backup contains only the Grid backup, it does not contain backups for reporting and NetMRI. Note that when you select this, the total backup time will increase.
        - **IP Address of FTP Server**: The IP address of the FTP server.
        - **Directory Path**: Enter the directory path of the file. For example, you can enter **/archive/backups**. The directory path cannot contain spaces and backslash (\). The folder or directory you enter here must already exist on the specified server. Do not include the file name in the directory path.
        - **Username**: Enter the username of your FTP account.
          Note that if you have configured AD server for authentication, you must specify "domain name\ \username".
        - **Password**: Enter the password of your FTP account.
        - **Recurrence**: Select how often the scheduled backups should occur. You can select **Weekly**, **Daily**, or **Hourly**. For information, see TFTP.
        - **Disable Scheduled Backup:** Select this if you want to disable automatic backups from occurring now, but want to save the settings for future us
    - **SCP**: Back up system files to an SSH server that supports SCP.
    - **Keep local copy**: Select this to also save a local copy of the backup file on your appliance. This is disabled by default. The local backup contains only the Grid backup, it does not contain backups for reporting and NetMRI. Note that when you select this, the total backup time will increase.
        - **IP Address of SCP Server**: The IP address of the SCP server.

- **Directory Path**: Enter the directory path of the file. For example, you can enter **/archive/backups**. The directory path cannot contain spaces and backslash (\). The folder or directory you enter here must already exist on the specified server. Do not include the file name in the directory path.
- **Username**: Enter the username of your SCP account.
  Note that If you have configured AD server for authentication, you must specify "domain name\ \username".
- **Password**: Enter the password of your SCP account.
- **Recurrence**: Select how often the scheduled backups should occur. You can select **Weekly**, **Daily**, or **Hourly**. For information, see the TFTP section.
- **Disable Scheduled Backup:** Select this if you want to disable automatic backups from occurring now.
  You can still save the settings for future use.
  Note that when you select **FTP** or **SCP**, ensure that you have a valid user name and password on the server prior to backing up the files.
  New status types such as **Upload keys triggered**, **Upload keys in progress**, **Upload keys done** are displayed in the *Reporting Restore* dialog box also.

- **Grid Master (Local)**: Back up to a local directory on the Grid Master. This is the default.
  By default, the Grid Master generates a backup file and saves it locally in its own storage at 3:00 AM daily. Be aware that backing up the Grid and saving it locally on an hourly basis increases the turnover of files stored on the Grid Master. Backing it up hourly to a remote server increases the overall amount of traffic on your network.

3. If the Grid has a discovery member, Grid Manager displays the **NIOS data** and **Discovery data** checkboxes. You can select the **NIOS data** checkbox, to back up NIOS configuration data for the Grid and select the **Discovery data** checkbox, to back up discovery data for the Grid.
   If the Grid has a reporting member, Grid Manager displays the **Infoblox Splunk App** checkbox. You can select the **Infoblox Splunk App** checkbox, to back up Splunk application reporting data.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Manually Backing Up Data Files

You can manually back up a NIOS data file in addition to scheduling your backups. If a Grid has a discovery member, you can also manually back up the current discovery database. Doing so backs up the complete discovery database that is resident on the Consolidator appliance, which is a member of the Grid. Keep in mind that discovery processes may be taking place on the associated NIOS appliances licensed for that task. NIOS will temporarily suspend the Discovery service while the backup is being retrieved from the Consolidator appliance.
To back up manually:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Backup** -> **Manual Backup** from the Toolbar.
2. In the *Backup* wizard, select the destination of the backup file from the **Backup to** drop-down list:
   - **My Computer**: Back up system files to a local directory on your computer. This is the default.
   - **TFTP**: Back up system files to a TFTP server.
     - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter **/archive/backups/Infoblox_2009_10_20_15_30.** The directory path cannot contain spaces and backslash (\).
     - **IP Address of TFTP Server**: Enter the IP address of the TFTP server to which you want to back up the system files.
   - **FTP**: Back up system files to an FTP server.
     - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter **/archive/backups/Infoblox_2009_10_20_15_30**. The directory path cannot contain spaces and backslash (\).
     - **IP Address of FTP Server**: The IP address of the FTP server.
     - **Username**: Enter the username of your FTP account.
       Note that if you have configured AD server for authentication, you must specify "domain name// username".
     - **Password**: Enter the password of your FTP account.
   - **SCP**: Back up system files to an SSH server that supports SCP.

- **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter **/archive/backups/Infoblox_2009_10_20_15_30**. The directory path cannot contain spaces and backslash (\).
- **IP Address of SCP Server**: The IP address of the SCP server.
- **Username**: Enter the user name of your SCP account.
  Note that if you have configured AD server for authentication, you must specify "domain name// username".
- **Use Keys**: If you select this checkbox, you can back up files to SCP without entering the password. The first time you select the checkbox, you need to enter the password. However, during subsequent times, the Infoblox server verifies whether Infoblox keys are available on the SCP server. If they are available, you can click the **Backup** button without entering the password. If Infoblox keys are not available on the SCP server, the following message is displayed:

  ```
  Infoblox SSH keys are not present on SCP server. Please upload the keys to the SCP server or download the keys and manually add it to the SCP server.
  ```

  Password: Enter the password of your SCP account.
- **Keys Type**: Select the SSH key type to be uploaded. At present, only ECDSA and RSA keys are supported. Click **Upload Keys** to upload the keys to the SCP server. If the keys are not available, click **Download Keys** to download the keys and manually add them to the SCP server.

Notes:

- If you are using Fedora, ECDSA keys are supported only on Fedora versions later than Fedora 12.
- When you select **FTP** or **SCP**, ensure that you have a valid user name and password on the server prior to backing up the files. Also ensure that the target SSH server has the required permissions for an SCP backup. The permission must be 755 and the target server must have write permission to the directory to which you upload the backup file.
- For an SCP backup, ensure that you are logged in as the user for whom the key was created. Also ensure that the .ssh directory on the server and the files it contains, have the correct permissions: `chmod 600 ~/.ssh/authorized_keys && chmod 700 ~/.ssh/`
- If you promote a Grid Master or perform an HA failover, you must upload the SSH key once again for a successful SCP backup using keys.

3. If the Grid has a discovery member, Grid Manager displays the **NIOS data** and **Discovery data** checkboxes. You can select the **NIOS data** checkbox, to back up NIOS configuration data for the Grid and select the **Discovery data** checkbox, to back up discovery data for the Grid.
   If the Grid has a reporting member, Grid Manager displays the **Infoblox Reporting & Analytics App** checkbox. You can select the **Infoblox Reporting & Analytics App** checkbox, to back up Splunk application reporting data.
4. Click **Backup**.

Downloading Backup Files

You can save an existing backup file, or create and save a new one to your local management system, a TFTP server, an FTP server, or a SCP server.
To download an existing backup file:

1. From the **Grid** tab, select the **Grid Manager** tab, and the click **Backup** -> **Manage Local Backup** from the Toolbar. Grid Manager displays the current backup files in the *Manage Local Backups* dialog box.
2. To download a backup file, select the checkbox of a backup file, and then click the Transfer icon. You cannot select multiple files for downloading.
3. Select one of the following from the **Backup to** drop-down list:
   - **My Computer**: Backup to a local directory on your computer. This is the default.
   - **TFTP**: Save the backup file to a TFTP server.
     - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter

`/archive/backups/Infoblox_2009_10_20_15_30`.

- **IP Address of TFTP Server**: Enter the IP address of the TFTP server to which you want to save the backup file.

- **FTP**: Save the backup file to an FTP server.
  - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter `/archive/backups/Infoblox_2009_10_20_15_30.`
  - **IP Address of FTP Server**: The IP address of the FTP server.
  - **Username**: Enter the username of your FTP server account.
  - **Password**: Enter the password of your FTP server account.
- **SCP**: Save the backup file to an SSH server that supports SCP.
  - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter **/archive/backups/Infoblox_2009_10_20_15_30**.
  - **IPAddressofSCPServer**: The IP address of the SCP server.
  - **Username**: Enter the username of your SCP server account.
  - **Password**: Enter the password of your SCP server account.
    Note that when you select **FTP** or **SCP**, ensure that you have a valid username and password on the server prior to backing up the files.

4. Click **Transfer Copy**.

Restoring Backup Files

You can restore a backup file of a NIOS configuration or a Discovery database to an appliance running the same NIOS version as that of the appliance from which the backup file originates. You can also restore a backup file from an appliance running a NIOS version to an appliance running a later NIOS version as long as the upgrade from the earlier NIOS version to the later version is supported. For example, you can restore a backup file from an appliance running NIOS 6.10.0 to an appliance running NIOS 7.3.200 because upgrading from NIOS 6.10.0 to 7.3.200 is supported. However, you cannot restore a backup file from an appliance running NIOS 6.9.0 to an appliance running NIOS 7.3.200 because upgrading from NIOS 6.9.0 to 7.3.200 is not supported.
You can restore an existing backup file on the appliance from which it originates, or restore a backup file from a different appliance (referred to as a forced restore). To download a backup file from a different appliance, see Downloading Backup Files from a Different Appliance below.
You must log in with a superuser account to back up and restore files. NIOS provides three ways to restore a backup file:

- From a local directory or the management system you use to operate the appliance
- From a TFTP server
- From a remote server using FTP. This option requires that you have a valid username and password on the FTP server prior to performing a backup or restore.

> **Note**
>
> When you restore NIC interfaces to a VM, ensure that you provision appropriate NIC interfaces with the database content that must be restored to avoid any errors.

To restore a backup file to the same independent appliance or Grid Master:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Restore** from the Toolbar.
2. In the *Restore* dialog box, choose one of the following from the **Restore from** drop-down list:
   - **My Computer**: Restore a file from your local computer. This is the default.
     - **Filename**: Click **Select File** to navigate to the configuration file.
   - **TFTP**: Restore a file from a TFTP server.

        - **Filename**: Enter the directory path and the file name you want to restore. For example, you can enter `/archive/backups/Infoblox_2009_10_20_15_30`.
        - **IP Address of TFTP Server**: Enter the IP address of the TFTP server from which you restore the configuration file.
    - **FTP**: Restore a file from an FTP server.
        - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter `/archive/backups/Infoblox_2009_10_20_15_30.`
        - **IP Address of FTP Server**: The IP address of the FTP server.
    - **Username**: Enter the username of your FTP server account.
    - **Password**: Enter the password of your FTP server account.
    - **Grid Master (Local)**: Restore from a local directory on the Grid Master. In the *Backup Set* table, select the file you want to restore.
3. To restore NIOS configuration data, select the **NIOS data** checkbox.
4. To restore Discovery data, select the **Discovery data** checkbox. Discovery data should be restored to Consolidator appliances with the correct licensing.
5. To download a backup file from one appliance to a different appliance, select **Force Restore from Different Grid** to enable the feature, and then select one of the following:
    - **Retain Current Grid Master IP Settings** (this is the default)
    - **Overwrite Grid Master IP Settings**
6. Click **Restore**. In the *Confirm Restore* dialog box, click **Yes**.
   After restoring the file, the appliance restarts. The restore process overwrites all existing data. All pending scheduled tasks are not restored or reverted.
7. Close your current browser window, wait a few minutes, and then reconnect to the NIOS appliance.

> **Note**
>
> You cannot restore a backup from a HA GM to a single node GM, if the HA GM has specific HA passive configuration.

Downloading Backup Files from a Different Appliance

When you "force restore" a NIOS appliance, you download a backup file from one appliance to a different appliance. To restore a backup file to the same appliance or Grid Master, use the Restore function as described in Restoring Backup Files.
To download a backup file from one appliance to a different appliance:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Restore** from the Toolbar.
2. In the *Restore* wizard, do the following:
    - **Restore from:** Choose a source from which you restore the configuration file, as described in Restoring Backup Files.
3. Select **Force Restore from Different Grid** to enable the feature, and then select one of the following:
    - **Retain Current Grid Master IP Settings** (this is the default)
    - **Overwrite Grid Master IP Settings**
4. Click **Restore**. In the *Confirm Restore* dialog box, click **Yes**.
   After restoring the file, the appliance reboots. The restore process overwrites all existing data. All pending scheduled tasks are not restored or reverted.
5. Close your current browser window, wait a few minutes, and then reconnect to the NIOS appliance.

Managing Upgrade Groups

To minimize the impact of Grid upgrades on your system operations, you can organize members into upgrade groups and schedule their software distributions. This is useful, for example, in a large Grid spanning multiple time zones where there are fluctuating network and downtime considerations at various locations. Note that you can also schedule their upgrades, depending on the existing releases and their upgrade paths. For information about the different upgrade methods, see *Lite Upgrades* and *Full Upgrades*

You can also import and export upgrade groups and their schedules in CSV format. For more information, see *Infoblox CSV Import Reference*.

Infoblox provides two default upgrade groups:

- Grid Master: After you configure the Grid Master, it automatically becomes the only member of this group. You cannot modify or delete this group.
- Reporting Member: After you configure a reporting member in a Grid, it automatically becomes the only member of this group. This group will be upgraded automatically after the Grid Master and before other upgrade groups. You cannot modify, delete, or schedule this upgrade group. For information about reporting, see *Infoblox Reporting and Analytics*.
- Reporting Member (when you have configured reporting clustering Grid): When you upgrade from NIOS 7.3.200 to a later release, the Grid will be upgraded to the single indexer mode. You can change the configuration after the upgrade. During an upgrade, the reporting members of the primary site are moved into separate groups to ensure that there are always some peers available to receive events sent by the forwarders. To achieve this, the replication factor must be equal to the search factor and the total number of reporting appliances.
  During an upgrade, data loss might happen if the peers that hold all searchable copies of a bucket are in the same group and they are all offline at the same time. To avoid this, ensure that you group the members in separate groups.
- Default: This is the default upgrade group to which the appliance automatically assigns Grid members. If you do not explicitly assign a member to an upgrade group, it remains in the Default group. You cannot delete or rename this group.
  Make sure that the default group has at least one member associated with it, otherwise the appliance displays that the upgrade process is still in progress even though it is complete. To avoid this, you can either use the `Infoblox > set grid_upgrade forced_end` command to stop the upgrade process or keep at least one member in the default group.

Grid Manager provides information about the upgrade group to which a member belongs. You can add or delete an upgrade group and monitor the software version that is currently running on the Grid and on individual member. You can do the following:

- Add an upgrade group, as described in Adding Upgrade Groups below.
- Modify an upgrade group, as described in Modifying Upgrade Groups below.
- View upgrade group information, as described in Viewing Upgrade Groups below.
- Delete an upgrade group, as described in Deleting Upgrade Groups below.

Adding Upgrade Groups

When you create an upgrade group, you select the Grid members for that group, and specify whether the software distribution and upgrade occur on all group members at the same time, or successively in the order they are listed in the group members list. A Grid member can belong to only one upgrade group.

> **Note**
>
> The appliance displays a warning message when you create an upgrade group that includes the two peers of a DHCP failover association. Infoblox recommends that you assign DHCP failover peers to separate upgrade groups to minimize the risk of a loss in DHCP services. For example, if DHCP failover peers are in the same upgrade group and its members upgrade simultaneously, the upgrade causes a loss in DHCP services.

Note the following recommendations when you create an upgrade group:

- Put the following members in the first upgrade group after the Grid Master upgrade: all Grid Master candidates, DNS primaries, and the DHCP logging member.
- To minimize the risk of a loss in DNS services, put the name servers for a zone in different upgrade groups, and assign the primary and secondary servers to separate upgrade groups.

To add an upgrade group:

1. From the **Grid** tab, select the **Upgrade** tab.
2. Click **Toggle Group List View** to display the list of upgrade groups, and then click the Add icon.
3. In the *Add Upgrade Group* wizard, complete the following:
    - **Name:** Enter a name for the upgrade group. The name can contain alphanumeric characters, spaces, underscores, hyphens, and dashes.
    - **Distribute to Members:** Select one of the following to specify how the Grid Master distributes software to the members in the group.
        - **Simultaneously:** Select this to distribute software upgrade files to all group members at the same time.
        - **Sequentially:** Select this to distribute software upgrade files to group members in the order they are listed in the group members list.
    - **Upgrade Members:** Select one of the following to specify how the group members upgrade to the new software version.
        - **Simultaneously:** Select this to upgrade all group members at the same time.
        - **Sequentially:** Select this to upgrade group members in the order they are listed in the group members list.
    - **Comment:** Enter useful information about the upgrade group, such as the location of the group.
4. Click **Next** to select members for the group. Complete the following:
    - Click the Add icon. Grid Manager adds a row to the Member Assignment table.
    - Click **Select**. In the *Member Selector* dialog box, select the members you want to add to the group, and then click the Select icon. Use Shift+click and Ctrl+click to select multiple members. Note that if you choose to distribute and upgrade members sequentially, the distribution and upgrade occur in the order the members are listed. You can reorder the list by dragging a member to a desired location or by selecting a member and using the up and down arrows next to the checkbox to place the member at a desired location. You can also delete a member from the list.
      After you add a member, the appliance adds it to the group members list. The first Grid member in the list determines the time zone of the group when you schedule the distribution and upgrade. Therefore, Grid Manager displays the time zone of the first Grid member in the list. (For information about setting time zones, see *Managing Time Settings*.)
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Modifying Upgrade Groups

You can modify an existing upgrade group to change the group name or how the distribution and upgrade are performed. You can also add and delete members.
To modify an upgrade group:

1. From the **Grid** tab, select the **Upgrade** tab, and then click **Toggle Group List View**.
2. Select an *upgrade_group* checkbox, and then click the Edit icon in the row. You can also click the Edit icon directly without selecting the checkbox.
3. The *Upgrade Group* editor provides the following tabs from which you can modify data:

- **General**: Modify the fields as described in Adding Upgrade Groups.
- **Member Assignment**: Add or delete members as described in Adding Upgrade Groups.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Viewing Upgrade Groups

In the **Upgrade** tab, Grid Manager lists the Grid Master group, the Default group, and other upgrade groups you have configured. You cannot modify or delete the Grid Master group. You can modify the Default group, but you cannot delete it. To view the members in a specific upgrade group, click the arrow next to the group name to expand the group. All groups are collapsed by default.
Before a distribution or upgrade starts, you can move members from one group to another, reorder the members, or remove a member from an upgrade group. The member you remove automatically joins the Default group. (For information, see Managing Distributions, in *Upgrading NIOS Software*.) You cannot add, delete, or reorder members in an upgrade group while a distribution or upgrade is in progress. You can skip a member in an upgrade group from a distribution only before the distribution starts, or after you pause it. For information, see Pausing and Resuming Distributions in *Upgrading NIOS Software*.
To view the upgrade groups in a Grid:

1. From the **Grid** tab, select the **Upgrade** tab, and then click **Toggle Group List View**.
   Grid Manager displays the Grid Master at the top of the list. All other upgrade groups are listed alphabetically after the Grid Master. You can click the arrow next to a group to view members in the group.
2. Grid Manager displays the following:
   - **Group**: The name of an upgrade group to which the member belongs.
   - **Member**: The name of the member.
   - **Status**: Displays the overall status of an upgrade group at the group level and individual status for each member when you expand the upgrade group. At the group level, this displays the most severe status among the members. For example, when there are three out of five members are offline, the overall status shows **3 of 5 members** in red, which means offline.
   - **IP Address**: The IP address of the member.
   - **Running Version**: The NIOS software version that is currently running on the member.
   - **Distribution Status**: The distribution status of the group.
   - **Timestamp**: The date, time, and time zone when a distribution or upgrade is complete.

You can hide some of the default columns, but you cannot sort the information in this table. You can use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches. You can also create a quick filter to save frequently used filter criteria. For information, see Using Quick Filters, in *Finding and Restoring Data*.

Deleting Upgrade Groups

When you delete an upgrade group, members in the upgrade group that you want to delete will be moved to the Default group. Grid Manager displays a warning before deleting an upgrade group.
To delete an upgrade group:

1. From the **Grid** tab, select the **Upgrade** tab, and then click **Toggle Group List View**.
2. Select an *upgrade-group* checkbox, and then click the Delete icon.
3. In the *Delete Confirmation* dialog box, click **Yes**.

Full Upgrades

A full upgrade occurs when there are database schema changes between the existing and upgrade releases. In general, when you upgrade to a major release, you are performing a full upgrade. Depending on the upgrade and revert paths that your existing release supports, you may or may not be able to schedule a full upgrade. A full upgrade that cannot be scheduled does not allow for data replication between the Grid Master and members. For information about supported upgrade and revert paths, refer to the latest release notes on the Infoblox Support site.
Depending on the upgrade paths your current release supports, when you schedule a full upgrade, the Grid Master

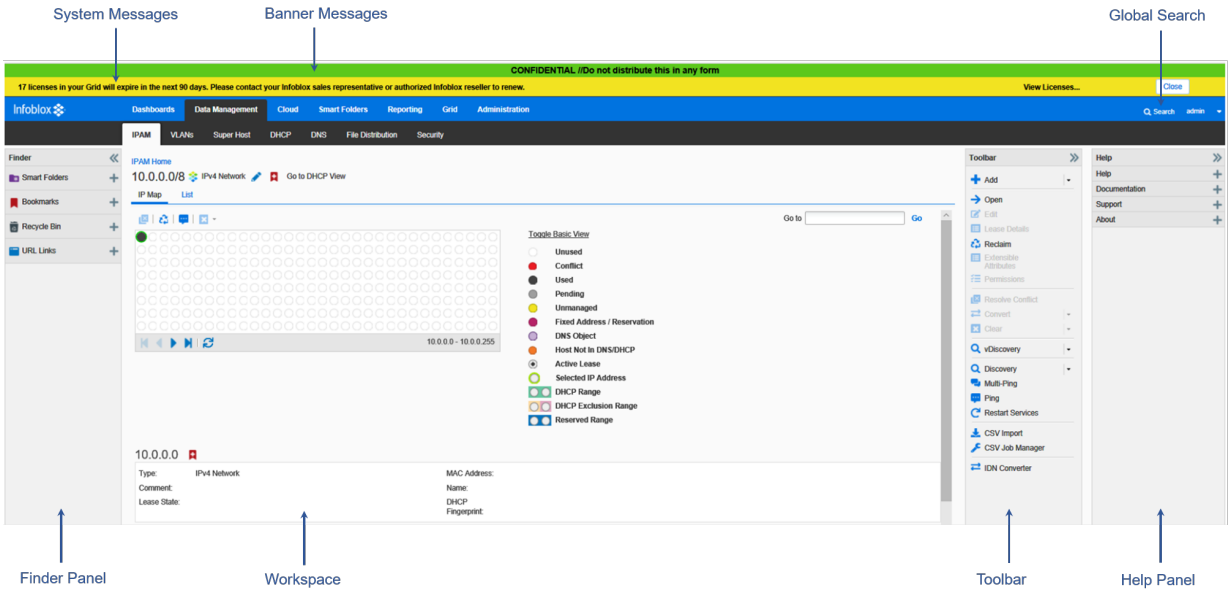
immediately replicates certain core network service tasks to Grid members while putting other tasks in queue until the members have been upgraded. For information about which data and tasks the Grid Master replicates to members immediately, see *Guidelines for Scheduling Full Upgrades* . For information about how to schedule an upgrade, see Scheduling Upgrades in *Upgrading NIOS Software*.

Using the Grid Manager Interface

This section explains the different components of Grid Manager and details how to use each of them. It covers the following topics:

About the Grid Manager Interface

Grid Manager provides an easy-to-use interface that simplifies core network services management. Its navigational tools enable you to quickly move through the application and retrieve the information you need. You can customize different elements in your workspace, and hide and display panels as you need them. It also provides different types of Help, so you can immediately access the information you need to complete your tasks.
The following Grid Manager Interface figure illustrates the typical layout of Grid Manager. It identifies common elements of the interface and features that you can use:
Grid Manager Interface



System Messages

Grid Manager displays system messages at the top of the screen. In wizards and editors, it displays messages at the top as well.

Note

Some configuration changes require a service restart. Grid Manager displays a message whenever you make such a change. Click the **Restart** icon that appears in the message to restart services.

Security and Informational Banners

Grid Manager displays banner messages on the header and footer of the screen. Only superusers can publish the informational and security banner. There are two types of banners:

- Security Banner - Security banner indicates the security level of the Infoblox Grid. There are five security levels to choose from the Security list box. The available security levels are Top Secret, Secret, Confidential, Restricted, and Unclassified.
- Informational Banner - You can use the informational banner for multiple uses, such as to indicate whether the Infoblox Grid is in production or a lab system. You can also publish messages of the day.

For more information about configuring security level banner and configuring informational level banner, see *Managing a Grid*.

Breadcrumbs Navigation

Breadcrumbs navigation displays your path to the current page. It helps you keep track of your location in Grid Manager. You can click any of the links to get back to a previous page.

Global Search

Use Global Search to find data. Grid Manager searches the entire NIOS database for data that matches the criteria you specify. For additional information on Global Search, see *Finding and Restoring Data*.

Finder Panel

The *Finder* panel appears on all pages in Grid Manager. It provides the following tools:

- Smart Folders: Use smart folders to organize your data according to criteria that you specify.
- Bookmarks: Stores data that you have marked for easy retrieval.
- Recycle Bin: Stores deleted objects that you can either restore or permanently remove.
- URL Links: You can add, modify, and delete third party URL links of frequently used portals and destination pages.

You can resize, collapse, and expand the Finder panel.

Toolbar Panel

The vertical Toolbar panel provides easy access to commands. The Toolbar is available in all pages, except the Dashboard. Its content changes depending on the type of data displayed in the work area. You can resize, collapse, and expand the *Toolbar* panel.

Help Panel

The *Help* panel provides the following types of Help:

- **Help:** Expand this section to view information about the window currently displayed.
- **Documentation:** Expand this section to download the latest versions of the Infoblox Administrator Guide and Infoblox API Documentation.
- **Support:** Expand this section to view links to the Infoblox web site and Technical Support site.
- About: Expand this section to view information about the NIOS software version.You can resize, collapse, and expand the Help panel. In addition, each dialog box also provides a Help panel that contains information specific to the dialog box. You can expand and collapse the Help panel in dialog boxes as well.

Wizards and Editors

Grid Manager provides a wizard for every object that you can create. You use wizards to enter basic information required to create an object. If you want to configure additional parameters, you can then save the object and edit it.
Note that all required fields are denoted by asterisks.
Your connection to Grid Manager may time out if a save operation takes longer than 120 seconds to complete. This can occur when multiple, complex operations are initiated by several users. It does not result in any data loss.

Tooltips

Tooltips display the function of each button. Hover your mouse over a button or icon to display its label.

Customizing Tables

Grid Manager uses dynamic tables to display information. You can customize tables by resizing columns, sorting the data, and selecting certain columns for display. Your settings remain active until you log out.
To resize columns in a table:

1. In the table, place your pointer on the right border of the header of the column you want to resize.
2. Drag the border to the desired width.

To sort the data displayed in a table, click the header title. You can click the header title again to reverse the sort order. Alternatively, you can do the following:

1. In the table, mouse over to a header title and click the down arrow key.
2. Select **Sort Ascending** or **Sort Descending**. To edit columns:
3. In the table, mouse over to a header title and click the down arrow key.
4. Select **Columns > Edit Columns**.
5. Do the following:
    - Width: Specify the width of the column in pixels. The minimum is five and the maximum is 999.
    - Sorted: Indicates whether the data in the column can be sorted
    - Visible: Click the checkboxes of the columns you want to display, and clear the checkboxes of those you want to hide.
6. Do one of the following:
    - Click **Apply** to apply your settings to the column.
    - Click **Cancel** to close the editor without saving your settings.
    - Click **Reset** to reset the settings to the default.

Grid Manager displays the selected column in the table.
To reorder columns in a table, drag and drop the columns to the desired positions.

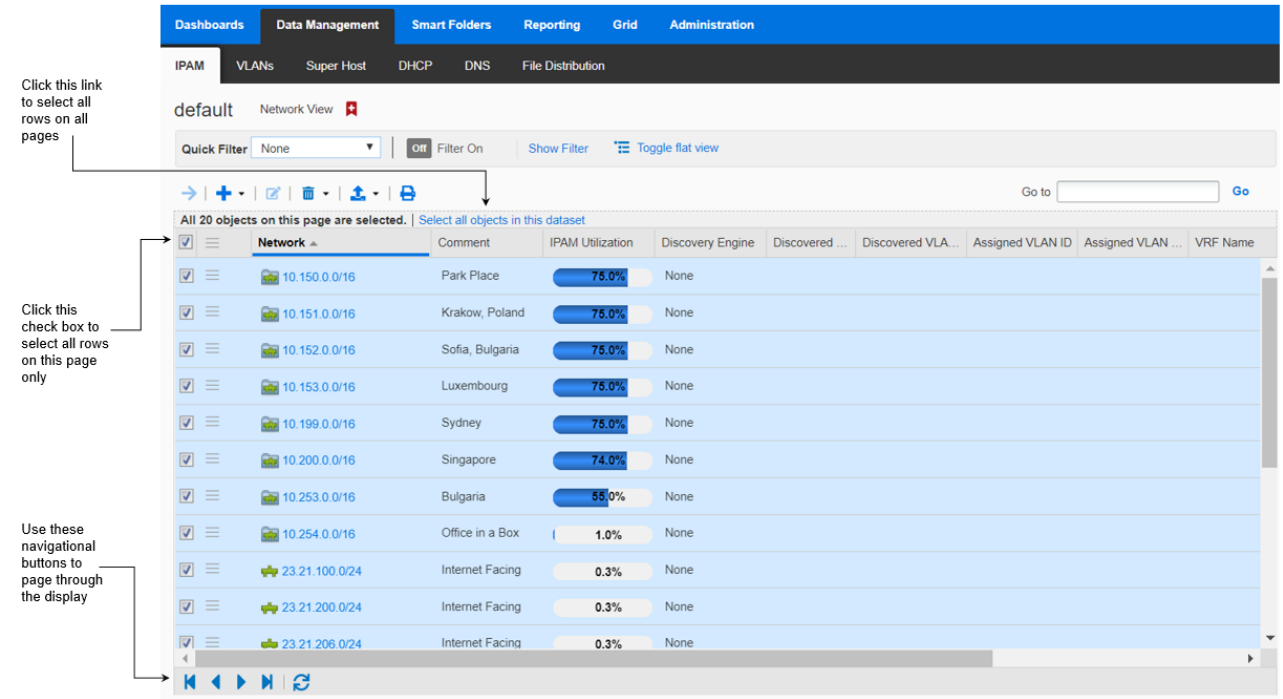
Selecting Objects in Tables

In a table, Grid Manager displays data on multiple pages when the number of items to be displayed exceeds the maximum number of items that can be displayed on one page. Use the navigational buttons at the bottom of the table to page through the display.
You can select multiple rows in a table. For example, in a Windows browser, you can do the following to select multiple rows:

- Use SHIFT+click to select multiple contiguous rows.
- Use CTRL+click to select multiple non-contiguous rows.
- Click the checkbox in the table header to select all rows on a page, as shown in the below figure Select all in a Table.

When you click the select all checkbox in a table that contains multiple pages, only the rows on the current page are selected. Grid Manager displays a message that indicates the total number of selected rows on the page. You can click **Select all objects in the dataset** to select all rows in the entire table. When you select all rows in the table, Grid Manager displays a message to indicate that. You can then click **Clear Selection** to deselect the rows.
After you select all rows on a page, you can deselect a specific row by clearing the checkbox of the row. You can also click a row (not the checkbox) in the table to select the item and deselect the others.
In a table, when you select all the objects for deletion, the objects that are not deleted from the database remain in the table after the operation is completed.

Select All in a Table

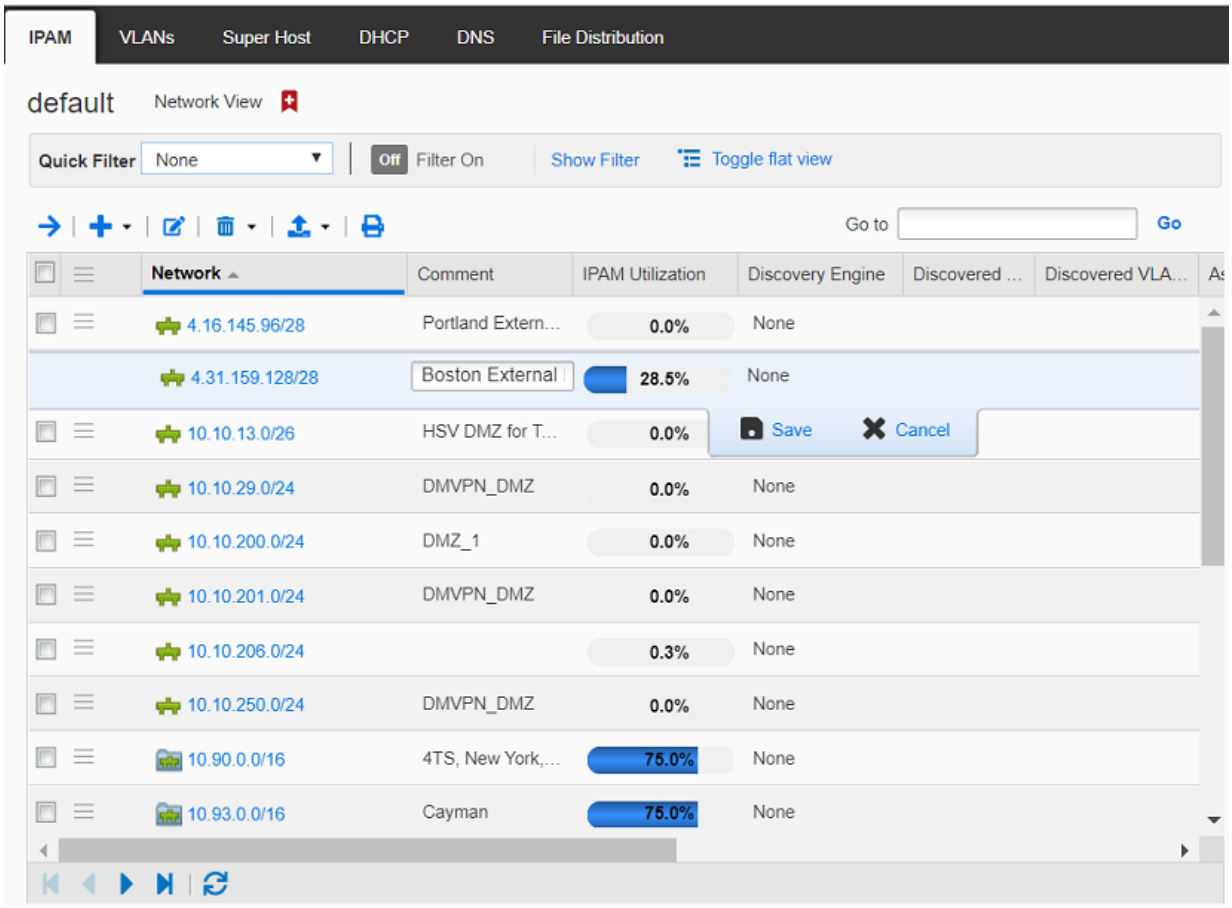


Modifying Data in Tables

Infoblox provides inline editing for certain fields in some tables. You can use this feature to modify data directly in a table instead of going through an editor.
To update information in a table, you must have read/write permission to the data. When you enter or select a new value, the appliance validates the data format before saving the updated data.
To modify data in a table:

1. From any panel that supports inline editing, double click the row of data that you want to modify. The appliance displays the inline editing editor in the selected row, as shown in the Inline Editing figure.
2. Depending on the data type, enter the new data in the field or select an item from the drop-down list. Note that some fields are read-only.
3. Click **Save** to save the changes, or click **Cancel** to discard them.

Inline Editing



Printing from Grid Manager

In Grid Manager, you can print information from panels and pages that support the Print function. Grid Manager prints data one page at a time. The amount of data that is displayed in a specific panel depends on the table size configuration that you set in your user profile. For more information about specifying the table size, see *Setting Login Options*.
To print:

1. Click the **Print** icon. You must allow pop-up windows in your browser for printing. Grid Manager displays a separate browser window.
2. Click **Print**.
   Grid Manager displays the *Print* dialog box.
3. Configure printer settings and parameters.
4. Depending on your browser, click **OK** or **Print**.

Scheduling Tasks

When you perform a task, such as adding a DNS zone or modifying a DHCP range, you can execute it immediately or schedule it for a future date and time, depending on your permissions. The scheduling feature is useful when you want to add, modify, or delete a record, or schedule a network discovery at a desired date and time. Using this feature, you can streamline your day-to-day operations. For example, you can schedule the deletion of records that you use for testing when the test time is up. You can also reassign an IP address to a fixed address when the location of the server to which the fixed address is assigned changes from one network to another.

Certain tasks, scheduled or not, may be subject to approvals if approval workflows are defined for specific admin groups. For information about how to define submitters and approvers for an approval workflow, see *Configuring Approval Workflows*.
Note that not all tasks can be scheduled or routed for approval. For a list of supported objects, see Supported Objects for Scheduled and Approval Tasks below.
When you schedule a task or submit it for approval, consider the following:

- The appliance cannot execute a scheduled or approval task that is associated with an extensible attribute, if you delete the extensible attribute after you have scheduled the task or submitted it for approval. For information about extensible attributes, see *About Extensible Attributes*.
- The appliance cannot execute, reschedule, or delete a task that is associated with a child object (such as a DHCP range) if you delete the parent object (such as a network) after you have scheduled the task or submitted it for approval.
- There are certain guidelines about scheduled and approval tasks when you upgrade the software, back up the database, and restore data. For information, see *Guidelines for Upgrading, Backing Up, and Restoring Data*.

You can schedule the addition, modification, and deletion of certain objects. For a list of supported objects, see Supported Objects for Scheduled and Approval Tasks below.
Depending on your permissions and the admin group to which you belong, your scheduled tasks may be subject to approvals by other admins in your organization. You may or may not receive email notifications about the status of your scheduled tasks depending on the configuration of the approval workflows. Approvers can reschedule your tasks after they have approved the tasks, if they have scheduling permissions. When you schedule and submit a task, you may need to enter a ticket number associated with the task or a comment about the task. For more information about approval workflows, see *Configuring Approval Workflows*.

Only superusers can view, reschedule, and delete all scheduled tasks. Limited-access admins can reschedule and delete only their scheduled tasks. If your scheduled tasks require approvals, the approvers who have scheduling permissions may reschedule your tasks to a different date and time after they have approved the tasks. Depending on your admin permissions, there are certain scheduled and approval tasks that you may or may not be able to perform. For more information about supported tasks for different admin groups, see *Configuring Approval Workflows*.
The appliance sends email notifications to local admins, except for those who do not have email addresses, when email notification is enabled for the admins and any of the following happens:

- A superuser schedules a task, and another superuser reschedules or deletes the task.
- A limited-access admin schedules a task, and a superuser reschedules or deletes the task.
- A superuser or a limited-access admin schedules a task, and the task fails.
- An admin is configured to receive notifications based on the configuration of an approval workflow. For information about approval workflows, see *Configuring Approval Workflows*.

Superusers can also grant scheduling permissions to other admin groups. When the scheduling permission is added or inherited from an admin role, limited-access admin groups can schedule tasks. For more information, see *Administrative Permissions for Discovery*.

Supported Objects for Scheduled and Approval Tasks

- DNS zones (authoritative, forward, stub, and delegated)
- DNS views
- DNS resource records (except SOA records)
- Import resource records to DNS zones
- Lock and unlock DNS zones
- Hosts
- Bulk hosts
- Roaming hosts
- Shared records
- Shared record groups
- IPv4 and IPv6 networks
- IPv4 and IPv6 network containers
- IPv4 and IPv6 shared networks

- IPv4 and IPv6 DHCP ranges
- IPv4 and IPv6 reserved ranges
- IPv4 and IPv6 fixed addresses
- IPv4 reservations
- DHCP fingerprints
- DHCP filters (MAC, option, NAC, relay agent, and DHCP Fingerprint)

Note
Only IPv4 MAC filters support approval workflows.

- IPv4 MAC address filter items
- Conversion of IPv4 and IPv6 static and dynamic leases
- Microsoft objects that are supported by NIOS
- Load balancer related objects
- DNS64 Synthesis Groups
- All IPAM tasks except CSV imports
- Response Policy Zones
- Response Policy records
- VLANs

You can also schedule the following operations or create approval workflows for them:

- Network Discovery
- Device Discovery
- VM Discovery
- Port Control provisioning tasks for setting Admin Status, VLAN assignments, and a Description;
- Defining infrastructure device port reservations for the following IPAM/DHCP objects:
    - IPv4 Reservations
    - IPv4/IPv6 Fixed Addresses
    - Hosts
    - Grid Members
    - IPv4 and IPv6 Networks
- Service restarts (for scheduled tasks only)

Note
Service restarts are not subject to approvals.

About Long Running Tasks

A long running task is a task that requires more than 30 seconds to complete and involves a large amount of data. When Grid Manager performs a long running task, it displays the *Long Running Task* dialog box that indicates whether you can run the task in the background. You can navigate to another tab or perform other functions only if the task can be run in the background. For information, see Running Tasks in the Background below.
Grid Manager disconnects if a task takes more than five hours to perform. Though you can log back in to Grid Manager while the appliance continues to perform the task, Grid Manager does not display the progress of the task.

Note

You cannot stop a long running task once you start it.

The appliance supports the following long running tasks:

- Restoring the database
- Backing up the database
- Backing up licenses

- Signing DNS zones
- Unsigning DNS zones
- Exporting DS records and trust anchors
- Deleting all objects in a table or dataset
- Modifying multiple extensible attributes
- Viewing DNS and DHCP configuration properties
- Migrating bloxTools data
- IPAM tasks on the Tasks Dashboard
- Downloading the following:
    - Audit logs
    - Syslog files
    - Support bundles
    - SNMP MIB files
    - NTP keys
    - HTTPS certificates
    - Traffic capture

Running Tasks in the Background

Grid Manager allows certain long running tasks to run in the background. You can navigate to other tabs and perform other functions when Grid Manager performs tasks in the background. However, when you make changes to objects that are currently affected by a long running background task, Grid Manger does not save the changes until after the long running task is completed. Grid Manager can perform up to 10 background tasks at a time.
You can run the following tasks in the background:

- Signing DNS zones
- Unsigning DNS zones
- Modifying multiple extensible attributes
- Deleting all objects in a table or dataset
- Migrating bloxTools data

To run a task in the background:

1. Perform the task following the instructions described in this guide.
2. In the *Long Running Task* dialog box, click **Run in Background**.

You can view the progress of the task by clicking the progress bar at the top of the interface.

Monitoring Long Running Tasks

When you have one or more tasks running in the background, Grid Manager displays a progress bar next to the Global Search icon at the top of the interface. You can click the progress bar to view detailed information about the tasks in the *Background / Long Running Task* viewer. In this viewer, Grid Manager displays a progress bar for each task that is currently running in the background. When all background tasks are completed, the progress bar at the top of the interface disappears. Grid Manager displays a message at the top of the interface when the task is completed successfully or if the task fails.
For other tasks that you cannot run in the background, the *Long Running Task* dialog box remains open until the task is completed. You cannot navigate to other tabs or perform other functions when the long running task is in progress. Grid Manager closes the dialog box when the task is completed. It also displays a message at the top of the interface when the task is completed successfully or if the task fails.

Viewing Tasks

The appliance displays scheduled tasks and approval tasks in the **Task Manager** tab of Grid Manager. Scheduled tasks are those with scheduled time listed and approval tasks contain approval status. A task can also be scheduled and queued for approval at the same time. By default, all completed and rejected tasks are displayed in **Task Manager** for up to 14 days before they are removed from the list. You can configure how long the completed and rejected tasks are displayed in **Task Manager** using the CLI command set delete_tasks_interval. For more information about the CLI

command, see *Infoblox CLI Guide*.
The appliance logs all tasks in the audit log and associates each with a task ID. By default, Grid Manager sorts tasks by Task ID in **Task Manager**. You can view tasks that you are allowed to see based on your permissions. For information about admin permissions, see *About Administrative Permissions*.
To view tasks:

1. From the **Administration** tab, select the **Workflow** tab -> **Task Manager** tab.
2. Grid Manager displays the following information for each task:

You can do the following in the **Task Manager** tab:

Field Name	Description
Action	The operation the appliance performs in this task. The can be: **Add**, **Modify**, **Delete**, **Network Discovery**, **Lock/Unlock Zone**, or **Restart Services**.
Affected Object	The name or value of the object that is associated with the task. For example, if the task involves an A record, this field displays the domain name of the record. If it is a fixed address, it displays the IP address of the fixed address.
Approval Status	The current approval status. Possible values are **Approved**, **Not Applicable**, **Pending**, and **Rejected**.
Approver	The username of the admin who has approved this task.
Approver Comment	Comments entered by the approver.
Associated Task	(hidden by default) Applies to Port Configuration tasks. If a port configuration task is dependent on an object change task (such as a new Fixed Address or an edit to an existing object), this could will show the Task ID value for the associated object change task.
Executed Time	The date, time, and time zone the task was executed.
Execution Status	The execution status of the task. Possible values are Completed, Failed, Pending, and Executing.
Object Type	The object type. For example, the appliance can display A Record or Fixed Address.
Scheduled Time	The date, time, and time zone when the appliance executes the task.
Submitted Time	The date, time, and time zone when the task was submitted.
Submitter	The username of the admin who scheduled or submitted the task.
Submitter Comment	Comments entered by the submitter.
Task ID	The ID associated with the task. The appliance assigns an ID to a task in chronological order. By default, the appliance sorts tasks by Task ID.

Field Name	Description
Task Details	Detailed information about the task. This message also appears in the audit log.
Ticket Number	For an approval workflow, this number may be entered by the submitter to associate the task with a help desk ticket number or a reference number.
Type	Indicates key information about certain types of executing/executed jobs. The Type column lists values for Port Control and for Object Change tasks undertaken by Grid Manager or submitted by Grid Manager for approval by the administrator.

- Sort the tasks in ascending or descending order by column, except for **TaskDetails**.
- Use filters and the search function to look for specific values.

> **Note**
>
> You cannot use the search function to search for approval or execution status. Use filters to search for these values.

- Create a quick filter to save frequently used filter criteria. Grid Manager provides the following default quick filters that you can select from the Quick Filter drop-down list: **PendingApprovals**, **RejectedTasks**, and **ScheduledTasks**. For more information about using quick filters, see *Finding and Restoring Data*.
- Export and print the information in the table.
- Control the display of information in the panel by toggling between a single-line view and a multi-line view.
- Reschedule a task, cancel a scheduled task, or execute a task immediately.
- For approvers, select a task and click the Approve icon to approve the task, or click the Reject icon to disapprove the task. You can also reschedule the task while approving it.

> **Note**
>
> If you have multiple pages of tasks in **Task Manager**, you can select multiple tasks on the current page for approval or disapproval. If you click the **Select all objects in this dataset** link to select all the tasks in the dataset, the Approve and Reject icons are disabled and you cannot approve or reject any task.

Using the Task Manager Action Menu

The Task Manager page provides an Action icon ☰ column with a series of menu options for features related to grid Manager tasks to manage task execution, scheduling and approval. Menu choices change based upon the context and the current state of tasks in the table; features available in the Action menu include the following:

Figure 1.6 Task Manager Action menu

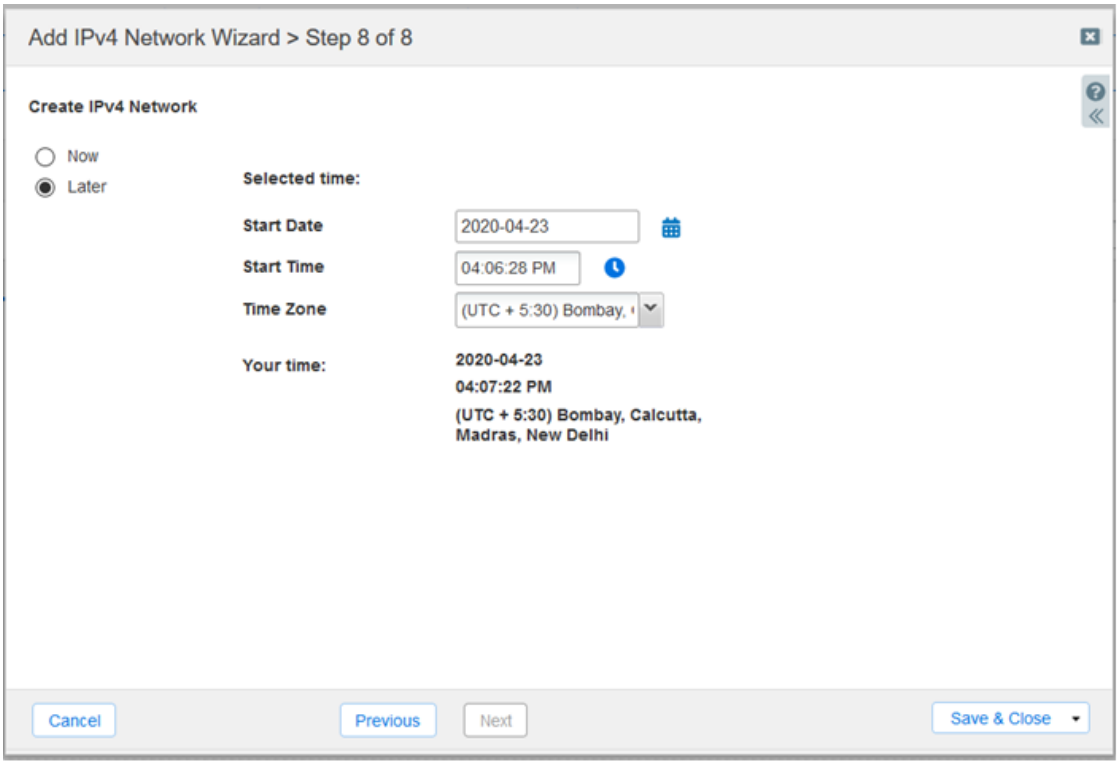
Features in Action Menu	Description
(*Appliesonlywith hNetworkInsig ht*) **Approve** and **Reject**	Enables admins to approve or reject a pending job; rejecting a job immediately cancels it.
AssociatedTas k (applies only with port configuration tasks)	Choosing this option opens the object change task, if any, for the currently selected port configuration task.
ExecutionLog	Opens a completed task's execution log window. the Execution Log lists the complete communications sequence sent to a device to perform a port control task.
ExecuteNow	Force a selected pending task to execute immediately.
Re-execute	Allows you to re-run the selected task. Combined with the Execution Log, this process can aid in troubleshooting a failed port control task.
Reschedule	Opens the Reschedule window for the selected task. To immediately execute this task, click **Now**. Or, in the *Reschedule* panel, click **Later**, and then specify a date, time, and time zone. You can reschedule the task if you have the applicable permissions. Click **Save** to commit the changes.
Delete	Deletes the pending task.
View	Opens the Task Viewer to the currently selected task. For related information about using the Task Viewer to View Job Logs and Approve Jobs, see *NetMRI Task Pack*.

Scheduling New IPAM/DHCP Objects and Associated Port Configurations

Specific IPAM/DHCP object types support scheduling of Port Configuration tasks as part of their object definition:

- New IPv4 and IPv6 Networks;
- IPv4 Reservations;
- Fixed IPv4 Addresses;
- Fixed IPv6 Addresses;
- Hosts;
- Infoblox Grid Members (including HA Pairs; discussed in the sections beginning in *Adding Grid Members*).

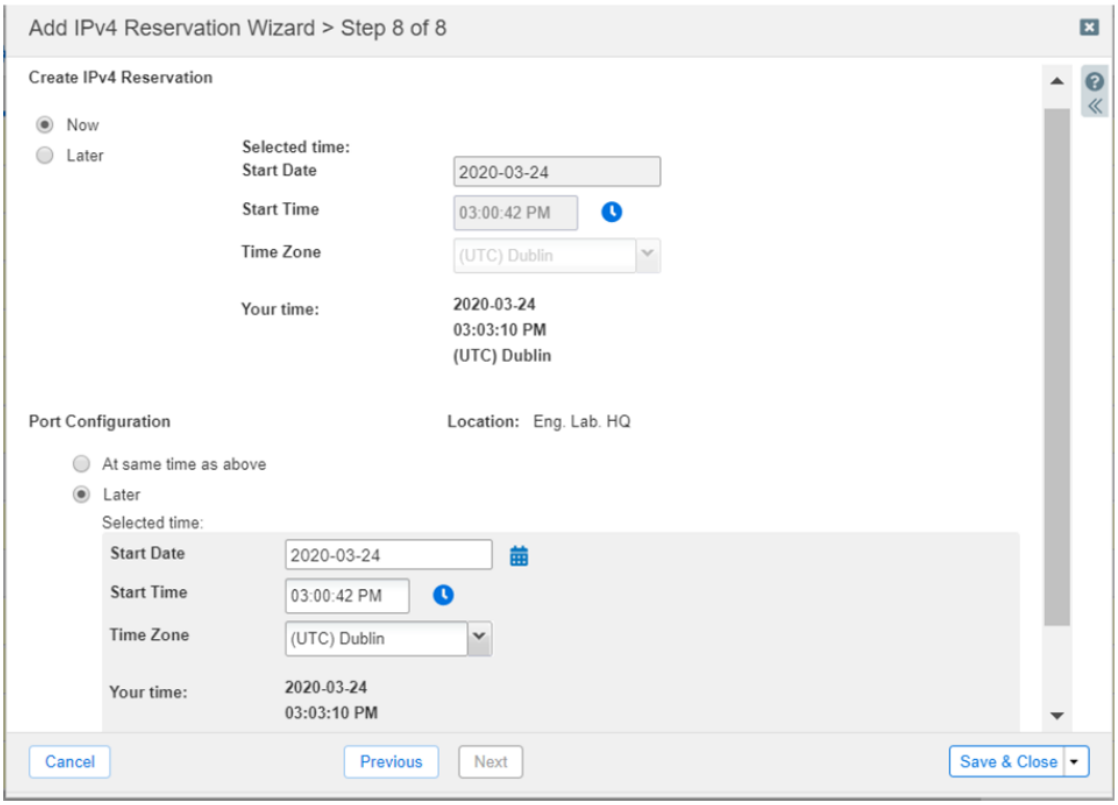
For all of these object types, you can click a **Schedule for Later** button at any step in the Wizard to commit the currently defined settings for the new object to a new Grid Manager task. For example, consider creating a new IPv4 network. After defining the IP address for the new network, you simply wish to create it and not to define any further configurations. Click **Schedule for Later** to skip the intervening Wizard steps and display the final Scheduling page of the Wizard, an example of which appears in the following Create Network Schedule for Later page figure.
Create Network Schedule for Later page



1. To create the new object immediately, select **Now** and click **Save & Close**.
2. You can choose to have Grid Manager create the object at a later time. To do so, select **Later**. Choose a **Selected time** by entering or selecting a **Start Date** (click the calendar icon to choose a calendar date) and a **Start Time** (click the clock icon to choose a specific time in fifteen minute increments), and choose a **Time Zone**.

When you step through the entire Wizard process (without clicking **Schedule for Later**) and if you also define port configuration settings, the object creation wizards provide a final Scheduling page with separate scheduling definitions, for the object and for the object's port configuration, as shown in the following figure.

Scheduling Create Object and Port Configuration



The final step for creating the Network, Fixed Address, Host, or IP reservation is to define when the task executes, including associated port control definitions. The port configuration is performed in a separate task, defined on the same wizard page. The port configuration task can be done at the same time that Grid Manager provisions the object, or may be scheduled for a later time.

1. To create the new object immediately, select **Now**.

   By selecting Now, no task is created by Grid Manager and it simply creates the object. The completed object creation appears in the audit log. For more information, see *Viewing Tasks*. Grid Manager creates a task for object creation only when you use **Schedule for Later**. Also, all port configuration and network provisioning instances create a new task under the Task Manager.

2. You can instruct Grid Manager to create the network at a later time. To do so, select **Later**. Choose a **Selected time** by entering or selecting a **Start Date** (click the calendar icon to choose a calendar date) and a **Start Time** (click the clock icon to choose a specific time in fifteen minute increments), and choose a **Time Zone**.

3. Port configuration and network provisioning tasks can be synchronized to take place at the same time as the creation of the new object under IPAM/DHCP; if so, keep the **At same time as above** option.Scheduling Recursive Deletions

   a. You can also schedule the task at a different time. To do so, select **Later** (under **Port Configuration**). Choose a **Selected time** by entering or selecting a **Start Date** (click the calendar icon to choose a calendar date) and a **Start Time** (click the clock icon to choose a specific time in fifteen minute increments), and choose a **Time Zone**.

   The Port Configuration provision cannot take place at a schedule time or date before the associated object creation.
   Object creation must successfully complete before its associated port configuration task begins.

4. Click **Save & Close** to complete the configuration.

> **Note**
>
> Port configuration tasks (or any operation that queries for or changes device configurations through Grid Manager, including Discovery) are subject to a feature called Blackout Periods, which are defined elsewhere in Grid Manager. Blackouts are a scheduled feature that instructs Grid Manager not to perform Discovery operations and Port Control/provisioning operations on the managed network at specified times, days and dates. See the section *Defining Blackout Periods* for details.

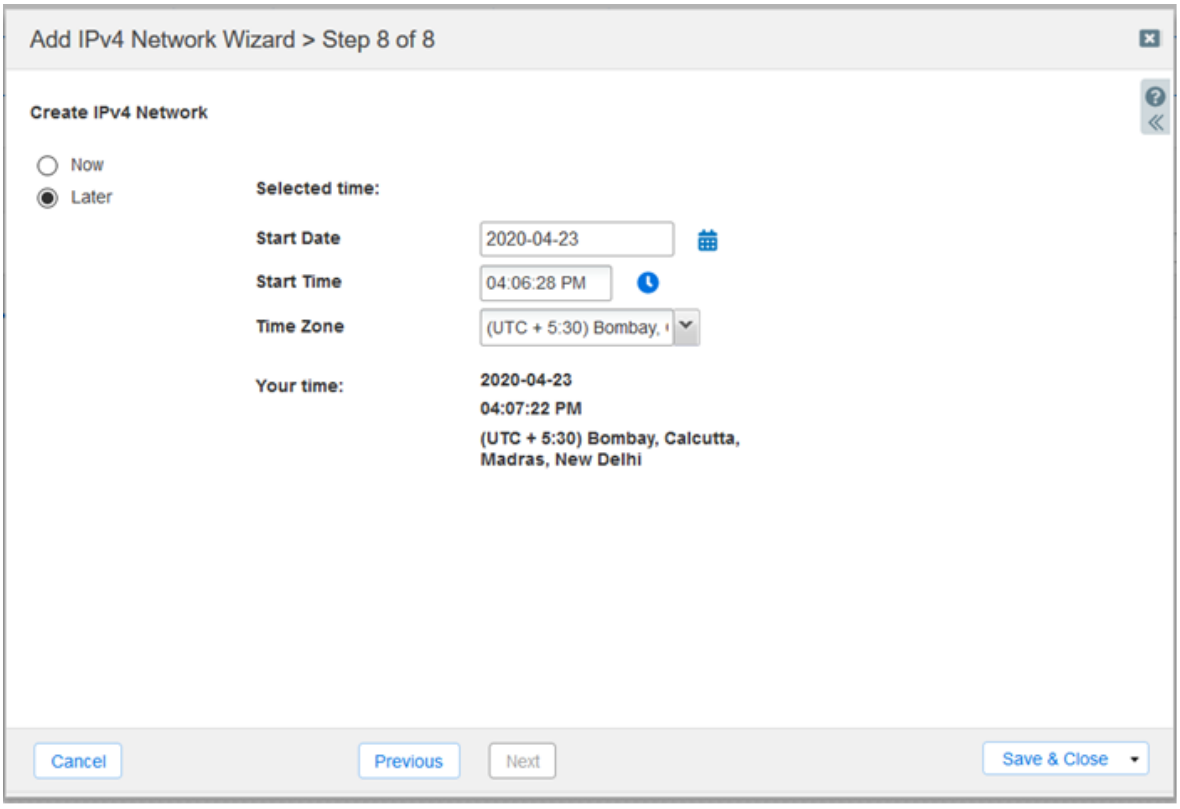
Scheduling Creation of new IPv4/IPv6 Networks and Associated Device Provisioning

Defining new IP networks in Grid Manager supports scheduled Network Provisioning tasks on discovered and managed infrastructure devices as part of their object definition:

- Provisioning IPv4 networks
- Provisioning IPv6 networks

These networks are managed on the IPAM and DHCP pages (unless the network is excluded from DHCP), with the difference that Network Insight provisions the network directly on the specified router or switch-router. You may define new networks under IPAM and under DHCP as one scheduled task, and may provision those networks on devices that are discovered and managed under Network Insight, as another scheduled task.
Both tasks may be separately scheduled. They can take place immediately: the network is created first, then the network is provisioned on the device, along with the necessary device configuration, which Grid Manager also handles using the required CLI credentials; or either or both tasks may be scheduled for a later time.
The scheduled IPv4 or IPv6 network must be created under IPAM or DHCP in Grid Manager before scheduled device configuration or provisioning of networks on those devices can take place.
When you define a new network under IPAM or DHCP, you can click **Schedule for Later** in any Wizard page to skip further configuration in the Wizard and commit the network settings to Grid Manager. If you do not want to provision the network, clicking **Schedule for Later** will display a shorter scheduling page:

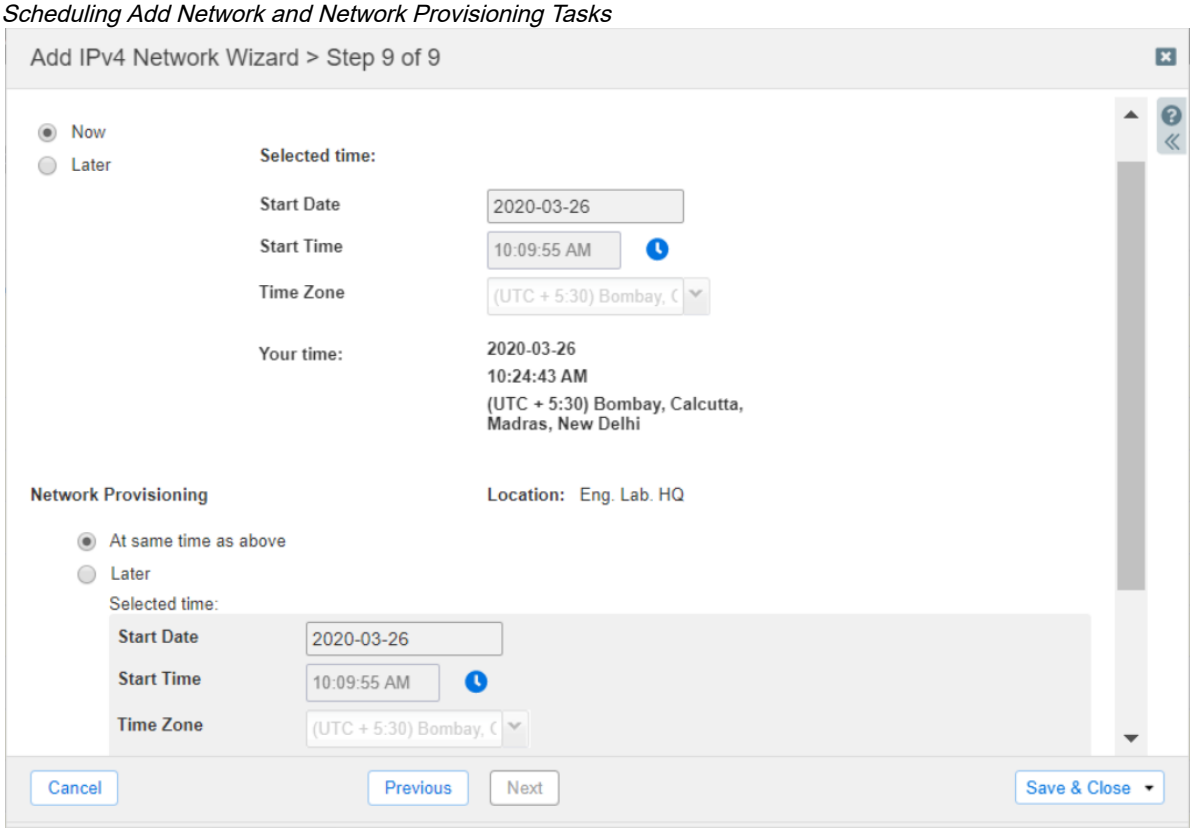
Create Network Schedule page (After clicking Schedule for Later)



In cases of this type, you schedule or execute only a single task: creating the new network under DHCP/IPAM. No network provisioning task takes place.

When you provision the network without clicking **Schedule for Later**, the wizard provides a final Scheduling page with an expanded set of two task schedules as shown in the below figure:

Scheduling Add Network and Network Provisioning Tasks



1. To immediately create the new network, you can select **Now**.
2. You can choose to have Grid Manager create the network at a later time. To do so, select **Later**. Choose a **Selected time** by entering or selecting a **Start Date** (click the calendar icon to choose a calendar date) and a **Start Time** (click the clock icon to choose a specific time in fifteen minute increments), and choose a **Time Zone**.
3. The Network Provisioning task can be synchronized to take place at the same time as the creation of the new network under IPAM/DHCP; if so, keep the **At same time as above** option.
4. You can also provision the network onto the device at a differently scheduled time. To do so, select **Later** (under **Network Provisioning**). Choose a **Selected time** by entering or selecting a **Start Date** (click the calendar icon to choose a calendar date) and a **Start Time** (click the clock icon to choose a specific time in fifteen minute increments), and choose a **Time Zone**.

> ⚠ **Note**
>
> Network provisioning tasks (or any operation that queries for or changes device configurations through Grid Manager, including Discovery) are subject to a feature called Blackout periods, which are defined elsewhere in Grid Manager. Blackouts are a scheduled feature that instructs Grid Manager not to perform Discovery operations and Port Control/provisioning operations on the managed network at specified times, days and dates. See the section *Defining Blackout Periods* for details.

Scheduling Additions and Modifications

You can schedule the addition and modification of an object. For example, you can schedule the addition of a DNS forward zone or the modification of a fixed address. After you schedule a task, administrators cannot modify the object associated with the scheduled task until after the appliance executes the task. However, the object can still be updated

with DHCP leases and other system services.
To schedule an addition or a modification:

1. Add or modify a record following the instructions described in this guide.
2. Click the Schedule icon at the top of the corresponding wizard or editor.
3. In the *Schedule Change* panel, complete the following:
    - **Now**: Select this to have the appliance perform the task when you save the entry. This is selected by default when there is no scheduled task associated with the object.
    - **Later**: Select this to schedule the task for a later date and time. Complete the following:
        - **Date**: Enter a date in YYYY-MM-DD (year-month-day) format. The appliance displays today's date. You can also click the calendar icon to select a date from the calendar widget.
        - **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
        - **Time Zone**: Select a time zone for the scheduled date and time from the drop-down list. This field displays the time zone of the browser that the admin uses to log in to Grid Manager.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Scheduling Appliance Operations

The appliance supports the scheduling of the following operations:

- IP discoveries—For information, see *About Discovery.*
- Service restarts—For information, see *Restarting Services*.

Scheduling Deletions

You can schedule the deletion of an object or an operation for a later date and time. However, you cannot schedule the deletion of a previously scheduled task.
To schedule a deletion:

1. Navigate to the object.
2. Select **Schedule Deletion** from the Delete drop-down menu.
3. In the *Schedule Deletion* dialog box, complete the following:
    - **Delete Now**: Select this to delete the object upon clicking **Delete Now**.
    - **Delete Later**: Select this to schedule the deletion at a later date and time. Complete the following:
        - **Date**: Enter the date in YYYY-MM-DD (year-month-day) format. The appliance displays today's date. You can also click the calendar icon to select a date from the calendar widget.
        - **Time**: Enter the time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
        - **Time Zone**: Select a time zone for the scheduled date and time from the drop-down list. This field displays the time zone of the browser that the admin uses to log in to Grid Manager.
4. Click **Schedule Deletion**.

The appliance performs the deletion at the scheduled date and time.

Scheduling Recursive Deletions of Network Containers and Zones

Superusers can determine which group of users are allowed to schedule the deletion of a network container and its child objects as well as a zone and its child objects. For information about how to configure the recursive deletion of network containers and zones, see *Managing a Grid.*
To schedule the recursive deletion of network containers and zones:

1. Navigate to the object.
2. Select **Schedule Deletion** from the Delete drop-down menu.
3. In the *Schedule Deletion* dialog box, complete the following:
    - **Delete Now**: Select this to delete the object upon clicking **Delete Now**.
    - **Delete Later**: Select this to schedule the deletion at a later date and time. Complete the following:

- **Date**: Enter the date in YYYY-MM-DD (year-month-day) format. The appliance displays today's date. You can also click the calendar icon to select a date from the calendar widget.
- **Time**: Enter the time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
- **Time Zone**: Select a time zone for the scheduled date and time from the drop-down list. This field displays the time zone of the browser that the admin uses to log in to Grid Manager. Select one of the following:
  - **Delete only the parent container**: Select this to delete only the parent objects and re-parent the child objects.
  - **Delete the parent container and its children**: Select this to delete the parent objects and all its child objects.

4. Click **Schedule Deletion**.

The appliance performs the deletion at the scheduled date and time.

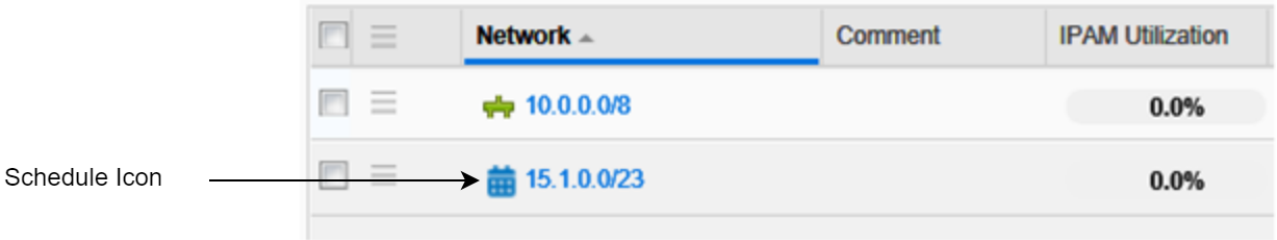
Viewing Scheduled Tasks

After you schedule a task, you can view the pending task in the **Administration** tab -> **Workflow** tab -> **Task Manager** tab. For more information, see *Viewing Tasks*. Superusers can view all scheduled tasks, and limited-access admins can view their own scheduled tasks.
In certain panels such as the Network list panel and Smart Folders, Grid Manager displays a calendar icon next to objects that are associated with scheduled tasks, except for the addition of an object. You can click the icon to view the configuration and schedule. You can also reschedule the task if you are the owner of the task, a superuser, or an approver of the task (after you have approved it). In the corresponding editor, the Schedule icon is green when there is a pending scheduled task.

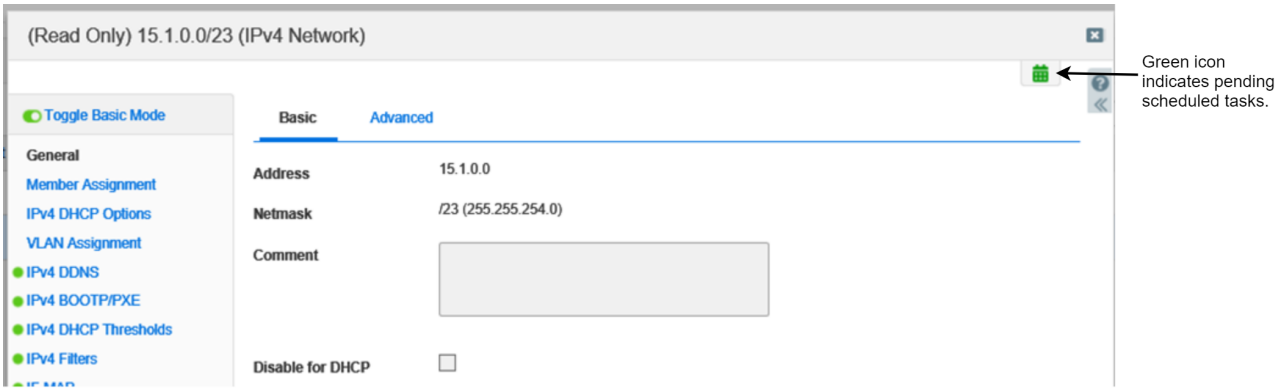
Icons for Scheduled Tasks

Grid Manager displays a scheduled task icon next to an object that is associated with a scheduled task (except for the addition of an object), as shown in the below Icon for a Scheduled Task figure. When you mouse over the icon, an informational dialog box appears displaying the type of action, the date and time of the scheduled task, and the person who scheduled the task.
You can click the icon and Grid Manager displays the corresponding editor (for modification) or the *Scheduled Deletion* dialog box (for deletion) in the read-only mode. If you are viewing a task that you scheduled, you can modify and save the schedule, but you cannot modify the configuration of the object. If you are not the owner of a scheduled modification or a superuser, you can only view the information. You cannot reschedule the task. If you are not the owner of a scheduled deletion or a superuser, Grid Manager does not display the *Scheduled Deletion* dialog box when you click the icon.

Icon for a Scheduled Task



In the editor, Grid Manager displays the Schedule icon in green to indicate a pending scheduled task associated with the corresponding object, as shown in the Scheduling Icon Indicating a Pending Task figure. You can click the Schedule icon to view the date and time of the scheduled task. You can also reschedule the task if you have the applicable permissions. For information, see *Rescheduling Tasks*.
Scheduling Icon Indicating a Pending Task



Pending Tasks for Operations

You can view all pending tasks for a network discovery or service restart in **Task Manager** if you have the applicable permissions. For information, see *Viewing Tasks*. You can also view the pending tasks in their corresponding dialogs. To view the pending tasks in an editor:

1. Network **Discovery**: From the **Data Management** tab, select the **IPAM** tab, and then click **Discovery** from the Toolbar.

   Service Restarts for the Grid: From the **Data Management** tab, select the **IPAM**, **DHCP** or **DNS** tab, and then click **Restart Services** from the Toolbar, or from the **Grid** tab, click **Restart Services** from the Toolbar.
   Service Restarts for Grid members: From the **Data Management** tab, select the **DHCP** or **DNS** tab -> **Members** tab, select a member checkbox, and then click **Restart Services** from the Toolbar.

2. Click the Schedule icon at the top of the wizard, and then select **Click here to view/manage the scheduled items**. Note that this link appears only when you have one or more scheduled tasks.

3. Grid Manager displays the following information in the *Scheduled Tasks*:

- **Scheduled Time**: The date, time, and time zone when the appliance executes the task.
- **Submitted Time**: The date, time, and time zone when the task was submitted.
- **Submitter**: The admin who scheduled the task.
- **Task Details**: The message that appears in the audit log.

By default, the appliance sorts the tasks by **Scheduled Time** starting with the earliest scheduled start time. You can do the following in this viewer:

- Sort the tasks in ascending or descending order by column, except for **Task Details**.
- Reschedule a selected task. For information, see *Rescheduling Tasks Associated with Operations.*
- Delete a selected task by selecting the task checkbox and clicking the Delete icon.
- Export and print the information in the table.

Rescheduling Tasks

Superusers can reschedule any scheduled task. Limited-access admins can reschedule only the tasks that they scheduled, depending on their permissions. Approvers can reschedule tasks that they have approved, if they have the scheduling permission. You can reschedule a task from different panels of Grid Manager, depending on your permissions. When you reschedule a task from the object list panel, Grid Manager displays the object or operation configuration in a read-only mode. You can modify the date and time to reschedule the task. However, you cannot modify the configuration of the object or operation. You can also reschedule your own task or a task you have approved from Task Manager.
To reschedule tasks associated with objects, see ReschedulingTasksAssociatedWithObjects below.
To reschedule tasks associated with operations, see ReschedulingTasksAssociatedwithOperations below.

Rescheduling Tasks Associated With Objects

You can reschedule a task associated with an object from the *Scheduled Tasks* viewer or in an editor if you have the applicable permissions.
To reschedule a task from **Task Manager**:

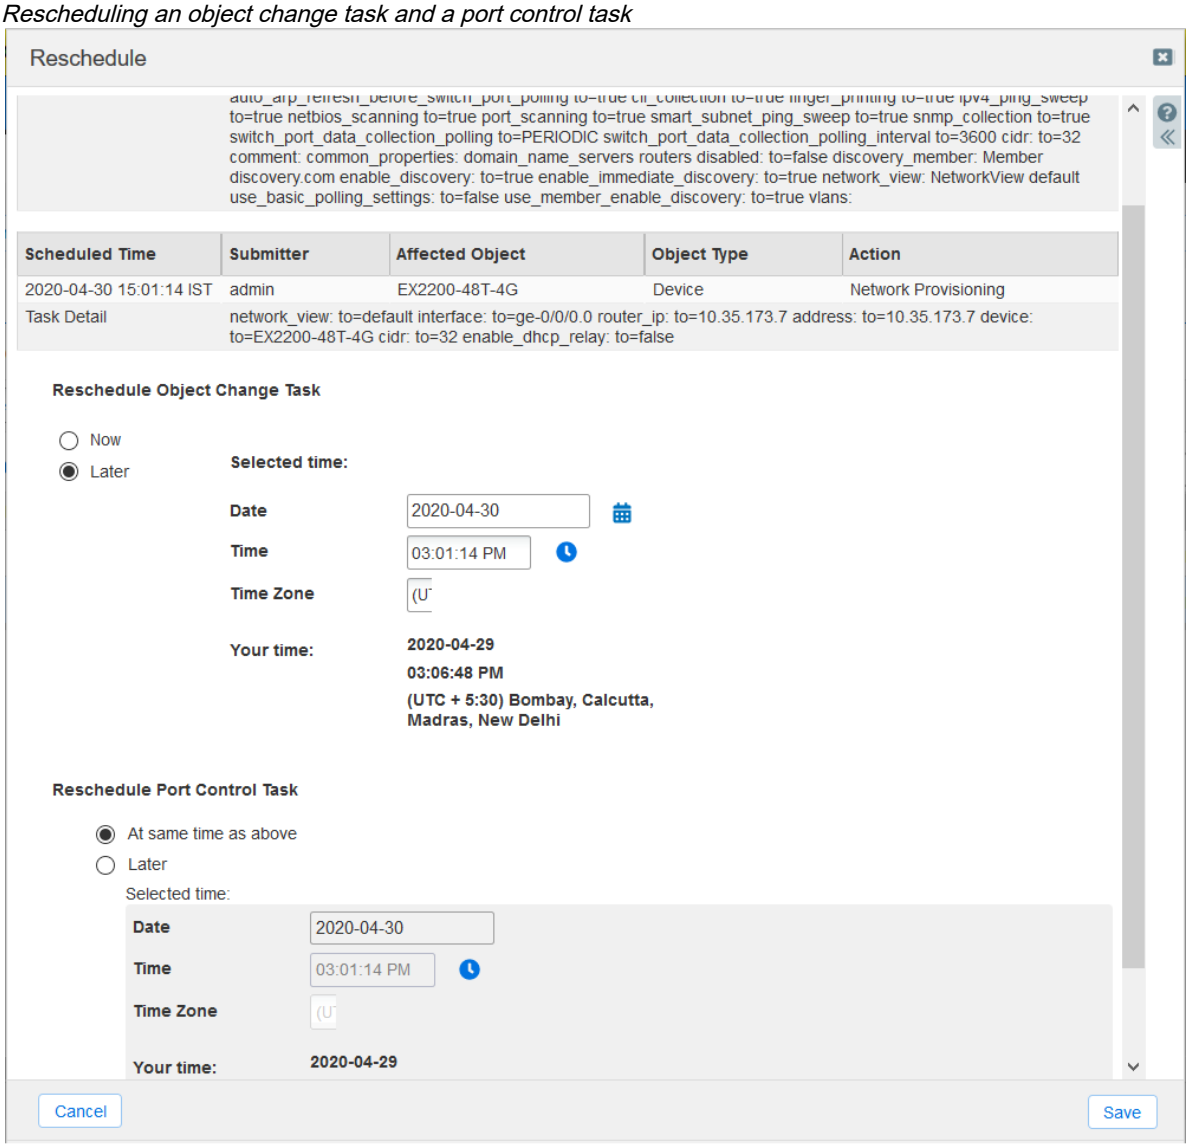
1. From the **Administration** tab, select the **Workflow** tab -> **Task Manager** tab -> *scheduled_task* checkbox, and then click the Reschedule icon.
2. In the *Reschedule* dialog box, modify the date and time when you want the appliance to execute the task. You can select **Now** to execute the task when you save the entry.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

To reschedule a task in an editor:

1. Navigate to the object with a scheduled task that you want to reschedule.
2. Click the scheduled task icon next to the object.
3. **For modification**: In the editor, click the Schedule icon at the top of the editor. In the *Schedule Change* panel, modify the date, time, and time zone. You can also select **Now** to execute the task upon saving the entry.
   For deletion: In the *ScheduleDeletio*n dialog box, modify the date, time, and time zone. You can also select **Delete Now** to delete the object upon clicking **Delete Now**. The appliance puts the deleted object in the Recycle Bin, if enabled.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Rescheduling object change tasks and associated port control tasks is a special case allowing for rescheduling of both tasks in the same editor:

Rescheduling an object change task and a port control task



Rescheduling Tasks Associated with Operations

To reschedule a network discovery or a service restart:

1. From the **Administration** tab, select the **Workflow** tab -> **Task Manager** tab -> *scheduled_task* checkbox, and then click the Reschedule icon.
   or
   Navigate to the operation and click the Schedule icon at the top of the wizard. In the *Schedule Change* panel, select **Click here to view/manage the scheduled items**. Grid Manager displays all scheduled tasks related to the operation in the *Scheduled Tasks* viewer. Select the task checkbox, and then click the Reschedule icon.
2. Grid Manager displays detailed information about the task in the *Reschedule* dialog box.
3. Modify the date and time when you want the appliance to execute the task. You can also select **Now** to execute the task when you save the entry.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Canceling Scheduled Tasks

To cancel a scheduled task:

1. From the **Administration** tab, select the **Workflow** tab -> **Task Manager** tab -> *scheduled_task* checkbox, and then click the Delete icon.
2. In the *Confirm Delete Request* dialog box, click **Yes**.

The appliance deletes the scheduled task and does not perform the scheduled operation. Therefore, no change is made to any record after you delete a scheduled task.

Performing Basic Operations Using Grid Manager

This section describes how to use some of the key NIOS features. It includes the following topics:

- *Logging on to the NIOS UI*
- *Setting Login Options*
- *Browser Limitations*
- *Multilingual Support*
- *Managing Internationalized Domain Names*
- *Finding and Restoring Data*
- *Opening Technical Support Requests*

Logging on to the NIOS UI

The NIOS UI (also called Grid Manager) is the web interface that provides access to your appliance for network and IP address management. It provides a number of tools that you can use to effectively manage your appliance and IP address space.

You can log in to Grid Manager as long as you have permission to log in to the NIOS appliance. Superusers have unrestricted access to Grid Manager. Limited-access users require read-only or read-write permission to the data that they want to manage through Grid Manager. Grid Manager allows limited-access users to view and manage only the data for which they have permission. For example, to view IPv4 networks, you must have at least read-only permission to IPv4 networks, or to run a discovery, you must have read/write permission to the Network Discovery feature.

Note that superusers must configure admin groups and accounts in Grid Manager application of the NIOS appliance. In Grid Manager, superusers can set and change permissions for specific objects, such as IPv4 networks, IPv6 networks, and resource records. For information about user accounts and administrative permissions, see *Managing Administrators*.

Before you log in to Grid Manager, ensure that you have installed your NIOS appliance as described in the installation guide, or the user guide that was shipped with your products and then configure your NIOS appliance accordingly. You must upload the CA certificate(s) that issued the client certificate to ensure a successful SSL/TLS connection to the appliance.

To log in to Grid Manager, complete the following:

1. Open an Internet browser window and enter **https://*<IPaddress_or_hostname_of_your_NIOSappliance>***. Grid Manager login page appears. For information, see *Supported Browsers*.
2. Enter your user name and password, and then click **Login** or press the **ENTER** key. The default user name is **admin** and the default password is **infoblox**. Note that if your password expired or was reset by a superuser, you may be required to enter a new password.
    - If you are a smart card user and two-factor authentication is enabled on the appliance, your user name, which is the same as your CN (common name) in the client certificate, appears automatically. Enter the password you use to log in to the user account. For information about two-factor authentication, see *Authenticating Admins Using Two-Factor Authentication*.

- In NIOS 8.5.2 or later, for a Grid Master or a standalone vNIOS instance deployed on AWS, you are prompted to reset the password on the first login attempt. You must reset the default password as a security requirement.
    - To reset, enter a new password and confirm it. The minimum password length must be four characters. It must consist of at least one uppercase character, one lowercase character, one numeric character, and one symbol character. Example: Infoblox1!.
      If the symbol character is at the beginning of the password, then include the password within quotes ("). Example: '@Infoblox123'.
    - Alternatively, you can define a new password in the **User data** field of the AWS console, in which case, you are not prompted to reset the password on the first login in Grid Manager. For more information, see *Provisioning vNIOS for AWS Using the BYOL Model* in the *Installation Guide for vNIOS for AWS documentation.*

3. Read the *Infoblox End-User License Agreement* (EULA), and then click **I Accept**.
   Note that if you want to view the privacy policy of Infoblox, then on the EULA screen, click **Infoblox Privacy Policy**. Grid Manager displays the policy on a new browser tab.
4. Click **OK**. The *Grid Setup* wizard appears.

Setting Login Options

Grid Manager provides several options that you can set to facilitate the login process. Additionally, you can manage CA (Certificate Authority) and server certificates on the NIOS appliance. You can import certificates, select and view their details, or remove them. To manage certificates, see *Managing Certificates*.

Specifying Grid Name and Host Name

To define the default host name that appears when the login prompt displays, complete the following:

1. On the **Grid** tab -> **Grid Manager** tab, expand the Toolbar and select **Grid Properties** -> **Set up (Grid Setup Wizard)**.
2. On the Welcome page, select **Configure a Grid Master**, and then click **Next**.
3. Enter the Grid name in the **Grid Name** field and the host name in the **Host Name** field.

Creating a Login Banner

You can create a statement that appears at the top of the *Login* screen (a banner message). This function is useful for posting security warnings or user-friendly information well above the username and password fields on the *Login* screen. A login banner message can be up to 3000 characters long. In a Grid, perform this task on the Grid Master.

To create a login banner, complete the following:

1. On the **Grid** tab -> **Grid Manager** tab, expand the Toolbar and select **Grid Properties** -> **Edit**.
2. In the *Grid Properties Editor*, on the **Security** tab, select **Enable Login Banner.** In the text field, enter the text that you want to be displayed on the login screen.
3. Save the configuration.

Changing the Password and Email Address

Grid Manager creates and stores a user profile for each admin user. Each user profile contains information about the admin group and admin type assigned to the user. You can modify certain information in your user profile any time after the initial login. You can change your password to facilitate future logins and add your email address for reference.

Note that when multiple users log in to Grid Manager using the same admin account, they share the same user profile and preference settings, such as the widget, table size and column settings, independent of their browser settings. Instead of using the same admin account for multiple users, you can add multiple users to the same admin group so they can share the same permissions. For information about configuring admin accounts and admin groups, see *Managing*

Administrators.

If you can access only the Tasks Dashboard, you may not see or configure certain fields in the *User Profile* editor.

To change your password and email address, complete the following:

1. At the top-right corner of the navigation bar, click the admin name and select **Profile** from the drop-down menu.
2. In the *User Profile* editor, complete the following:
    - **Name**: Displays your user name.
    - **Last Login**: Displays the timestamp of your last log in.
    - **Type**: Displays your user type. There are two user types: **Local** and **Remote**. Local type admin accounts are stored in the NIOS database. Remote type admin accounts are stored on another server, such as a RADIUS server. Grid Manager automatically deletes remote user profiles if users have not logged in for more than six months.
    - **Group**: Displays the admin group to which your account belongs. The admin group determines your administrative permissions. Only superusers can define admin groups through Grid Manager.
    - **Password**: You can set a new password according to the requirements that are displayed.
        - **Set Password**: If you are a local user, select this checkbox to set a new password for your account. If you are a remote user, this field does not appear.
        - **Old Password**: Enter your current password.
        - **New Password**: Enter the new password, and then re-enter it in the **Retype Password** field.
    - **Email Address**: Enter your email address. Note that this address simply provides contact information. By default, this field is blank.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Specifying the Table Size

You can specify the amount of data Grid Manager must display in a table or a single list view. You can improve the display performance by setting a smaller table size. The setting you specify here applies to all tables in Grid Manager. Note that if you can access only the Tasks Dashboard, you cannot configure table size.

To specify table size, complete the following:

1. At the top-right corner of the navigation bar, click the admin name and select **Profile** from the drop-down menu.
2. In the *User Profile* editor, in the **Table Size** field, specify the number of lines of data you want a table or a single list view to contain. You can set the number of lines from 10 to 256. The default is 20.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Selecting Your Home Page

When you first log in to Grid Manager, the Tasks Dashboard is your home page. You can change your home page for subsequent logins. You can specify the maximum number of widgets that can be configured per dashboard. You can set up to 20 widgets per dashboard. You can also set the auto refresh rate for dashboard widgets. This interval specifies how often the content of the dashboard widgets is refreshed.

To change your home page, complete the following:

1. At the top-right corner of the navigation bar, click the admin name and select **Profile** from the drop-down menu.
2. In the *User Profile* editor, complete the following:
    - **Default Dashboard**: Select **Status** or **Task** from the drop-down list.
    - **Maximum Widgets per Dashboard**: Specify the maximum number of widgets that can be configured per dashboard. You can enter a value between 1 and 20. The default value is 10. This limit does not apply to the default dashboard.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Grid Manager displays the selected dashboard as your home page when you log in the next time.

Setting the Browser Time Zone

You can specify the time zone that Grid Manager uses to convert all displayed time values, such as the last discovered and last login time. Grid Manager sets the time zone based on the time zone of your browser when you set the time zone to auto-detect in the *User Profile* editor. When you set the time zone of your browser to auto-detect and Grid Manager cannot automatically determine the time zone when you log in, the time zone is set to the UTC (Coordinated Universal Time) standard. In this case, you can manually change the time zone in the *User Profile* editor.

To manually set the time zone of your browser, complete the following:

1. At the top-right corner of the navigation bar, click the admin name and select **Profile** from the drop-down menu. The *User Profile* editor displays your username, user type, and admin group.
2. In the *User Profile* editor, select the time zone Grid Manager uses to convert all displayed time values. The default is **Auto-detect time zone**. You must select a specific time zone when Grid Manager cannot automatically detect the time zone of your browser.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Browser Limitations

- When you use Internet Explorer 7 or 8 without installing the latest updates, Grid Manager may stop loading a page when you navigate from one tab to another or when you use the back navigation button to go back to a previous page. To solve this problem, you can press Ctrl+F5 to refresh the browser or install the latest updates.
- When you use the zoom function in Internet Explorer 7 running on Microsoft Windows XP, Grid Manager may not properly display some pop up windows. This is a known issue in Internet Explorer 7.
- In Internet Explorer 8, Grid Manager does not display the directory path of an uploaded file. Instead, it displays "fakepath" in place of the directory path. To resolve this issue, you can add Grid Manager as a trusted site or enable the "Include local directory path when uploading files to a server" feature in the browser. For information, refer to the MSDN documentation at *https://msdn.microsoft.com/en-us/library/ms535128.aspx*.
- When you use FireFox to access Grid Manager, tooltips do not display for disabled drop-down menu items. In addition, when you run a large query of smart folders, Grid Manager may display a warning message about "Unresponsive Script". Click **Continue** to proceed.
- Depending on the browser you use, Grid Manager may display a dialog box that indicates the system is unavailable during a system restart or reboot.
- Infoblox strongly recommends that you do not log in to Grid Manager from different browser windows using the same user account. Depending on the browser you use, it may cache user information in one session and apply it to another session. This can cause inconsistent behaviors within the browser sessions.

Multilingual Support

The NIOS appliance supports UTF-8 (Unicode Transformation Format-8) encoding for the following:

- Hostnames for Microsoft Windows clients that support Microsoft Windows code pages. For information about Configuring UTF-8 Encoding for Hostnames, see *Configuring UTF-8 Encoding for Hostnames*.
- Input fields through Grid Manager.

UTF-8 is a variable-length character encoding standard for Unicode characters. Unicode is a code table that lists the numerous scripts used by all possible characters in all possible languages. It also has a large number of technical symbols and special characters used in publishing. UTF-8 encodes each Unicode character as a variable number of one to four octets (8-bit bytes), where the number of octets depends on the integer value assigned to the Unicode character. For information about UTF-8 encoding, refer to *RFC 3629* (*UTF-8, a transformation format of ISO 10646*) and the *ISO/IEC 10646-1:2000 Annex D*. For information about Unicode, refer to *The Unicode Standard*.
Depending on the OS (operating system) your management system uses, you must install the appropriate language files in order to enter information in a specific language. For information about how to install language files, refer to the documentation that comes with your management system.

UTF-8 Supported Fields

The NIOS appliance supports UTF-8 encoding in all of the comment fields and most input fields. You can enter non-English characters in these data fields through Grid Manager and the Infoblox API. When you use the Infoblox API, all the non-ASCII strings must be UTF-8 encoded so that you can use Unicode characters. The NIOS appliance does not support UTF-8 encoding for data that is configurable through the Infoblox CLI commands.
In general, the following items support UTF-8 encoding:

- All the predefined and user-defined extensible attributes.
- All the comment fields in Grid Manager.
- File name fields for FTP and TFTP backup and restore operations.
- The login banner text field. When you use the serial console or SSH, the appliance cannot correctly display the UTF-8 encoded information that you enter for the login banner.

> **Note**
>
> For data fields that do not support UTF-8 encoding, the appliance displays an error message when you use non-English characters.

UTF-8 Support Limitations

The NIOS appliance has the following UTF-8 support limitations:

- Object names that have data restrictions due to their usage outside of the Infoblox database do not support UTF-8 encoding. For example, IP addresses and Active Directory domain names.
- When importing a database, most of the ASCII control characters cannot be encoded. This might cause failures in upgrades or database restore operations.
- Search is based on the Unicode standard. Depending on the language, you might not be able to perform a case-sensitive search.
- Binary data is encoded as text.
- UTF-8 encoding does not fully support regular expressions. It matches constant strings. However, It does not encode characters that are inside square brackets or followed by regular expressions such as *, ?, or +.
- You can use UTF-8 characters to authenticate both the User Name and Password through the Infoblox GUI, but not through the Infoblox CLI.
- You cannot use UTF-8 characters to name a custom DHCP fingerprint. For information about DHCP fingerprint detection, see *DHCP Fingerprint Detection*.

Managing Internationalized Domain Names

The Infoblox Grid supports IDNs (Internationalized Domain Names) for DNS zones and resource records to provide the flexibility of specifying domain names in non-English characters.
An IDN is a domain name that contains a language-specific script or alphabet, such as Arabic, Chinese, Russian, Devanagari, or the Latin alphabet-based characters with diacritics, such as French. IDNs are encoded in multi-byte Unicode and are decoded into ASCII strings using a standardized mechanism known as Punycode transcription. For example, DNS Zone 'инфоблокс.рф' (IDN in Russian) can be written as ‘xn--90anhdigczv.xn--p1ai’ in the punycode representation. In addition, the appliance has a built-in conversion tool to assist you in identifying and troubleshooting an IDN or the punycode representation of an IDN. For information about how to decode IDNs, see Decoding IDNs and Encoding Punycode below. The appliance supports IDNs in certain fields. There are certain guidelines and limitations about IDN support.

Decoding IDNs and Encoding Punycode

You can encode non-English characters into punycode and decode punycode to obtain a domain name in its original character set. You can encode IDNs and decode punycode simultaneously. You can use special characters.
To encode non-English character set into punycode and decode punycode:

1. Select any tab in Grid Manager, and then click **IDN Converter** from the Toolbar.
2. In the *IDN Converter* wizard, complete the following:
    - Specify the domain name in the **Unicode** text box and click **Convert to Punycode**. The **Punycode** field displays the punycode representation of the domain name.
    - Specify the punycode representation of a domain name in the **Punycode** field and click **Convert to Unicode**.
      The **Unicode** field displays the domain name in its original character set.
      Note that you can use special characters in the **Unicode** and **Punycode** fields.
    - Click **Clear** to clear the entries. Note that when you click **Clear** for a specific conversion, the appliance clears only the error message that corresponds to that conversion.
3. Click **Close**.

IDN Supported Fields

The NIOS appliance supports IDNs in all domain name fields. For information about IDNSupportForDNS Zones, see *Domains and Zones .* You can enter non-English characters in the domain name fields through Grid Manager and the Infoblox API. The NIOS appliance does not support IDNs for data that is configurable through the Infoblox CLI commands. You can use the punycode representation to configure data through the CLI commands.
The appliance supports IDNs in the following:

- You can use UTF-8 characters when defining your own hostname checking policy. For information, see *Specifying Hostname Policies*.
- You can use both IDNs and punycode to search for IDN data through Global Search. For more information about using Global Search, see *Finding and Restoring Data*.
- Use smart folders to organize and monitor IDN data. However, if the content in a smart folder contains IDNs, then the punycode representation is not available. For information, see *Smart Folders*.
- You can import data that contains IDNs in CSV format for the supported fields and objects using CSV import. For more information, see *Importing and Exporting Data using CSV Import*. For a list of supported record types and specific guidelines for creating a data file, refer to the *Infoblox CSV Import Reference*.
- The IPAM tab displays IDNs for DNS resource records associated with IP addresses, such as A records, AAAA records, hosts, and PTR records. For information, see *About IP Address Management*.
- The audit log entries are displayed in their original characters. The audit log contains IDN data as received by the appliance and as specified by the administrators. Note that the punycode representation generated by NIOS is not displayed in the audit log.
- When you upgrade from a previous NIOS release, the appliance converts all punycode to IDNs. If the conversion fails, the appliance retains the punycode representation to avoid upgrade failure. For information about upgrades, see *Guidelines for Upgrading, Backing Up, and Restoring Data*.
- When you restore a backup file from a previous NIOS release, the appliance converts all punycode to IDNs. If the conversion fails, the appliance retains the punycode representation to avoid failure to restore the database. For information, see *Guidelines for Upgrading, Backing Up, and Restoring Data*.
- If synchronized data between the appliance and Microsoft servers contains IDNs, the IDNs are preserved. For information, see *Managing Microsoft DNS Services*.

IDN Support Limitations

The appliance has the following IDN support limitations:

- F5® load balancers does not support IDNs. The NIOS appliance does not encode punycode to IDNs for F5 load balancer related objects. Only the punycode representation is available.
- Multi-Grid configuration does not support IDNs.

- The Infoblox CLI does not support IDNs.
- If a resource record containing an IDN is added to the Infoblox Grid through DDNS updates, the domain name field displays the record name in UTF-8 encoded format. For more information, see *Managing Resource Records*.
- The following FQDNs does not support IDNs:
    - FQDN of an external DNS Server (direct or via name server group)
    - FQDN of a DNS root server
    - FQDN of a Microsoft server
    - FQDN of an Infoblox Grid Member
    - FQDN of an external authentication source (Active Directory, LDAP, OCSP, RADIUS, TACACS+)
    - FQDN of an NTP server
    - FQDN of a Thales Luna HSM Module
    - FQDN of an email relay server
    - FQDN of a vSphere/ESX server
    - FQDN of a Kerberos Key Distribution Center

Using IDNs for Unsupported Objects

The appliance accepts only punycode entries for objects that do not support IDNs. To use IDNs for these objects, manually convert IDNs to punycode and use the punycode representation.
Use the punycode representation of IDNs for the following:

- When you configure domain names in forwarder servers, NXDOMAIN rulesets, blacklist rules, and DNS resolver search lists.
- When you configure domain names for DHCP and DHCPv6 services, including DDNS domain name, any DHCP options that accept domain names (host-name (12) string) or lists of domain names (domain-search (119) domain-list), and DHCPv6 options that accept domain names (dhcp6.fqdn (39) string) or lists of domain names (dhcp6.domain-search (24)) domain-list.
- When you add domains in the Inclusion list and Exclusion list. For information about Excluding Domains From Query and Response Capture, see *Capturing DNS Queries and Responses*.
- When you configure rules for a local RPZ and RPZ feed. For information, see *Configuring Local RPZs* and *Configuring Infoblox Threat Intelligence Feed*.

Displaying IDN Entries in Punycode

The appliance displays IDN entries in punycode for the following:

- The data of a zone for which an Infoblox Grid member is the secondary server.
- The CLI commands dig, ddns_add, ddns_delete, show dns, and set dns support punycode only. For information about CLI commands, refer to the *Infoblox CLI Guide*.
- All syslog entries generated by DNS.
- IDN data in database files is stored in punycode.
- The DNS cache of a Grid member that contains IDNs.
- The **Reporting** tab displays all report data that contains IDNs in punycode. For information, see *Predefined Dashboards*.

Finding and Restoring Data

Grid Manager provides tools for organizing and quickly retrieving your DNS, DHCP and IP address management data. The *Finder* panel, which appears on all pages in Grid Manager, provides tools for organizing your data. The *Finder* panel provides easy access to the following:

- *Using Bookmarks*
- *Using the Recycle Bin*
- *Managing Third Party URL Links*
- *Using Filters*
- *Using Quick Filters*

- *Using Global Search*
- *Using the Go To Function*

- Smart Folders: Contains a hierarchical list of smart folders that are available in My Smart Folders. For information, see *Smart Folders*.
- Bookmarks: Contains bookmarked objects, such as networks and IP addresses.
- Recycle Bin: Contains deleted objects that can be restored or permanently removed.
- URL Links: Contains a list of third-party URLs that you previously added. You can add more URL links, and modify and delete existing URL links. For information, see Managing Third Party URL Links below.

In the *Finder* panel, you can expand and collapse these sections. To expand a section, click the **+** icon next to the header. To collapse a section, click the **-** icon.
In addition, Grid Manager also provides the following:

- Filters to customize data displays. For more information, see Using Filters and Using Quick Filters below.
- Global Search to search the NIOS database for objects that match your criteria. For more information, see Applying Quick Filters below.
- Go To function to quickly locate an object. For more information, see Using the Go To Function below.

Using Bookmarks

The Bookmarks section displays objects for which you have created bookmarks. You can create bookmarks for objects such as networks, DNS zones, and admin groups. To bookmark an object, navigate to its page and click the Bookmark icon at the top of the page. If you have more than one network view, Grid Manager displays the name of the bookmark with the network view to which the object belongs. For example, when you bookmark IP address 10.128.0.10 in the default network view, Grid Manager displays the bookmark as default > 12.128.0.10.
However, if you have only one network view, Grid Manager displays only the object name 12.128.0.10. If you create a bookmark before adding more network views, the bookmark name (without the network view) remains the same. You can rename the bookmark at any time. You can create only one bookmark for each object, up to 500 objects. When your bookmarks are close to 500, you may want to remove some to create room for new ones.
You can perform the following in Bookmarks:

- Access a bookmarked object
- Edit the name of a bookmark
- Delete a bookmark

To access a bookmarked object, click the name of the bookmark. Grid Manager displays the network view to which the bookmarked object belongs. For example, clicking on the bookmark of network 10.0.1/24 takes you to the network list view. You cannot access an object that has been deleted.
You can arrange the order of the bookmarked objects by dragging and dropping the objects in the *Finder* panel.

To edit the name of a bookmark:

1. Mouse over to the bookmark.
2. Click the Edit icon.
3. Modify the name of the bookmark. Note that you cannot create multiple bookmarks with the same name.

To delete a bookmark:

1. Mouse over to the bookmark.
2. Click the Delete icon. Grid Manager removes the bookmark.

Using the Recycle Bin

The Recycle Bin section contains objects that you deleted. It provides a way to restore data where the deletion of the object (such as a network) could result in a major data loss.
You must enable the Recycle Bin in Grid Manager to store and restore deleted objects. For information about how to enable and disable the Recycle Bin, see Enabling and Disabling the Recycle Bin below. When you use the Recycle Bin, you can restore deleted objects to the active configuration. You can also permanently remove the objects from the

Recycle Bin. If you do not enable the Recycle Bin, the appliance immediately removes objects from the database when you delete them using Grid Manager.

> **Note**
>
> When you upgrade to a new NIOS release, the appliance permanently deletes the objects from the Recycle Bin.

On a NIOS appliance, only superusers have permissions to fully manage the Recycle Bin. If you have limited-access permissions, you can view, restore, and permanently remove only the objects that you deleted.
For Cloud Network Automation, the Recycle Bin is not supported on the Cloud Platform Appliance. Only deletions perform on the Grid Master are stored in the Recycle Bin. Deleted objects can only be restored from the Grid Master. For information about Cloud Network Automation, see *Deploying Cloud Network Automation*.

You can do the following in the Recycle Bin:

- View deleted objects
- Restore deleted objects
- Remove deleted objects
- Empty the Recycle Bin

Enabling and Disabling the Recycle Bin

To enable or disable the Recycle Bin:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Grid Properties** -> **Edit** from the Toolbar.
2. In the *Grid Properties* Editor, select the General tab, and then complete the following:
   Select **Enable Recycle Bin** to enable the Recycle Bin
   or
   Deselect **Enable Recycle Bin** to disable the Recycle Bin.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Viewing Objects in the Recycle Bin

Grid Manager displays the short name of all deleted objects in the Recycle Bin. For example, the short names for hosts and resource records are their domain names, and the short names for fixed addresses and reservations are their IP addresses.
The Recycle Bin does not display all deleted objects; it can display up to 15 of the most recently deleted objects. When the Recycle Bin contains objects that are not displayed in the *Finder* panel or multiple objects that have the same name, the **Show All** button appears. Click the button to display the *Recycle Bin* dialog box that contains detailed information about each deleted object. When you have multiple deleted objects that use the same name, you may want to view detailed information about the deleted objects before taking any action. You can remove and restore selected objects and empty the Recycle Bin in the *Recycle Bin* dialog box.
You can do the following in the *Recycle Bin* dialog box:

- Sort the data in ascending or descending order by column.
- Use filters and the search function to look for specific objects. For information about filters, see Using Filters below.
- Create a quick filter to save frequently used filter criteria. For information, see Using Quick Filters below.
- Use the **GoTo** function to quickly find the data in the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **GoTo** field and select the object from the possible matches.

To view detailed information about deleted objects:

1. In the *Finder* panel, expand **Recycle Bin**.
2. Click **Show All**.

Grid Manager displays the *Recycle Bin* dialog box that contains the following information for each object:

- **Name**: The short name of the object. For example, the short names for fixed addresses and reservations are their IP addresses.

- **Type**: The object type.
- **Parent/Container**: The parent object or parent container to which the object belongs.
- **Admin**: The admin name of the user who deleted the object.
- **Data**: The data that the object contains, if any.
- **Network View**: The network view to which the object belongs.
- **Time**: The time stamp when the object was deleted. To close the dialog box, click **Close**.

Restoring Objects from the Recycle Bin

You can restore deleted objects from the Recycle Bin only if you enable the Recycle Bin, and only if you select an object in the panel. You can restore only one object at a time. Deleted objects are stored in the Recycle Bin until you delete them or empty the bin.

To restore items from the Recycle Bin:

1. In the *Finder* panel, expand **Recycle Bin**.
2. Select the object you want to restore.
3. Click the Restore icon.

Grid Manager restores the object to its corresponding container or configuration. You can confirm the restoration by checking that the object does not appear in the Recycle Bin any longer, and that it is reestablished in the appropriate panel in the GUI.

Deleting Objects in the Recycle Bin

You can permanently delete individual objects in the Recycle Bin only if the Recycle Bin is enabled.

To delete objects in the Recycle Bin:

1. In the *Finder* panel, expand **Recycle Bin**.
2. Select the object you want to delete.
3. Click the Delete icon.
   Grid Manager displays the *Confirm Delete* dialog box.
4. Click **Yes** to delete the object.

Emptying the Recycle Bin

You can permanently delete the contents of the Recycle Bin, if enabled. Only superusers can empty the Recycle Bin. Because the Recycle Bin can grow large, you can periodically empty the Recycle Bin to free up disk space.

To empty the Recycle Bin:

1. In the *Finder* panel, expand **Recycle Bin**.
2. Click **Empty**.
   Grid Manager displays the *Confirm Empty Recycle Bin* dialog box to confirm that you wish to empty the Recycle Bin.
3. Click **Yes**.

Managing Third Party URL Links

In the URL Links section, you can add the URL links of frequently used third party portals and destinations.

Adding URL Links

To add URL links:

1. In the *Finder* panel, expand **URLLinks**.
2. Click **Add**.

3. In the *URL Configuration* dialog box, complete the following:
    - **URL**: Enter the URL of the destinati characters. When you enter the URL, the appliance validates the entry. You cannot save the entry if the URL is not in a valid format.
    - **Name**: Enter a name that represents the portal or site of the URL.
    - **Setasglobalparameter**: This field appears only if you log in as a superuser. Select this checkbox to make the URL link globally available to all users.
    - **Logo**: Click **Upload** to add a logo to the URL. The appliance displays the logo in 16x16 pixels. Click **ResettoDefault** to use the default logo.
4. Save the configuration.

Modifying URL Links

To modify the information you entered for an existing URL link:

1. In the *Finder* panel, expand **URLLinks**.
2. Hover your mouse over the URL you want to modify, and then click the Edit icon.
3. In the *URLConfiguration* dialog box, modify the information as described in Adding URL Links.

Deleting URL Links

To permanently delete an URL link:

1. In the *Finder* panel, expand **URLLinks**.
2. Hover your mouse over the URL you want to delete, and then click the Delete icon.
3. In the *DeleteURLLink* dialog box, click **Yes**.

Using Filters

You can control the amount and the kind of data displayed in a specific panel by adding filter criteria. When you add filter criteria, the appliance screens the data based on your filter rules and displays only the information that matches the rules. To narrow your search for specific information, you can add up to 10 filter rules. In some panels, such as the DHCP Networks tab, you can switch between viewing information with and without the filter criteria by toggling the filter on and off. You can save filter criteria as quick filters so you can reuse the same filter rules to obtain updated information without redefining them each time you log in to the appliance.
You can also use filters to find objects that have failed an operation. When you try to modify multiple objects with the same extensible attribute, the appliance may not modify all of the selected objects. For information about extensible attributes, see *Managing Extensible Attributes*. For example, after you modify the extensible attribute "Building" with new value "West", you can find the objects that are not updated by defining a filter with "Building" "does not equal" "West".
Depending on the filter criteria, you can use different filter operations to narrow down your search results. Grid Manager supports the following filter operations based on your selected filter criteria:

- **equals:** Defines a specific value for a selected filter criterion
- **does not equal:** Defines a selected filter criterion that does not equal a specific value
- **begins with:** Specifies a beginning value for a selected filter criterion
- **does not begin with:** Specifies a selected filter criterion that does not begin with a specific value
- **has a value:** Specifies a selected filter criterion that contains a value
- **does not have a value:** Specifies a selected filter criterion that does not contain a value
- **belongs to:** Defines a selected filter criterion that belongs to a specific parent object
- **Inheritance State equals:** Specifies a specific inheritance state

To use a filter:

1. In a panel, click **Show Filter** to enable the function.
2. In the filter section, complete the following:
    - In the first drop-down list, select a field such as an object name, comment, or an extensible attribute (fields with a gray background) as the filter criterion. Grid Manager displays only the supported fields.
    - In the operator drop-down list, select an operator for the filter criterion. Depending on what you select in the first filter field, this list displays the relevant operators for the selection. The operator **Inheritance State**

equals is displayed only when you select an inheritable extensible attribute from the **Type** drop-down list. This operator is not displayed if the extensible attribute is not inheritable.
    - In the value field, enter or select the attribute value for the first filter field. Depending on what you select for the first two filter fields, you can either enter a value or select an attribute from a drop-down list. For example, if you select an extensible attribute in the first filter field, you can enter the attribute value here. If you select an inheritable extensible attribute from the **Type** drop-down list, and select **Inheritance State equals** in the operator drop-down list, the value field displays a drop-down list with these values: **Inherited** and **Overridden/No Parent**. When you select **Inherited**, extensible attributes that are inherited by the descendants are listed. When you select **Overridden/No Parent**, extensible attributes which are overridden or do not have a parent are listed.
3. Optionally, click the **+** icon to add another filter rule. You can add up to 10 filter rules.
4. Click **Apply** to apply the rules
   or
   Click **Reset** to clear the filter criteria.

To view information with or without the filter criteria:

- Click **ToggleFilterOn** to apply filter criteria to the displayed data. Grid Manager displays only the filtered data in the panel.
  or
  Click **ToggleFilterOff** to have the appliance list all data without applying filter criteria.

Using Quick Filters

A quick filter saves filter rules that you define in a specific panel. You can reuse a quick filter to find updated information in a panel without specifying the same rules each time. Superusers can define quick filters and share them with local users. Limited-access users can only create quick filters for their own use. You can create up to 10 global and 10 local quick filters in each panel that supports filters.
The appliance supports the following quick filters:

- System quick filters: These are predefined filters. You cannot modify the criteria of these filters. System quick filters are prefixed with \[S\] in the quick filter list. Infoblox currently supports the following system quick filters in the DNS data panels:
    - **All Forward Mapping Zones**: This quick filter displays all forward mapping zones in lexicographical order.
    - **All Reverse Mapping Zones**: This quick filter displays all IPv4 and IPv6 reverse mapping zones in numerical order. The appliance displays IPv4 zones before IPv6 zones.
    - **All IPv4 Reverse Mapping Zones**: This quick filter displays only the IPv4 reverse mapping zones in numerical order.
    - **All IPv6 Reverse Mapping Zones**: This quick filter displays only the IPv6 reverse mapping zones in numerical order.
    - **RPZ Logs:** This quick filter displays only the RPZ syslog messages in CEF format. This option is displayed only in the **Syslog** when RPZ license is enabled.
- Global quick filters: Only superusers can define global quick filters. You can make global filters available to all users. Limited-access users can use global quick filters, but they cannot modify them. Global filters are prefixed with \[G\] in the filter list.
- Local quick filters: Limited-access users can create local quick filters for their own use. You cannot share local quick filters with other users in the Grid. Local filters are prefixed with \[L\] in the filter list.

> **Note**
>
> In the default DNS zone view, the appliance displays forward mapping zones first, followed by IPv4 reverse mapping zones, and then IPv6 reverse mapping zones.

Adding Quick Filters

To add quick filters:

1. In a panel that supports filters, click **Show Filters**.
2. In the filter section, define filter criteria for the quick filter, as described in Using Filters.

3. Click **Save**.
4. In the *Save Quick Filter* dialog box, complete the following:
    - **Name**: Enter a name for the quick filter. The name must be 20 characters or longer. Ensure that you use a unique name for each quick filter in a particular filter category. For example, you can use the same filter name for both a global and local filter, but you cannot do so for two local filters.
    - **Set as a global quick filter**: This displays only if you log in as a superuser. Select this checkbox to make the quick filter globally available to all users.
5. Save the configuration.

The appliance adds the quick filter to the quick filter drop-down list in the specified panel.

Modifying Quick Filters

To modify quick filters:

1. In a panel that supports filters, click **ShowFilters**, and then select the quick filter you want to modify from the **QuickFilter** drop-down list.
2. In the filter section, click the Edit icon next to the filter name.
3. Modify the filter criteria, as described in Using Filters.
4. Click **Save**.
5. In the *SaveQuickFilter* dialog box, you can click **Save** to save the modified filter criteria under the same quick filter name. You can also modify the quick filter name, as described in Modifying Quick Filters, and save the entry as a new quick filter.
6. Save the configuration.

Applying Quick Filters

To apply quick filters:

1. In a panel that supports filters, click **Show Filters**, and select the quick filter from the **Quick Filter** drop-down list.
2. Based on the filter criteria, the appliance displays the filtered information in the panel. The selected quick filter remains active in the panel until you select another quick filter.

Turning Off Quick Filters

You can do one of the following to turn off a quick filter:

- Select **None** from the quick filter drop-down list.
- Click **ToggleFilterOff** or **Reset** in the filter section.
- Delete a quick filter, as described in Deleting Quick Filters.

Deleting Quick Filters

To delete quick filters:

1. In a panel that supports filters, click **ShowFilters**, and then select the quick filter you want to delete from the **QuickFilter** drop-down list.
2. In the filter section, click the Delete icon next to the filter name.
3. In the *DeleteQuickFilter* dialog box, click **Yes** to permanently delete the quick filter.

Using Global Search

You can use the global search function to search the entire NIOS database for data that matches a specific value and filter criteria. You can define filter criteria and enter applicable search values to refine the search. Grid Manager supports regular expressions in global search. Grid Manager can display up to 500 search results. When search results exceed 500, a warning message appears and you may want to refine your search. Search results remain in the *Search* dialog box until you reset the search parameters or log out of Grid Manager. You can search for DNS zones and resource records that contain IDNs. For information about IDNs, see *Managing Internationalized Domain Names*.
Based on your search requirements, you can choose to perform a basic search or an advanced search.

A basic global search provides a faster way to locate frequently searched results using one specific filter criterion. It is designed to handle a large amount of data in an efficient manner. Supported filtering objects are DNS name (FQDN or CNAME only), DUID, IP address and MAC address. This is the recommended global search method if you have a large data set and only need to search by a single filter criterion. You cannot use regular expressions in a basic global search.
An advanced global search allows you to perform complex searches by defining multiple filter criteria. You can add up to 10 filtering rules. You can also include existing extensible attributes for the matching objects.
Note that if a search result contains duplicate records, the appliance displays only one record and discards others. For example, if the canonical name matches an alias name, the appliance displays only one CNAME record in the result.

Note

- Depending on the size of your database, global search may take a long time to complete. Grid Manager times out when queries or searches take longer than 120 seconds. To expedite searches, use filters to refine the search criteria. You can also use basic global searches if you have a large data set and you only need to search by a single filter criterion.
- To search for any DHCP objects or its attributes using Global Search, you must have DHCP license installed.

You can also do the following in the Results table:

- Click the Open icon to view detailed information of the matching object.
- Click the Edit icon to edit the matching object information. For information about Editing Matching Objects in Search Results, see below.
- Click the Extensible Attributes icon to edit the value of the respective extensible attribute. For information about Editing Multiple Extensible Attributes in Search Results, see below.
- Click the Export icon to export the data displayed in the Results table.
- Click the Print icon to print the data displayed in the Results table.

To perform a global search:

1. Click the Global Search icon on the navigation bar.
   By default, the appliance opens the **Basic** tab of the *Search* dialog box.
2. Do one of the following:
   - If you want faster search results and you can search by DNS name, DUID, IP address, or MAC address, do the following in the **Basic** tab:
     Include Network Insight Devices and Interfaces: This appears only when you have the Network Insight license installed. Select this checkbox to include devices and interfaces discovered through Network Insight. Note that it might take longer than expected for the appliance to return results for these objects. The setting is saved between user sessions.
     - **ChooseFilter**: Select a value from the drop-down list. You can explicitly search by DNS name (FQDN or CNAME only), DUID, IP address, or a MAC address. Note that you can apply only one filter at a time.
     - **ChooseOperator**: Select an operator for the filter criterion. Depending on what you select in the first filter field, this list displays the relevant operators for the selection. Possible values include **equals**, **beginswith**, and **contains**. For example, if you choose a **DNSName** filter, **contains** is the only applicable operator.
     - In the value field, enter the value for the filter field. For example, if you select DUID in the first filter field, you can enter the DUID of the client's device in the value field.
   - If you have a more complex search requirement and need to include multiple filter criteria, do the following in the **Advanced** tab:
     - In the first field, enter the value that you want your search results to match. For example, if you want to search for hostnames that contain "Infoblox," enter **Infoblox** in this field. You can also specify the value of an inheritable extensible attribute. You can use regular expressions in the search value.
     - In the **Type** drop-down list, select an object type, comment, or an extensible attribute (fields with a gray background) as the filter criterion. Grid Manager displays all the supported fields in the drop-down list. The default is **Type**. Grid Manager searches all objects when you use the default. You can narrow down the search and improve the search performance by selecting an object type. Extensible attributes are displayed with a gray background.

- In the operator drop-down list, select an operator for the filter criterion. Depending on what you select in the first filter field, this list displays the relevant operators for the selection. The operator **InheritanceStateequals** is displayed only when you select an inheritable extensible attribute from the **Type** drop-down list. This operator is not displayed if the extensible attribute is not inheritable.
- In the value field, enter or select the attribute value for the first filter field. Depending on what you select for the first two filter fields, you can either enter a value or select an attribute from a drop-down list. For example, if you select an extensible attribute in the first filter field, you can enter the attribute value here. If you use the default **Type** in the first filter field, you can select an object or record type from the drop-down list. The default is **ALL**. Grid Manager searches all object types when you use the default. If you select an inheritable extensible attribute from the **Type** drop-down list, and select **InheritanceStateequals** in the operator drop-down list, the value field displays a drop-down list with these values: **Inherited** and **Overridden/NoParent**. When you select **Inherited**, extensible attributes that are inherited by the descendants are listed. When you select **Overridden/NoParent**, extensible attributes which are overridden or do not have a parent are listed.
- Optionally, click the **+** icon to add another filter. You can add up to 10 filter rules.
- **IncludeExtensibleAttributesValues**: Select this checkbox to include extensible attributes in the search results for the matching objects. Once selected, this configuration affects all future searches for the current user. Note that it might take longer for the search results to appear if there are a large number of extensible attributes associated with the matching objects.

3. Optionally, you can click **Reset** to clear the search results and start a new search. You can also click the Refresh icon to refresh the search results.
   Grid Manager stores the search results until you reset the search parameters or log out.
4. After you finish defining filters, click **Search** or press **Enter**.

> **Note**
>
> You can save each search that contains multiple filter criteria as a quick filter for future use. For information about quick filters, see Using Quick Filters above.

In the Results table, Grid Manager displays the following information:

- **Name**: The name of the matching object. This field displays the name of the matching object and the path to the matching object if the object is a network or an IP address. You can click the link to open, view, and edit the object.
- **Type**: The type of the matching object. For example, bulk host, NS record, forward-mapping authoritative zone, or network container.
- **MatchedProperty**: The attribute or property of the matching object. For example, if the search value matches the email address that corresponds to a hostname, this field displays **Email**. If the search value matches the DNS view of a resource record in a DNS zone, this field displays **DNSView/FQDN**.
- **MatchedValue**: The value of the matching object. For example, if an IP address contains the search value, this field displays the IP address. If a hostname contains the search value, this field displays the hostname.
- **IPAddress**: The IP address of the matching object. When you click the IP address link, Grid Manager displays the corresponding IP address panel from which you can view detailed information.
- **Comment**: Comments that were entered for the matching object.
- **Site**: Values that were entered for the matching object.

> **Note**
>
> If you have selected to include extensible attribute values, you can select the corresponding columns to be displayed in the search results. Extensible attribute columns are hidden by default.

Editing Matching Objects in Search Results

Grid Manager displays search results in the Results table. You can open and view detailed information about an object. You can also edit the properties of a selected object.

To edit an object in the Results table:

1. In the Results table, select the object checkbox.

2. Click the Open or Edit icon. You can also click the link of an object if Grid Manager displays the path. Grid Manager displays the object in the corresponding editor depending on the type of object you selected.
3. Edit the properties of the object in the editor.
4. Save your changes.

Deleting Matching Objects in Search Results

You can delete one or multiple matching objects in the search Results table.

To delete a matching object:

1. In the Results table, select the object checkbox. You can delete multiple objects.
2. Click the Delete icon.
3. In the *Delete Confirmation* dialog box, click **Yes**.

Grid Manager deletes the selected objects from the database. Most deleted objects are stored in the Recycle Bin.
You can print search results. You can also export search results in CSV (comma separated value) format. For information about CSV Import and Exporting Displayed Data, see *Importing and Exporting Data using CSV Import*.

Editing Multiple Extensible Attributes in Search Results

You can edit one or multiple extensible attributes of the matching objects in the search Results table using the *Multi-Select Edit Extensible Attributes* editor. When you change multiple extensible attribute values for selected objects, the values of all selected extensible attributes will be updated.

To edit multiple extensible attributes:

1. In the Results table, select the object checkbox. You can edit multiple extensible attribute values.
2. Click the Extensible Attributes icon.
3. In the *Multi-Select Edit Extensible Attributes* editor, click on the **Value** column to edit the value of the respective extensible attribute. For information about which values you can edit-Editing Multiple Extensible Attribute Values, see *Managing Extensible Attributes*.

Using the Go To Function

You can use the **Go To** function to quickly locate an object, such as a network or a DNS zone. With the autocomplete feature, you can just type the first few characters of an object name in the **Go to** field and select the object from a list of possible matches. You can also enter the entire object name, and then click **Go** to locate a specific object.

To use the Go to function:

1. From a selector, enter the first few characters of the object name in the **Go to** field. Grid Manager displays up to ten possible matches in a drop-down list.
2. Click the object from the drop-down list or use the up and down arrow keys to select the object and then press **Enter**. Grid Manager completes the operation based on the selected object.

Opening Technical Support Requests

When you encounter product issues or require assistance, you can send a request to Infoblox Technical Support by opening a support case through Grid Manager. When you submit a support case, product information such as software version and serial number is automatically collected from the NIOS appliance on which you create the support case. You should however provide detailed information about the issue or your request, business impact, and contact information to ensure that the support request is being addressed by the appropriate resources in a timely manner. When you submit a support request, Infoblox Technical Support automatically authenticates and authorizes the contact email address that you use. It sends a confirmation email to the contact email address if the email address is registered on the Infoblox Technical Support server. If the authentication fails, you will receive an email.

> **Note**
>
> Make sure that you enable DNS Resolver or Use SMTP Relay to create a support case from the GUI. For information about enabling DNS resolution and notifying administrators, see *Enabling DNS Resolution* and *Notifying Administrators*.

Complete the following to create a support case:

> **Note**
>
> Click **Go to the Editor** and enable **DNS Resolver** or **Use SMTP Relay** if you have not already enabled either one of them.

1. **Admin**: At the top right corner of the navigation bar, click the Admin name and select **Open a Support Case** from the drop-down menu.
   Support: From the Help panel -> click **Support** -> **Open a Support Case.**
2. In the *Open Support Case* editor, complete the following:
   - **To Email Address**: Enter an email address to access Infoblox Technical support. The default is *support@infoblox.com.* If you change the default email address, the email is sent to the updated email address instead of Infoblox Technical Support. Sending the email to your own email address allows you to verify and alter the email content before you forward the email to *support@infoblox.com* or another email address.
   - **Contact Email Address**: Enter your email address or another contact email to which a confirmation is sent when the support case is created. Ensure that the contact email is legitimate and approved by Infoblox as this contact becomes the primary contact for the support case.
   - **CC Email Addresses**: Click the Add icon to add additional email addresses. This is optional.
   - **CaseType**: From the drop-down menu, select the case type:
     - **Administrative Issue**: Select this if the request is related to administrative issues.
     - **Administrative Question**: Select this if you have administrative questions.
     - **Product Issue**: Select this if the request is related to product issues.
     - **Product Question**: Select this if you have questions about Infoblox products.
   - **Severity**: Select how urgent or severe this request affects your business.
     - **Low**: Select this if the business impact is low.
     - **Medium**: Select this if the issue has moderate impact on your business.
     - **High**: Select this if this issue is urgent and requires immediate attention.
   - **Subject**: Enter a subject line for your support case.
   - **Description**: Enter a detailed description about the issue.
   - **Attach a file**: You can attach a file that contains additional information about your support case. Relevant information can help the Infoblox Support team to identify problems and troubleshoot issues in a more efficient manner.
3. Click **Send&Close** to create the support case. Optionally, click **Send&New** to send the current request and then create a new support request.

> **Note**
>
> It might take up to 15 minutes before you get an email confirmation.

Dashboards

The Dashboard is your home page on Grid Manager and provides easy access to tasks and a quick overview to the status of your Grid and DNS, DHCP and IPAM services. It provides easy access to tasks and a quick view to the status of your Grid and core network services. Grid Manager provides the following dashboards:

- **Tasks**: The Tasks dashboard contains task packs that provide easy access to commonly performed tasks. A task pack is a collection of tasks that belong to a specific service or function, such as IPAM or Automation. For more information, see *Tasks Dashboard*.

- **Status**: A status dashboard contains widgets from which you can view and manage DNS, DHCP, and IPAM status and data. You can configure multiple status dashboards for managing a large number of Grid members. For more information, see *Status Dashboard*.
- **Reporting Clustering Status**: The Reporting Clustering Status dashboard displays the reporting clustering status. This tab is displayed only if you have configured reporting clustering. For more information, see *Report Clustering Dashboard*

When you first log in to Grid Manager, the tasks dashboard is your home page. You can change your home page for subsequent logins.

To change your home page:

1. Navigate to any tab in Grid Manager (except for the **Dashboards** tab).
2. Click **User Profile** from the Toolbar and complete the following In the *User Profile* dialog box:
   Default Dashboard: Select **Status** or **Task** from the drop-down list.
3. Save the configuration.

Grid Manager displays the selected dashboard as your home page when you log in the next time.

Tasks Dashboard

The Tasks Dashboard provides easy access to commonly performed tasks, such as adding networks and adding host records. Tasks are grouped by service-specific task packs. You must install valid licenses on the appliance to see and perform specific tasks on the Tasks Dashboard. For information about the required licenses for IPAM tasks, see *IPAM Task Pack.*
You must also have at least read-only permission to a task-related object to add or hide the task in its task pack. To execute a task, you must have the appropriate permissions to the member and objects that are related to the tasks. For example, to add a host record from the Tasks Dashboard, you must have at least read-only permission to the host records task and read/write permission to the zone and network in which the host records are created. For information about permissions, see *Administrative Permissions for Common Tasks*.

Task Packs

Grid Manager displays task packs, including the IPAM and NetMRI task packs, based on valid licenses installed on the appliance. To access the IPAM task pack, you must have valid DNS or DHCP license installed on the NIOS appliance. To access the Automation task pack, you must first set up an Infoblox NetMRI appliance, install the Automation Change Management license on the NIOS appliance, and register as a user. For information about how to activate the Automation task pack, refer to the *Infoblox NetMRI Administrator Guide*.

> ⚠ Note
>
> The Tasks Dashboard will not appear in the NIOS system if no task packs are licensed for the system. Some task packs will also have dependencies. For example, the NetMRI Task Pack licensing activates along with either the MS license or the NIOS DHCP/DNS combination license. Should either of those licenses be disabled for any reason, the NetMRI Tasks will also be disabled.

To use the Automation Task Pack, you must enable the NetMRI Tasks feature set and establish a working connection between the NIOS appliance and an Infoblox NetMRI appliance. See *Enabling NetMRI Tasks* for details. Each task in a task pack opens a workflow dialog in which you can create task-related objects without navigating through other tabs and editors in Grid Manager. Depending on the task you perform, Grid Manager displays task results in the Result page from which you can access newly created objects, such as networks and host records. Note that when a task takes longer than usual to complete, it becomes a long running task. For information about long running tasks, see *About Long Running Tasks*.
With valid licenses and proper registrations, Grid Manager displays the following task packs in the Tasks Dashboard:

- *Status Dashboard*

- *IPAM Task Pack*
- *NetMRI Task Pack*

Status Dashboard

A status dashboard contains widgets from which you can view and manage data. Widgets are the building blocks of status dashboards. For more information about widgets, see Adding Widgets to Dashboards below. They provide information about different aspects of your Grid and networks. For example, the *Member Status* widget provides general information about a Grid member, and the *Network Statistics* widget provides data for a specified network.

The appliance provides a default status dashboard. Grid Manager displays the default dashboard only when there is more than one widget on the dashboard. You can add and modify widgets in the default dashboard, but you cannot rename or delete it. From a dashboard, you can access your most commonly accessed tasks and monitor appliance status. You can configure your own status dashboards to which you can add widgets that help you manage different data. Configuring multiple status dashboards helps organize widgets in a meaningful way and improves dashboard and widget performance. This is especially useful when you have a Grid serving a large number of Grid members. When you configure a new dashboard, you can use the existing dashboard as a template. You can create up to 100 copies at a time using the **Add Dashboard** option. For information about how to add status dashboards, see Adding Status Dashboards below.

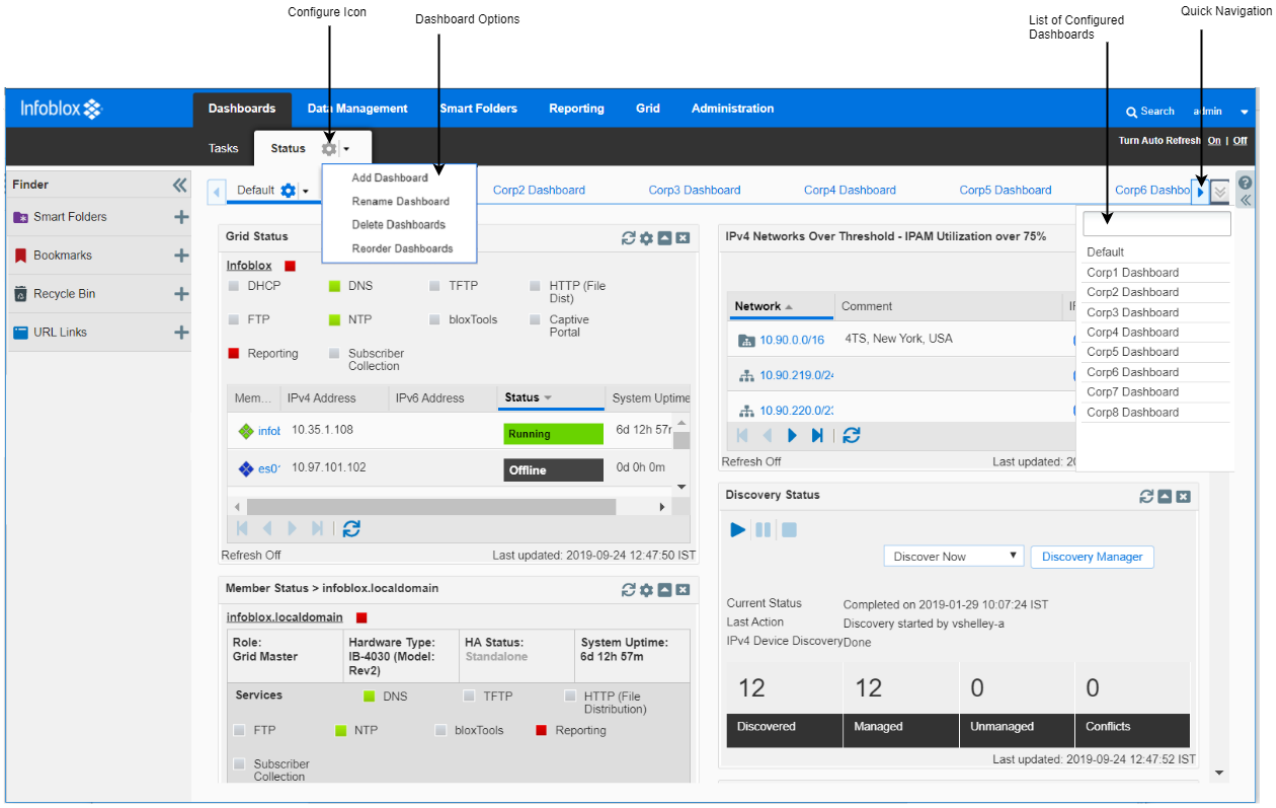
You can add widgets to different dashboards, however, you can add only one widget at a time on each dashboard. The default number of widgets per dashboard is 10. The maximum number of widgets that you can add on each dashboard is 20 at a time. You can define the number of widgets that can be configured on each dashboard in **User Profile**. This limitation applies only to dashboards that you configure and does not apply to the default dashboard. For information about how to specify the widget limit, see Configuring Widget Limit per Dashboard below.

Grid Manager provides a default Security dashboard if you have installed any or all of the following licenses on the appliance: **Threat Protection**, **RPZ**, and **Threat Analytics**. The Security dashboard contains widgets that help you monitor the security status of the Grid. In the Security dashboard, you can add and remove widgets, but you cannot rename or delete them.

> **Note**
>
> To ensure that the Security dashboard displays correct data, use NTP to synchronize the time of the Grid members with that of the Grid Master.

If you have configured a lot of status dashboards, you can use the Quick Navigation icon to quickly access each status dashboard. For information, see Using Quick Navigation below. The Status Dashboard figure below illustrates the typical layout in Grid Manager after you configure multiple status dashboards.

Status Dashboard



Configure Icon Dashboard Options List of Configured Dashboards Quick Navigation

You can do the following on the **Status** tab:

- Add new status dashboards, as described in Adding Status Dashboards below.
- Rename a dashboard, as described in Renaming Status Dashboards below.
- Copy or move a widget, as described in Copying or Moving Widgets below.
- Reorder dashboards, as described in Reordering Status Dashboards below.
- Delete dashboards, as described in Deleting Status Dashboards below.
- Configure widget limit, as described in Configuring Widget Limit per Dashboard below.
- Configure Security dashboard properties, as described in Configuring Security Status Thresholds below.Adding Widgets to Dashboards

You can add all or some of the following widgets to your status dashboards depending on whether you are managing a Grid, an independent appliance, or an Infoblox Orchestration server:

- Grid Status
- Grid Upgrade Status
- Member Status (System Status)
- DNS Statistics
- Ranges Over Threshold
- IPv4 Failover Associations Status
- DHCP Statistics
- Network Statistics
- IPv4 Networks Over Threshold
- Discovery Status
- Advanced Discovery Status
- My Commands
- DDNS Statistics
- System Activity Monitor

- File Distribution Statistics
- Active WebUI Users
- Microsoft Servers Status Widget
- CSV Import Manager
- Pending Approvals
- Infoblox Community
- Mobile Devices Status
- Threat Protection Status for Grid
- Threat Protection Status for Member
- DNS Integrity Check
- *Cloud Statistics*
- Security Status for Grid
- Security Status for All Members
- Pool Licenses Statistics
- DNS Record Scavenging

Grid Manager displays the Security dashboard if you have any or all of the following licenses installed on your appliance: **Threat Protection**, **RPZ**, and **Threat Analytics**. The Security dashboard contains the following widgets, depending on the licenses installed on your appliance:

- Security Status for Grid
- Security Status for All Members
- Threat Protection Status for Grid
- Threat Protection Status for Member
- Response Policy Zone (RPZ) Status for Grid
- Response Policy Zone (RPZ) Status for Member

Note that you must have at least read-only permission to the objects that a widget displays. Otherwise, though you are allowed to select and place the widget on the dashboard, it does not display any information.

To add widgets to your dashboard:

1. **Default Status Dashboard**: From the **Dashboards** -> **Status** tab -> **Default** tab, click the Configure icon -> **Add Content**. This is applicable when you have the default dashboard only.
   Configured Status Dashboards: From the **Dashboards** -> **Status** tab, select the configured status dashboard, click the Configure icon -> **Add Content**.
   Security Status Dashboard: From the **Dashboards** -> **Status** tab -> **Security** tab, click the Configure icon -> **Add Content**. This is applicable only when at least one member in the Grid has Threat Protection, RPZ, or Threat Analytics license. Note that the Security Status dashboard is a default dashboard and it cannot be renamed or deleted.
   Grid Manager displays thumbnails of the available widgets. Use the scroll bar on the right to scroll through the widgets, as illustrated in the below Widgets Panel figure.
2. Click an icon on the filter panel, as illustrated in the Widgets Panel figure, to add a widget to the desired dashboard. The Filter panel is categorized into the following:
   Cloud
   Security
   DNS/DHCP
   Reset
   When you click on an icon, Grid Manager displays thumbnails of the widgets belonging to the respective filter. If you click filters one after the other without clicking **Reset**, Grid Manager displays thumbnails of all widgets along with the icon that indicates the category to which the widget belongs. Click **Reset** to view only those widgets that belong to the selected category.
3. Select and drag a widget to the desired location on your dashboard. You can also click icon to add a widget to the desired dashboard.
   After you add a widget to the dashboard, you can configure it to provide relevant data. You can also copy or move a widget, by selecting and dragging it to its new location on your dashboard. Grid Manager saves your dashboard configuration and displays it the next time you log in.
   You can turn on auto-refresh by clicking **On** in the **Turn Auto Refresh** field at the top of the dashboard to

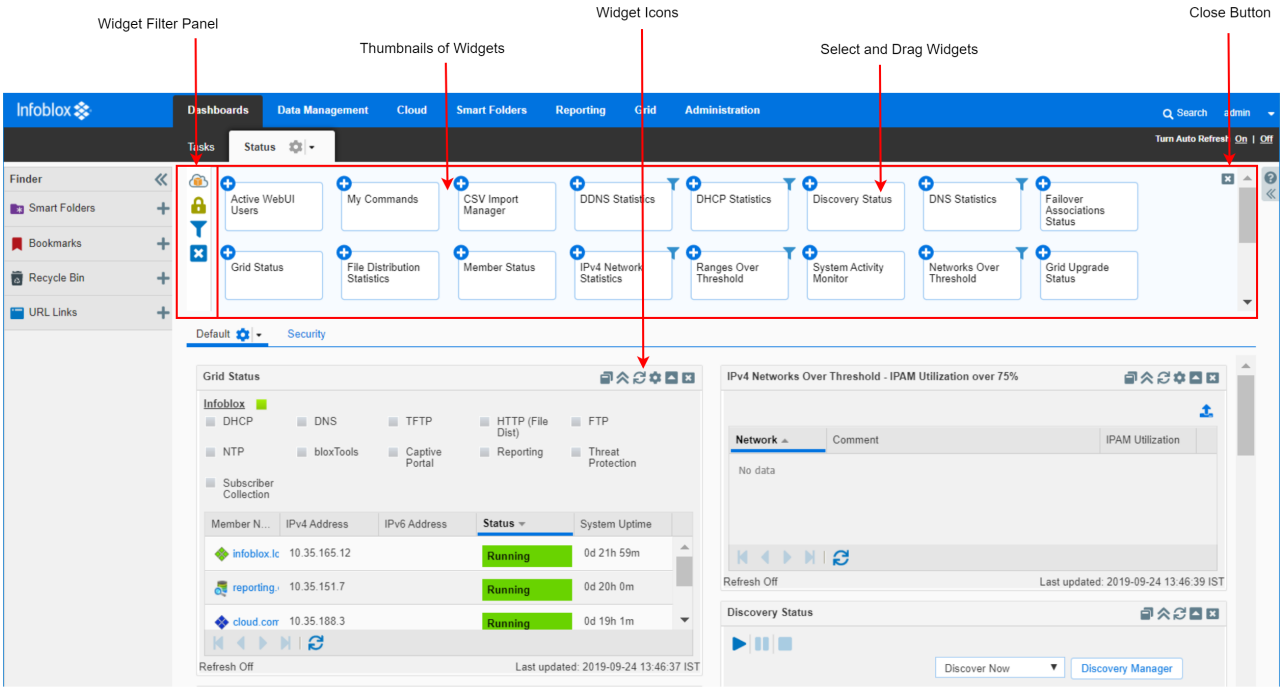
periodically refresh the contents of all widgets in the dashboard. Click **Off** to disable auto-refresh for all widgets in the dashboard. When auto-refresh is disabled, you can enable it for individual widgets by clicking the Configure icon in the corresponding widgets. You can specify the auto-refresh period in seconds. The default auto-refresh period is 30 seconds.

> **Warning**
>
> If the *Detailed Status panel* is open, the following actions take place:
>
> - Grid Manager auto refreshes at a rate of 30 seconds.
> - Widgets that support user-specified auto refresh, refresh at the rate specified in the **Auto Refresh Period** field.
>
> Therefore, even if you set the session timeout to be to greater than the auto refresh rate, auto refresh still takes place. The Grid Manager session does not time out because auto refresh takes precedence over the session timeout.

Widgets have the following icons:

- **Copy/Move**: Click to copy or move the widget from a dashboard to another. For information about how to copy or move, see Copying or Moving Widgets below.
- **Span Up/Span Down**: Click to resize the widget. Click **Span Up** to increase the width of the widget. Click **Span Down** to decrease the width of the widget. Note that the fully spanned widgets are moved to the top of the dashboard.
- **Refresh**: Click to update the content of the widget. Each widget contains a status bar at the bottom that displays the last date and time it was updated.
- **Configure**: Click to hide and show the configuration options of the widget.
- **Toggle**: Click to minimize and restore the widget.
- **Close**: Click to remove the widget from a dashboard.

Widgets Panel



Configuring Widget Limit per Dashboard

You can define the number of widgets that can be configured on each dashboard. This limitation applies only to dashboards that you configure and does not apply to the default dashboard.

1. From the **Dashboards** -> **Status** tab, click the Configure icon -> **User Profile**.
2. In the *User Profile* editor, complete the following:
   Maximum Widgets per Dashboard: Specify the maximum number of widgets that can be configured per Dashboard. You can enter a value between 1 and 20. The default value is 10. This limit does not apply to the default dashboard.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Adding Status Dashboards

You can create your own status dashboards and add the widgets that you need. You can configure up to 100 status dashboards at a time. When you create multiple instances of a dashboard, the appliance names each dashboard by adding an incremental suffix to the name of the new dashboard. For example, if you name a new dashboard "Corp_Dashboard" and specify the number of instances as three, then the appliance creates three instances of this new dashboard. In this example, the appliance creates three dashboards: Corp_Dashboard, Corp_Dashboard1, and Corp_Dashboard2. Note that the dashboards you create will not be available to other users. You cannot share dashboards you have created with other users.

Note that "Security" is reserved for the default Security dashboard. Grid Manager displays an error message if you name a new dashboard "Security".

To add a new status dashboard, complete the following:

1. From the **Dashboards** -> **Status** tab, click the Configure icon -> **Add Dashboard**.
2. In the *Add Dashboard* wizard, complete the following:
   - **Name**: Enter a name for the new dashboard.
   - **Add <> instances of this new dashboard**: Enter the number of dashboards you want to create. The maximum number of dashboards you can create is 100 at a time.
   - **Copy initial content from an existing dashboard**: Select this checkbox if you want the appliance to copy the contents from an existing status dashboard into the new dashboard. After you select this checkbox, the appliance displays the list of configured dashboards. Select a dashboard from the list. By default, this checkbox is not selected.
3. Save the configuration.

The appliance displays all dashboard instances on the **Status** tab.

Using Quick Navigation

You can use the Quick Navigation icon to quickly access a specific dashboard. The appliance provides the Quick Navigation icon at the right corner of the status dashboards, as illustrated in the *Status Dashboard* figure above.

To quickly navigate to a dashboard, complete the following:

1. From the **Dashboards** -> **Status** tab, click the Quick Navigation icon at the right corner of the dashboards. The list of configured dashboards is displayed.
2. Select a dashboard or specify the name of the dashboard in the text box. The appliance displays the selected dashboard.

Renaming Status Dashboards

You can rename only the status dashboards that you have configured. You cannot rename the default dashboard and the Security dashboard.

To rename a dashboard, complete the following:

1. From the **Dashboards** -> **Status** tab, click the Configure icon -> **Rename Dashboard**.
2. In the *Rename Dashboard* wizard, complete the following:
   - **Select a dashboard**: Select a dashboard from the drop-down list.
   - **Name**: Enter the new name of the dashboard.
3. Do one of the following:

- Click **Save and Close** to save the new name and close the wizard.
- Click **Save** to save the new name and continue to rename other dashboards.

To rename a specific dashboard:

1. From the **Dashboards** -> **Status** tab, select a dashboard that you want to rename.
2. Click the Configure icon -> **Rename Dashboard**.
3. In the *Rename Dashboard* wizard, enter the new name in the **Name** text box.
4. Click **Save and Close** to save the new name and close the wizard.

Copying or Moving Widgets

You can copy or move a widget from one dashboard to another. When you add a widget that already exists, the appliance displays an error message. When you move a widget, it is moved from the source to the destination dashboard. The moved widget will not be available in the source dashboard anymore. When you copy a widget, the widget is duplicated and is available in both the source and destination dashboards. Note that the Copy/Move icon is not available in a widget if the appliance has only the default status dashboard.

To move or copy a widget, complete the following:

1. From the **Dashboards** -> **Status** tab, select a status dashboard.
2. Select the widget that you want to copy or move, and then click the Copy/Move icon.
3. In the *Copy/Move <name of the widget>* wizard, complete the following:
    - **Copy**: Select this to copy a widget.
    - **Move**: Select this to move a widget.
    - **To Dashboard**: Select the name of the destination dashboard.
4. Click **OK**.

Reordering Status Dashboards

You can change the order of your status dashboards. When you add a new status dashboard, it is added as a tab. When you create multiple instances of a dashboard, they are added as subsequent tabs. You can arrange the order of each dashboard through the reordering process.

To reorder status dashboards, complete the following:

1. From the **Dashboards** -> **Status** tab, click the Configure icon -> **Reorder Dashboards**.
2. The following are displayed in the *Order Dashboards* wizard:
    - **Ordering**: You can use the up and down arrows to move dashboards in the desired order or drag and drop them to the desired positions.
    - **Dashboard**: Displays the list of all the status dashboards.
3. Click **OK** to save the changes.

Deleting Status Dashboards

You can delete status dashboards that you have configured. You cannot delete the default status dashboard and the Security dashboard. You can delete multiple dashboards at the same time. Note that you cannot restore a deleted dashboard.

To delete multiple dashboards, complete the following:

1. From the **Dashboards** -> **Status** tab, click the Configure icon -> **Delete Dashboards**.
2. In the *Delete Dashboards* wizard, select the **Dashboard** checkbox. You can select multiple checkboxes for multiple dashboards.
3. Click **Delete**.
4. Click **Yes** in the *confirmation* dialog box. To delete a specific dashboard:
5. From the **Dashboards** -> **Status** tab -> select the <*Status Dashboard*> tab.
6. Click the Configure icon -> **Delete Dashboard**.
7. *In the Delete Confirmation* dialog box, click **Yes**.

Configuring Security Status Thresholds

You can configure thresholds to determine the overall status of Threat Protection, DNS RPZ (Response Policy Zone), and DNS Threat Analytics services in the Grid. Grid Manager provides a view of the overall security status of the Grid in the *Security Status for Grid* dashboard widget. For information, see Security Status for Grid below.

To configure the thresholds for security status, complete the following:

1. From the **Dashboards** -> **Status** tab, click the Configure icon -> **Global Dashboard Properties**.
2. In the *Global Dashboard Properties* editor, complete the following:
    - **Threat Protection Thresholds**: Define the thresholds for each severity level of the threat protection events for the following colors:
        - **Yellow**: Specify the low threshold value for **Critical**, **Major**, and **Warning** severity level. The default values are 1, 20, and 100 for **Critical**, **Major**, and **Warning** respectively.
        - **Red**: Specify the high threshold value for **Critical**, **Major**, and **Warning** severity level. The default values are 5, 100, and 1000 for **Critical**, **Major**, and **Warning** respectively.

          Depending on the specified thresholds, Grid Manager determines the status of threat protection service as follows, which is displayed in the **Status** column of the *Security Status for Grid* widget:
        - **Green (OK)**: When the number of threat protection events are less than the low threshold value specified for the yellow color for all the severity levels.
        - **Yellow (Warning)**: When the number of threat protection events equals or exceeds the threshold value specified for the yellow color but less than the threshold value specified for the red color for any of the severity levels.
        - **Red (Critical)**: When the number of threat protection events equals or exceeds the high threshold value specified for the red color for any of the severity levels.
    - **Response Policy Zone Thresholds**: Define the threshold values for the following colors to determine the overall status of RPZ:
        - **Yellow**: Specify the low threshold value for **Blocked**, **Substitute**, and **Passthru** RPZ rules. The default values are 10, 1, and 100 for **Blocked**, **Substitute**, and **Passthru** respectively.
        - **Red**: Specify the high threshold value for **Blocked**, **Substitute**, and **Passthru** RPZ rules. The default values are 100, 10, and 1000 for **Blocked**, **Substitute**, and **Passthru** respectively.

          Depending on the specified thresholds, Grid Manager determines the status of RPZ as follows, which is displayed in the **Status** column of the *Grid Security Status* widget:
        - **Green (OK)**: When the number of RPZ hits are less than the low threshold value specified for the yellow color for all the rule types.
        - **Yellow (Warning)**: When the number of RPZ hits equals or exceeds the threshold value specified for the yellow color but less than the threshold value specified for the red color for any of the rule types.
        - **Red (Critical)**: When the number of RPZ hits equals or exceeds the high threshold value specified for the red color for any of the rule types.
    - **Threat Analytics Thresholds**: Define the thresholds for the following colors, to determine the overall status of DNS Threat Analytics:
        - **Yellow**: Specify the low threshold value for DNS Tunneling events. The default value is 1.
        - **Red**: Specify the high threshold value for DNS Tunneling events. The default value is 5.

          Depending on the specified thresholds, Grid Manager determines the status of DNS Threat Analytics as follows, which is displayed in the **Status** column of the *Grid Security Status* widget:
        - **Green(OK)**: When the number of DNS tunneling attacks are less than the low threshold value specified for the yellow color.
        - **Yellow(Warning)**: When the number of DNS tunneling attacks equals or exceeds the threshold value specified for the yellow color but less than the threshold value specified for the red color.
        - **Red(Critical)**: When the number of DNS tunneling attacks equals or exceeds the high threshold value specified for the red color.
3. Save the configuration.

> **Note**
>
> If you have configured the same threshold value for both Yellow and Red color in the *Global Dashboard Properties* editor and if the same number of events are triggered, then Grid Manager displays the status in red in the *Grid Security Status* widget.

Grid Status

The *Grid Status* widget provides status information about the Grid members and services. Add the *Grid Status* widget to your Dashboard to monitor the Grid status.
You can configure the *Grid Status* widget to display information about all Grid members or only Grid members that have service errors. To modify the *Grid Status* widget, click the Configure icon and select one of the following:

- **Show all Grid members** (this is the default)
- **Only show members with service warnings or errors:** When you select **Only show members with service warnings or errors**, the widget displays only the members that have service errors. The widget does not display any data in the member table if all the services on all members are running properly.
- **Group Members by**: If you want to group members by the same extensible attribute value, select this and choose an extensible attribute from the drop-down list. The appliance groups Grid members that have the same extensible attribute value, and the Grid Status displays the following information:
  - **<Extensible Attribute Name>**: The value of the selected extensible attribute. You can click the link of the extensible attribute value to view all the members in this group in the Grid/Members view.
  - **Status**: This is the overall status for all members in the group. Depending on the status of each member, the overall status can be one of the following:
    - **Working**: Indicates that all the members in the group are running properly.
    - **Warning**: Indicates that one of the members in the group has operational problems. For example, if there are two members in a group with one member **Running** and another member is **Offline**, then the overall status will be **Warning**.
    - **Failed**: Indicates that at least one of the members in the group is in the failed status and none of the members in the group are in the **Running** or **Working** status. For example, if there are two members in the group and one of them is in **Failed** status and the other is **Offline**, then the overall status is **Failed**.
    - **Offline**: Indicates that one or more members in the group is offline and none of the members in the group are in the **Failed** or **Running** status. For example, if a member is in the **Working** status and another member is in the **Offline** status, then overall status is **Offline**.
    - **Inactive**: Indicates that one or more members in the group is inactive and none of the members in the group are in the **Failed**, **Offline**, **Working**, or **Running** status.
    - **Unknown**: Indicates that the status of all the members in the group is unknown.

> **Note**
>
> You can click a member link to monitor the detailed status of the selected member. Grid Manager displays the **Grid** tab -> **Member** tab. You can click on a group to show the members of the group in the Grid/Members view.

The *Grid Status* widget also displays the following information in the member table:

- **Member Name**: The name of the member.
- **IPv4 Address**: The IPv4 address of the member.
- **IPv6 Address**: The IPv6 address of the member.
- **Status**: The current status of the member.
- **System Uptime:** The duration of time (days, hours, and minutes) that the Grid member has been up and running.

In the upper section of the widget, Grid Manager displays the overall status of the Grid. The Grid status represents the status of the most critical member in the Grid. When all Grid members are running properly, the overall Grid status is green. When one of the members has operational issues, the overall Grid status is red. The status icon can be one of the following:

Icon	Color	Meaning
	Green	All Grid members are operating normally in a "Running" state.
	Yellow	At least one of the Grid members is connecting or synchronizing with its Grid Master.
	Red	At least one of the Grid members does not have a Grid license, is offline, upgrading, downgrading, or shutting down.

This section also displays the overall operational status of the DNS, DHCP, NTP, FTP, TFTP, HTTP (File Distribution), bloxTools, Captive Portal, Subscriber Collection, Cloud DNS Sync, DNS Accelerator usage, and Reporting services that are currently running on the Grid. The status icon can be one of the following:

Icon and Color	Meaning
 Green	The enabled service is running properly on one or more Grid members.
Yellow	At least one of the Grid members is having issues with the enabled service.
 Red	The enabled service is not running properly on at least one of the members. (A red status icon can also appear temporarily when the service is enabled and begins running, but the monitoring mechanism has not yet notified Grid Manager.)
Gray	**The service is not configured or is disabled on at least one Grid member.**

Grid Upgrade Status

The *Grid Upgrade Status* widget provides upgrade status of the Grid Master and members. Add the *Grid Upgrade Status* widget to your Dashboard to monitor the upgrade status of the Grid and its members.

The *Grid Upgrade Status* widget displays the following information:

- **Upgrade Status**: The current upgrade status of the Grid. This can be **Running**, **Paused**, **Canceled**, or **Inactive**.
- **Grid Member Upgrade Process Status**: The pie chart shows the number of members that are still processing the upgrade, members that have completed the upgrade, and members that are waiting for the upgrade to happen.
- **Detailed Upgrade Status**: Click this link to access the **Grid** tab -> **Upgrade** tab to see detailed information about the upgrade.

The table on the right shows a summary of the upgrade status of the upgrade groups. It displays the following information:

- **Group**: The name of the upgrade group.
- **Date/Time**: The date and time when the upgrade started on this upgrade group. Note that the time zone is the time zone of the first member in the upgrade group.
- **Completed**: Indicates whether the upgrade is complete or not.

Member Status (System Status)

The *Member Status* widget provides status information about the system resources and services of a Grid member, including the reporting server. The *System Status* widget provides the operational status about an independent appliance. Add a *Member Status* widget to your Dashboard for each Grid member that you want to monitor. The widget

always displays the services that a Grid member is running. You can then configure it to display additional information and specify how the information is displayed.

You can modify the *Member Status* or the *System Status* widget by clicking the Configure icon. If you have an independent appliance, you can only configure some of the following:

- For *Member Status* widget only: Click **Select Member** to select a Grid member for display. When you select the reporting server, the widget displays reporting usage.
- Select the information you want to display:
  - **Show Role:** For *Member Status* widget only. Click to display whether the appliance is a Grid Master, Grid Master candidate, or Grid member. An independent appliance does not have a Grid license installed.
  - **Show Hardware Type:** Click to display the appliance hardware model.
  - **Show HA Status:** Click to display whether the appliance is part of an HA pair. It displays one of the following:
    - **Standalone**: The Grid member is an independent appliance.
    - **HA OK**: The Grid member is part of an HA pair that is functioning properly.
    - **HA Broken**: The appliance is part of an HA pair that is not operating properly. You can check the logs to determine the problem.
  - **Show System Uptime:** Click to display the duration of time (days, hours, and minutes) that the Grid member has been up and running.
- **Statistics:** Select the data that you want to display and its format:
  - **CPU:** Click to display the percentage of CPU that is in use. Select either **Dial** or **Bar** for the display format.
  - **Memory:** Click to display the current percentage of memory that is in use. Select either **Dial** or **Bar** for the display format.
  - **Database:** Click to display the percentage of the database that is in use. Select either **Pie** or **Bar** for the display format.
  - **Disk:** Click to display the percentage of the data partition on the hard disk drive in use. Select either **Pie** or **Bar** for the display format.
  - **System Temperature:** Click to display the system temperature. Depending on the hardware model, the system temperature may not be available. Select to display the temperature in either **Celsius** or **Fahrenheit**.
  - **CPU Temperature**: Click to display the CPU temperature. Depending on the hardware model, the CPU temperature may not be available. Select to display the temperature in either **Celsius** or **Fahrenheit**.

Click the Configuration icon again to hide the configuration panel after you complete the modification.

Grid Manager displays the hostname of the appliance at the top of the widget. You can click the name link to view detailed information about the appliance. The widget also displays the upgrade status if the member is currently in the process of an upgrade. If the member is scheduled for an upgrade, the **Scheduled for upgrade** link appears. You can click this link to access the **Grid** tab -> **Upgrade** tab to view more details about the date and time of the scheduled upgrade.

The widget also displays the service status of the following: FTP, TFTP, HTTP (File Distribution), DNS, DHCP, NTP, bloxTools, Captive Portal, Subscriber Collection, Cloud DNS Sync, DNS Accelerator, and Reporting in the *Services* section. The service status can be one of the following:

Icon	Color	Meaning
	Green	The service is enabled and running properly.
	Yellow	The service is enabled, but there may be some issues that require attention.
	Red	The service is enabled, but it is not running properly or is out of synchronization. (A red status icon can also appear temporarily when a service is enabled and begins running, but the monitoring mechanism has not yet notified the GUI engine.)

Icon	Color	Meaning
	Gray	The service is not configured or is disabled.

The widget also displays the statistics you specified, such as CPU usage, memory, and database usage, in the format you selected.
When you select the reporting server, you can also see the reporting usage information:

- **Reporting Usage**: Displays the daily consumption rate for the reporting service.

For more information about reporting, see *Infoblox Reporting and Analytics*.

DNS Statistics

The *DNS Statistics* widget provides statistics for a member or for a zone. The zone statistics are cumulative, collected from all the members that are authoritative servers for zones or are hosting stub zones. The widget displays the totals for each type of DNS response as well as a line graph that tracks the responses per second.

You can add a *DNS Statistics* widget to your Dashboard for each zone or member DNS server on the Grid. To configure the *DNS Statistics* widget, click the Configure icon and do the following:

- Click **Select Member**. In the *Member Selector* dialog box, choose a Grid member to display statistics for all its stub zones and authoritative zones.
  or
- Click **Select Zone**. In the *Zone Selector* dialog box, choose a DNS zone to display statistics for that zone only.

The widget displays only the option that you selected on your subsequent logins. For example, if you clicked **Select Member**, the widget displays the **Select Member** option only, and not the **Select Zone** option, when you log in again.

- **Graph Configuration**: Select which DNS messages you want to track in the **Responses per Second** graph.
  - **Success**: The number of successful queries.
  - **NXDOMAIN**: The number of queries for domain names that did not exist in the database.
  - **Referral**: The number of queries that became referrals.
  - **NXRRSET**: The number of queries for domain names that did not have the requested records.
  - **Failure:** The number of queries that failed due to reasons other than nonexistent domain names or records in a domain.
  - **Recursion**: The number of recursive queries for which the name server sent queries to other name servers.

The widget displays the following information:

- **DNS Responses** tab: Displays a pie chart and the total number of each type of message. It also displays the total number of full and incremental zone transfers that the Grid member performed.
- **Responses per Second** tab: Displays a line graph that tracks the DNS responses received per second, within an hour. The time is displayed according to the time zone specified in the User Profile. If the auto-detect time zone option is enabled and Grid Manager cannot determine the browser time zone, then the time is displayed in UTC format. You can mouse over the graph to display the coordinates of any point in the graph.

Ranges Over Threshold

The *Ranges Over Threshold* widget enables you to monitor IPv4 DHCP range usage from your Dashboard. It lists the IPv4 ranges that are allocated above a specified threshold and thus may warrant your attention. The default threshold is 75%. For information, see *Configuring Thresholds for DHCP Ranges*. Note that the appliance highlights disabled IPv4 ranges in gray.

The widget displays the IPv4 ranges with utilization percentages that surpass the threshold. To configure the *Ranges Over Threshold* widget, click the Configure icon and do the following:

- **Network View**: Select a network view in which you want to monitor the IPv4 ranges. This field is displayed only when you have more than one network view.
- **Threshold**: Enter a new threshold value. The default is 75%.
  In addition, you can do the following:
- Click the Export button to export the list of IPv4 ranges that surpass the threshold to a file in CSV format.
- Click the Refresh button to refresh the data in the list.

IPv4 Failover Associations Status

The *IPv4 Failover Associations Status* widget enables you to monitor the status of the failover associations from your Dashboard. It lists all the failover associations in the Grid and displays their names and status. The widget also displays the primary and secondary servers in the association. When you click a failover association link or a status link, Grid Manager displays the Failover Association section where you can get detailed information about the failover association. For information, see *Managing Failover Associations*.

In addition, you can do the following:

- Click the Export button to export the list of failover associations to a file in CSV format.
- Click the Refresh button to refresh the data in the list.

DHCP Statistics

The *DHCP Statistics* widget displays statistics about the different types of DHCP messages that a Grid member sends and receives. The widget displays the totals for each type of DHCP message as well as a line graph that tracks the messages per second.
You can add a *DHCP Statistics* widget to your Dashboard for each member DHCP server in the Grid. If the DHCP service is not enabled or is offline, the widget displays a message indicating that the DHCP statistic are not available.

To configure the *DHCP Statistics* widget, click the Configure icon and do the following:

- **Protocol:** Select either **IPv4** or **IPv6.**
- Click **Select Member**. In the *Member Selector* dialog box, select a Grid member from the list.
- **Graph Configuration**: This section lists IPv4 or IPv6 messages, depending on the protocol you selected.
- Select which IPv4 messages you want to track in the **Messages per Second** graph.
  - **Discovers:** The number of DHCPDISCOVER messages that the Grid member received from DHCP clients. A DHCP client broadcasts a DHCPDISCOVER message to obtain an IP address.
  - **Offers:** The number of DHCPOFFER messages that the Grid member sent to DHCP clients. If the Grid member has an IP address that it can allocate to the DHCP client that sent the DHCPDISCOVER message, the Grid member responds with a DHCPOFFER message that includes the IP address and configuration information.
  - **Requests:** The number of DHCPREQUEST messages that the Grid member received from DHCP clients. A DHCP client sends DHCPREQUEST messages when it selects a lease, connects to the network, and if it renews the lease.
  - **Acks:** The number of DHCPACK messages that the Grid member sent to DHCP clients. When the Grid member receives a DHCPREQUEST message, it responds with a DHCPACK message to confirm the IP address selected by the DHCP client.
  - **Nacks:** The number of DHCPNACK messages that the Grid member sent to DHCP clients. The Grid member sends a DHCPNACK message when a DHCP client requests an IP address that is not valid for the network.
  - **Declines:** The number of DHCPDECLINE messages that the Grid member received. A DHCP client sends a DHCPDECLINE message to a DHCP server when it discovers that the IP address offered by a DHCP server is already in use.
  - **Informs:** The number of DHCPINFORM messages that the Grid member received. A client that did not receive its IP address from the DHCP server can send it a DHCPINFORM message to retrieve configuration parameters, such as the IP addresses of DNS servers in the network.
  - **Releases:** The number of DHCPRELEASE messages that the Grid member received. A DHCP client sends a DHCPRELEASE message when it terminates its lease and releases its IP address.
- Select which IPv6 messages you want to track in the **Messages per Second** graph.

- **Declines**: The number of Decline messages that the Grid member received. A DHCP client sends a Decline message to a DHCP server when it discovers that the IP address offered by a DHCP server is already in use.
- **Renews**: The number of Renew messages that the Grid member received. A DHCP client sends a Renew message to a DHCP server to extend the lifetimes on the leases granted by the DHCP server and to update other properties.
- **Information Requests:** The number of Information-Request messages that the Grid member received. A client sends an Information-Request message to retrieve configuration parameters, such as the IP addresses of DNS servers in the network.
- **Solicits**: The number of Solicit messages that the Grid member received, including Solicit messages embedded in Relay-Forward messages. A DHCP client sends a Solicit message to locate DHCP servers.
- **Requests**: The number of Request messages that the Grid member received. A DHCP client sends a Request message to request one or more IP addresses and configuration parameters from a DHCP server.
- **Rebinds**: The number of Rebind messages that the Grid member received. A DHCP client sends a Rebind message to extend the lifetime of its lease and to update configuration parameters.
- **Releases**: The number of Release messages that the Grid member received. A DHCP client sends a Release message when it terminates its lease and releases its IP address.
- **Advertises**: The number of Advertise messages that the Grid member sent. When a DHCP server receives a Solicit message, it can respond with an Advertise message to indicate that the server is available for DHCP service.
- **Replies**: The number of Reply messages that the Grid member sent. A DHCP server sends a Reply message that includes IP addresses and configuration parameters when it responds to Solicit, Request, Renew or Rebind message. It sends a Reply message with configuration parameters only when it responds to an Information-Request message.

The widget displays the following information:

- **DHCP Messages** tab: Displays a pie chart and the totals for each type of DHCP message. It also displays the number of Deferred Updates, which are DDNS update requests which are deferred because the DNS primary was not reachable when the update was first attempted.
- **Messages per Second** tab: Displays a line graph that tracks the DHCP messages that were sent and received per second, within an hour. The time is displayed according to the time zone specified in the User Profile. If the auto-detect time zone option is enabled and Grid Manager cannot determine the browser time zone, then the time is displayed in UTC format. You can mouse over the graph to display the coordinates of any point in the graph.

Network Statistics

The *Network Statistics* widget provides information about IP address usage in an IPv4 network. You can monitor several networks simultaneously to view the distribution of address resources. Such information can indicate if there is a sufficient number of available addresses in each network. It can also provide information about the distribution of address resources, indicating if there are too many unused addresses in one network while all the addresses in another are in use.

Add a *Network Statistics* widget to your Dashboard for each network that you want to monitor. You can monitor IPv4 networks only.
To configure the *Network Statistics* widget, click the Configure icon and do the following:

- Select one of the following chart types:
  - **Pie**
  - **Bar**
- Click **Select Network**. In the *Network Selector* dialog box, choose a network from the list and click **Select**.
  Note that if multiple network views were previously configured, Grid Manager displays the default network view. You can choose another network view from the drop-down list, and then select a network. The *Network Statistics* widget displays the following information about the selected network:
- **IPAM Utilization:** When you define a network, this is the percentage based on the IP addresses in use divided by the total addresses in the network. For example, in a /24 network, if there are 25 static IP addresses defined and a DHCP range that includes 100 addresses, the total number of IP addresses in use is 125. Of the possible 256 addresses in the network, the IPAM utilization is about 50% for this network. When you define a network container that contains subnets, this is the percentage of the total address space defined within the container

regardless of whether any of the IP addresses in the subnets are in use. For example, when you define a /16 network and then 64 /24 networks underneath it, the /16 network container is considered 25% utilized even when none of the IP addresses in the /24 networks is in use.
You can use this information to verify if there is a sufficient number of available addresses in a network. The IPAM utilization is calculated approximately every 15 minutes.

- **Unmanaged:** The number of discovered IP addresses that do not have corresponding records on the appliance, such as A records, PTR records, fixed address records, host records, or leases. To obtain this data, you must run a discovery process on the network first.
- **Conflicts:** The number of IP addresses that have either a MAC address conflict or a DHCP range conflict. To obtain this data, you must run a discovery process on the network first. A discovered host has a MAC address conflict when its MAC address is different from that specified in its fixed address, DHCP lease, or host record. A discovered host has a DHCP range conflict when it is part of a DHCP range, but it does not have a matching fixed address or DHCP lease, and it is not part of an exclusion range.

Network Users - Active Users

The *Network Users Active Users* widget displays up to 10 active users for Windows devices managed by the Grid. To modify the *Network Users Active Users* widget, click the Configure icon and select one of the following:

- **Only show networks with**: Select **At least** or **Fewer than** from the drop-down list and specify the number of users in the **Users** field. The default values are set to **At least** and **10** users.
- **All Network Views**: Select this to monitor active users on the managed Active Directory domains in all network views.
- **Select Network View**: Click Select to select the network view in which you want to monitor active users.
The *Network Users-Active Users* widget displays the following information:
- **Network:** The network address. You can click the network link to view network details.
- **Active Users**: All users who are currently using the Active Directory domains. You can also export the list to a .csv file.

IPv4 Networks Over Threshold

The *IPv4 Networks Over Threshold* widget enables you to monitor IPv4 network and IP address usage from your Dashboard. It lists the IPv4 networks that are allocated above a specified threshold and thus might warrant your attention. The default threshold is 75%.

For network containers, the threshold is the percentage of IP address space that has been allocated. For subnets, it is the percentage of used addresses, except the broadcast and network addresses. The widget displays the network containers and subnets with utilization percentages that surpass the threshold.

You can also select to view IPv4 cloud networks only if you have deployed Cloud Network Automation. For information about this feature, see *Deploying Cloud Network Automation*.

To configure the *Networks Over Threshold* widget, click the Configure icon, and then complete the following:

- **Threshold**: Enter a new threshold value. The default is 75%.
- **Type**: Select **IPAM Utilization** or **IPv4 DHCP Utilization**. For information, see *Managing IPv4 DHCP Data*.
- **All Network Views**: Select this to monitor threshold for IPv4 networks in all network views.
- **Select Network View**: Click Select to select the network view in which you want to monitor the threshold.

To view information related to cloud networks, select **View Cloud Networks Only**, and then select one of the following:

- **All Tenants**: Displays information for all tenants.
- **Select Tenant**: Click **Select** to select a specific tenant. In addition, you can do the following in this widget:
- Click the Export button to export the list of networks that surpass the threshold to a file in CSV format.
- Click the Refresh button to refresh the data in the list.

Port Status

The Port Status widget provides a quick way to inspect the interface status for any discovered device in the network. The widget shows an overview of all interfaces on all devices or for a single device (called the Data Scope).

Click the Configure icon to change settings for the widget.

1. You can choose a **Bar** or **Pie** chart for the **Total Switch or Switch-Router** chart, which shows the percentage of ports that are operationally Active and that are operationally Down.
2. Under **Data Scope**, the **All Devices** setting allows the widget to show the total counts for all discovered network infrastructure devices. This is the default.
3. To use the widget to display port information for a single device, such as a switch, enable the **Select Device** radio button. Choose the device in the *Device Selector* window. The widget adjusts its reported values to the scale of the selected device.
4. You can also choose the **Media Type**. to further filter port status information. Choices include: **Ethernet Interface, Layer 2 Virtual LAN, Proprietary Serial Interface, Proprietary Virtual/Internal Interface, Loopback Interface** and **Tunnel Interface**.

The counters in the widget include **Total Switch and Switch-Router Ports, Total Down Switch and Switch-Router Ports** and **Total Active Switch and Switch-Router Ports**.

Discovery Status

The appliance can run an IP discovery to detect and obtain information about active hosts in specified networks. For information about the discovery process, see *About Discovery*.

You can add the *Discovery Status* widget to your Dashboard. From this widget, you can access Discovery Manager and configure parameters for a discovery. You can do the following from the widget:

- Start a discovery immediately. For more information about immediate discovery, see *Configuring IP Discovery*.
- Schedule a discovery for a later date and time. For more information about discovery, see *Configuring IP Discovery*.
- Configure a recurring discovery. For more information about recurring discovery, see *Configuring IP Discovery.*
- Click the Start button to start a discovery process.
- Click the Pause button to temporarily pause the process.
- Click the Stop button to stop the process.

This widget displays the status of discovery tasks. If there are no active discovery tasks, the widget displays the discovery results of the previous tasks. For information about starting and scheduling a discovery task, see *Guidelines Before Starting a Discovery.*
After you start a discovery, the *Discovery Status* widget displays a status bar that indicates the discovery is in progress. It also tracks the number of networks in an IP discovery. You can click the Refresh icon to update the discovery status.

The widget displays the following information about the discovery process:

- **Current Status**: If a discovery is in progress, this field displays its current status. Otherwise, it displays the date and time of the last discovery.
- **Last Action**: Displays the last operation and the admin who initiated it.
- **IPv4 Device Discovery:** Displays the total number of IPv4 networks and the IPv4 network and IP address range on which the IP discovery is currently running. You can click **Refresh** to update this information.

The *Discovery Status* widget also displays the following information about the last discovery:

- **Discovered:** The total number of active hosts in the network.
- **Managed:** The number of discovered IP addresses that are managed by the NIOS appliance. These IP addresses have an A record, PTR record, fixed address record, host record, lease, or are within a configured DHCP range.
- **Unmanaged:** The number of discovered IP addresses that do not have corresponding records on the appliance, such as A records, PTR records, fixed address records, host records, or leases.
- **Conflicts:** The number of discovered hosts that have a MAC address conflict or are part of a configured DHCP range, but do not have a fixed address or lease record and are not part of an exclusion range.

Advanced Discovery Status

With the correct licensing, dedicated NIOS appliances operating as Grid members can perform infrastructure device discovery. NIOS appliances with the Discovery license operate primarily for discovery tasks and do not perform core DNS or DHCP network functions. Discovery appliances, called Probes, collect all network device data and compile it into a database. A separate NIOS appliance, called a Consolidator, aggregates the collected device information from the Probes and synchronizes with the Infoblox Grid Master.

For more information about discovery and its features and requirements, see *Infoblox Network Insight* and its associated sections.

The Advanced Discovery Status widget provides several basic counts describing the general state of device discovery within the Grid, and for networks outside the Grid being inventoried by the NIOS appliances designated for discovery. The widget divides counters into two categories: **Networks** and **Assets**. Network counters refer to counts of managed and unmanaged networks discovered by Probe appliances. Asset counters refer to counts of specific types of network devices, termed Assets, which are comprised of end hosts, enterprise servers, enterprise printers, and any other enterprise asset that exists in an end-user network segment. The widget counters include:

In the **Networks** category:

- **Discovered:** The total number of networks discovered by Probe appliances.
- **Managed:** The number of discovered networks that are currently managed by the NIOS Grid. These IP networks have been converted from Unmanaged status to Managed status.
- **Unmanaged:** The number of discovered networks that are counted as Unmanaged by the NIOS Grid Master. After a network is discovered and catalogued by a Probe appliance, its default state as a network is Unmanaged.

In the **Assets** category:

- **Discovered:** The total number of Assets discovered by Probe appliances.
- **Managed:** The number of discovered assets that are currently managed by the NIOS Grid. These devices have been converted from Unmanaged status to Managed status.
- **Unmanaged:** The number of IPs with discovered data that are counted as Unmanaged by the NIOS Grid Master, and have not been converted into a Host or a Fixed IP Address. After an Asset is discovered and cataloged by a Probe appliance, its default state is Unmanaged.
- **Conflicts:** The number of discovered assets that have a MAC address conflict or are part of a configured DHCP range, but do not have a fixed address or lease record and are not part of an exclusion range.

My Commands

The *My Commands* widget provides easy access to commands that you frequently use, so you can perform your tasks without leaving the Dashboard. You can add one *My Commands* widget to your Dashboard.

To configure the *My Commands* widget, click the Configure icon and do the following:

- Select a command from the **Available** list and click the **>** arrow to move it to the **Selected** list. You can always toggle the commands between the two lists. Select multiple commands by using SHIFT-click and CTRL-click.

DDNS Statistics

The *DDNS Statistics* widget provides information about the dynamic DNS (DDNS) updates that occur on the DNS service of a selected Grid member. The widget displays the total number of DDNS updates that succeeded, failed, and that were rejected. It also displays a line graph that tracks the status of the DDNS updates per second.

You can add a *DDNS Statistics* widget to your Dashboard for each DNS server on the Grid that accepts dynamic DNS updates.

To configure the *DDNS Statistics* widget, click the Configure icon and do the following:

- Click **Select Member**. In the *Member Selector* dialog box, select a Grid member from the list.

- **Graph Configuration**: Select which updates you want to track in the **Updates per Second** graph:
  - **Success:** The number of DDNS update requests that succeeded.
  - **Prerequisite Reject:** The number of DDNS update requests that were rejected because the prerequisite conditions specified in the request were not met.
  - **Reject:** The number of DDNS update requests that were rejected by the DNS service.
  - **Failure:** The number of DDNS update requests that failed.

The widget displays the following information:

- **DDNS Updates** tab: Displays totals for each type of update.
- **Updates per Second** tab: Displays a line graph that tracks the status of the DDNS updates. The time is displayed according to the time zone specified in the User Profile. If the auto-detect time zone option is enabled and Grid Manager cannot determine the browser time zone, then the time is displayed in UTC format. You can mouse over the graph to display the coordinates of any point in the graph.

System Activity Monitor

The *System Activity Monitor* widget provides information about the following resources on the selected Grid member: CPU and its utilization, system memory, NIC usage, top processes, and information about VLAN interfaces. By default, the widget displays the system activity of the Grid Master. You can add a *System Activity Monitor* widget to your Dashboard for each Grid member whose resources you want to monitor.

To configure the *System Activity Monitor* widget, click the Configure icon and select a Grid member and the resources that you want to track:

- Click **Select Member**. In the *Member Selector* dialog box and select a Grid member from the list.
- **CPU:** Select which type of CPU usage you want to track:
  - **User:** The CPU usage of user applications, such as programs and libraries.
  - **System:** The CPU usage of the kernel and drivers.
  - **Idle:** The percentage of CPU that is not in use.
- **System Memory:** Select which portion of the system memory you want to track:
  - **Real Memory Used:** The physical RAM usage.
  - **Swap Used:** The swap area usage. The swap area is the disk area that temporarily holds a process memory image.
- **NIC Usage:** Select how you want to measure network traffic:
  - **Bytes:** Reports the number of bytes.
  - **Packets:** Reports the number of packets.
- **NIC Settings**: Select the port on which you want to measure network traffic. If you have configured VLANs, Grid Manager displays them in the format LAN1 nnnn or LAN2 nnnn, where nnnn represents the associated VLAN ID. For example, a VLAN configured on LAN1 can be displayed as LAN1 297 and a LAN2 VLAN can be LAN2 21. For more information about VLANs, see *VLAN Management*.

  > **Note**
  >
  > For vNIOS appliances, some of the options in the drop-down list may vary depending on your vNIOS configuration. For example, if you are using a single network interface instance of vNIOS for GCP, you will see choices specific to the LAN1 interface only. For more information, see the vNIOS documentation specific to your product at *Appliances*.

- **CPU Utilization and Top N Processes:** Set the auto refresh period in this section. NIOS displays the information for all available cores.
  - **Auto Refresh Period for CPU Utilization and Top N Processes:** Enter the time interval in seconds for the CPU Core Utilization graph and the top N process data to auto refresh and display the CPU core utilization information. If you enter 12, the graph displays new information after every 12 seconds. You can enter a minimum refresh interval of 10 seconds and a maximum refresh interval of 30 seconds. By default, the time interval is set to 10 seconds. This field is applicable only to the **CPU Utilization** and **Top N Processes** tabs.
- **Auto Refresh Period:** Enter the refresh interval in seconds for the data in the **CPU**, **System Memory**, and **NIC Usage** tabs to auto refresh.

The *System Activity Monitor* widget displays a tab for each resource: **CPU**, **System Memory**, **NIC Usage**, **CPU Utilization**, **Top N Processes**.

Each tab contains a line graph that tracks the resource utilization per second.

- **CPU:** The graph on the **CPU** tab tracks the percentage of CPU usage.
- **System Memory:** The graph on the **System Memory** tab tracks the memory utilization percentage.
- **NIC Usage:** The graph on the **NIC Usage** tab tracks either bytes or packets per second.
- **CPU Utilization:** If you select the **Live** option, the graph tracks live CPU utilization data for the last 10 minutes for all CPUs in your Grid member. The graph is refreshed based on the time interval you specify in the **Auto Refresh Period for CPU Utilization and Top N Processes** field. Each CPU is denoted in a different color. If you select the **Historical** option, you can view the CPU utilization data for up to a maximum of past 60 minutes based on the time range you specify in the **Earliest** and **Latest** fields. For example, if you enter 2019-09-05 and 09:20:42 AM in the **Earliest** field and 2019-09-05 and 10:20:42 AM in the **Latest** field, the graph displays the CPU utilization data for 5th September 2019 between 9:20:42 AM and 10:20:42 AM. You can view data for a maximum of past of 5 days but the time difference between **Earliest** and **Latest** time should not exceed 60 minutes.
- **Top N Processes:** If you select the **Live** option, the table displays the process ID and name of the top N processes that are consuming CPU utilization. N is the number that you specify in the **Number of Top Processes** field on the **Monitoring** tab of the *Grid Properties* editor. It also displays the percentage of CPU utilized by each process. The data is refreshed based on the time interval you specify in the **Auto Refresh Period for CPU Utilization and Top N Processes** field. If you select the **Historical** option, you can view past top N process data based on the time range you specify in the **Earliest** and **Latest** fields. For example, if you enter 2019-09-05 and 09:20:42 AM in the **Earliest** field and 2019-09-05 and 10:20:42 AM in the **Latest** field, the graph displays the top process data on 5th September 2019 between 9:20:42 AM and 10:20:42 AM. You can view data for a maximum of 5 days.

The time is displayed according to the time zone specified in the User Profile. If the auto-detect time zone option is enabled and Grid Manager cannot determine the browser time zone, then the time is displayed in UTC format. You can mouse over the graph to display the coordinates of any point in the graph.

File Distribution Statistics

The *File Distribution Statistics* widget enables you to monitor the status of file distributions services from the Dashboard. The widget provides an overall status of file distribution on all members in the Grid. It also displays the file system utilization for the file distribution subsystem.

The service status displays one of the following:

- **OK**: All file distribution services are running properly.
- **Stopped**: All file distribution services are stopped.
- **Warning**: The file distribution services are not running properly.
- **Error**: The file distribution services encounter an error.

You can click the link to view detailed information about the file distribution services. Grid Manager displays the Members tab on the File Distribution tab.

To configure the *File Distribution Statistics* widget, click the Configure icon and select one of the following chart types:

- **Pie**
- **Bar**

The *File Distribution Statistics* widget displays the following information:

- **File System Utilization:** The percentage of utilization of the overall allocated file distribution subsystem space on all members. You can use this information to verify if there is sufficient space for file distribution in the Grid.

Active WebUI Users

The *Active WebUI Users* widget provides information about the users who are logged in to Grid Manager or System Manager. It does not include users who are using the Infoblox API or are logged in to the serial console.

You can add only one *Active WebUI Users* widget to the Dashboard. You must have a superuser account to add this

widget to the Dashboard.

It displays the following information about each user:

- **User ID:** The user name.
- **Source Address:** The IP address of the management station the user used to connect to Grid Manager.
- **Logged In Since:** The date and time the user logged in.
- **Idle Time:** The number of minutes the user has not had any activity on Grid Manager. Note that the idle session timeout is 2 hours, so the idle time is cleared every 2 hours.
- **User Agent:** The system used to access Grid Manager, such as the browser version and platform information. You can sort the columns and hide or display each one. You can also export the list to a .csv file.

Microsoft Servers Status Widget

The *Microsoft Servers Status* widget displays the operational status of each Microsoft server managed by the Grid. Grid Manager displays this widget only when at least one member in the Grid has a Microsoft management license. You can configure this widget to display the status of all Microsoft servers or only those with warnings and errors. You can also view the monitor and control status for the DNS and DHCP service on the Microsoft server. To modify the *Microsoft Servers Status* widget, click the Configure icon and select one of the following:

- **Show all Microsoft servers**
- **Only show servers with service warnings or errors**

The *Microsoft Servers Status* widget displays the following information about each Microsoft server:

- **Server Name**: The hostname of the Microsoft server.
- **IP Address**: The IP address of the Microsoft server.
- **Status**: The connection status of the Microsoft server.
  - **OK:** The Grid member is connected to the Microsoft server.
  - **Connecting:** The Grid member is connecting to the Microsoft server.
  - **Error:** The Grid member tried to connect to the Microsoft server, but failed. You can check the syslog for any messages.
  - **Not Available:** The Microsoft server is disabled. The Grid member does not try to connect to disabled servers.
- **DNS**: The status of the DNS service on the Microsoft server. The DNS service status can be one of the following:

Icon	Color	Meaning
	Green	The DNS service is functioning properly.
	Red	The Microsoft server is unavailable.
	Yellow	The DNS service is starting or stopping.
	Gray	The DNS service is stopped or management of the Microsoft DNS server is disabled.

- **DHCP**: The status of the DHCP service on the Microsoft server. The DHCP service status can be one of the following:

Icon	Color	Meaning
	Green	The DHCP service is functioning properly.
	Red	The Microsoft server is unavailable.
	Yellow	The DHCP service is starting or stopping.
	Gray	The DHCP service is stopped or management of the Microsoft DHCP server is disabled.

- **Active Directory Sites**: The status icon in green indicates the synchronization status of Active Directory Sites on the Microsoft server.
- **Enable DNS Monitor & Control**: Displays **Yes** if the monitor and control status is enabled for the DNS service on the Microsoft server and displays **No** if it is disabled.
- **Enable DHCP Monitor & Control**: Displays **Yes** if the monitor and control status is enabled for the DHCP service on the Microsoft server and displays **No** if it is disabled.

CSV Import Manager

The **CSV Import Manager** on the Status Dashboard displays the status of CSV import jobs you have submitted. You can start a file import from **CSV Import Manager** and control and monitor it from this widget. You can also launch **CSV Import Manager** from the Task Dashboard or the Toolbar. You can also delete uploaded CSV files. For more information, see *Importing and Exporting Data using CSV Import*. You can click the Refresh icon or configure auto refresh to update the status.

The widget displays the following information about the import jobs that were submitted in the past 30 days:

- **User Name**: The admin user who submitted the CSV import. Only superusers can view this column.
- **Status**: The current status of the import job. The status can be one of the following:
  - **Import successful**: The import is completed without errors. Check the **Message** field for information about the import.
  - **Import unsuccessful**: The import is completed, but with errors. Check the **Message** field for information about the error message.
  - **Import pending**: The job is in queue for execution.
  - **Import in progress**: The job is being executed.
  - **Import stopped:** The job has been stopped. You can select the job and restart the import.
  - **Test successful**: Test is completed without errors. Check the **Message** field for information about the test.
  - **Test unsuccessful:** Test is completed, but with errors. Check the **Message** field for information about the error message.
  - **Test pending**: Test is in queue for execution.
  - **Test in progress**: Test is in progress.
  - **Test stopped**: Test has been stopped. You can select the job and restart the import.
  - **Saved file**: The data file has been uploaded, but the import has not started.
    Note that after a product restart, which can be caused by a failover, all **Import in progress** jobs go into **Import stopped** state; all **Import pending** jobs continue to be queued for execution.
  - **Submitted**: The timestamp when the job was submitted.
  - **Completed**: The timestamp when the job was completed. This field is blank if the job has not been completed yet.
  - **File Name**: The CSV data file name.
  - **Message**: This field displays the number of rows of data that has been processed and the number of rows of data the import has detected errors. Depending on the import options, Grid Manager displays the row

number at which it stops the import when it encounters an error, or the total number of rows it has processed by skipping over the erroneous data. For example, if there are 100 rows of data and you select "On error: Stop importing," and there is an error in row 90, the appliance displays **90of100completed,1error**. If you select "On error: Skip to the next row and continue," the appliance displays **100 of 100 completed, 1 error**.
- **File Size**: The CSV data file size.

> **Note**
>
> Superusers can view all CSV import jobs and limited-access users can view only the jobs they submitted.

Pending Approvals

The *Pending Approvals* widget provides information about tasks that are pending your approvals. Add the *Pending Approvals* widget to your Dashboard to monitor tasks that require your approvals.
You can select a task and perform the following:

- Click the Approve icon to approve the task.
- Click the Reject icon to disapprove the task.

You can also click **Task Manager** to access the **Administration** tab -> **Workflow** tab -> **Task Manager** tab.
The *Pending Approvals* widget displays the following information about each task that requires your approval:

- **Task ID**: The ID associated with the task. The appliance assigns an ID to a task in chronological order.
- **Submitter**: The username of the admin who scheduled or submitted the task.
- **Ticket Number**: The reference number entered by the submitter to identify the task. You can enter up to 20 alphanumeric characters.
- **Scheduled Time**: The date, time, and time zone when the task was scheduled for execution.
- **Affected Object**: The name or value of the object that is associated with the task. For example, if the task involves an A record, this field displays the domain name of the record. If it is a fixed address, it displays the IP address of the fixed address.
- **Object Type**: The object type. For example, the appliance can display A Record or Fixed Address.
- **Action**: The operation the appliance performs in this task. The operation can be: **Add**, **Modify**, **Delete**, or **Network Discovery**.
- **Submitte Time**: The date, time, and time zone when the task was submitted. You can select this for display. It is not displayed by default.

Infoblox Community

The *Infoblox Community* widget displays the latest news from Infoblox. It provides links to video clips that show you how to perform certain tasks, such as how to prepare for IPAM Express and how to add a network. You can click available links in the widget to get more information about Infoblox products and solutions.
Note that content in the *Infoblox Community* widget may not be displayed in certain versions of Mozilla FireFox, Google Chrome, and Microsoft Internet Explorer due to restrictions these browsers use to block certain secure data.
Follow these steps to unblock the *Infoblox Community* widget and view data in your respective browser:

- **MozillaFireFox**: Click the *Shield* icon in the address bar and choose **DisableProtectiononThisPage** from the drop-down list. The icon in the address bar changes to a warning triangle and content is displayed in the *InfobloxCommunity* widget. For more details, refer to information at *https://blog.mozilla.org/tanvi/2013/04/10/mixed-content-blocking-enabled-in-firefox-23/*.
- **Google Chrome**: Click the *Shield* icon in the address bar and click **Load unsafe script** in the pop-up box. Chrome automatically refreshes the webpage and loads the content in the *Infoblox Community* widget. For more details, refer to information at *https://support.google.com/chrome/answer/1342714?hl=en*.
- **Internet Explorer**: Click the *Compatibility View* icon adjacent to the address bar. The browser refreshes and the *Security Warning* dialog box is displayed. Click **No** in the dialog box. The **Only Secure content is displayed** pop-up blocker is displayed at the bottom of the browser. Click the **Show all content** button in this pop-up blocker to view the content. For more details, refer to the information at *http://windows.microsoft.com/en-in/internet-explorer/use-compatibility-view#ie=ie-8*.

Mobile Devices Status

The *Mobile Devices* widget provides information about the number of active leases of the DHCP fingerprint devices managed by the Grid. The widget displays a pie chart indicating the number of active leases in percentile for each of the device category. You can click the Refresh icon or configure auto refresh to update the status.

> **Note**
>
> The *Mobile Devices* widget updates its data every 15 minutes. A device might not be displayed in this widget if its lease expires within 15 minutes.

To configure the *Mobile Devices* widget, click the Configure icon and do the following:

- Click **Select Network View**. In the *Network View Selector* dialog box, select a network view from the list and click **OK**.

Note that if multiple network views were previously configured, Grid Manager displays the default network view. You can select another network view from the *Network View Selector* dialog box.
The widget displays the number of active leases for the following device classes:

- **MacOS** - Displays all devices that were detected to be running Mac OS.
- **Windows** - Displays all devices that were detected to be running Windows.
- **Android Mobile** - Displays Smartphones/PDAs/Tablets that were detected to be running Android.
- **Apple Mobile** - Displays Smartphones/PDAs/Tablets that were detected to have Apple in the DHCP fingerprint information.
- **No Match** - Displays all devices whose fingerprint information does not match with any of the standard/custom DHCP fingerprint data stored in the appliance. For information about Standard and Custom DHCP Fingerprints, see *Standard and Custom DHCP Fingerprints*.
- **Other** - Displays all devices that belong to a device class other than those listed above.

List of device types and classes

Category	Device Class	Device Type
Windows	Windows	Microsoft Windows 2000
		Microsoft Windows 2003
		Microsoft Windows 8
		Microsoft Windows Vista/7 or Server 2008
		Microsoft Windows XP
Mac OS	Macintosh	Apple Mac OS 9
		Apple Mac OS X, TV (HD)
Apple Mobile	Smartphones/PDAs/Tablets	Apple iPod
		Apple iPod, iPhone, iPad or TV (SD)

Category	Device Class	Device Type
Android Mobile	Smartphones/PDAs/Tablets	Android Phone/Tablet (Generic)
		Android Phone/Tablet (HTC, older devices)
		Android Phone/Tablet (Motorola, older devices)
		Android Phone/Tablet (Sony Ericsson, older devices)
		Android Phone/Tablet (Unknown devices)
		Android Phone/Tablet (Vizio tablet, Others)
		Android Phone/Tablet (newer devices)
		Android tablets (Samsung, Others)
		ZTE N9120 Android

DNS Integrity Check

The DNS Integrity Check widget displays status about DNS data discrepancies that have been detected through DNS integrity check that is designed to mitigate DNS domain hijacking. This widget displays top-level or parent authoritative zones that have been selected for DNS data monitoring. For information about how to configure DNS integrity check to mitigate possible DNS domain hijacking, see *Configuring DNS Integrity Check for Authoritative Zones*.
The widget displays the following information (note that this table is sorted by **Status.):**

- Left click the Action icon next to a zone to perform the following:
  - **View Syslog**: Select this to open the *Syslog Preview* dialog and view data discrepancy events for the selected zone.
  - **Check Now**: Select this to perform DNS integrity check to immediately query current DNS data from the top-level parent domain. When you select this, verbose logging for DNS integrity check is automatically enabled. After the operation is complete, the appliance updates the timestamp for the **Last Checked** column.
- **Zone**: Displays the name of the top-level authoritative zones that is being monitored for DNS integrity check. You can click the zone name and the appliance opens the zone viewer for the selected zone.
- **Status**: Displays the current DNS data discrepancy status. The status can be one of the following:
  - **Critical** (red): Data in the NS RRsets for the authoritative and delegate zones are completely out of synchronization.
  - **Severe** (orange): Some data in the NS RRset between the authoritative and delegate zones overlaps and some data is different.
  - **Warning** (yellow): The NS RRset for the authoritative zone is a subset of the NS RRset for the delegate zone. It is possible that incorrect IP addresses have been entered at the registrar.
  - **Informational** (blue): The NS RRset for the delegate zone is a subset of the NS RRset for the authoritative zone. This could indicate a possible delay in domain registration.
  - **Normal** (green): There are no DNS data discrepancies between the NS RRsets for the authoritative and delegated zones.
  - **None** (black): No DNS discrepancies data has been collected or DNS integrity check has not been performed.
- **Last Checked**: The timestamp in YYYY-MM-DD HH:MM:SS when the parent domain was last queried for its DNS data.

- **Description**: Information about the zone.

Previewing Syslog Events

When you select **View Syslog** from the *DNS Integrity Check* widget for a selected zone, the *Syslog Preview* dialog is displayed. You can view related syslog events for the selected zone in this dialog, as follows:

- **Timestamp**: The timestamp in YYYY-MM-DD HH:MM:SS when the event was logged.
- **Facility**: The location that determines the processes and daemons from which the log messages are generated.
- **Level**: The severity level of the DNS data discrepancies. This can be **Critical**, **Severe**, **Warning**, **Information**, or **Normal**. For more information, see descriptions for the **Status** field.
- **Server**: The name of the Grid member that performed the data check.
- **Message**: Syslog information about the event. If you have enabled verbose logging, this displays detailed information about the event. For information about how to enable verbose logging, see *Configuring DNS Integrity Check for Authoritative Zones*.

You can also click **Go to Syslog Viewer** on the upper right corner of the dialog to view all events in the syslog. For more information about the syslog, see *Viewing the Syslog*.

Cloud Statistics

The *Cloud Statistics* widget appears only when you have deployed the Cloud Network Automations license on the Grid Master. This widget displays statistical information for cloud objects. It contains the following tabs: *Tenant & VMs*, *Fixed vs. Floating* and *Available vs. Allocated*. You must install valid cloud related licenses to access this widget. For more information about installing licenses and enabling Cloud Network Automation, see *Deploying Cloud Network Automation*.
To modify the *Cloud Statistics* widget, click the Configure icon and select one of the following:

- **Show Statistics From:**
  - **All Tenants**: Select this to display statistics for all tenants.
  - **Select Tenant**: Click **Select** to choose a specific tenant for which statistics are displayed.
- **Show:**
  - **All IP Addresses**: Select this to display all IP address allocation for all tenants or the tenant of your choice.
  - **Fixed**: Select this to display only fixed IP address allocation for all tenants or the tenant of your choice. Fixed IP addresses correspond to OpenStack Fixed IP Addresses.
  - **Floating**: Select this to display only floating IP address allocation for all tenants or the tenant of your choice. Floating IP addresses correspond to OpenStack Floating IP Addresses.

Dig Request

The *Dig Request* widget enables you to perform a DNS lookup on the Grid Master or on the specified Grid member and displays the output of the dig command.

> **Note**
>
> When RPZ license is installed on both the Grid Master and the Grid member, the RPZ rule might not be triggered if you perform dig on the Grid member from the Grid Master.

To perform a DNS lookup using the dig command, complete the following:

- **Run dig command on**: Select one of the following. The default is **Grid Master**.
  - **Grid Master**: Select this to perform a DNS lookup on the Grid Master.
  - **Grid Member**: Select this to perform a DNS lookup on the Grid member. Click **Select Member** to select a Grid member. If there are multiple members, the *Member Selector* dialog box is displayed, from which you can select a member. Click the required member name in the dialog box. You can also click **Clear** to clear the displayed member and select a new one.
- **Name Server to Query(Optional)**: Optionally, specify the name server on which you want to perform a DNS lookup. You can enter either the name, IPv4 address, or IPv6 address of the name server.

- **Record Type**: Select the resource record type from the drop-down list. You can select **Any** to query all the resource record types or select one of the following from the drop-down list: **A**, **AAAA**, **CAA, CNAME**, **DNAME**, **MX**, **NAPTR**, **NS**, **PTR**, **SRV**, **TXT**, **AXFR**. If the record type is **Unknown**, then directly enter the type of unknown record. For example, for an unknown record of type RP, enter **RP.** The default is **Any**.
- **Send Recursive Query**: Select this to send recursive queries for the domain. This checkbox is selected by default.
- **Domain Name to Query**: Enter the domain name to query.

Click **Perform Dig**. The widget displays the status and output of the dig command.
Note that if you have installed RPZ license and enabled RPZ logging in the Grid, you can view RPZ syslog messages by clicking **View RPZ Syslog** if the specified domain name matches the RPZ rule.

Security Status for Grid

The *Security Status for Grid* widget displays the overall status of Threat Protection, RPZ (Response Policy Zone), and DNS Threat Analytics services on the Grid members that support Infoblox Advanced DNS Protection, hardware or Software ADP, and Infoblox Threat Insight. Grid Manager displays this widget only when at least one member in the Grid has the Threat Protection, RPZ, or Threat Analytics license installed. You can add this widget to the Security dashboard to monitor the overall security status of the Grid. The statistics displayed in this widget are cumulative, collected from all the Grid members that support Infoblox Advanced DNS Protection, hardware or Software ADP, and Infoblox Threat Insight. This widget displays data for the last 30 minutes. The overall status of Threat Protection, RPZ, and DNS Threat Analytics is determined by the threshold values configured in the *Global Dashboard Properties* editor. For information, see Configuring Security Status Thresholds below.

> **Note**
>
> If the Threat Protection license is not installed on any of the Grid members, Grid Manager does not display any threat protection related information in this widget. Similarly, if the RPZ license is not installed on any of the Grid members, Grid Manager does not display RPZ and DNS Threat Analytics related information in this widget and if the Threat Analytics license is not installed on any of the Grid members, Grid Manager does not display DNS Threat Analytics related information in this widget.

The widget displays the following information for Threat Protection, RPZ, and DNS Threat Analytics:

- **Status**: It displays the overall status of the security service in the Grid based on the events collected from all the members that support Infoblox Advanced DNS Protection and Infoblox Threat Insight. It represents the status of the most critical member in the Grid.
  The status icon can be one of the following for the Threat Protection, RPZ, and DNS Threat Analytics service:
  - **OK** (Green): The license for the security service is installed and the security service is running. The rulesets for the security service are available and the number of events triggered are less than the yellow and red threshold values configured in the *Global Dashboard Properties* editor for the corresponding security service.
  - **Warning** (Yellow): The license for the security service is installed and the security service is running. The rulesets for the security service are available and the number of events triggered for any of the parameters equals or exceeds the yellow threshold value, but less than the red threshold value configured in the *Global Dashboard Properties* editor for the corresponding security service.
  - **Critical** (Red): The license for the security service is installed and the security service is running. The rulesets might not be available or the number of events triggered for any of the parameters, equals or exceeds the red threshold value configured in the *Global Dashboard Properties* editor for the corresponding security service.
  - **Not Setup** (Black): The license for the security service is installed, but the security service is not running.
  - **Unknown** (Black): The data is not available from the Grid member.

You can hover your mouse over the Threat Protection, RPZ, and Threat Analytics status icon and view the *Threat Protection Status for Grid* widget, *Response Policy Zone (RPZ) Status for Grid* widget, and *Threat Analytics Status for Grid* widget respectively. For information about *Threat Protection Status for Grid* widget, *Response Policy Zone (RPZ) Status for Grid* widget, and *Threat Analytics Status for Grid* widget, see below Threat Protection Status for Grid, Response Policy Zone (RPZ) Status for Grid, and Threat Analytics Status for Grid respectively.

- **Events from <> of <> security capable members**: This column displays the cumulative event counts collected from the online Grid members that support the Infoblox Advanced DNS Protection and Infoblox Threat Insight.

    - **Threat Protection**: Displays the total threat protection event counts for the following severity levels:
        - **Critical** (Red): The total number of critical events.
        - **Major** (Orange): The total number of major events.
        - **Warning** (Yellow): The total number of warning events.
        - **Informational** (Blue): The total number of informational events.
    - **RPZ**: Displays the total number of hits received for the following RPZ rules:
        - **Blocked hits** (Red): Total number of queries that triggered a Block (No Data) or Block (No Such Domain) RPZ rule.
        - **Passthru hits** (Yellow): Total number of queries that triggered a Passthru RPZ rule.
        - **Substituted hits** (Orange): Total number of queries that triggered a Substitute (Domain Name) or Substitute (Record) RPZ rule.
    - **Analytics**: Displays the total number of DNS tunneling events.
- **Definitions/Rules**: This column displays the status of the latest ruleset available in the database. For RPZ, the definition status is based on the latest RPZ feed received from Infoblox specific feeds. You can hover your mouse over the definition status to see the RPZ definition status when RPZ definitions exists.
- **Configuration Status**: This column indicates whether the security service is enabled and running properly or not. Grid manager displays a green check mark if the security service is enabled and running properly in the Grid. If the security service is disabled, a gray pause mark is displayed. You can hover your mouse over the gray pause mark to see the status of the security service.

In addition, you can click the Configure icon and do the following:

- Click **Configure Security Status Thresholds** to configure the thresholds for the security status of the Grid. In the *Global Dashboard Properties* editor, you can define the threshold values for Threat Protection, RPZ, and DNS Threat Analytics. For information, see Configuring Security Status Thresholds below.
- Select the **Auto Refresh Period** checkbox to turn on auto-refresh and specify the auto-refresh period in seconds. The default auto-refresh period is 30 seconds.

> **Warning**
>
> If the *Detailed Status panel* is open, the following actions take place:
> - Grid Manager auto refreshes at a rate of 30 seconds.
> - Widgets that support user-specified auto refresh, refresh at the rate specified in the **Auto Refresh Period** field.
>
> Therefore, even if you set the session timeout to be to greater than the auto refresh rate, auto refresh still takes place. The Grid Manager session does not time out because auto refresh takes precedence over the session timeout.

Click the Configure icon again to hide the configuration panel after you complete the modification.

Security Status for All Members

The *Security Status for All Members* widget displays information about the status of all the Grid members that support Infoblox Advanced DNS Protection, hardware or Software ADP, and Infoblox Threat Insight. Grid Manager displays this widget only when at least one member in the Grid has the Threat Protection or RPZ license. You can add this widget to the Security dashboard to monitor the status of the Grid members that support Infoblox Advanced DNS Protection, hardware or Software ADP, and Infoblox Threat Insight.

> **Note**
>
> When an HA Grid Master fails over, the new active node re-collects data from all the Grid members. Hence, it might take a few seconds until the data is displayed in the Security dashboard. When an HA Grid member fails over, the Grid Master stops collecting data from the HA member.

The *Security Status for All Members* widget displays the following information:

- **Overall Status**: The current overall security status of the members that support Infoblox Advanced DNS Protection and Infoblox Threat Insight. This can be **OK**, **Warning**, **Critical**, or **Unknown**.

The security status for a member might be **Unknown** if NTP service is out of synchronization for the member. Hence, to ensure that the correct data is displayed for the member, use NTP to synchronize the time of the member with that of the Grid Master.

- **Member**: The name of the member. You can hover your mouse over the member name and view the *Member Status* widget. For information about the *Member Status* widget, see Member Status (System Status) below.
- **IPv4 Address**: The IPv4 address of the member.
- **IPv6 Address**: The IPv6 address of the member.
- **Threat Protection Status**: The status of the threat protection service running on the member. This can be either **OK**, **Warning**, **Critical**, **NotSetup,** or **Unknown**. You can hover your mouse over the threat protection status and view the *Threat Protection Status for Member* widget. For information about the *Threat Protection Status for Member* widget, see Threat Protection Status for Member below.
- **RPZ Status**: The status of the RPZ service running on the member. This can be either **OK**, **Warning**, **Critical**, **NotSetup,** or **Unknown**. You can hover your mouse over the RPZ status and view the *ResponsePolicyZone(RPZ)Statistics* widget. For information about the *Response Policy Zone (RPZ) Statistics* widget, see Response Policy Zone (RPZ) Status for Member below.
- **Analytics Status**: The status of the DNS Threat Analytics service running on the member. This can be either **OK**, **Warning**, **Critical**, **NotSetup**, or **Unknown**.

You can also do the following in this widget:

Warning

If the *Detailed Status panel* is open, the following actions take place:

- Grid Manager auto refreshes at a rate of 30 seconds.
- Widgets that support user-specified auto refresh, refresh at the rate specified in the **Auto Refresh Period** field.

Therefore, even if you set the session timeout to be to greater than the auto refresh rate, auto refresh still takes place. The Grid Manager session does not time out because auto refresh takes precedence over the session timeout. For more information about widgets, see *Status Dashboard*.

- Turn on auto-refresh. Click the Configure icon and select the **AutoRefreshPeriod** checkbox to turn on auto-refresh. Specify the auto-refresh period in seconds. The default auto refresh period is 30 seconds.
- Click the Action icon (shown as a gear in each row of the table) next to the overall status of each member, and select **ViewSyslog** to view all the events logged in the syslog. Grid Manager displays the syslog messages in the Syslog Preview window.
- Click the Export icon to export the data displayed in this widget.
- Click the Print icon to print the data displayed in this widget.
- Click **Response Policy Zones** link in the **GoTo** field at the top of the widget to view the RPZs configured on the member. Grid Manager displays the **Response Policy Zones** tab on the **DNS** tab. To navigate back to the Security dashboard, click **Back to Security Dashboard** at the top left corner of the navigation bar in the **Response Policy Zones** tab.
- Click **Threat Protection** link in the **Go To** field at the top of the widget to view the threat protection rulesets configured on the member. Grid Manager displays the **Threat Protection Rules** tab on the **Security** tab. To navigate back to the Security dashboard, click **Back to Security Dashboard** at the top left corner of the navigation bar on the **Threat Protection Rules** tab.
- Click **Threat Analytics** link in the **Go To** field at the top of the widget to view the whitelist domains configured on the member. Grid Manager displays the **Threat Analytics** tab. To navigate back to the **Security** dashboard, click **Back to Security Dashboard** at the top right corner of the panel on the **Threat Analytics** tab.
- Click **Members** link in the **Go To** field at the top of the widget to view the members configured in the Grid. Grid Manager displays the **Members** tab on the **Grid Manager** tab. To navigate back to the Security dashboard, click **Back to Security Dashboard** at the top left corner of the navigation bar on the **Members** tab.

Threat Protection Status for Grid

The *Threat Protection Status for Grid* widget displays the statistical information about the threat protection events triggered on all the members in the Grid that support Infoblox Advanced DNS Protection, hardware or Software ADP, and Infoblox Threat Insight. This widget contains the following tabs: *Total Events by Severity*, *Top 10 Grid Members*, *Events*

Over Time, *Top 10 Rules*, and *Top 10 Clients*.
You can do the following in this widget:

> **Warning**
>
> If the *Detailed Status panel* is open, the following actions take place:
> - Grid Manager auto refreshes at a rate of 30 seconds.
> - Widgets that support user-specified auto refresh, refresh at the rate specified in the **Auto Refresh Period** field.
>
> Therefore, even if you set the session timeout to be to greater than the auto refresh rate, auto refresh still takes place. The Grid Manager session does not time out because auto refresh takes precedence over the session timeout.

- Turn on auto-refresh.
  Click the Configure icon, select the **Auto Refresh Period** checkbox, and specify the refresh period in seconds. The default auto refresh period is 30 seconds. You can click the Configure icon again to hide the configuration panel.
- Click the **Total Events by Severity** tab to view information about threat protection related events by the severity level.
- Click the **Top 10 Grid Members** tab to view information about the top 10 Grid members that have the most number of threat protection events.
- Click the **Events Over Time** tab to view information about the total event count for each type of event severity in the given time frame.
- Click the **Top 10 Rules** tab to view information about the top 10 threat protection rules with the most number of hits.
- Click the **Top 10 Clients** tab to view information about the top 10 clients that have the most number of threat protections events.

Total Events by Severity

The **Total Events by Severity** tab displays statistics about the Threat Protection events for each type of event severity. This tab displays a bar chart that lists the total event counts for each severity level. Each severity level is represented by a different color. The event statistics are cumulative, collected from all the members in the Grid that support Infoblox Advanced DNS Protection and Infoblox Threat Insight.
This line graph displays the event counts for the following severity levels:

- **Critical** (Red): The total number of critical events.
- **Major** (Orange): The total number of major events.
- **Warning** (Yellow): The total number of warning events.
- **Informational**(Blue): The total number of informational events.

If you have configured a reporting member in the Grid, the **Go To History** link is displayed on this tab. You can click **Go To History** to view the *Threat Protection Event Count By Severity Trend* report on the **Reporting** tab. To navigate back to the Security dashboard from the **Reporting** tab, click **Back to Security Dashboard** at the top left corner of the navigation bar in the **Reporting** tab.

Top 10 Grid Members

The **Top 10 Grid Members** tab displays a stacked bar chart that tracks the top Grid members with the most total counts of threat protection events. Each severity level is represented with a different color. The report displays the top 10 members in descending order.
If you have configured a reporting member in the Grid, the **Go To History** link is displayed on this tab. You can click **Go To History** to view the *Threat Protection Event Count By Member/Member Group Trend* report on the **Reporting** tab. To navigate back to the Security dashboard from the **Reporting** tab, click **Back to Security Dashboard** at the top left corner of the navigation bar on the **Reporting** tab.

Events Over Time

The **Events Over Time** tab displays a line graph that tracks the event count for each event severity in a given time frame. You can view the event counts for the following severity level: Critical, Major, Warning, and Informational. The event statistics are cumulative, collected from all the members in the Grid that supports Infoblox Advanced DNS Protection and Infoblox Threat Insight. Each severity level is represented with a different color.
If you have configured a reporting member in the Grid, the **Go To History** link is displayed on this tab. You can click **Go To History** to view the *Threat Protection Event Count By Severity Trend* report on the **Reporting** tab. To navigate back to the Security dashboard from the **Reporting** tab, click **Back to Security Dashboard** at the top left corner of the navigation bar on the **Reporting** tab.

Top 10 Rules

The **Top 10 Rules** tab displays a horizontal bar chart that tracks the top threat protection rules that have the most number of hits. Each severity level is represented with a different color. The report displays the top 10 rules in descending order.
If you have configured a reporting member in the Grid, the **Go To History** link is displayed in this tab. You can click **Go To History** to view the *Threat Protection Top Rules Logged* report in the **Reporting** tab. To navigate back to the Security dashboard from the **Reporting** tab, click **Back to Security Dashboard** at the top left corner of the navigation bar on the **Reporting** tab.

Top 10 Clients

The **Top 10 Clients** tab displays a horizontal bar chart that tracks the total number of threat protections events triggered by top clients (source IP addresses). This tab displays the IP addresses of the top 10 clients. For NAT clients, it displays the NAT addresses for the clients.
If you have configured a Reporting member in the Grid, the **Go To History** link is displayed on this tab. You can click **Go To History** to view the *Threat Protection Top Rules Logged by Source* report on the **Reporting** tab. To navigate back to the Security dashboard from the **Reporting** tab, click **Back to Security Dashboard** at the top left corner of the navigation bar on the **Reporting** tab.

> **Note**
>
> The data displayed in this widget may not be consistent with the data displayed in the *Threat Protection Top Rules Logged by Source* report.

Threat Protection Status for Member

The *Threat Protection Status for Member* widget displays statistics about the threat protection events for a specific Grid member that supports Infoblox Advanced DNS Protection, hardware or Software ADP. For information about the threat protection feature, see *About Infoblox Advanced DNS Protection*.
To configure the *Threat Protection Status for Member* widget, click the Configure icon and complete the following:

- Click **Select Member**. In the *Member Selector* dialog box, select a Grid member from the list that supports Infoblox Advanced DNS Protection, hardware or Software ADP.
- Select either **Dial** or **Bar** as the display format for the following resources: **Smart NIC CPU**, **Traffic being dropped**, **Traffic being received**. Note that Smart NIC CPU selection is displayed only when you select a Grid member that supports Infoblox Advanced DNS Protection.
- **SNIC Settings**: Select the interface for which you want to view the interface usage information. You can select one of the following from the drop-down list: **HA**, **LAN1**, or **LAN2**. You can view the interface usage information for the selected interface in the **Interface Usage** tab. This is displayed only when you select a Grid member that supports Infoblox Advanced DNS Protection.
  Note that you can select the HA port even though the Grid member is not an HA pair, because the HA port on a single member can be exposed to potential attacks.
- **NIC Settings**: Select the interface for which you want to view the interface usage information. You can select one of the following from the drop-down list: HA, LAN1, or LAN2. You can view the interface usage information for the

selected interface in the Interface Usage (LAN1) tab. This is displayed only when you select a Grid member that supports Software ADP.
- **Events Over Time**: Select the severity level, **Critical**, **Major**, **Warning**, or **Informational**, to view the details for a specific severity level. You can select one or all the available severity levels.
- Select the **Auto Refresh Period** checkbox to turn on auto-refresh, and specify the auto-refresh period in seconds. The default is 30 seconds.

Warning

If the *Detailed Status panel* is open, the following actions take place:
- Grid Manager auto refreshes at a rate of 30 seconds.
- Widgets that support user-specified auto refresh, refresh at the rate specified in the **Auto Refresh Period** field.

Therefore, even if you set the session timeout to be to greater than the auto refresh rate, auto refresh still takes place. The Grid Manager session does not time out because auto refresh takes precedence over the session timeout.

Click the Configure icon again to hide the configuration panel after you complete the modification. You can do the following in this widget:

- Click the **Summary** tab to view the statistics for the following resources in the format you selected:
- **Smart NIC CPU**: The percentage of Smart NIC CPU that is in use. This is displayed only when you select a Grid member that supports Infoblox Advanced DNS Protection.
- **Traffic being dropped**: The percentage of traffic dropped. It is displayed for both LAN1 and LAN2 interfaces.
- **Traffic being received**: The percentage of traffic received. It is displayed for both LAN1 and LAN2 interfaces.
- Click the **Events Over Time** tab to view information about the threat protection event counts for each severity level over the given time frame. It displays line graphs that show the threat protection event counts for each event severity over the last 30 minutes. Each event severity is represented by a different color line graph. You can hover your mouse over the graph to view the coordinates of any point in the graph. You can also click the Events Over Time legend and use it as a filter to view the graph for specific severity level.
- Click the **Top 10 Rules** tab to view information about the threat protection rules that have the most number of hits. It displays a bar chart to track the top 10 threat protection rules with the most number of hits for critical, major, and warning severity levels. Each event severity is displayed in a different color.
  If you have configured a Reporting member in the Grid, the **Go To History** link is displayed on this tab. You can click **Go To History** to view the *Threat Protection Top Rules Logged* report on the **Reporting** tab. To navigate back to the Security dashboard from the **Reporting** tab, click **Back to Security Dashboard** at the top left corner of the navigation bar in the **Reporting** tab.
- Click the **Top 10 Clients** tab to view information about the top sources (client IP addresses) that triggered threat protection rules. It displays a bar chart to track the top 10 clients with the most number of hits.
  If you have configured a Reporting member in the Grid, the **Go To History** link is displayed on this tab. You can click **Go To History** to view the *Threat Protection Top Rules Logged by Source* report on the **Reporting** tab. To navigate back to the Security dashboard from the **Reporting** tab, click **Back to Security Dashboard** at the top left corner of the navigation bar on the **Reporting** tab.
- Click the **Interface Usage** tab to view information about the interface usage (in megabytes per second) over a given time frame. It displays line graphs that show the interface usage trends for the selected interface over the last 30 minutes. You can hover your mouse over the graph to view the coordinates of any point in the graph.
- Click the **Smart NIC CPU** tab to view the information about the percentage of CPU usage over a given time frame. It displays line graphs that show the CPU usage trends over the last 30 minutes. You can hover your mouse over the graph to view the coordinates of any point in the graph. This is displayed only when you select a Grid member that supports Infoblox Advanced DNS Protection.

Response Policy Zone (RPZ) Status for Grid

The *Response Policy Zone (RPZ) Status for Grid* widget provides statistical information about RPZ hits for the Grid. This widget contains the following tabs: **Top 10 Grid Members**, **RPZ Recent Hits**, **Trend** and **Health**.
You can do the following in this widget:

- Select a graph configuration, **Client Hits**, **Passthru Hits**, **Blocked Hits**, or **Substituted Hits**, to view details of a specific RPZ rule. You can select either one or all the available graph configurations. Note that **Client Hits** is displayed only when the graph type is **Line Diagram**.
- Select a graph type, **Stacked Diagram** or **Line Diagram**, to display data in the required diagrammatic format. This option is enabled only when you click the **Trend** tab and disabled when you click the **Top 10 Grid Members**, **RPZ Recent Hits**, or **Health** tabs. For more information, see Trend below.
- Click the **Top 10 Grid Members** tab to view information about the top 10 Grid members that have the most number of RPZ hits. For more information, see Top 10 Grid Members below.
- Click the **RPZ Recent Hits** tab to view information about the latest five RPZ hits with unique client addresses. For more information, see RPZ Recent Hits below.
- Click the **Trend** tab to view RPZ hit statistics for the Grid. For more information,
- see Trend below.
- Click the **Health** tab to view information about RPZ zones and their last updated times. For more information, see Health below.

Note that you must install the RPZ license and enable **RPZ logging** to access this widget. For more information about installing licenses and enabling RPZ logging, see *License Requirements and Admin Permissions* and *Using a Syslog Server.*

Top 10 Grid Members

The **Top 10 Grid Members** tab displays a stacked bar chart that tracks the top Grid members with the most total counts of RPZ hits. Each RPZ hit type is represented with a different color. The report displays the top 10 members in descending order.

RPZ Recent Hits

The **RPZ Recent Hits** tab displays the data that is collected from the most recent hits of five unique clients, identified by their IP addresses, during the last 24 hours. NIOS retrieves this data from the syslog. This tab does not display any data when there are no syslog messages or if RPZ logging is disabled. NIOS displays an error message if RPZ logging is disabled. For more information about enabling RPZ logging and *Setting DNS Logging Categories*, see *Using a Syslog Server.*
Grid Manager retrieves recent hits from the Grid members. If a member has an RPZ license installed, then NIOS will parse the syslog every 60 seconds to collect the data. NIOS parses the generated data to identify the five most recent hits. It searches for these fields in the syslog message: CEF: data string(RPZ syslog) and src fields.
The NIOS appliance remembers the start and end time of previously searched operations to optimize the recent hits data collection, so that the same data is not searched again. Note that when the same client makes repeated queries in the last 24 hours, then there might be less than five unique client hits. You cannot sort or filter values on this tab.
This tab displays the following information:

- **Client IP Address**: IP address of the client that made the recent hits.
- **Requested FQDN**: The domain name or IP address that triggered the RPZ rule. For example, consider an RPZ rule test.com.rpz.com, which queries for test.com. In this example, test.com is the requested FQDN.
- **RPZ Entry**: The RPZ rule that queried a domain name or an IP address. In the above example, *test.com.rpz.com* is the RPZ rule.
- **Timestamp**: The date and time when the hit occurred.

Consider an example in which you query an RPZ zone and the NIOS appliance logs the following message in the syslog:

```
CEF:0|Infoblox|NIOS|6.9.0-219291|RPZ-QNAME|NODATA|4|app=DNS dst=10.35.101.14
src=10.36.0.251 spt=44460 view=_default qtype=A msg="rpz QNAME NODATA
rewrite w18.vg \[A\] via w18.vg.fireeye.com"
```

This tab displays information in the corresponding fields as follows:

Fields	Description
Client IP Address	Data is retrieved from the src field. Example: `10.36.0.251`
Requested FQDN	It is retrieved from the data between the `rewrite` and `[A] via` fields. Example: *`w18.vg`*.
RPZ Entry	It is retrieved from the data after the `via` in `msg` field. Example: *`w18.vg.fireeye.com`*
Timestamp	This is listed in the syslog.

You can export data displayed in this tab by clicking the *Export* icon. For more information about exporting displaying data, see *Importing and Exporting Data using CSV Import*.

Trend

The **Trend** tab displays statistics of RPZ hits during the last 60 minutes for the Grid. You can use a stacked graph or a line graph to view the hits. Each of the RPZ policy is represented with a different color. This tab displays the following information:

- **Client Hits**: Total number of queries that triggered an RPZ policy. Note that this option is not displayed when you choose **Stacked Diagram**, but displayed only when you choose **Line Diagram**.
- **Passthru** Hits: Total number of queries that triggered a **Passthru RPZ** rule. For more information about passthru rules, see *Configuring Rules for RPZs*.
- **Blocked Hits:** Total number of queries that triggered a **Block (No Data)** or **Block (No Suc hDomain)** RPZ rule. For more information about Managing Block (No Data) Rules or Managing Block (No Such Domain) Rules , see *Configuring Rules for RPZs*.
- **Substitute Hits**: Total number of queries that triggered a **Substitute (Domain Name)** or **Substitute (Record)** RPZ rule. For more information, see *Managing Substitute (Domain Name) Rules* and *Managing Substitute (Record) Rules*.
- **Timestamp**: The graph displays a 24 hours time window. Note the following about this tab:
- The statistical data in DNS service will be reset when you stop and restart the DNS service or if you force an active DNS service to restart regardless of its state. This results in loss of prior data.
- Using this graph, you can view the timestamp of statistics collection.

Health

The **Health** tab displays information of RPZ zones and their last updated date and time. This data is retrieved directly from the database. Note that you cannot sort or filter values on this tab. You can export the data displayed on this tab by clicking the *Export* icon. For more information, see *Exporting Displayed Data*.

Response Policy Zone (RPZ) Status for Member

The *Response Policy Zone (RPZ) Status for Member* widget provides statistical information about RPZ hits for the selected member. This widget contains the following tabs: **RPZ Recent Hits**, **Trend**, and **Health**.
You can do the following in this widget:

- Click **Select Member**. In the *Member Selector* dialog box, choose a Grid member to view the RPZ hits, or statistics, or RPZ zones and their last updated date and time.
- Select a graph configuration, **ClientHits**, **Passthru Hits**, **Blocked Hits**, or **Substituted Hits**, to view details of a specific RPZ rule. You can select either one or all the available graph configurations. Note that **Client Hits** is displayed only when the graph type is **Line Diagram**.

- Select a graph type, **Stacked Diagram** or **Line Diagram**, to display data in the required diagrammatic format. This option is enabled only when you click the **Trend** tab and disabled when you click the **Top 10 Grid Members**, **RPZ Recent Hits**, or **Health** tabs. For more information, see Trend below.
- Click **View Syslog** to view the last 20 RPZ events that are logged in the syslog. For more information, see Previewing the Syslog below.
- Click the **RPZ Recent Hits** tab to view information about the latest five RPZ hits with unique client addresses. For more information, see RPZ Recent Hits below.
- Click the **Trend** tab to view RPZ hit statistics on the selected member. For more information, see Trend below.
- Click the **Health** tab to view information about RPZ zones and their last updated times. For more information, see Health below.

Note that you must install the RPZ license and enable **RPZ logging** to access this widget. For more information about installing licenses and enabling RPZ logging, see *License Requirements and Admin Permissions* and *Setting DNS Logging Categories*.

RPZ Recent Hits

The **RPZ Recent Hits** tab displays the data that is collected from the most recent hits of five unique clients, identified by their IP addresses, during the last 24 hours. NIOS retrieves this data from the syslog. This tab does not display any data when there are no syslog messages or if RPZ logging is disabled. NIOS displays an error message if RPZ logging is disabled. For more information about enabling RPZ logging, see *Setting DNS Logging Categories*.
Grid Manager retrieves recent hits from the selected member. If a member has an RPZ license installed, then NIOS will parse the syslog every 60 seconds to collect the data. NIOS parses the generated data to identify the five most recent hits. It searches for these fields in the syslog message: CEF: data string(RPZ syslog) and src fields.
The NIOS appliance remembers the start and end time of previously searched operations to optimize the recent hits data collection, so that the same data is not searched again. Note that when the same client makes repeated queries in the last 24 hours, then there might be less than five unique client hits. You cannot sort or filter values on this tab.
This tab displays the following information:

- **Client IP Address**: IP address of the client that made the recent hits.
- **Requested FQDN**: The domain name or IP address that triggered the RPZ rule. For example, consider an RPZ rule *test.com.rpz.com*, which queries for *test.com*. In this example, *test.com* is the requested FQDN.
- **RPZ Entry**: The RPZ rule that queried a domain name or an IP address. In the above example, *test.com.rpz.com* is the RPZ rule.
- **Timestamp**: The date and time when the hit occurred.

Consider an example in which you query an RPZ zone and the NIOS appliance logs the following message in the syslog:

```
CEF:0|Infoblox|NIOS|6.9.0-219291|RPZ-QNAME|NODATA|4|app=DNS dst=10.35.101.14
src=10.36.0.251 spt=44460 view=_default qtype=A msg="rpz QNAME NODATA
rewrite w18.vg \[A\] via w18.vg.fireeye.com"
```

This tab displays information in the corresponding fields as follows:

Fields	Description
Client IP Address	Data is retrieved from the src field. Example: `10.36.0.251`
Requested FQDN	It is retrieved from the data between the `rewrite` and `[A] via` fields. Example: *`w18.vg.`*

Fields	Description
RPZ Entry	It is retrieved from the data after the `via` in `msg` field. Example: `w18.vg.fireeye.com`
Timestamp	This is listed in the syslog.

Trend

The **Trend** tab displays statistics of RPZ hits on the selected member during the last 60 minutes. You can use a stacked graph or a line graph to view the hits. DNS service generates RPZ statistics for the selected member. Each of the RPZ policy is represented with a different color. This tab displays the following information:

- **Client Hits:** Total number of queries that triggered an RPZ policy. Note that this option is not displayed when you choose **Stacked Diagram**, but displayed only when you choose **Line Diagram**.
- **Passthru Hits**: Total number of queries that triggered a **Passthru** RPZ rule. For more information about passthru rules, see *Managing Passthru Rules*.
- **Blocked Hits:** Total number of queries that triggered a **Block (No Data)** or **Block (No Such Domain)** RPZ rule. For more information, see *Managing Block (No Data) Rules* or *Managing Block (No Such Domain) Rules* respectively.
- **Substituted Hits**: Total number of queries that triggered a **Substitute (Domain Name)** or **Substitute (Record)** RPZ rule. For more information, see *Managing Substitute (Domain Name) Rules* and *Managing Substitute (Record) Rules*.
- **Timestamp**: The graph displays a 24 hours time window.
  Note the following about this tab:
- The statistical data in DNS service will be reset when you stop and restart the DNS service or if you force an active DNS service to restart regardless of its state. This results in loss of prior data.
- Using this graph, you can view the timestamp of statistics collection.

Health

The **Health** tab displays information of RPZ zones on the selected member and their last updated date and time. This data is retrieved directly from the database. Note that you cannot sort or filter values on this tab. You can export the data displayed on this tab by clicking the *Export* icon.

Previewing the Syslog

You can view the RPZ events that are logged in the syslog for a selected Grid member. Note that the preview displays only the last 20 RPZ events from the syslog. This wizard displays the following information:

- **Timestamp**: The date and time when the hit occurred.
- **Facility**: The location on the syslog server sorting the log message.
- **Level**: The severity of the message. This can be **ALERT**, **CRITICAL**, **DEBUG**, **EMERGENCY**, **ERROR**, **INFO**, **NOTICE**, or **WARNING**.
- **Server**: The name of the server that logged this message, plus the process ID.
- **Message**: Detailed information about the RPZ query. You can click the **Go to Syslog Viewer** link to view the RPZ events that are logged in the syslog. NIOS displays all the RPZ events that are logged in the syslog for the selected member and the **Quick Filter** is set to **RPZ Incident Logs** by default. For more information, see

Tenant & VMs

The *Tenant & VMs* tab displays a table that shows the total number of **Tenants**, **Cloud VMs**, and **IP Addresses**, depending on your configuration. It also displays the average number of cloud VMs and IP addresses per tenant.

Fixed vs. Floating

The *Fixed vs. Floating* tab displays IP address allocation for cloud objects. It displays the total number of fixed address allocation and floating address allocation, depending on your configuration. It also displays a pie chart indicating the percentage for each allocation.

Available vs. Allocated

The *Available vs. Allocated* tab displays IP address allocation for available versus allocated IP addresses. It displays the total number of available IP addresses versus allocated IP addresses, depending on your configuration. It also displays a pie chart indicating the percentage for each allocation.

Threat Analytics Status for Grid

The *Threat Analytics Status for Grid* widget displays the statistical information about the DNS tunneling events. This widget contains the following tabs: *Detections Over Time*, *Top 10 Grid Members*, and *Detections*.
You can do the following in this widget:

> **Warning**
>
> If the *Detailed Status panel* is open, the following actions take place:
> - Grid Manager auto refreshes at a rate of 30 seconds.
> - Widgets that support user-specified auto refresh, refresh at the rate specified in the **Auto Refresh Period** field.
>
> Therefore, even if you set the session timeout to be to greater than the auto refresh rate, auto refresh still takes place. The Grid Manager session does not time out because auto refresh takes precedence over the session timeout. For more information about widgets, see *Status Dashboard*.

- Turn on auto-refresh.
  Click the Configure icon, select the **AutoRefreshPeriod** checkbox, and specify the refresh period in seconds. The default auto refresh period is 30 seconds. Click the Configure icon again to hide the configuration panel after you complete the modification.
- Click the *Detections Over Time* tab to view information about the detected DNS tunneling events in a given time frame.
- Click the *Top 10 Grid Members* tab to view information about the top 10 Grid members with the most total counts of detections by type.
- Click the *Detections* tab to view information about all the detected DNS tunneling events.

Detections Over Time

The **Detections Over Time** tab displays a line graph that tracks the number of detected DNS tunneling events over the given time frame. You can hover your mouse over the graph to view the coordinates of any point in the graph.

Top 10 Grid Members

The **Top 10 Grid Members** tab displays a stacked bar chart that tracks the top Grid members with the most total counts of detected DNS tunneling events by type. The report displays the top 10 Grid members in descending order.

Detections

The **Detections** tab displays information about all the detected DNS tunneling events. This tab displays the following information about each detection in table format:

- **Client IP Address**: The IP address of the client.
- **Domain**: The domain name of the client.
- **Timestamp**: The timestamp when the event occurred.

- **Module**: Displays the threat analytics module.

Threat Analytics Status for Member

The *Threat Analytics Status for Member* widget displays statistics about the DNS tunneling events for a specific Grid member.
To configure the *Threat Analytics Status for Member* widget, click the Configure icon and complete the following:

> **Warning**
>
> If the *Detailed Status panel* is open, the following actions take place:
> - Grid Manager auto refreshes at a rate of 30 seconds.
> - Widgets that support user-specified auto refresh, refresh at the rate specified in the **Auto Refresh Period** field.
>
> Therefore, even if you set the session timeout to be to greater than the auto refresh rate, auto refresh still takes place. The Grid Manager session does not time out because auto refresh takes precedence over the session timeout. For more information about widgets, see *Status Dashboard*.

- Click **Select Member** to select a Grid member. If there are multiple members, the *MemberSelector* dialog box is displayed, from which you can select a member. Click the required member name in the dialog box. You can also click **Clear** to clear the displayed member and select a new one.
- Select the **Auto Refresh Period** checkbox to turn on auto-refresh, and specify the auto-refresh period in seconds. The default is 30 seconds.

Click the Configure icon again to hide the configuration panel after you complete the modification.

You can do the following in this widget:

- Click the **Detections Over Time** tab to view information about the DNS tunneling event count for the selected Grid member in a given time frame. It displays a line graph that tracks the number of DNS tunneling event detections in a given time frame. You can hover your mouse over the graph to view the coordinates of any point in the graph.
- Click the **Detections** tab to view information about all the detected DNS tunneling events. This tab displays the following information in table format:
  - **Client IP Address**: The IP address of the client.
  - **Domain**: The domain name of the client.
  - **Timestamp**: The timestamp when the event occurred.
  - **Module**: Displays the threat analytics module. This tab displays only the last 15 detections.

Pool Licenses Statistics

The *Pool Licenses Statistics* widget displays information about pool license allocation in your Grid. Pool licenses are dynamic service and feature licenses, such as vNIOS, DNS, DHCP, and Cloud Platform that you purchase for vNIOS and cloud deployments based on your evolving business needs. The Grid Master keeps track of dynamic licenses that are allocated to vNIOS members and adjusts the total number of available dynamic licenses for each feature and service. In the widget, you can select the license type and Grid Manager displays the total numbers of assigned and available licenses based on the selected license type.
To configure the *Pool Licenses Statistics* widget, click the Configure icon and complete the following:

- **Show Usage for**: From the drop-down list, select a license type for which you want the appliance to display dynamic license usage.

The widget displays license usage and the numbers of assigned and available licenses.
You can also view the total number of dynamic licenses installed for each feature and service, the number of active and available licenses, their usage, and other related information on the Grid tab -> Licenses tab -> Pool tab of Grid Manager. For information about how to view dynamic licenses, see *Managing Licenses*.

DNS Record Scavenging

The DNS Record Scavenging dashboard widget displays statistics about the scavenging of stale DNS records. The widget displays the following information for the current or last known scavenging activities:

- **Status**: The status of the scavenging operation.
- **Start**: The start time of the scavenging operation.
- **End**: The end time of the scavenging operation.
- **User**: The user who initiated the scavenging operation.
- **Selected Object**: The Grid, view, or zone affected by record scavenging.
- **Action**: The action applied to the scavenging operation.
- **Processed Records**: The number of DNS records processed.
- **Reclaimable Records**: The number of DNS records marked as reclaimable.
- **Reclaimed Records**: The number of DNS records removed during the scavenging operation.

Click an icon on the filter panel, as illustrated in the Figure 2.2, to add a widget to the desired dashboard. Filter panel is categorized in to the following: Cloud , Security , DNS/DHCP , and Reset . When you click on an icon, Grid Manager displays thumbnails of the widgets belonging to the respective filter. If you click filters one after the other without clicking Reset, Grid Manager displays thumbnails of all widgets along with the icon that indicates the category to which the widget belongs. Click Reset to view only those widgets that belong to the selected category.

IPAM Task Pack

The IPAM task pack contains the following tasks:

- Add Networks
- Add Hosts
- Add Fixed Addresses
- Add A Record
- Add CNAME Record
- Add TXT Record
- Add MX Record
- CSV Import

Depending on your administrative permissions and the Dashboard template configuration, Grid Manager displays tasks you can access in specific task packs. You can configure your task packs by adding or hiding certain tasks. For information about Dashboard templates, see *Configuring Dashboard Templates*.

To hide tasks in a task pack:

1. Click the Configure icon at the upper right corner of the task pack.
2. In the configuration panel, select the tasks you want to hide from the Active Tasks table. You can use SHIFT+click and CTRL+click to select multiple tasks.
3. Click the left arrow to move the selected tasks to the Available Tasks table.

Click the Configuration icon again to hide the configuration panel after you complete the modification.

Required Licenses for IPAM Tasks

The below Required Licenses for IPAM Tasks table lists the required licenses for viewing and performing IPAM tasks on the Tasks Dashboard.
Required Licenses for IPAM Tasks

Task	Required Licenses
Add Networks	DHCP or MSMGMT license
Add Hosts	DNS or DHCP license

Task	Required Licenses
Add Fixed Addresses	DHCP or MSMGMT license
Add A Record	DNS or MSMGMT license
Add CNAME Record	DNS or MSMGMT license
Add TXT Record	DNS or MSMGMT license
Add MX Record	DNS or MSMGMT license

For information about how to install licenses, see *Managing Licenses*.

Add Networks

You can create IPv4 and IPv6 networks from the Tasks Dashboard (either from scratch or from a network template that contains predefined properties). You can also create networks from the **Data Management** tab. For more information about IPv4 and IPv6 networks, see *Configuring IPv4 Networks* and *Configuring IPv6 Networks*.

To add networks from the Tasks Dashboard:

1. Click **Add Networks** in the IPAM task pack and complete the following in the *Add Networks* wizard:
    - **Regional Internet Registry**: This section appears only when support for RIR updates is enabled. For information about RIR, see *RIR Registration Updates*. Complete the following to create an RIR IPv4 network container or network:
        - **Internet Registry**: Select the RIR from the drop-down list. The default is **RIPE**. When you select **None**, the network is not associated with an RIR organization.
        - **Organization ID**: Click **Select Organization** and select an organization from the *RIR Organization Selector* dialog box.
        - **Registration Status**: The default is **Not Registered**. When adding an RIR allocated network, you can change this to **Registered** and select the **Do not update registrations** checkbox below. Note that when you select **API** as the communication method, the registration status will be updated automatically after the registration update is completed. However, when you select **Email** as the communication method, the registration status will not be automatically updated. If you are creating a new network and the registration update is completed successfully, the status will be changed to **Registered**. If the update fails, the status will be changed to **Not Registered**. The updated status and timestamp are displayed in the **Status of last update** field in the *IPv4 /IPv6 Network Container* or *IPv4/IPV6 Network* editor.
        - **Registration Action**: Select the registration action from the drop-down list. When you select **Create**, the appliance creates the IPv4 or IPv6 network and assigns it to the selected organization. When you select **None**, the appliance does not send registration updates to RIPE. When you are adding an existing RIR allocated network to NIOS, select **None**. When you are adding networks to an RIR allocated network (a parent network), select **Create**. Ensure that the parent network associated with an RIR organization already exists.
        - **Do not update registrations**: Select this checkbox if you do not want the appliance to submit RIR updates to RIPE. By default, the appliance sends updates to the RIR database based on the configured communication method.
    - **Network View**: This appears only when you have multiple network views. From the drop-down list, select the network view in which you want to create the network.
    - **Protocol**: Select **IPv4** to add IPv4 networks and **IPv6** to add IPv6 networks.
    - **Netmask**: Enter the netmask or use the netmask slider to select the appropriate number of subnet mask bits for the network.
    - **Template**: Click **Select Template** to select a network template. When you use a template to create a network, the configuration of the template applies to the new network. If the template specifies a fixed

netmask, you cannot edit the netmask in this dialog. You can click **Clear** to remove the template. For information about templates, see *About IPv6 Network Templates*.

- **Use Active Directory Sites:** This checkbox is displayed only if you install the Microsoft license. Click the Add icon to associate multiple Active Directory Sites with the network. When you click Add, the appliance displays the following:
  - **Active Directory Domain**: The Active Directory Domains that are synchronized from the Microsoft server.
    Click an Active Directory Domain that you want to associate.
    To search for a particular Active Directory Domain, specify the respective name and click **Go**. If there are multiple Active Directory Domains, the appliance displays the list of such domains by paging to the next page. You can use the page navigation buttons that are displayed at the bottom of this column to navigate through the Active Directory Domains. You can also refresh the values in the column using the Refresh icon.
  - **Active Directory Site**: The Active Directory Sites that are associated with the selected Active Directory Domain. Click an Active Directory Site that you want to associate with the network.
    To search for a particular Active Directory Site, specify the respective name and click **Go**. If there are multiple Active Directory Sites, the appliance displays the list of such sites by paging to the next page. You can use the page navigation buttons that are displayed at the bottom of this column to navigate through the Active Directory Sites. You can also refresh the values in the column using the Refresh icon.
  - Click **Add** to add the selected Active Directory Sites to the network or click **Cancel** to cancel the operation. The appliance displays these domains and sites in the respective columns. Click the x icon if you want to close the Active Directory Domains and Sites selector.
  - Click the Delete icon to delete Active Directory Sites that are associated with the network.

For more information about Active Directory Domains and Sites, see *Configuring Active Directory Sites and Services*.

NIOS may execute discovery on the newly created network after you save your settings. When you create a network in NIOS, it inherits its discovery capabilities (whether or not it is immediately discovered, its polling settings, and any possible exclusions from discovery), from its parent network (if it has one) or its network container. If the new network is a parent network, it inherits its polling settings from the Grid and its discovery member selection and Enable Discovery action must be defined by the user.

- **Networks**: Do one of the following to add new networks:
  Click the Add icon to create a new network.
  - For IPv4 networks: Grid Manager adds a row to the table. Enter the network address in the **Network** field. Click the Add icon to add another network. You can also select a network and click the Delete icon to delete it.
  - For IPv6 networks: If you are adding a network for a previously defined global IPv6 prefix, you can select the prefix from the **IPv6 Prefix** drop-down list. The default is **None**, which means that you are not creating an IPv6 network for a previously defined subnet route. If you have defined a global prefix at the Grid level, the default is the global prefix value. Click **Add** and Grid Manager adds a row to the table. Enter the network address in the **Network** field. When you enter an IPv6 address, you can use double colons to compress a contiguous sequence of zeros. You can also omit any leading zeros in a four-hexadecimal group. For example, the complete IPv6 address 2001:0db8:0000:0000:0000:0000:0102:0304 can be shortened to 2001:db8::0102:0304. Note that if there are multiple noncontiguous groups of zeros, the double colon can only be used for one group to avoid ambiguity. The appliance displays an IPv6 address in its shortened form, regardless of its form when it was entered. Click **Add** again to add another network. You can also select a network and click the Delete icon to delete it.
    or
    Click the Next Available icon to have the appliance search for the next available network. For more information about the next available network, see *Configuring the Next Available Network or IP Address*. Complete the following in the Next Available Networks section:
  - **Create new network(s) under**: Enter the network container in which you want to create the new network. When you enter a network that does not exist, the appliance adds it as a network container. When you enter a network that is part of a parent network, the parent network is converted into a network container if it does not have a member assignment or does not contain address ranges, fixed addresses, reservations, shared networks, and host records that are served by DHCP. When you enter a network that has a lower CIDR than an existing network, the appliance creates the network as a parent network and

displays a message indicating that the newly created network overlaps an existing network. You can also click **Select Network** to select a specific network in the *Network Selector* dialog box. For information about how the appliance searches for the next available network, see *Configuring the Next Available Network or IP Address*.

- **Number of new networks**: Enter the number of networks you want to add to the selected network container. Note that if there is not enough network space in the selected network to create the number of networks specified here, Grid Manager displays an error message. The maximum number is 20 at a time. Note that when you have existing networks in the table and you select one, the number you enter here includes the selected network.
    - Click **Add Next** to add the networks. Grid Manager lists the networks in the table. You can click **Cancel** to reset the values.

Note that you must click Add Next to add the network container you enter in the Next Available Networks section. If you enter a network in the Next Available Networks section and then use the Add icon to add another network, the appliance does not save the network you enter in the Next Available Networks section until you click Add Next.

- **Extensible Attributes**: Click the Add icon to enter extensible attributes. Grid Manager adds a row to the table each time you click the Add icon. Select the row and the attribute name from the drop-down list, and then enter the value. All inheritance attributes which can be inherited from a parent object will be automatically inherited when you add a network. Inheritable extensible attributes that are required are automatically displayed. Optional extensible attributes that are not inheritable are not automatically displayed. For more information about extensible attributes, see *Managing Extensible Attributes*.
- If you are adding an RIR network, the RIR network attribute table appears. For information about these attributes and how to enter them, see *Managing RIR Attributes*.
  Preview RIR Submissions: Click this to view the updates before the appliance submits them to the RIPE database. This button is enabled only when the registration action is **Create**, **Modify**, or **Delete**, and the **Do not update registrations** checkbox is not selected.

2. Save the configuration.
or

Click the **Schedule** icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, click **Later** and enter a date, time, and time zone. For information, see *Managing Extensible Attributes*.

The appliance saves the networks you just created, and Grid Manager displays them in the Result page. When you click a newly created network on this page, Grid Manager displays the **IP Map** panel from which you can view detailed information about the network. For information about the IP Map panel, see *Viewing and Managing IPv4 Addresses*.

You can also add and modify other information about the networks you just created. For information about modifying network information, see *Managing IPv4 DHCP Data* and *Managing IPv6 DHCP Data*.

Add Hosts

Host records provide a unique approach to the management of DNS, DHCP, and IPAM data. By using host records, you can manage multiple DNS records and DHCP and IPAM data collectively, as one object on the appliance. You can add IPv4 and IPv6 addresses to host records from the Tasks Dashboard or the **Data Management** tab. Note that when you add a host record from the Tasks Dashboard, they are configured only for DNS. For more information about Infoblox host records, see *About Host Records*.

To add host records from the Tasks Dashboard:

1. Click **Add Hosts** in the IPAM Task Pack and complete the following in the *Add Hosts* wizard:
    - **Network View**: This appears only when you have multiple network views. From the drop-down list, select the network view in which you want to create the host record.
    - **Zone Name**: Click **Select** to select a DNS zone from the *Zone Selector* dialog box.
    - **Exclude from Network Discovery** and **Immediate Discovery**. When creating the new Host record, you can direct NIOS to immediately discover the host, or to exclude it from network discovery. By default, the Add Hosts task enables immediate discovery.
    - **DNS View**: Displays the DNS view of the selected zone.
    - **Hosts**: Do one of the following to add a host record:

Click the Add icon and the appliance adds a row to the table. Complete the following in the table to add a new host record:

- **Name**: Enter the name of the host record.
- **Zone**: Displays the DNS zone you select in **Zone Name**. When you enter a different zone here, the appliance displays an error message.
- **Address**: Enter the IP address you want to associate with this host record.

  or

  Click the Next Available icon to have the appliance search for the next available IP address for the host record. For information about the next available IP address, see *Configuring the Next Available Network or IP Address*. Complete the following in the Next Available IP section:

- **Create new host addresses under**: Click **Select** to select the network or address range in the *Network/Range Selector* dialog box from which you want the appliance to search for the next available IP address for this host record.
- **Number of new host addresses**: Enter the number of host addresses. Note that if there is not enough space in the selected network or address range to create the number of host addresses specified here, Grid Manager displays an error message. The maximum number is 20 at a time. Note that when you have existing host addresses in the table and you select one, the number you enter here includes the selected host address.
- Click **Add Next** to add the IP addresses to their corresponding hosts. Grid Manager lists the host addresses in the table. Ensure that you enter a name for each host record.
- **Extensible Attributes**
  - **Apply to all above hosts**: Select this to associate extensible attributes with all hosts that you have defined. This is selected by default. You can define and associate multiple extensible attributes with multiple hosts at once.
  - **Apply to selected host**: Select this to associate extensible attributes with the selected host only. Note that when you select this option for another host in the list, the **Extensible Attributes table** is refreshed for you to associate a different set of extensible attributes with the selected host.
  - **Extensible Attributes table:** Click the Add icon to enter extensible attributes. The appliance adds a row to the table each time you click the Add icon. Select the row and the attribute name from the drop-down list, and then enter the value. All inheritance attributes which can be inherited from a parent object will be automatically inherited when you add a host. Inheritable extensible attributes that are required are automatically displayed. Optional extensible attributes that are not inheritable are not automatically displayed. For more information about extensible attributes, see *Managing Extensible Attributes*.

2. Save the configuration. or

Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, click **Later** and enter a date, time, and time zone. For information about how to schedule a task, see *Scheduling Tasks*.

The appliance saves the host records you just created, and Grid Manager displays them in the Result page. When you click a newly created host on this page, Grid Manager displays the **Data Management** -> **DNS** -> **Zones** tab from which you can view information about the host record.

You can also add and modify other information about the host records. For information about modifying host information, see *About Host Records*.

Add Fixed Addresses

You can add IPv4 and IPv6 fixed addresses from the Tasks Dashboard or from the **Data Management** tab. For more information about fixed addresses, see *Configuring IPv4 Fixed Addresses* and *Configuring IPv6 Fixed Addresses*.

To add fixed addresses from the Tasks Dashboard:

1. Click **Add Fixed Addresses** in the IPAM task pack and complete the following in the *Add Fixed Addresses* wizard:
   - **Network View**: This appears only when you have multiple network views. From the drop-down list, select the network view in which you want to create the fixed address.
   - **Protocol**: Select **IPv4** to add IPv4 addresses and **IPv6** to add IPv6 addresses.

- **Template**: Click **Select Template** to select a fixed address template. When you use a template to create a fixed address, the configuration of the template applies to the new fixed address. You can also click **Clear** to remove the template. For information about templates, see *Managing DHCP Templates*.
- **Exclude from Network Discovery** and **Immediate Discovery**. When creating the new fixed address, you can direct NIOS to immediately discover the device associated with the fixed address, or to exclude it from network discovery. By default, the Add Fixed Addresses task enables immediate discovery.
- **Addresses**: Do one of the following to add fixed addresses:

Click the Add icon and Grid Manager adds a row to the table. Complete the following to create fixed addresses:

- For IPv4 fixed addresses: Enter the IPv4 address and MAC address. Click the Add icon to add another fixed address.
- For IPv6 fixed addresses: Enter the IPv6 address and DUID. Click the Add icon again to add another fixed address.

or
Click the Next Available icon to have the appliance search for the next available address. Complete the following:

- **Create new fixed addresses under**: Click **Select** to select the network or address range in the *Network/Range Selector* dialog box from which you want the appliance to search for the next available IP address for this fixed address.
- **Number of new fixed addresses**: Enter the number of fixed addresses you want to add to the selected network or address range. Note that if there is not enough space in the selected network or address range to create the number of fixed addresses specified here, Grid Manager displays an error message. The maximum number is 20 at a time. Note that when you have existing fixed addresses in the table and you select one, the number you enter here includes the selected fixed address.
- Click **Add Next** to add the fixed addresses. The appliance lists the fixed addresses to the table. Ensure that you enter the MAC address or DUID for each fixed address.
- **Extensible Attributes** table: Click the Add icon to enter extensible attributes. The appliance adds a row to the table each time you click the Add icon. Select the row and the attribute name from the drop-down list, and then enter the value. All inheritance attributes which can be inherited from a parent object will be automatically inherited when you add a fixed address. Inheritable extensible attributes that are required are automatically displayed. Optional extensible attributes that are not inheritable are not automatically displayed. For more information about extensible attributes, see *Managing Extensible Attributes*.

2. Save the configuration.
or

Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, click **Later** and enter a date, time, and time zone. For information, see *Scheduling Tasks*.

The appliance saves the fixed addresses you just created, and Grid Manager displays them in the Result page. When you click a newly created fixed address on this page, Grid Manager displays the **Data Management** -> **IPAM** -> **IP Map** or **List** tab from which you can view information about the fixed address.

You can also add and modify other information about the fixed addresses you just created. For more information about modifying fixed address information, see *Managing IPv4 DHCP Data* and *Managing IPv6 DHCP Data*.

Add A Record

An A (address) record is a DNS resource record that maps a domain name to an IPv4 address. You can add an A record from the Tasks Dashboard or from the **Data Management** tab. For more information about managing A records, see *Managing Resource Records*.

To add networks from the Tasks Dashboard:

1. Click **Add A Record** in the IPAM task pack and complete the following in the *Add A Record* wizard:
2. In the *Add A Record* wizard, do the following:
    - **Name**: If Grid Manager displays a zone name, enter the hostname that you want to map to an IP address. The displayed zone name can either be the last selected zone or the zone from which you are adding the host record. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click a zone name

in the dialog box and then enter the hostname. The name you enter is prefixed to the DNS zone name that is displayed, and the complete name becomes the FQDN (fully qualified domain name) of the host. For example, if the zone name displayed is corpxyz.com and you enter admin, then the FQDN becomes admin.corpxyz.com. Ensure that the domain name you enter complies with the hostname restriction policy defined for the zone. To create a wildcard A record, enter an asterisk * in this field.

- **DNS View**: This field displays the DNS view to which the DNS zone belongs.
- **Shared Record Group**: This field appears only when you are creating a shared record from the **Data Management** tab. Click **Select Shared Record Group**. If you have only one shared record group, the appliance displays the name of the shared record group here. If you have multiple shared record groups, select the shared record group in the *Shared Record Group Selector* dialog box. You can use filters or the **Go to** function to narrow down the list.
- **Hostname Policy**: Displays the hostname policy of the zone.
- In the **IP Addresses** section, click the Add icon and do one of the following:
    - Select **Add Address** to enter the IPv4 address to which you want the domain name to map.
      or
    - Select **Next Available IPv4** to retrieve the next available IP address in a network.
      If the A record is in zone that has associated networks, the *Network Selector* dialog box lists the associated networks. If the zone has no network associations, the *Network Selector* dialog box lists the available networks. When you select a network, Grid Manager retrieves the next available IP address in that network.
    - **Comment**: Optionally, enter additional information about the A record.
    - **Create associated PTR record:** Select this option to automatically generate a PTR record that maps the specified IP address to the hostname. To create the PTR record, the reverse-mapping zone must be in the database.
    - **Disable**: Select this checkbox to disable the record. Clear the checkbox to enable it.

3. Click **Next** to define extensible attributes. For information, see *Managing Extensible Attributes*.
4. Save the configuration or click the Schedule icon at the top of the wizard to schedule this task. For information about how to schedule a task, see *Scheduling Tasks*.
5. Click **Restart** if it appears at the top of the screen.

Add CNAME Record

A CNAME record maps an alias to a canonical name. You can use CNAME records in both IPv4 forward- and IPv4 reverse-mapping zones to serve two different purposes. (At this time, you cannot use CNAME records with IPv6 reverse-mapping zones.) For more information about CNAME records, see *Managing CNAME Records*.

To add a CNAME record from the Tasks Dashboard:

1. Click **Add CNAME Record** in the IPAM task pack and complete the following in the *Add CNAME Record* wizard:

- **Network View**: This appears only when you have multiple network views. From the drop-down list, select the network view in which you want to create the CNAME record.
- **Alias**: Click **Select Zone** to select a DNS zone from the *Zone Selector* dialog box. If you have only one zone, Grid Manager displays the zone name here when you click **Select Zone**. Enter the alias for the canonical name. For an IPv4 reverse-mapping zone, enter the host portion of an IP address. For example, if the full IP address is 10.1.1.1 in a network with a 25-bit netmask, enter 1. (The 10.1.1.0/25 network contains host addresses from 10.1.1.1 to 10.1.1.126. The network address is 10.1.1.0, and the broadcast address is 10.1.1.127.)
- **DNS View**: Displays the DNS view of the selected zone.
- **Shared Record Group**: This field appears only when you are creating a shared record from the **Data Management** tab. Click **Select Shared Record Group**. If you have only one shared record group, the appliance displays the name of the shared record group here. If you have multiple shared record groups, select the shared record group in the *Shared Record Group Selector* dialog box. You can use filters or the **Go to** function to narrow down the list.
- **Canonical Name:** This field displays the domain name of either the current zone or the last selected zone. To add a CNAME record to a forward-mapping zone, enter the complete canonical (or official) name of the host. To add a CNAME record to a reverse-mapping zone, enter *host_ip_addr.prefix.network* **.in-addr.arpa** (host IP address + 2317 prefix + network IP address + in-addr.arpa). For example, enter 1.0.25.1.1.10.in-addr.arpa. This IP address must match the address defined in the PTR record in the delegated child zone.
- **Comments:** Enter useful information about this record.

- **Disable:** Select the checkbox to disable the record without deleting its configuration. Clear the checkbox to enable the record.

2. Save the configuration, or click **Next** to define extensible attributes. For information about extensible attributes, see *Managing Extensible Attributes*.
or
3. Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, click **Later** and enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Click **Restart** if it appears at the top of the screen.

Add TXT Record

A TXT (text record) record contains supplemental information for a host. For example, if you have a sales server that serves only North America, you can create a text record stating this fact. You can create more than one text record for a domain name. You can add a TXT record from the Tasks Dashboard or the **Data Management** tab. For more information about TXT records, see *Managing TXT Records*.

To add TXT records from the Tasks Dashboard:

1. Click **Add TXT Record** in the IPAM task pack and complete the following in the *Add TXT Record* wizard:

- **Network View**: This appears only when you have multiple network views. From the drop-down list, select the network view in which you want to create the TXT record.
- **Name**: If Grid Manager displays a zone name, enter the name to define a TXT record for a host or subdomain. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click a zone name in the dialog box. Then, enter the TXT record name. The appliance prefixes the name you enter to the domain name of the selected zone. For example, if you want to create a TXT record for a web server whose host name is www2.corpxyz.com and you define the TXT record in the corpxyz.com zone, enter **www2** in this field. To define a TXT record for a domain whose name matches the selected zone, leave this field empty. The appliance automatically adds the domain name (the same as the zone name) to the TXT record. For example, if you want to create a TXT record for the corpxyz.com domain and you selected the corpxyz.com zone, leave this field empty.
- DNS View: Displays the DNS view of the selected zone.
- **Shared Record Group**: This field appears only when you are creating a shared record from the **Data Management** tab. Click **Select Shared Record Group**. If you have only one shared record group, the appliance displays the name of the shared record group here. If you have multiple shared record groups, select the shared record group in the *Shared Record Group Selector* dialog box. You can use filters or the **Go to** function to narrow down the list.
- **Text:** Enter the text that you want to associate with the record. It can contain substrings of up to 255 bytes, up to a total of 512 bytes. Additionally, if you enter leading, trailing, or embedded spaces in the text, add quotes around the text to preserve the spaces. For example: " v=spf1 include:corp200.com -all "
- **Comments:** Enter useful information about this record.
- **Disable:** Select the checkbox to disable the record without deleting its configuration. Clear the checkbox to enable the record.

2. Save the configuration, or click **Next** to define extensible attributes. For information, see *Managing Extensible Attributes*.
or
Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, click **Later** and enter a date, time, and time zone. For information, see *Scheduling Tasks*.

3. Click **Restart** if it appears at the top of the screen.

> ⚠ Note
> In a signed zone, if you add or delete a TXT record that has @in its host name, you must also create or delete the corresponding NSEC3 record.

Add MX Record

An MX (mail exchanger) record maps a domain name to a mail exchanger. A mail exchanger is a server that either delivers or forwards mail. You can specify one or more mail exchangers for a zone, as well as the preference for using each mail exchanger. A standard MX record applies to a particular domain or subdomain. You can add an MX record from the Tasks Dashboard or the **Data Management** tab. For more information about MX records, see *Managing MX Records*.

To add MX records from the Tasks Dashboard:

1. Click **Add MX Record** in the IPAM task pack and complete the following in the *Add TXT Record* wizard:

- **Network View**: This appears only when you have multiple network views. From the drop-down list, select the network view in which you want to create the MX record.
- **Mail Destination:** If Grid Manager displays a zone name, enter the mail destination here. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *ZoneSelector* dialog box. Click a zone name in the dialog box, and then enter the mail destination. If you want to define an MX record for a domain whose name matches the zone you selected, leave this field blank. Grid Manager automatically adds the domain name (the same as the zone name) to the MX record. For example, if you want to create an MX record for a mail exchanger serving the corpxyz.com domain and you selected the corpxyz.com zone, and leave this field empty. If you want to define an MX record for a subdomain, enter the subdomain name. The appliance prefixes the name you enter to the domain name of the selected zone. For example, if you want to create an MX record for a mail exchanger serving site1.corpxyz.com—a subdomain of corpxyz.com—and you define the MX record in the corpxyz.com zone, enter site1 in this field.If you want to define an MX record for a domain and all its subdomains, enter an asterisk (*) to create a wildcard MX record.
- **DNS View:** Displays the DNS view of the selected zone.
- **Shared Record Group**: This field appears only when you are creating a shared record from the **Data Management** tab. Click **Select Shared Record Group**. If you have only one shared record group, the appliance displays the name of the shared record group here. If you have multiple shared record groups, select the shared record group in the *Shared Record Group Selector* dialog box. You can use filters or the **Goto** function to narrow down the list.
- Host Name Policy: Displays the hostname policy of the selected zone. Ensure that the hostname you enter complies with the hostname restriction policy defined for the zone.
- **Mail Exchanger:** Enter the fully qualified domain name of the mail exchanger. You can even enter a dot character in this field (.). When you enter a dot, it mean that the domain is a parked domain and will not receive or send email.
- **Preference:** Select an integer from 10 to 100, or enter a value from 0 to 65535. The preference determines the order in which a client attempts to contact the target mail exchanger with 0 being the highest preference.
- **Comment:** Enter useful information about this record.
- **Disable:** Select the checkbox to disable the record without deleting its configuration. Clear the checkbox to enable the record.

2. Save the configuration, or click **Next** to define extensible attributes. For information, see *Managing Extensible Attributes*.

or
Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, click **Later** and enter a date, time, and time zone. For information about scheduling tasks, see *Scheduling Tasks*.

3. Click **Restart** if it appears at the top of the screen.

CSV Import

You can access **CSV Import Manager** and perform CSV imports, manage import jobs, and view import status. You can perform CSV imports from the Task Dashboard and the Toolbar. You can also click **CSV Import Manager,** which allows for importing of data, managing import jobs, and viewing import status.

You can click **New CSV import job** icon in the **CSV Job Manager** wizard to import a CSV file to the database. You can also verify the content in your CSV file before replacing the content of the database with the content in the imported CSV file. For detailed information about the CSV import feature, see *Importing and Exporting Data using CSV Import*.

NetMRI Task Pack

The NetMRI Tasks pack or, alternatively, Automation Tasks pack, requires the configuration, licensing and connection of an Infoblox NetMRI appliance to support automation tasks.

This topic describes the following:

Enabling NetMRI Tasks

After you install the NetMRI appliance into a managed network and ensure the appliance is reachable by the NIOS Grid Master, register the NetMRI appliance with NIOS.

1. Click the Configure icon at the top right corner of the **Tasks** page.
2. Choose **Enable NetMRI Tasks**.
   The Enable NetMRI Tasks dialog box appears, requesting verification of your action:
   Though you can see the change immediately, other users who are currently logged in will not see the change until they log in again.
   Are you sure you want to proceed?
3. Click **Yes** to enable the NetMRI Tasks set.
   After a moment, the NetMRI Tasks panel appears.

> **Note**
>
> If two superusers are logged in to the NIOS system and one superuser enables the NetMRI Tasks pack on their console, the other superuser will not see the task pack on their console until their next login;
> the **Disable NetMRI Tasks** from the Configure icon menu shows the correct state.

Disabling NetMRI Tasks

To disable the NetMRI Tasks pack:

1. Click the Configure icon at the top right corner of the Tasks page.
2. Choose **Disable NetMRI Tasks**.
   The Disable NetMRI Tasks dialog box appears, requesting verification of your action:
   Though you can see the change immediately, other users who are currently logged in will not see the change until they log in again.
   Are you sure you want to proceed?
3. Click **Yes** to disable the NetMRI Tasks pack.

Registering NetMRI with NIOS

You must register a NetMRI appliance with NIOS using Grid Manager to support NetMRI Tasks. You need an account with admin privileges on the NetMRI appliance and the appliance hostname or IP address.

> **Note**
>
> Ensure that the user account that you use for the registration and further communication between the products is identical to the existing valid account on the NetMRI appliance.

To register NetMRI with NIOS:

1. From the **Dashboards** tab, select the **Tasks** tab.
2. At the top right corner of the **Automation Tasks** panel, click the down arrow icon -> **NetMRI Registration**.
3. In the **NetMRI Registration** dialog, do the following:
    a. Enter the IP address or resolved host name of the NetMRI appliance supporting the Automation Tasks pack.
    Note that when you register NetMRI with a NIOS HA pair, you can register only one interface at a time. Use the IP address of the LAN1 interface, not the VIP address, for registration. When an HA failover occurs, the NetMRI registration is disabled. You can register the NetMRI appliance again after the failover.
    b. Enter the **Admin Password**.
4. Click **Register**.

After registration, the **NetMRI Registration** menu item changes to read **NetMRI Deregistration** to support disconnecting from the NetMRI appliance.

> **Note**
>
> After you successfully register a NetMRI appliance with NIOS, you can use the Ecosystem > Cisco ISE Endpoint feature. It is available with the NetMRI license or Network Insight license that is installed by default on the discovery member in NIOS installations. This feature enables you to enhance identity management across devices and applications that are connected to your network routers and switches. You can monitor domain users, the IP addresses they log on to, the login status, and the time duration of their current status in the **IPAM** tab. For information about how to collect user and device information from Cisco ISE, see *Integrating Cisco ISE into NIOS*.

Running NetMRI Tasks

The NetMRI task pack contains the following tasks:

- Network Provisioning
- Port Activation
- VLAN Reassignment
- Bare Metal Provisioning
- Rogue DHCP Server Remediation

Depending on your administrative permissions, Grid Manager displays tasks that you can access in the **Automation tasks** panel. You can configure the displayed tasks pack by adding or hiding tasks.

To hide tasks:

1. Click the Configure icon at the upper right corner of the **Automation Tasks** panel.
2. In the **Active Tasks** pane, select the tasks you want to hide from the pack. You can use SHIFT+click and CTRL+click to select multiple tasks.
3. Click the left arrow to move the selected tasks to the **Available Tasks** pane.
4. Click the Configuration icon again to hide the panes.

NetMRI Task Options

Tasks allow the assignment of job scripts to change and expand task functionality. These scripts reside on the NetMRI appliance and must be readable by the NIOS system to run the automation tasks. You can also select different scripts to

execute for automation tasks that provide that feature in NIOS. Three NetMRI tasks allow for the choosing of non-default scripts for task operation:

- Network Provisioning Task
- Port Activation Automation Task
- Specifying a Port Activation Script

Network Provisioning

The Network Provisioning task runs in two modes: a basic mode with a much shorter list of configuration options, and a more complex mode that provides detailed configuration for provisioning a network, including the use of NIOS network views, extensible attributes and network templates.

New networks can be provisioned on routed networks and on switched networks. In the latter case, you can specify the new VLAN number and VLAN name for provisioning, along with the Device Group Device and Interface. the Device Group values are taken from the Device Groups defined on the NetMRI appliance from which NIOS obtains its data.

Network Provisioning supports two types of networks: IPv4, in which the new network is IPv4 only, and IPv4 and IPv6, in which the new network runs both protocol stacks.

Simple vs. Complex Provisioning

Use of a Network View determines whether you use the simple or detailed views of provisioning a network. A network view is a single routing domain with its own networks and shared networks. In NIOS, all networks must belong to a network view. You can manage networks in one network view independently of other network views. Because network views are mutually exclusive, the networks in each view can have overlapping address spaces with multiple duplicate IP addresses without impacting network integrity.

Also, the same network segment can be present in multiple network views. When you create a new network, you select one view in which to place it, and preserve those values to apply to another view.
You also have the option to provision a single network segment without recourse to NIOS network views. The simple network provisioning option (accessible by simply clicking the IPv4 tool at the top of the Network Provisioning dialog box) allows you to specify as few as three values to configure a network.

The NIOS system also provides a **default** network view, which appears as an option for network provisioning.

If a single network view is configured in NIOS, you will not see a **Network View** option in the Network Provisioning task.

Applying Extensible Attributes

Extensible attributes are associated with a specific network view, and are referenced by the Network Provisioning task. Should you configure a new network using a network view, you may need to consider the application of extensible attributes to the new network (they are not automatically applied, but will appear in the Network Provisioning dialog if those attributes are defined in the chosen Network View). Extensible attributes are generally defined for descriptive and tracking purposes in the network. A network view may have attributes such as Building, Country, Region, Site, State or VLAN, for example. Attributes are defined for network views in NIOS but are not defined by the NetMRI appliance.

If the NIOS system supports only a single network view, no View selections are made for the purposes of network provisioning.

To perform an automatic network provisioning task:

1. From the **Dashboards** tab, select the **Tasks** tab -> **Network Provisioning**.
2. Select the network type for provisioning: **IPv4** or **IPv4 and IPv6**.
3. To configure IPv4 provisioning:
    a. Enter the required name value in the **Interface Hostname** field. (Examples include "eth0" and "serial0.")
    b. Select the **DNS Zone** under which the hostname operates.
    c. Choose a device group from the **Device Group** drop-down list.
    d. From the Device drop-down list, choose the switch or router on which the network will originate.
    e. If the selected device is a router, the **VLAN Number** and **VLAN Name** fields will be disabled.

f. From the **Interface** list, choose the interface to which the network will be reassigned. The drop-down list contains all the interfaces from the chosen network device, and also shows the ports' respective states (up/down, up/up and so on).
g. If the chosen device is a switch, enter the new **VLAN Number** on which the new network segment runs.
h. If the chosen device is a switch, enter the new **VLAN Name** on which the new network segment runs.
i. Click **Provision Network** to commit settings.
j. Enter the **Parent Network** value (or click Select Network to choose the parent network from a list if using a Network View).
k. Choose the **Network Template** from the drop-down list if one is provided by the chosen Network View. The Network template is otherwise optional.
l. The Provision Network task provides subnetting tools.
m. Drag the **Netmask** slider to the required CIDR mask bit depth (1-32).
n. In the **New Network** field, enter the IP prefix for the new network.
o. In the **Router Address** field, enter the IP address for the router interface.
p. Select any **Extensible Attributes** in the list if they are provided; otherwise, you can create new ones by clicking Add and choosing the **Attribute Name**, **Value** and the **Required** setting.

4. To configure IPv6 provisioning:

a. Enter the **Parent Network** value. Or, if using a Network View, click **Select Network** to choose the parent network from the list.
b. Choose the **Network Template** from the drop-down list if one is provided by the chosen Network View. The Network template is otherwise optional.
The Provision Network task provides subnetting tools.
c. **Drag the Netmask** slider to the required CIDR mask bit depth (1-32).
d. In the **New Network** field, enter the IP prefix for the new network.
e. In the **Router Address** field, enter the IP address for the router interface.
f. Select any **Extensible Attributes** in the list if they are provided; otherwise, you can create new ones by clicking Add and choosing the **Attribute Name**, **Value** and the **Required** setting.

5. Enter the required name value in the **Interface Hostname** field. (Examples include "eth0" and "serial0.")
6. Select the **DNS Zone** under which the hostname operates.
7. Choose a device group from the **Device Group** drop-down list.
8. From the Device drop-down list, choose the switch or router on which the network will originate.
9. If the selected device is a router, the **VLAN Number** and **VLAN Name** fields will be disabled.
10. From the **Interface** list, choose the interface to which the network will be reassigned. The drop-down list contains all the interfaces from the chosen network device, and also shows the ports' respective states (up/down, up/up and so on).
If an interface shows **Routed** or **Switched**, it cannot be selected for provisioning as it is already being used as part of an active network.
11. If the chosen device is a switch, enter the new **VLAN Number** on which the new network segment runs.
12. If the chosen device is a switch, enter the new **VLAN Name** on which the new network segment runs.
13. Click **Provision Network** to commit settings.

The system sends the configuration request to the NetMRI appliance and displays the task configuration sequence.

Defining Options for the Network Provisioning Task

The Network Provisioning task provides several configuration options that affect how the task operates.

Hostname provisioning for interfaces is useful for troubleshooting purposes in the network, usually to ensure that an admin knows which router interface they are connecting through to communicate with the device. The hostname value is actually provisioned from within the Network Provisioning task. Enabling the Hostname Required? checkbox sets the NetMRI appliance to provision the network with hostnames applied to the router interfaces for easier identification.

Network provisioning requires that the system know exactly which IP address the gateway for the network will reside. For provisioning most networks, an Offset value of 1 indicates that the provisioned network gateway IP address ends with the host address of **...1, as in 192.168.1.1. An Offset value of 1 will be by far the most common value for provisioning networks. Specifying an offset value other than 1 indicates that the gateway IP is a specified number of host values from the prefix address of the network. For example, setting an IPv4 Gateway Address Offset of 12 indicates that the IP for the**

gateway ends in *..*.12, as in 10.1.1.12. Offsets work the same way for any size network: for an example such as 10.1.1.64/26, and an offset of 12, the provisioned gateway IP would be 10.1.1.76.

> ⚠ Note
> Make sure the defined offset value lies within the addressable boundaries of the provisioned network.

The same principles also apply for IPv6 networks, except that the IPv6 value is entered manually in hexadecimal instead of being selected from a drop-down list. Most provisioned IPv6 networks will use a /64 network address.

You can also select a different script from the default for the Network Provisioning task. To define settings for the Network Provisioning task:

1. From the **Dashboards** tab, select the **Tasks** tab. Under the **Network Provisioning** task, click the settings icon on the top right.
2. If the provisioning process requires a hostname, enable the **Hostname Required?** checkbox. (The network interface hostname ("eth0," "serial0") and the Zone that it belongs to are defined in the Network Provisioning task.)
3. Choose a gateway offset value from the **IPv4 Gateway Address Offset** drop-down list. If no value is selected, the offset value defaults to 1 for the provisioned network address.
4. If an IPv6 offset is required for provisioning an IPv6 network or for provisioning a network that supports both IPv4 and IPv6 addressing, enter the **IPv6 Gateway Address Offset** value in hexadecimal. If no value is entered, the offset value defaults to 0000.0000.0000.0001 for the provisioned network address, indicating an offset value of 1 for the gateway IP address.
5. In the **Script Name** dropdown, choose the script that you wish to run for the Port Activation task. The scripts are located on the Trinzic Automation 4000 appliance, and referenced for use by NIOS. By default, the bundled **Port Activation** script is selected.
6. Click **Save**.
7. Click **Cancel** to close the dialog.

The system sends the request to the NetMRI appliance and displays a **Provisioning Network Config updated** notification message.

Port Activation

The Port Activation task provides a central console on which the interfaces for any device anywhere in the managed network can be conveniently enabled or disabled. Ports can be taken administratively Up or Down using this task, and all interfaces on a selected device can be activated or deactivated with a series of mouse clicks.

1. From the **Dashboards** tab, select the **Tasks** tab -> **Port Activation**.
2. Choose the **Device Group** from the drop-down list.
3. From the **Device** drop-down list, choose the network device on which port activation will be executed.
   The **Interfaces** table lists all interfaces on the current device. The **VLAN** and **VLAN Name** columns list the VLAN assigned to each port (VLAN 1/Default resides on all ports without an explicit VLAN assignment). The **OP Status** column will show the current state of each interface.
4. Scroll down the table to locate the interface(s) you want to activate.
5. From the **Admin Status** column, select **Up** (or **Down**) from the drop-down list for the chosen interface.
6. Set any other interfaces on the current device based on your assigned task.
7. Click **Apply**.

The system sends the request to the NetMRI appliance and displays the task configuration sequence.

The Port Activation task will also write the full running configuration to memory, making it the saved configuration. If the user made a change to the running configuration, in parallel with the port activation change, and did not save it, those changes will also be saved.

Specifying a Port Activation Script

The Port Activation task provides a central console on which the interfaces for any device in the managed network can be conveniently activated. Ports can be taken administratively Up or Down using this task, and all interfaces on a selected device can be activated or deactivated with a series of mouse clicks.

The NetMRI appliance provides the ability to create new automation scripts for many purposes. You may, for example, wish to create a new Port Activation script and use that as an automation task.

To select a different script from the default choice in the software:

1. From the **Dashboards** tab, select the **Tasks** tab. Under the **Port Activation** task, click the settings icon.
2. For Port Activation Options, choose a new script from the **Script Name** drop-down list. The scripts are located on the Trinzic Automation 4000 appliance, and automatically referenced for use by NIOS. By default, the bundled **Port Activation** script is selected.
3. Click **Save**.

The system sends the request to the NetMRI appliance and displays a notification message.

VLAN Reassignment

VLANs can be reassigned to new interfaces on individual L2/L3 switches in the managed network. A VLAN can have a path across several switches; when you make changes on a given switch, make sure that the path is maintained.

To ensure end-to-end connectivity, you may need to change VLAN port assignments on more than one switch in the path. This feature operates with the VLAN Trunking Protocol (VTP). VLAN switching is changed across one port per switch at a time. Should you need to change VLAN assignments across more than one switch in the path, plan accordingly.

VLANs must already be configured on the switch(es) being changed, and be detected by the NetMRI appliance.

1. From the **Dashboards** tab, select the **Tasks** tab -> **VLAN Reassignment**.
2. Begin by selecting the Device Group from the drop-down list. For **VLAN Reassignments**, you typically choose the Switching device group.
3. From the **Device** drop-down list, choose the switch on which port reassignment will be executed.
4. From the **Port** list, choose the interface to which the VLAN will be reassigned. The **Port** list also shows the Administrative and Operational states of each interface on the current device (Administratively Up/Operationally Down, for example.)
   Note that you can reassign a VLAN to a port that is operationally or administratively Down.The Current VLAN value will show the VLAN to which the selected interface is currently assigned.
5. Choose the new VLAN value for port reassignment from the **New VLAN** drop-down list.
6. Click **Move VLAN**.

The system sends the configuration request to the NetMRI appliance and displays the task configuration sequence.

The VLAN Reassignment task will also write the full running configuration to memory, making it the saved configuration. If the user made a change to the running configuration, in parallel with the port activation change, and did not save it, those changes will also be saved.

Assigning a New Script to the VLAN Reassignment Task

The NetMRI appliance provides the ability to create new automation scripts for many purposes. You can create and assign a new VLAN Reassignment script and use that for the automation task.

To select a different script from the default choice in the software:

1. From the **Dashboards** tab, select the **Tasks** tab. Under the **VLAN Reassignment** task, click the settings icon.
2. For Port Activation Options, choose a new script from the **Script Name** drop-down list.
3. Click **Save** to commit settings.

The system sends the request to the NetMRI appliance and displays a notification message.

The VLAN Reassignment task will also write the full running configuration to the device's memory, making it the saved configuration. If the user made a change to the running configuration, in parallel with the port activation change, and did not save it, those changes will also be saved.

Bare Metal Provisioning

The **Bare Metal Provisioning** automated task enables automated installation of new switches and routers into the network. The Trinzic Automation task enables cost and convenience savings by detecting the default behavior of new devices on the network, pointing them to customized TFTP servers from which standardized bare-metal configuration files are downloaded and installed onto the new devices.

The **Bare Metal Provisioning** automated task does not provide NIOS-based optional settings; configuration for this task is done in the Trinzic Automation 4000 NetMRI user interface. The automated task is automatically triggered by detection of a network device requiring configuration.

Rogue DHCP Server Remediation

All DHCP servers on the network should be under administrative control. If any device offering DHCP leases to clients on the network is not properly administered, it violates many security guidelines and at the very least may cause configuration problems throughout the network. Some events may be unwitting or innocuous (an office worker installing a wireless access point in their cube to share a resource), or may be an attempt to hijack clients and steal information. To prevent such issues, the Rogue DHCP Server Remediation task enables the detection, location and isolation of such devices.

Viewing Tasks Execution Logs and Approving Tasks in the Task Viewer

You can view the logged results from any task run from the **Automation Tasks** panel through Grid Manager's Task Viewer that displays the following pages:

- **Job History**: Provides a log history of all NetMRI tasks that have recently run, including all automation task types in the dashboard.
- **Issues & Approvals**: Provides links to two important items:
  - **Issue Details**: Displays details about any network issue related to NetMRI tasks and jobs in an Issue Viewer from the NetMRI appliance.
  - **Approve Jobs**: These are jobs that must be approved before the NetMRI appliance can execute the job. For example, the **Isolate Rogue DHCP Server** job must be approved before it will run and attempt to isolate the detected rogue DHCP server in the network.

To view and approve tasks:

1. From the **Dashboards** tab, select the **Tasks** tab.
2. In the **Automation Tasks** panel, click the down arrow icon on the right and select **Task Viewer**.
   The Task Viewer window appears, displaying a scrollable and sortable Job History table. Important columns include the **Start Time**, the **Job ID** (a numeric value with a clickable link to the TAE Job Details Viewer, which will open in a new browser tab), the **Job Name**, the **User** account that executed the task, the job **Status** and the **# Devices** (the number of devices) against which the task ran. The Job History page shows the most recent subset of executed NetMRI jobs. A yellow bar at the top of the table provides a **click here to see more** link, which takes the user to the NetMRI appliance **Job History** page in a new browser tab.
3. If an item appears in the **Issues & Approvals** page, do one of the folllowing in the **Action** column:
   a. To view an issue in more detail, click an **Issue Details** link. This displays the NetMRI appliance Job Details page in a new browser tab for the selected job.
   b. To approve a job, click an **Approve Job** link. This displays the **Summary** page of the NetMRI Job Wizard. Click **Approve Job**.
4. Click **Close** to close the Task Viewer.

Viewing Tasks Execution Logs in NetMRI

You can start NetMRI directly from the Grid Manager's Dashboards tab to view tasks execution logs:

1. From the **Dashboards** tab, select the **Tasks** tab.
2. In the **Automation Tasks** panel, click the down arrow icon on the right and select **Launch NetMRI**.
   NetMRI launches in a new browser tab.
3. Go to **Configuration Management –> Job Management** side tab –> **Scripts** and check the Last Run column.

Report Clustering Dashboard

The **Reporting Clustering Status** dashboard provides detailed information on the status of the entire indexer cluster. You can get information on the status of each peer node, search head, and indexes. You can view the number of peers (reporting members), searchable copies, and number of copies (buckets).

> ⚠ Note
>
> The **Reporting Clustering Status** dashboard is available only when you configure the reporting clustering and you must also have the global read-only permissions for Grid Reporting Properties.

The default dashboard includes the following information:

- Indicates whether the reporting data is fully searchable. Displays **Yes** to indicate that all buckets in the cluster have a primary copy.
- Indicates whether the search and replication factors are met.
- Displays the number of indexes and peers that are searchable.

This dashboard might also display the following messages depending on the health of your cluster: Some data is not searchable, All Data is Searchable, Replication factor not met, and Search factor is not met.

Viewing Reporting Clustering Status

To view the *Reporting Clustering Status* dashboard:

1. From the **Dashboards** -> **Reporting Clustering Status** tab. In the **Peers** tab, you can view the following information:
    - **Peer Name**: The name of the reporting member.
    - **Fully Searchable**: Indicates whether the peer currently has a complete set of primaries and is fully searchable.
    - **Status**: The status of the reporting member.
    - **Buckets**: The number of copies stored on the peer node. The number of buckets for which the peer has copies

- The **Indexes** tab displays the following information:
    - **Index Name**: The name of the indexer.
    - **Fully Searchable**: Indicates whether the peer currently has a complete set of primaries and is fully searchable.
    - **Searchable Data Copies Status**: The status of the reporting member.
    - **Replicated Data Copies**: The replicated number of copies.
    - **Buckets**: The number of buckets for which the peer has copies.
    - **Cumulative Raw Data Size**: The size of the index, excluding hot buckets.
- The **Search Heads** tab displays the following information:
    - **Search Head Name**: Name of the search head.
    - **Status**: The status of the search head.

Configuring Dashboard Templates

Superusers can specify the tasks an admin group can perform from the **Tasks Dashboard** tab by creating a dashboard template and assigning it to the admin group. When you create a dashboard template, you define the tasks users in an admin group can perform and specify whether the users can configure their own dashboards when they log in to Grid Manager. When you assign a dashboard template to an admin group, all users in this group can see and perform the tasks you define in the template, provided that the users also have the correct

permissions to the objects related to the tasks. For information about administrative permissions, see *Administrative Permissions for Dashboard Tasks*.

If the assigned template is unlocked, users can configure tasks on their dashboard. If you lock the dashboard template, users cannot configure task packs on their own dashboards.
Superusers can also restrict limited-access users to access only the **Tasks Dashboard** tab when they log in to Grid Manager. These users cannot manage other core network services through Grid Manager. They can only see the **Tasks Dashboard** tab and access only the tasks defined in the dashboard template, if applicable. This feature is useful when you want to define different levels of admin users and restrict them to specific tasks based on their organizational functions. For information about how to set this restriction and creating limited-access admin groups, see *About Admin Groups*.
To configure and apply dashboard templates, complete the following:

1. Configure dashboard templates, as described in *Configuring Dashboard Templates*.
2. Assign dashboard templates to admin groups, as described in *About Admin Groups*.

Adding Dashboard Templates

Only supersuers can configure dashboard templates. Limited-access users may configure task packs depending on the configuration of their assigned dashboard templates.
To add a dashboard template:

1. Log in as a superuser.
2. From the **Dashboards** -> **Tasks** tab, click the Configure icon at the top right corner of a task pack.
3. Select tasks from the Active Tasks table and use the left arrow to move them to the Available Tasks table to hide the tasks, and vice versa. Grid Manager displays the tasks you place in the Active Tasks table. Repeat the steps for all task packs.
4. At the top right corner of the Tasks Dashboard panel, click the Configure icon -> **Configure Template**.
5. In the Dashboard template configuration section, click **Create new template**.
6. In the *Save Dashboard Template* dialog box, complete the following:
    - **Name**: Enter a name for the new dashboard template.
    - **Locked**: When you select this checkbox and assign this template to an admin group, users in the admin group can only perform the tasks you configure to appear in this template. They cannot configure their dashboards. When you clear this checkbox, users can still only see the tasks you configure for this template, but they can now configure tasks in the task packs on their dashboards. Note that when you lock a template, it applies to all users in the admin group, including those who have customized dashboards.
7. Click **Save & Close**.

The appliance saves the template and adds it to the **Template** drop-down list.

Resetting Dashboard Templates

Only users with an unlocked dashboard template assigned can reset their dashboards to the template that was originally assigned to them. Users with locked dashboard template cannot configure or reset their dashboards. Also, only superusers can configure dashboard templates.
To reset a dashboard template:

1. Select the **Dashboards** -> **Tasks** tab.
2. For superusers: At the top right corner of the Tasks Dashboard panel, click the Configure icon -> **Reset**. Note that the Configure icon appears only if you are a superuser.
   For limited-access users: At the top right corner of the Tasks Dashboard panel, click **Reset**.
   The appliance reset your dashboard to the original dashboard template that was assigned to your admin group.

Modifying Dashboard Templates

You can modify an existing dashboard template by locking or unlocking it, and adding or removing tasks from a task pack. However, you cannot change the name of the template. When you change the name of a template, the

appliance clones the template and adds the new template to the list. Note that when you modify a locked template that is assigned to an admin group, users in the group automatically adopt the changes you make to the template the next time they log in to Grid Manager.
To modify a dashboard template:

1. From the **Dashboards** -> **Tasks** tab, click the Configure icon at the top right corner of the panel.
2. In the Dashboard template section, select the template you want to modify from the **Template** drop-down list. Note that Grid Manager displays [L] before the name of a locked template.
3. In the task pack, click the Configure icon at the top right corner.
4. Select tasks from the Active Tasks table and use the left arrow to move them to the Available Tasks table to hide the tasks, and vice versa. Grid Manager displays the tasks you place in the Active Tasks table. Repeat the steps for all task packs.
5. Click **Save**.
6. In the *Save Dashboard Template* dialog box, modify other information, as described in Configuring Dashboard Templates.
7. Click **Save & Close**.

Deleting Dashboard Templates

Only superusers can delete dashboard templates. To delete a dashboard template that is currently assigned to an admin group, you must first unassign the template from the admin group. For more information about creating limited-access admin groups, see *About Admin Groups.*
To delete a dashboard template:

1. From the **Dashboards** -> **Tasks** tab, click the Configure icon at the top right corner of the panel.
2. In the Dashboard template section, select the template you want to delete from the **Template** drop-down list.
3. Click **Delete**.
4. In the *Delete Dashboard Template* dialog box, click **Yes**.

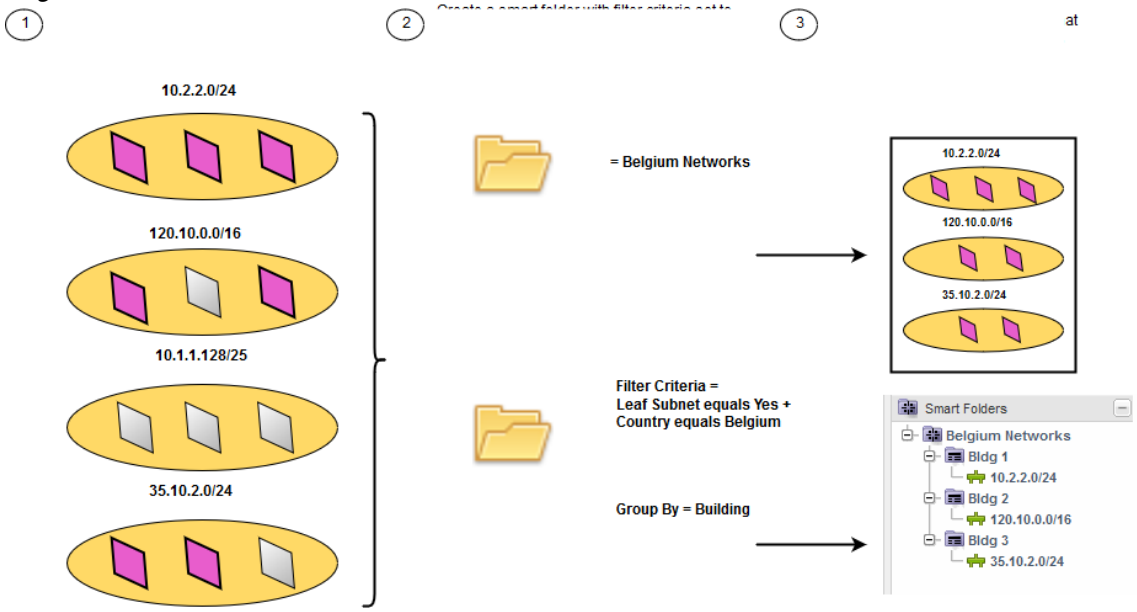
Assigning Dashboard Templates

After you create a dashboard template, you can assign it to an admin group. Admin users in this admin group can access the tasks you define in the template.
To assign a dashboard template to an admin group, see *About Admin Groups.*

Smart Folders

Use smart folders to organize your core network services data. Depending on your administrative roles and business needs, you can filter your data by object types, names, extensible attributes, and discovered data such as conflicts, unmanaged data, or the virtual entity data, and then place the filtered results in a smart folder. You can also group the filtered results by defining up to 10 extensible attributes as the Group By rules. For example, you can create a smart folder that contains all the networks you manage in Belgium, and then group the networks by building number, as illustrated in the figure below.
Once you set up a smart folder, the appliance displays up-to-date information based on your filter and grouping criteria each time you access the folder. You can also view and modify object information in the folder. For information, see *Viewing and Modifying Data in Smart Folders*. With smart folders, you can organize your data in a meaningful way and quickly obtain the information you need to perform specific tasks without searching the entire database.

1 Creating Smart Folders



Before you set up your smart folders, decide how you want to organize your data. You can specify search and Group By criteria to help you group information in a meaningful way. You can also decide whether you want to include objects that do not contain attribute values when you use the Group By criteria to group filtered data by extensible attributes. For information, see *Creating Smart Folders*. Note that a smart folder becomes invalid when you delete an extensible attribute that the folder uses as a filter or Group By criterion. You must redefine the extensible attribute and reconfigure the folder criteria to validate the smart folder.

In Grid Manager, you can create smart folders in both the Global Smart Folders and My Smart Folders panels. In Global Smart Folders, you can create smart folders to which other administrators can create links. Only administrators with superuser accounts can create, edit, and delete global smart folders. You can create personal folders as well as links to global smart folders in My Smart Folders. For information, see *My Smart Folders and Predefined Smart Folders*.

Each smart folder you create can contain up to 2,000 objects. When the number of objects exceeds 2,000, Grid Manager sorts and displays the first 2,000 objects only. It also displays a warning message at the top of the panel. In this case, you may want to redefine your filter criteria to further refine the filtered data in your smart folders.

To create smart folders, follow these procedures:

1. Determine how you want to organize your core network services data.
2. Identify the fields that you want to use to group networks or define extensible attributes for the data that you want to track. For information about extensible attributes, see *Managing Extensible Attributes*.
3. Create smart folders in either the My Smart Folders or Global Smart Folders panel. For information, see *Creating Smart Folders*.

> ⚠ **Note**
>
> Infoblox strongly recommends that you use **Type** as one of the filter criteria to improve system performance.

Global Smart Folders

You can create global smart folders to share among administrators. You must log in as a superuser account to create, edit, and delete global smart folders. All other users have read-only access to global smart folders. You can create as many folders as you need in Global Smart Folders, but Grid Manager displays a maximum of 500 smart folders in the list panel. You can also save a local copy of an existing folder, depending on your administrative permissions. For information, see *Saving Smart Folders Data*.

Grid Manager displays a list of global smart folders in the list panel.
When you log in as a superuser and mouse over a global smart folder, the following icons appear:

- **Information**: Displays information about the selected smart folder. Information includes comments and filter criteria for the folder. It also displays the Group By rules.
- **Edit**: Click this icon to edit the definition and filter criteria for the smart folder.
- **Create link**: Click this icon to create a link to the smart folder. The link to this folder is placed in My Smart Folders.
- **Delete**: Click this icon to delete the smart folder. This operation does not affect the objects that are in the folder. Only the smart folder is deleted.

Creating Smart Folders

You can create personal smart folders in My Smart Folders. You can also create global folders to share among administrators in Global Smart Folders when you log in as a superuser account. Each time you access a smart folder, you obtain up-to-date information about the core network services data that match the filter criteria you set for the folder. You can also set Group By rules to group the filtered data by extensible attributes. Grid Manager displays a hierarchical view of the data using the Group By rules you define.
To create a smart folder:

1. Click the **Smart Folders** tab.
2. Click the **My Smart Folders** tab to create a personal smart folder.
   or
   If you logged in with a superuser account, click the **Global Smart Folders** tab to create a global smart folder.
3. Click **Create**.
4. In the *SmartFolder* data panel, complete the following:
   - **Name**: Enter the name of the smart folder.
   - **Comment**: Optionally, enter additional information about the smart folder.
   - In the first drop-down list, select a field as the filter. You can select a network view or a record type as the filter. Grid Manager highlights extensible attributes and Active Directory Sites in gray. You can also group the default data by adding a Group By rule without adding a filter.
     Note that Infoblox strongly recommends that you use Type as the first criterion to improve system performance.
   - In the second drop-down list, select an operator for the filter.
   - Enter or select a value for the selected field and operator. Depending on the field and operator that you select, the field can be a text or an integer field. It can also be a drop-down list or a calendar widget. For example, if you select **Network/Zone/Range/Member** in the **Type** field, Grid Manager displays all the networks, zones, DHCP ranges, and members in the results table. The results table may display the name in its native characters if the name was originally entered as an IDN (Internationalized Domain Name). For example, the **Name** column in the results table displays 网络 , a zone name in Chinese.
   - Optionally, click **+** to add another filter. You can also click **Apply** to view the filtered data in the results table.
   - Optionally, select the **Group Results** checkbox to organize the filtered data. You can also disable a **Group By** filter by deselecting the checkbox.
   - From the Group by drop-down list, select an extensible attribute or an Active Directory Site by which you want to group the filtered data. For example, if you want to group the filtered data by building number, you can select **Building** from the drop-down list. To add additional Group By rules, click the **+** icon, and then select a field from the drop-down list. You can apply up to 10 Group By rules. You can also delete a rule by selecting the rule and clicking the **-** icon.
   - After you add all filter criteria and **Group By** rules, click **Apply**. Grid Manager displays the filtered data in the results table. Note that in the **Name** field, the appliance highlights disabled DHCP objects in gray. A DHCP object can be a DHCP range, fixed address, reservation, host configured for DHCP, or roaming host with an allocated IP address. If you select to include objects with no attribute values in the **Group By** rules, the appliance may take longer to process the results. You can also choose to display Active Directory Site values in the table.
5. Click **Save** to save the smart folder.

Viewing and Modifying Data in Smart Folders

After you set up a smart folder, the appliance searches for matching objects based on the filter criteria you specified for the folder. Grid Manager also groups the objects by the Group By rules you specify. If you select to include objects with no attribute values, the appliance may take longer to process the results. Each smart folder you create can contain up to 2,000 objects. When the number of objects exceeds 2,000, Grid Manager sorts and displays the first 2,000 objects and shows a message at the top of the panel. In this case, you may want to redefine your filter criteria to further refine the filtered data in your smart folders.

Grid Manager displays smart folders hierarchically in a tree view based on your Group By rules as follows:

- Smart Folder section in the Finder panel.
- Selectors from which you can select a smart folder.

In the smart folder list panel however, Grid Manager displays all the smart folders in a flat list. You can modify some of the data in the table. Double-click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *About the Grid Manager Interface*.

In the smart folder data panel, Grid Manager displays the first hierarchical level of the smart folder based on your Group By rules. If you do not configure any Group By rules, Grid Manager displays all the objects in the results table. If you select to include objects with no attribute values, Grid Manager also includes these objects in the hierarchical view. Depending on your Group By rules, you can view detailed information about the objects by clicking the object link and drilling down to the lowest hierarchical level, and then opening an object. To go back to a previous hierarchical view, click the link of the corresponding level in the breadcrumb.

To view detailed information about an object, complete the following:

1. In the Smart Folder data panel, click the object link until you drill down to the last hierarchical level of the folder.
2. Grid Manager displays the following information:
    - **Name**: The name or IP address of the object.
    - **Comment**: Information about the object.
    - **Type**: The object type.
    - **Site**: The site to which the object belongs. This is one of the predefined extensible attributes.
      You can also select other available extensible attributes for display, and sort the data in ascending or descending order by column.
3. Select an object checkbox, and then perform one of the following:
    - Click the Open icon to display the data in the network list or IP address list.
    - Click the Edit icon to modify or schedule the modification of the object configuration. Grid Manager displays the corresponding editor depending on the object you select.
    - Click the Delete icon to delete the object or click the Schedule Deletion icon to schedule the deletion of the object.

You can also print or export the data in this panel. For information, see *Using the Grid Manager Interface*.

Modifying and Deleting Smart Folders

After you create a smart folder, you can either modify its filter and grouping criteria. You can even delete personal smart folders in My Smart Folders.

Modifying Smart Folders

1. Go to **Smart Folders**.
2. Click **My Smart Folders** to modify personal smart folders.
   or
   Click **Global Smart Folders** to modify global smart folders if you logged in with a superuser account.
3. Mouse over to the smart folder that you want to modify.

4. Click the Edit icon. You can also click the Edit icon next to the name of the smart folder in the data panel.
5. Make the appropriate changes in the Smart Folder data panel as described in *Creating Smart Folders*.

Deleting Smart Folders

You can delete personal smart folders in My Smart Folders. However, you must log in as a superuser account to delete global smart folders.
To delete a smart folder:

1. Click the **Smart Folders** tab.
2. Click the **My Smart Folders** tab to delete personal smart folders.
   or
   Click the **Global Smart Folders** tab to delete global smart folders.
3. Mouse over to the smart folder that you want to delete.
4. Click the Delete icon. In the *Delete Smart Folder* dialog box, click **Yes**.

Saving Smart Folders Data

You can make a copy of an existing smart folder, add or change filter criteria, and then rename the folder accordingly. You can also create a local copy of the global smart folder in its current state for editing purposes. In My Smart Folders, you can save a folder copy only in My Smart Folders. In Global Smart Folders however, you can save a folder copy in either My Smart Folders or Global Smart Folders**.** You must have superuser permissions to save a global smart folder copy in Global Smart Folders. Note that when the original global smart folder is updated, information in your local copy is not updated.

To save a copy of a smart folder:

1. Click **My Smart Folders** to save a folder copy in this tab.
   or
   Click **Global Smart Folders** to save a folder copy in either this tab or My Smart Folders. To save a smart folder copy in Global Smart Folders, log in as a superuser account.
2. Select the smart folder that you want to save as a copy.
3. Click **Save copy as**.
4. Grid Manager saves the folder copy in My Smart Folders when you save the folder copy in this tab.
   or
   The *Save Smart Folder As* dialog box appears when you perform this function in Global Smart Folders. Select one of the following:

- **MySmartFolders**: Saves the copy in My Smart Folders.
- **Global Smart Folders**: Saves the copy in Global Smart Folders.

Click **OK**.

> ⚠ **Note**
>
> For the folder copy, the appliance appends the word Copy to the original name of the smart folder. You can change the name of the folder at anytime by editing the folder.

Printing and Exporting Data in Smart Folders

You can print the list of networks that are on the current smart folder page, or you can export all the data in CSV (comma separated value) format. For more information, see *Scheduling Tasks* and *Importing and Exporting Data using CSV Import*.

My Smart Folders and Predefined Smart Folders

Grid Manager has two types of smart folders available:

- My Smart Folders
- Pre-defined Smart Folders

My Smart Folders

In My Smart Folders, you can create personal smart folders and links to global smart folders. When you create links to global smart folders, you can only view information in the folders. However, you can create a local copy of the global smart folder in its current state for editing purposes. Note that when the original global smart folder is updated, information in your local copy is not updated. For information, see *Saving Smart Folders Data*. When you delete a link to a global smart folder in this tab, only the link is deleted. There is no impact on the information in the original global smart folder.
Grid Manager displays a list of smart folders in the list panel. The same list of smart folders is also displayed in the *Finder* panel. For more information, see *About the Grid Manager Interface*.
When you mouse over a smart folder in the list panel, the following icons appear:

- **Information**: Displays information about the selected smart folder. Information includes comments and filter criteria of the folder. It also displays how you grouped the filtered data.
- **Edit**: Click this icon to edit the definition and filter criteria for the smart folder.
- **Delete**: Click this icon to delete the smart folder. This operation does not affect the objects or networks that are in the folder. Only the smart folder is deleted.

Predefined Smart Folders

The appliance can detect remote clients through their DHCP fingerprints, or through device information discovered through SNMP and other device and network detection protocols. You can use predefined smart folders to view lease history, IP addresses, network infrastructure devices, and other related information for remote clients that contain DHCP fingerprint information related to the following device groups:

- **Smartphone,PDA,Tablet Devices**: Includes all devices that were detected as smartphones, PDAs, and tablets.
- **Microsoft Windows Devices**: Includes all devices that were detected to be running Windows OS.
- **Apple MAC OS Devices**: Includes devices that were detected to be running MAC OS.
- **Conflicts**: Includes hosts detected in the network that have a MAC Address conflict. A discovered host has a MAC address conflict when its MAC address is different from that specified in its fixed address, DHCP lease, or host record.
- **Discovered Routers/Switches**: Includes core network infrastructure devices of the specific Router, Switch, or Switch-Router types discovered by NIOS using the discovery feature set. Clicking on a device name opens the device page under **DataManagement–>Devices** and shows the **Interfaces** page for the chosen device.
- **Active Directory Sites**: Includes all names that were detected as Active Directory Sites. Clicking on an Active Directory Site opens the *Active Directory Site Properties* editor where you can edit the name, add, or delete networks that are associated with the Active Directory Site. For more information, see *Managing Active Directory Sites and Associated Networks*.
- **Gaming Console Devices**: Includes devices that were detected as gaming consoles.
- **Router and Wireless Access Point Devices**: Includes devices there were detected as routers or wireless access point devices.
- **Unmanaged**: Shows all unmanaged devices.

Importing and Exporting Data using CSV Import

Use **CSV Import** to import DNS, DHCP, IPAM data, and subscriber site data through Grid Manager. You can use this feature to migrate or add new data, overwrite existing data, merge new data with existing data, delete existing data, or replace certain existing data in the database.
To import new data, you must first prepare a data file (include all required fields and follow the proper syntax), and then start an import through Grid Manager. You can also export existing data to a data file, modify the data, and then import the modified data to the database. You can either overwrite existing data with the modified data or merge new data with the existing data. You can also delete data that is no longer required or replace certain existing data with new data in the file. Note that the replace option is valid for authoritative zone data only whereas other options are valid for all supported objects including zones. The replace operation creates a snapshot or a backup of the existing data in the database before replacing the database with the data in the imported CSV file.
The appliance supports CSV import for most record types. You can use IDNs and punycode for the domain name field for most of the DNS object types. For information about IDNs and punycode, see *Support for Internationalized Domain Names*. Only superusers can import A and AAAA records with a blank name. Limited-access users must have read/write permission to **Adding a blank A/AAAA record** in order to import A and AAAA records with a blank name, otherwise the CSV import operation might fail. You can assign global permission for specific admin groups and roles to allow to import A and AAAA records with a blank name. For more information, *Administrative Permissions*. For each supported record type, you must include all required fields in the header row of the dataset that you want to import. For a list of supported record types and specific guidelines for creating a data file, refer to the *Infoblox CSV Import Reference*.
To import a data file:

1. Create a data file if you do not already have one. Follow the guidelines for the supported objects to ensure that you include all the required fields in the file. For more information, refer to *Infoblox CSV Import Reference*. You can also export existing data and then update the file for re-import. For more information, see Exporting Data to Files below.
2. Configure import options, see below.
3. Start a CSV import. For information, see Configuring Import Options below.

> **Warning**
>
> CSV imports and operations that involve massive data such as deleting large zones and recursive deletion of networks and all child objects, will significantly affect member performance, resulting in service outage.

When you submit multiple CSV imports, the appliance puts the import jobs in queue and executes them one at a time in the order they are submitted. When a job is being executed, it is in the **Import in progress** state. When a job is in queue for execution, it is in the **Import pending** state. You can import multiple CSV files at a time, but at any given time you can execute only one single task. Note that only one task at a time will be in the **Import in progress** state, while the others are in the **Import pending** state. You can view the status of each import job through **CSV Job Manager**. Superusers can view all import jobs while limited-access users can view only the jobs they submitted.
To access **CSV Job Manager**, from the **Data Management** tab, click **CSV Job Manager** from the Toolbar and select **Jobs Manager**, or from the **Tasks Dashboard**, click **CSV Import** in the IPAM Task Pack. Superusers and limited-access users that have applicable configurations and permissions can perform CSV imports and exports. For information about user permissions for CSV imports and exports, see CSV Import User Permissions below.
You can do the following in **CSV Import**:

- Add, overwrite, append, replace or delete data through the imported CSV file, as described in *Configuring Import Options*.
- Verify the content in the CSV file, as described in Configuring Import Options.
- View a list of CSV import jobs, as described in Creating a Data File for Import.
- Add and start CSV import jobs, upload data files, stop CSV imports, or edit the options of the uploaded file, as described in Modifying CSV Import Jobs.
- Delete uploaded jobs, as described in Deleting Uploaded Jobs.

- Download the following: imported files, import errors, import results, or snapshots, as described in Downloading Files.
- Select a pending or saved job, and then click the Cancel icon to cancel the job.
- Click the Refresh icon to refresh the **CSV Job Manager**.

⚠

Notes

- The list of CSV import jobs is not restored when you restore a backup file or when you promote a master candidate.
- Superusers can view any jobs in the **CSV Job Manager**, and limited-access users can only view jobs they submitted.
- A non-superuser can import or export CSV files for subscriber records.

CSV Import User Permissions

Superusers can perform any CSV import tasks. You must assign limited-access users the correct configurations and permissions so they can perform CSV imports and exports. For information about how to configure the CSV Import task for limited-access users, see *Configuring Dashboard Templates*. Limited-access users can import data to which they have proper permissions. For information about admin permissions, see *About Administrative Permissions*. Changes you make to user permissions can affect CSV import and export behaviors. The following table lists actions performed on user permissions and the corresponding effects on CSV imports and exports:

Actions taken on user permissions	CSV import and export behaviors associated with the affected user account
Delete a user account	• CSV import jobs remain in the system and are accessible by superusers only. • All pending import jobs cannot be executed due to authentication failures. • If the action is taken during an import job that is in progress, the rest of the import will fail. • All stopped and successful jobs are available to superusers only.
Modify a user account	• If the action is taken during an Import in progress import job, the rest of the import will fail.
Remove user permissions in a user account	• Pending import jobs may be completed with errors.

CSV Import Limitations

Ensure that you understand the following limitations before you start an import:

- You can import multiple CSV files at a time, but at any given time you can execute only one single task. The import tasks are queued. Note that only one task at a time will be in the **Import in progress** state, while the others are in the **Import pending** state.
- Do not use UTF-8 characters in the CSV file name.
- When you perform a CSV import that includes objects that have scheduled changes or updates associated with them, the import fails. Only superusers can cancel the scheduled changes.
- When you stop an import, the appliance completes the import of the data row it is currently processing before it stops the import. You cannot resume the import from where it stopped.
- You cannot roll back to previous data.
- The following data cannot be imported: Microsoft management, DNSSEC, and GSS-TSIG data.

- CSV import does not support DNSSEC zones, though resource records added for a signed zone are supported.
- Only editable data can be imported. Discovered data cannot be imported or manipulated.
- When you promote a new Grid Master during an import, the import stops; and it does not restart on the new Grid Master. When a failover occurs during an import, the import stops on the old active node, and it does not restart on the new active node.
- It may take longer than expected to import a large number of DHCP ranges that are associated with a single MAC address filter.
- When a CSV import starts, the appliance validates the first 100,000 rows of data in the CSV file. If the file contains more than 100,000 rows of data, the appliance validates the rest of the data as the import progresses.
- The appliance supports up to one million rows of data in each CSV import.
- You cannot import network containers.
- To successfully import RIR (Regional Internet Registries) organizations, you must also specify the maintainer password. Note that the password field is not exported during a CSV export. For information about RIR updates, see *RIRRIR Registration UpdatesRegistrationRIR Registration UpdatesUpdates.*
- You can use the **Replace** operation to replace the current data in the database with the data in the imported CSV file. Note that the replace option is valid for authoritative zone data only whereas the other options are valid for all supported objects including zones. For more information, see Configuring Import Options below.
- The **Replace** operation is available only for authoritative zones. This operation does not support DNS records that are automatically generated or exported, but it supports NS records that are created manually.
- Use the delete function to delete import jobs that are uploaded. You can delete the content of a CSV file that you have imported to the database. Note that you cannot delete jobs that are already imported.
- When you import CSV files for NS record updates, you must specify a value for **zone_nameservers**. NIOS displays an error message if you do not specify a value for this field when you import the CSV file.
- When you perform a CSV export of automatically created NS records using Infoblox API, the **zone_nameservers** field will have an empty value. Therefore, if you import the previously exported CSV file that includes automatically created NS records through the Infoblox GUI, then the CSV import fails, and Grid Manager displays an error message.
- If you upload a file and preview the file using the **Preview** option, and later update the content of the same CSV file, and then try to view the edited file using the same *Preview* wizard, you may not be able to see the changes. Infoblox recommends that you start a fresh CSV import to upload the edited file and navigate to the *Preview* wizard to preview the file.
- You cannot perform the CSV import operation on a Microsoft Server zone object, but NIOS allows you to perform the CSV import operation on records within a Microsoft Server zone. You may not see an error message when you perform a CSV import using the replace operation on a Microsoft Server zone.
- You cannot perform merge, custom, and replace operations for subscriber records.
- A non-superuser can import or export CSV files for subscriber records.

Configuring Import Options

You can import CSV files and perform various operations to update the data in the database. You can choose from several import options: add, override, merge, delete, and replace. You can add new rows from the imported file to the database, overwrite existing rows in the database, append rows to the existing rows in the database, delete existing rows in the database, or replace the existing rows in the database. You can verify whether the data in the imported file is appropriate using the **Test** option before you import the file to the database. You can also view the results and progress details of the operation.
To import a CSV file, complete the following:

1. From the **Data Management** tab, click **CSV Job Manager** from the Toolbar.
2. In the *CSV Job Manager* wizard, select **CSV Import** and click the New CSV import job icon.
3. In the *New CSV Import Wizard*, complete the following:
    - **Type of Import**
      For all supported objects (including zones)
        - **Add**: Select this to add new rows from the imported CSV file to the database. NIOS updates the database with the new data that you have added to the imported CSV file and retains the rows that do not have any changes.
        - **Override**: Select this to overwrite the existing data in the database with the data from the uploaded file. You cannot add new rows or delete existing rows. If you want to overwrite values in the

required fields, you must include the required fields and the corresponding _NEW_XXXX fields in the data file.
- **Merge**: Select this to add values from the imported CSV file to the existing columns in the database that do not have any data. It does not overwrite the existing data, even if the data file contains new values for certain fields. If you want to overwrite values in the required fields, you must include the required fields and the corresponding _NEW_XXXX fields in the data file.
- **Delete**: Select this to delete the rows in the imported CSV file from the database.
- **Custom**: Select this to apply custom import actions for individual data rows in your CSV file. When preparing the CSV file for import with the **Custom** option, add an **IMPORT-ACTION** column to the file and specify a custom import action for each data row. Use the following abbreviations for import actions: 'I' (INSERT), 'M' (MERGE), 'O' (OVERRIDE), 'IM' (INSERT+MERGE), 'IO' (INSERT+OVERRIDE), 'D' (DELETE).

- **For zones only**
  - **Replace**: Select this to replace the contents of the database with data provided in the CSV file. NIOS cancels the replace operation and will not save the changes if it encounters an error. You can replace the DNS records of a zone by importing a zone file that was exported previously. You can only replace DNS records that are manually created. NIOS generates a results file listing the file name, action performed, date and time, and result at the end of the validation. You can view the results file only after the replace operation is complete. NIOS generates the backup file automatically for every replace operation and saves it in the Infoblox Grid. Note that the CSV file must contain data for one authoritative zone only, that is, you cannot insert records from different authoritative zones into a single CSV file for replace operation.
    Note: The replace operation might affect system performance if you try to replace a zone with a lot of changes. Infoblox recommends that you perform the replace operation for large import files (more than 10,000 rows of changes) during non-peak hours. This operation ignores _new_XXX fields in the imported CSV files.

4. Click **Next** to import the CSV file.
   - **Import Type**: Displays the type of import option you have selected.
   - Click **Choose** and select the CSV file that you want to import, and then click **Open**.
   - **On Error:** Select one of the following to tell the appliance what to do when it encounters an error during an import:
     - **Stop import**: Select this to stop the data import once it encounters an error in the uploaded file. Grid Manager displays the row number at which it stops the import when it encounters an error. NIOS saves the changes made to the CSV file before an error occurs. For example, if there are 100 rows of data and you select this option, and there is an error in row 90, the appliance displays **90 of 100 completed, 1 error**.
     - **Skip to the next row and continue**: Select this to skip over errors and continue the data import. You can download an error report to identify the erroneous data. NIOS displays the total number of rows it has processed by skipping over. For example, if there are 100 rows of data and you select this option, the appliance displays **100 of 100 completed, 1 error**.
5. Click **Next** to preview your CSV file. In the File Preview table, Grid Manager displays the header row, the first six rows, and up to 15 columns of the imported data. You cannot edit the data here. Field names with asterisks ⭐ indicate required fields. Note that you must define these fields in the imported file. If any of the required fields are missing, the appliance generates an error during the import operation. You can do the following in this wizard:
   - **Import type**: The type of import option you have selected.
   - **Filename**: The name of the CSV file you have selected.
   - **Separator**: Select a separator for your CSV file from the drop-down list. The default value is **Comma**.
   - **OnError**: The option you have selected.
6. Click **Test** to verify the content in your CSV file. Click **Yes** in the *Test CSV Import for Replace Operation* dialog box to verify the content or click **No** to cancel the operation.
   NIOS automatically analyzes the data in the imported file for any syntax errors or other violations. You can also view a detailed report of the file that you are importing. Note that you can run the test as a background task. This report also displays information about the number of deleted, updated and added files. It also displays error messages, if any. NIOS generates a results file listing the file name, action performed, date and time, result, and the number of failures at the end of the validation. You can view the results file only after the replace operation is complete.
   Note that the **Test** button is enabled only when you select the **Replace** operation and is disabled for other import options.

7. Click **Import** to import the CSV file to the database. Click **Yes** in the dialog box to import the CSV file or **No** to cancel the operation.
8. You can view the progress and results of your import operation in the *CSV Import Progress* wizard. This wizard displays the following information:
    - **Import type**: The type of import option you have selected.
    - **Filename**: The name of the CSV file you have selected.
    - **Separator**: The separator you have selected for your CSV file. The default value is **Comma**.
    - **On Error**: The option you have selected when the import operation encounters an error.
    - **Current status**: If an import is in progress, this field displays its current status. Otherwise, it displays the date and time of the last import.
    - **Last action**: Displays the last operation and the admin who initiated it.
    - **Rows Completed:** The number of rows of data the import has processed. Depending on the import options, Grid Manager displays either the row number at which it stops an import when it encounters an error or the total number of rows it has processed by skipping over the erroneous data. For example, if there are 100 rows of data and you select "On error: Stop importing," and there is an error in row 90, Grid Manager displays **90 of 100** here. If you select "On error: Skip to the next row and continue," Grid Manager displays **100 of 100** here and displays **1** in **Rows with Errors**.
    - **Rows with Errors:** The number of rows of data the import has detected errors. Click **Download Errors** to download the CSV file that contains the fields and the rows of erroneous data. You can use this report as a reference to update the data file before you import the file again.
9. You can also perform the following actions if needed:
    - To cancel the import operation, click **Stop Import** before the operation is complete.
    - To close the wizard and execute the operation in the background, click **Close & Run in Background**.
    - When the operation is complete, you can click **Download errors** to download and view the errors. The **Download errors** button is enabled only if the operation encounters errors.
    - Click **Save & Close** to save the operation and close the wizard.

Note

Superusers can view all CSV import jobs and limited-access users can view only the jobs they submitted.

Viewing CSV Import Jobs

You can view the status of import jobs. To view the status:

1. From the **Data Management** tab, click **CSV Job Manager** from the Toolbar.
2. In the **CSV Job Manager** wizard, click **CSV Import**. Grid Manager displays the following information about the import jobs that were submitted in the past 30 days:
    - **User Name**: The admin user who submitted the CSV import. Only superusers can view this column.
    - **Status**: The current status of the import job. The status can be one of the following:
        - **Import successful**: The import is completed without errors. Check the **Message** field for information about the import.
        - **Import unsuccessful**: The import is completed, but with errors. Check the **Message** field for information about the error message.
        - **Import pending**: The job is in queue for execution.
        - **Import inprogress**: The job is being executed.
        - **Import stopped**: The job has been stopped. You can select the job and restart the import.
        - **Test successful**: Test is completed without errors. Check the **Message** field for information about the test.
        - **Test unsuccessful**: Test is completed, but with errors. Check the **Message** field for information about the error message.
        - **Test pending**: Test is in queue for execution.
        - **Test inprogress**: Test is in progress.
        - **Test stopped**: Test has been stopped. You can select the job and restart the import.

- **Saved file**: The data file has been uploaded, but the import has not started.
  Note that after a product restart, which can be caused by a failover, all **Import in progress** jobs go into **Import stopped** state; all **Import pending** jobs continue to be queued for execution.
- **Submitted**: The timestamp when the job was submitted.
- **Completed**: The timestamp when the job was completed. This field is blank if the job has not been completed yet.
- **File Name**: The CSV data file name.
- **Message**: This field displays the number of rows of data that have been processed and the number of rows of data the import has detected errors. Depending on the import options, Grid Manager displays the row number at which it stops the import when it encounters an error, or the total number of rows it has processed by skipping over the erroneous data. For example, if there are 100 rows of data and you select "On error: Stop importing," and there is an error in row 90, the appliance displays 90 of 100 completed, 1 error. If you select "On error: Skip to the next row and continue," the appliance displays **100 of 100 completed, 1 error**.
- **FileSize**: The size of the imported CSV file.

Superusers can view all CSV import jobs and limited-access users can view only the jobs they submitted.

Modifying CSV Import Jobs

You can modify the options of the CSV file that you have already uploaded, delete the jobs that are uploaded, or download the uploaded file or error file. After you configure the import options, you can select a data file and start an import operation or upload a data file. For more information about configuring import options, see as described in Configuring Import Options.
To edit the options of a file, complete the following:

- From the **Data Management** tab, click **CSV Job Manager** from the Toolbar.
- In the *CSV Job Manager* wizard, select **CSV Import** and select the import job that you want to update, click the Action icon

  and select **Edit**.
- In **Edit-CSV Import Job**, select a type of import and perform the operations mentioned in Configuring Import Options.
- Click **Download** to download the uploaded file, snapshot file, or the results file.
- Click **Save & Close** to save the changes.

Deleting Uploaded Jobs

You can delete import jobs that are uploaded. You cannot delete jobs that are already imported. You can delete the content of a CSV file that you have imported to the database. Note that the CSV import files and the backed up files are saved for a period of 30 days, but the size limit is set to 1 GB. If these files increase in size, NIOS removes the older files from the Grid. NIOS generates a syslog message if it encounters an error when generating the backup file.

Note

When you delete a parent object from the CSV file, the child objects associated with the parent objects are also deleted.

To delete uploaded jobs, complete the following:

1. From the **Data Management** tab, click **CSV Job Manager** from the Toolbar.
2. In the *CSV Job Manager* wizard, select **CSV Import** and select the import job that you want to delete, click the Action icon and select **Delete** or click the Delete pending job icon.
3. Click **Yes** to delete the uploaded job or **No** to cancel the operation in the *Cancel Import Job* wizard.

Downloading Files

You can download various types of files based on the import operation that you have selected. You can download the following files: uploaded, error, results, and snapshot. Superusers can download the original imported file.

Downloading Uploaded or Error Files

You can download CSV files that are already uploaded or download error files to check the errors that the import operation encountered. The download options are valid for all import operations, except replace.

To download the file, complete the following:

- From the **Data Management** tab, click **CSV Job Manager** from the Toolbar.
- In the *CSV Job Manager* wizard, select **CSV Import** and select the import job that you want to download, click the Action icon and select **Download**.
    - **Uploaded File**: Select this to download the uploaded CSV import file.
    - **Error File**: Select this to download the error file. This option is enabled only if the import operation encountered an error.

You can export these files to your local system.

Downloading Uploaded, Snapshot, or Results Files

You can view the uploaded, result, and snapshot files. The snapshot and results files are enabled only for replace operation.

To download the file, complete the following:

1. From the **Data Management** tab, click **CSV Job Manager** from the Toolbar.
2. In the *CSV Job Manager* wizard, select **CSV Import** and select the import job that you want to download, click the Action icon and select **Edit**.
3. In **Edit - CSV Import Job**, click the arrow beside the **Download** option and select one of the following:
    - **Uploaded File**: Select this to download the uploaded CSV import file. The uploaded report displays the content of the imported file, before it was uploaded, that is before the content of the database is changed.
    - **Snapshot File**: Select this to download the backup file. NIOS automatically creates a backup of the database before replacing the content of the database with the content in the imported CSV file. This option is enabled only for the replace operation. NIOS generates an error message and saves it in the syslog and the infoblox.log file when the backup file is not generated. You can download the backup file after the replace operation is complete. NIOS saves the backup file and other results file in the Grid for a period of 30 days. The name of the backup file has the following format: `csv-snapshot-10-\[view\]-\[zone\]-\[timestamp\].csv where 10 is the import ID of the CSV import task, view is the DNS view name, zone is the FQDN of the zone being replaced and timestamp is the timestamp at when the file is generated.`
    - **Results File**: Select this to download the results file. The file displays the content of the database after the content of the file replaced the content of the database. You can view the results file only after the replace operation is complete.

You can export these files to your local system.

Creating a Data File for Import

If you are migrating new data into the database, you must prepare the data file using the correct format and syntax before you can import it successfully. You must include all the required fields and understand the dependencies among some of the fields. For detailed information about the guidelines, supported record types, and interdependencies among fields, refer to the *Infoblox CSV Import Reference*.

Exporting Data to Files

You can export existing data to a CSV file. The appliance marks all required fields with an asterisk ⭐ in the exported file. It also adds a _new_XXXX field to each required field so you can use this field to update data. You cannot stop an export once you start it.

To export all data to a CSV file:

1. From Grid Manager, navigate to the panel that contains the data you want to export. For example, if you want to export data for all DNS zones, select the **Data Management** tab -> **DNS** tab -> **Zones** tab.
2. In the panel, select **Export data in Infoblox CSV Import format** from the **Export** drop-down menu.
3. In the *Export* dialog box, complete the following:
    a. **Separator**: Select the separator used in the data file. The default is Comma.
    b. Click **Export**.

The appliance exports all the fields of the records that are displayed in this panel based on your filter criteria. You can either open the data file or save it to your computer. The appliance uses a default file name depending on the panel from which you perform the export. For example, when you export the data from the **IPAM** tab, the default file name is *Allnetworks.csv*. When you export data from the **DNS** tab, the default file name is *Allzones.csv*. The file contains a header row that includes all the fields of the corresponding record type. You can update this data file, and then re-import the data into the database.
You can also export the displayed fields in a panel.

Exporting New CSV Jobs

You can use the *Global CSV Export Wizard* to export multiple objects at once. You can export multiple object data types to a single CSV file through Grid Manager. Objects that have the least or no dependencies on other objects are placed at the top of the list and the most dependent objects are displayed at the bottom of the list. The export command will not re-execute after a Grid Manager HA failover.
For standalone appliances, the Grid Manager sends a single CSV export request that contains both Grid and member CSV headers to export Grid and member properties. Similarly, Grid Manager combines GridDns and MemberDns headers to export DNS properties and GridDhcp and MemberDhcp headers to export DHCP properties.
You cannot export the default DNS view if you have not created a custom DNS view. To export the default DNS view, you must either create custom DNS views or use the **CSV Global Export** option.
Note that when you use the **Global CSV Export** option to export either all objects, all DNS objects, or all PTR records, the appliance also exports the PTR system generated records from the auto-created zone "0.0.127.in-addr.arpa". When you use the same file for import operation, the CSV import operation might fail due to the presence of these system generated records. Infoblox recommends that you select the **Skip to next row and continue** option while performing the CSV import operation. When you select this option, CSV import skips these rows with appropriate error messages and then processes other rows in the CSV file.
To export DNS and DHCP data:

1. From the **Data Management** tab, click **CSV Job Manager** from the Toolbar.
2. In the *CSV Job Manager* wizard, click **CSV Export**. Click the New CSV Export job icon and specify the following in the *Global CSV Export Wizard*:
    - **Separator**: Select a separator from the drop-down list: **Comma**, **Semicolon**, **Space**, and **Tab**.
    - **All Objects**: The checkbox is selected by default. When you select this checkbox, all DHCP, global, and DNS objects are selected by default.

- **All DHCP Objects**: Select this checkbox to select all DHCP objects that are listed. To select specific DHCP objects, clear this checkbox and select respective checkboxes next to the DHCP object names.
- **Global Objects**: Select this checkbox to select all global objects that are listed. To select specific global objects, clear this checkbox and select respective checkboxes next to the global object names.
- **All DNS Objects**: Select this checkbox to select all DNS objects that are listed. To select specific DNS objects, clear this checkbox and select respective checkboxes next to the DNS object names.

3. Click **ExportD ata** to start the export process. In the *Start global CSV Export* dialog box, click **Yes** to confirm or click **No** to cancel the process.
4. Grid Manager displays the CSV export progress and results in the *CSV Global Export progress* dialog box. It displays the following information:
   - **Separator**: The separator used in the CSV file.
   - **Approximate number of objects to be exported**: Indicates the approximate number of objects to be exported.
   - **Number of objects exported**: Indicates the total number of objects that are exported.
   - **Current status**: Indicates the current status of the export process.
5. Click **Close** to exit.

Managing CSV Export Jobs

You can view the list of CSV export operations using the **CSV Job Manager**.

1. From the **Data Management** tab, click **CSV Job Manager** from the Toolbar. In the *CSV Job Manager* wizard, click **CSV Export**.
2. Grid Manager displays the following information:
   - **User Name**: The admin user who submitted the CSV export. Only superusers can view this column.
   - **Status**: The current status of the export job. The CSV export process runs in an asynchronous mode similar to the CSV import. The status can be one of the following:
     - **Export pending**: The job is in queue for execution.
     - **Export running**: The job is being executed.
     - **Export stopped**: The job has been stopped. You can select the job and restart the export.
     - **Export completed**: The export is completed without errors. Check the **Message** field for information about the export.
     - **Export failed**: The export is completed, but with errors. Check the **Message** field for information about the error message.
   - **Submitted**: The timestamp when the job was submitted.
   - **Completed**: The timestamp when the job was completed. This field is blank if the job has not been completed yet.
   - **Failed Description**: The appliance displays the error message in the **Failed Description** column if the CSV export fails. You cannot start a failed CSV export task.
   - **File Size**: The size of the generated CSV file.

Completed CSV export jobs are deleted 30 days from the date of submission. You can also perform the following operations:

- Select a completed CSV export task and download the exported file.
- Cancel or stop a pending CSV export task using the **Delete** option.
- Purge all export tasks after an upgrade or restore.
- Start a new global CSV export job.

Modifying CSV Export Jobs

You can cancel an export job that is in progress or download an exported job. You can also schedule new export jobs. The appliance deletes the CSV jobs that are completed after 30 days from the date of submission.
To update an exported job or delete one:

1. From the **Data Management** tab, click **CSV Job Manager** from the Toolbar.
2. In the *CSV Job Manager* wizard, click **CSV Export**.
3. Select the export job that you want to update, click the Action icon. Click **Cancel** to cancel the export job that is in progress. You can also click the **Cancel job** icon to delete the file. Click **Download file** to download the exported file.
4. Click the New CSV Export job icon to export a new job.
5. Click **Close** to exit.

Exporting Displayed Data

You can export visible information, such as global search results and the syslog file, in CSV format from panels and pages that support the Export function, and then easily convert the file to PDF and other file formats. You can also export all data in a specific panel.
To export displayed data:

1. From Grid Manager, navigate to the panel that contains the data you want to export. For example, if you want to export data for DNS zones, select the **Data Management** tab -> **DNS** tab -> **Zones** tab.
2. In the panel, select **Export visible data** from the **Export** drop-down menu.
3. In the *Export* dialog box, click **Start**. Grid Manager displays a message about the time required to export data could be long depending on the amount of data.
4. Click **Download** when the export is finished.
5. Depending on your browser and operating system, you may need to do one of the following in the *Opening .csv* dialog box:
    - **Open with**: Select a program with which you want to open the .csv file.
    - **Save to Disk**: Select this if you want to save the .csv file to your local computer.
    - **Do this automatically for files like this from now on**: Select this checkbox if you want Grid Manager to use the same method for future exports. When you select this checkbox, Grid Manager does not display the *Opening .csv* dialog box in the future.
6. Click **OK**.

Depending on the selected option, Grid Manager opens the file using the program you select, or saves the file to your local computer.

SSL and TLS Protocols

When you log in to the NIOS appliance, your computer makes an HTTPS (Hypertext Transfer Protocol over Secure Sockets Layer protocol) connection to the NIOS appliance. HTTPS is the secure version of HTTP, the client-server protocol used to send and receive communications throughout the Web. HTTPS uses SSL (Secure Sockets Layer) and/or TLS (Transport Layer Security) protocols to secure the connection between a client and server. SSL/TLS provides server authentication and encryption. The NIOS appliance supports TLS versions 1.0, 1.1, and 1.2. TLS provides cipher suites that are used to negotiate the security settings for the secure connection. Infoblox has provided a few CLI commands so you can enable and disable specific cipher suites. For detailed information about these CLI commands, see *Using the NIOS CLI* .
Note that enabling or disabling the TLS ciphers will enable or disable the equivalent SSHd cipher. The following table lists the TLS suite name and the corresponding OpenSSL suite name, SSHd cipher name, and SSHd MAC name:

TLS Cipher Suites

TLS Suite Name	Open SSL Suite Name	SSHd Cipher	SSHd MAC

TLS_DHE_RSA_WITH_AES_256_CBC_SHA	DHE-RSA-AES256-SHA	aes256-cbc	hmac-sha1, hmac-sha1-etm@openssh.com
TLS_DHE_DSS_WITH_AES_256_CBC_SHA	DHE-DSS-AES256-SHA	aes256-cbc	hmac-sha1, hmac-sha1-etm@openssh.com
TLS_RSA_WITH_AES_256_CBC_SHA	AES256-SHA	aes256-cbc	hmac-sha1, hmac-sha1-etm@openssh.com
TLS_DH_RSA_WITH_3DES_EDE_CBC_SHA	EDH-RSA-DES-CBC3-SHA	3des-cbc	hmac-sha1, hmac-sha1-etm@openssh.com
TLS_DH_DSS_WITH_3DES_EDE_CBC_SHA	EDH-DSS-DES-CBC3-SHA	3des-cbc	hmac-sha1, hmac-sha1-etm@openssh.com
TLS_RSA_WITH_3DES_EDE_CBC_SHA	DES-CBC3-SHA	3des-cbc	hmac-sha1, hmac-sha1-etm@openssh.com
TLS_DHE_DSS_WITH_AES_128_CBC_SHA	DHE-DSS-AES128-SHA	aes128-cbc	hmac-sha1, hmac-sha1-etm@openssh.com

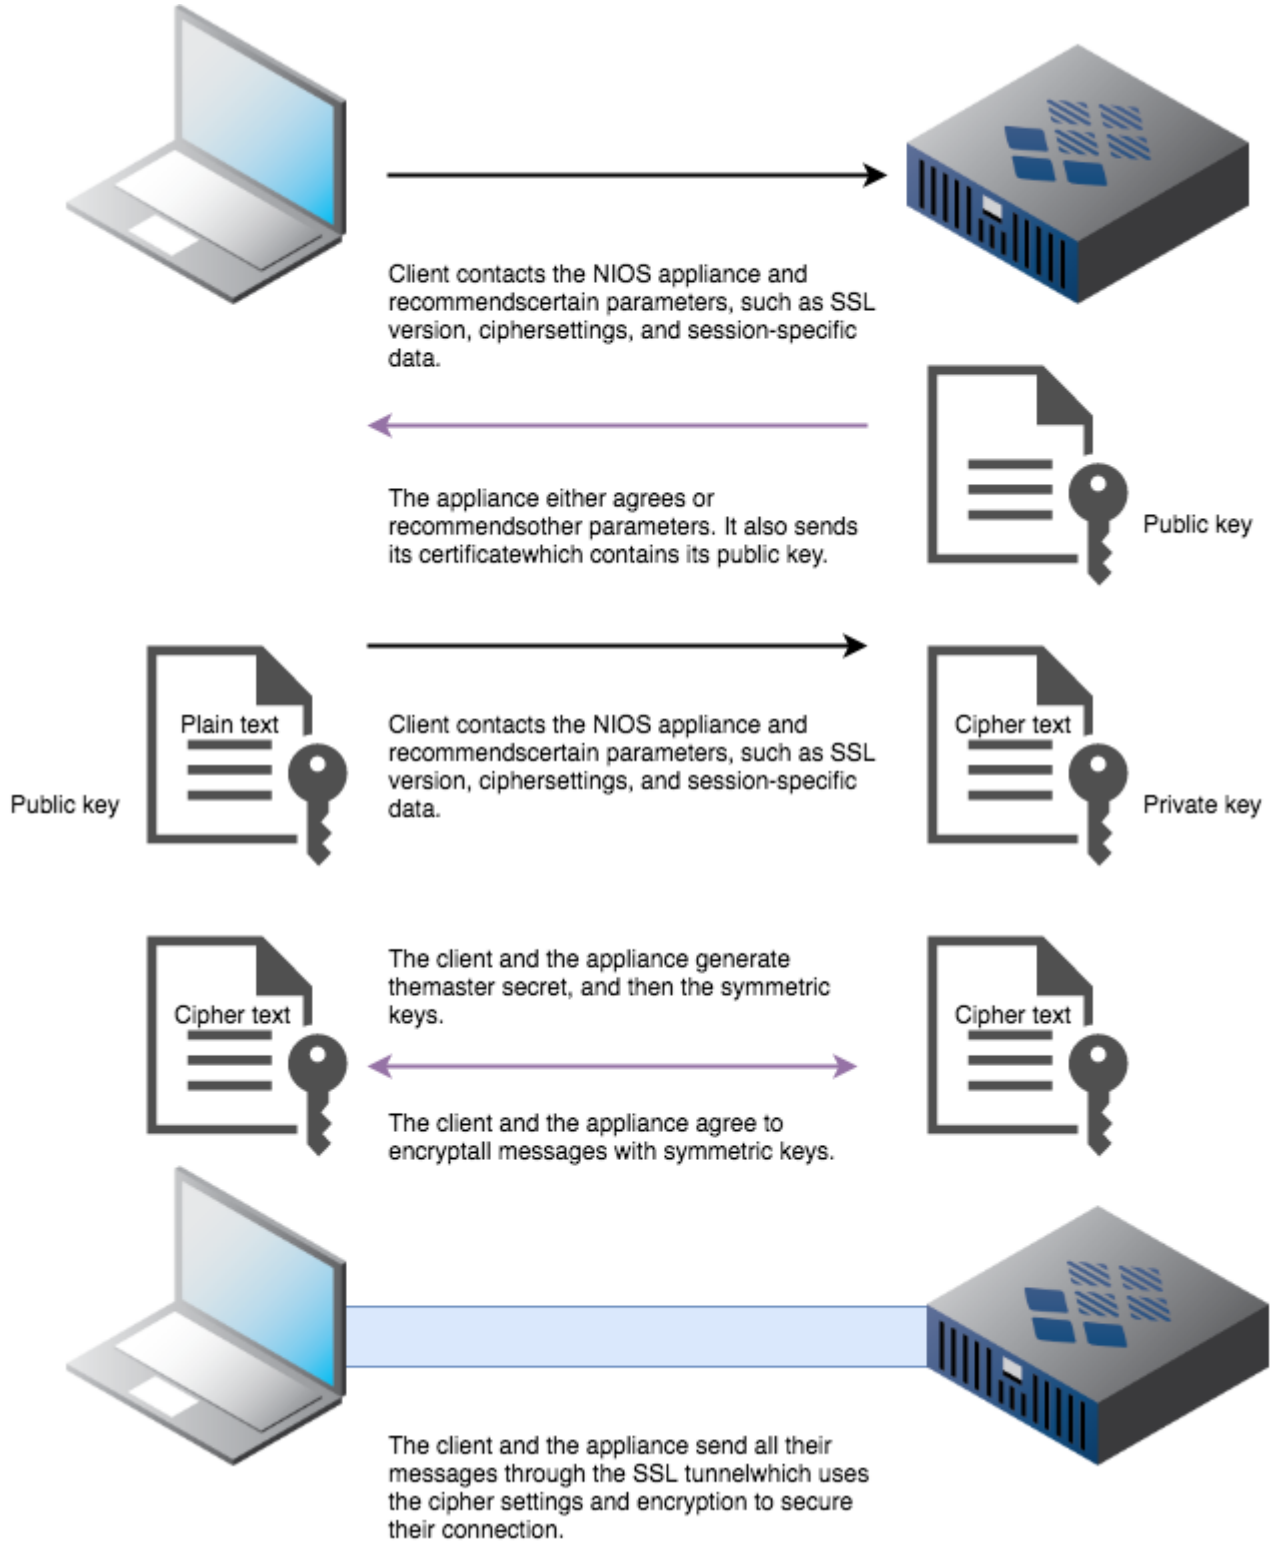
TLS_RSA_WITH_AES_128_GCM_SHA256	AES128-GCM-SHA256	aes128-gcm@openssh.com	hmac-sha2-256, hmac-sha2-256-etm@openssh.com
TLS_RSA_WITH_AES_128_CBC_SHA256	AES128-SHA256	aes128-cbc	hmac-sha2-256, hmac-sha2-256-etm@openssh.com

When a client first connects to a server, it starts a series of message exchanges, called the SSL/TLS handshake. During this exchange, the server authenticates itself to the client by sending its server certificate. A certificate is an electronic form that verifies the identity and public key of the subject of the certificate. (In SSL/TLS, the subject of the certificate is the server.) Certificates are typically issued and digitally signed by a trusted third party, the Certificate Authority (CA). A certificate contains the following information: the dates it is valid, the issuing CA, the server name, and the public key of the server. For information about certificates, see *ManagingOManaging CertificatesCertificates*.

A server generates two distinct but related keys: a public key and a private key. During the SSL/TLS handshake, the server sends its public key to the client. Once the client validates the certificate, it encrypts a random value with the public key and sends it to the server. The server decrypts the random value with its private key.

The server and the client use the random value to generate the master secret, which they in turn use to generate symmetric keys. The client and server end the handshake when they exchange messages indicating that they are using the symmetric keys to encrypt further communications.

SSL/TLS Handshake



To avoid possible attacks in which HTTP or HTTPS connections are made to a web server and stay open much longer than they should be, Infoblox provides the `set connection_limit` and `show connection_limit` CLI commands that you can use to mitigate these attacks. In general, these attacks can result in the web server reaching its maximum number of concurrent connections, and thus denying connections from legitimate sources. You can use the

CLI commands to limit the number of concurrent HTTP and HTTPS connections from a given client that corresponds to a particular IP address. For information about the CLI commands and how to use them, see *Using the NIOS CLI.*

Managing Certificates

This topic covers the following sections:

- *About Client Certificates*
- *About Validate Certificates*

About Client Certificates

This section covers the following:

- *Generating a Client Certificate*
- *Viewing Client Certificates*
- *Downloading Client Certificates*

You can generate client certificates for a Grid Master or a Grid Master candidate, and then send it to another server, such as a Hardware Security Module (HSM).

Generating a Client Certificate

To generate a client certificate:

1. Grid: From the **Grid** tab, select the **Grid Manager** tab.
   Grid Master Candidate: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox.
2. From the Toolbar, click **Certificates** -> **Client Cert** -> **Generate Client Certificate**, and select either **RSASHA1** or **RSASHA256**.
   - If you are generating a certificate for an HSM group with Thales Luna 4 devices, you must select **RSASHA1**; and if the certificate is for an HSM group with Thales Luna 5 or Luna 6 devices, select **RSASHA256**.

The appliance displays a confirmation dialog after it generates the certificate. If a certificate had been previously generated, the appliance displays a dialog warning that if the previous certificate was registered with a server, then the new certificate must be registered with the server.

Viewing Client Certificates

To view the client certificates that were generated:

1. Grid: From the **Grid** tab, select the **Grid Manager** tab.
   Grid Master Candidate: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox.
2. From the Toolbar, click **Certificates** -> **Client Cert** -> **View Client Certificate**, and select either **RSASHA1** or **RSASHA256.**

The appliance displays the selected certificate.

Downloading Client Certificates

To download a client certificate:

1. Grid: From the **Grid** tab, select the **Grid Manager** tab.
   Grid Master Candidate: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox.
2. From the Toolbar, click **Certificates** -> **Client Cert** -> **Download Client Certificate**, and select either **RSASHA1** or **RSASHA256.**

3. Save the certificate.

About Validate Certificates

You can view the status results of the certificates uploaded by clicking **Validate Certificates**. The **Validate Certificates** feature validates the following:

- All the certificate files will be validated through OpenSSL command on each file.
- The certificates serial number stored in the database (one.x509_certificate DB objects), and saves the certificates to temporary files.

To view the validated certificates in Grid Manager:

1. Grid: From the **Grid** tab, click **Certificates** in the Toolbar > **Validate Certificates**.
   The *Certification Validation Results* dialog displays the following:
   - **Filename/Serial number**: Displays the filename of the certificate files in the folder (For example, ocsp_ca_cert.pem) or the serial number of the certificates in the database ((For example, 4786438514b4fa8325d750a39ca79....)
   - **Verification Result**: Displays the certificate result and the certificate status. For example:
     - Valid certificate:
       /storage/tmp/cert1.pem: OK (folder/temporary files/certificate name.pem: OK)
     - Expired certificate:
       /infoblox/security/certs/ocsp_ca_cert.pem: C = IN, ST= Karnataka, L = Bengaluru, 0 = Infoblox, OU= QA, CN = adityagfc33.inca.infoblox.com, emailAddress = adityag@infoblox.com error 10 at O depth lookup:certificate has expired OK
       (folder/temporary files/certificate name.pem: certificate has expired message OK)
     - Invalid certificate
       /infoblox/security/certs/ocsp_ca_cert.pem: C = IN, ST = Karnataka, O = Infoblox, OU = QA2, CN = test.inca.infoblox.com error 20 at 0 depth lookup:unable to get local issuer certificate Warning: contains CA certificate(s) without SKI
       (folder/temporary files/certificate name.pem: issuer certificate Warning message stating contains CA certificate(s) without SKI OK)
2. Click **Close to** exit the *Certification Validation Results* dialog.

> ⚠ Note
> - For valid self-signed certificates, Grid Manager does not display any additional information. However, for expired and invalid certificates Grid Manager displays the issuer/subject information in the *Certification Validation Results* screen.
> - Warning messages are displayed for expired certificates and for certificates with no SKI (Subject Key Identifier) in the concatenated certificate file.

Configuring Approval Workflows

Approval workflows support routing certain core network service tasks submitted by an admin group to another for approval. You can add an admin group to an approval workflow and define the group as a submitter or approver group. Note that only superusers can create approval workflows. For information about how to set up admin groups, see *About Admin Groups*.
In an approval workflow, you can add a submitter group and an approver admin group that you have previously defined. You can also define when and to whom email notifications are sent, and configure options such as whether submitters or approvers must enter a comment or a ticket number when they submit tasks for approval. Approval workflows are useful when you want to control tasks that require reviews. For example, if you have a group of help desk users who can add, modify, and delete hosts and you want members of an operation group to review these tasks, you can define the help desk users as submitters, and then set up members of the operation group as approvers. You can then add the submitter and approver groups to an approval workflow and configure notifications options and other configurations, such as allowing the approvers to reschedule the submitted tasks.

Not all core network service tasks can be routed for approval. You can configure approval tasks associated with certain objects. For a list of supported objects, see *Scheduling Tasks*.

> **Note**
>
> When an admin group is defined as a submitter group, there are certain operations the submitters cannot perform even though they may have the permissions to do so. For information about such operations, see Unsupported Operations for Submitters below.

To create an approval workflow, complete the following:

1. If you have not already done so, set up admin groups that you can configure as submitter groups and approver groups in an approval workflow, as described in *About Admin Groups*.
2. Create an approval workflow and configure email notifications and other options, as described in Creating Approval Workflows below.

You can do the following after you have created approval workflows:

- View a list of approval workflows, as described in Viewing Approval Workflows below.
- Modify approval workflows, as described in Modifying Approval Workflows below.
- Delete approval workflows, as described in Deleting Approval Workflows below.
- View a list of approval tasks, as described in Viewing Approval Tasks below.
- View approval notifications, as described in Viewing Workflow Notifications below.

Supported Tasks for Different Admin Groups

Depending on your admin permissions, you may or may not be able to perform certain tasks that are subject to approvals. Supported Tasks for Different Admin Groups lists specific tasks and indicates which admin group can perform the tasks.

Supported Tasks for Admin Groups

Admin groups that can perform the task			
Tasks related to approval workflows	**Submitters**	**Approvers**	**Superusers**
Change the schedule of a task when it is pending approval	Yes	No	Yes
Change the schedule of a task after it has been approved	Yes (Task is re-submitted for approval)	Yes	Yes
Execute the task now when it is pending approval	No	No	No
Delete a task after it has been approved but pending execution	No	No	Yes
Delete a task after it failed or has been executed	No	No	Yes
Delete tasks by selecting the **Select all objects in this dataset** option	Yes	Yes	Yes

Admin groups that can perform the task			
Tasks related to approval workflows	**Submitters**	**Approvers**	**Superusers**
Note: Not all tasks are deleted, depending on the task status and the admin who performs the deletion			

Creating Approval Workflows

Before you create an approval workflow, ensure that you have admin groups that you can define as submitters and approvers. Note that a submitter group can be added to only one approval workflow, and approver groups can be added to multiple workflows. An approver can choose to approve a task and either keep or change the date and time when the task is executed. For information about scheduling and rescheduling tasks, see *Scheduling Tasks*. An approver can also reject a submitted task.
All submitted tasks are executed based on submitter permissions. When an admin submits a task, the appliance logs the task in the audit log and associates it with a task ID. You can view your tasks in **Task Manager**, as described in *Viewing Tasks*. Depending on your configuration, you can control when and to whom email notifications are sent. For example, you can configure the appliance to send notifications to only the approver each time when a task requires approval, or send notifications to both the submitter and approver group each time when a task is disapproved.

To create an approval workflow

1. From the **Administration** tab, select the **Workflow** tab -> **Approval Workflows** tab, and then click the Add icon
2. In the *Add Approval Workflow* wizard, complete the following:

- **Submitter Group**: From the drop-down list, select the admin group whose submitted tasks require approvals. Note that performing CSV imports do not require approvals. If there is a warning that the submitter group has CSV import permission, you may want to remove the permission.
- **Approver Group**: From the drop-down list, select the group that can approve tasks submitted by admins of the submitter group. If the approver group you select does not have the permission to schedule tasks, the approvers cannot reschedule the execution dates and times of the tasks when they approve them.
- **Ticket Number**: From the drop-down list, select one of the following to determine whether a ticket number is required when a submitter submits a task for approval.
    - **Required**: The submitter must enter a ticket number when submitting a task.
    - **Optional**: The submitter can choose to enter a ticket number or not when submitting a task.
    - **Not Used**: The **Ticket Number** field does not appear when the submitter creates a task.
- **Submitter Comment**: From the drop-down list, select whether the submitter must enter a comment or not when submitting a task for approval. You can select **Required**, **Optional**, or **Not Used**.
- **Approver Comment**: From the drop-down list, select whether the approver must enter a comment or not when approving a task. You can select **Required**, **Optional**, or **Not Used**.**Submitter Group**: From the drop-down list, select the admin group whose submitted tasks require approvals. Note that performing CSV imports do not require approvals. If there is a warning that the submitter group has CSV import permission, you may want to remove the permission.

3. Click **Next** and complete the following to specify notification options for the workflow:

- **Approver Notification Address(es)**: Select one of the following to specify to which approver email addresses the appliance sends workflow notifications. The default is **Group Email Address(es)**.
    - **Group Email Address(es)**: Select this if you want the appliance to send notifications to the list of email addresses configured for the admin group. For information about how to configure this list, see *About Admin Groups*.

        - **User Email Address(es)**: Select this if you want the appliance to send notifications to individual email addresses of the admin group.
    - **Notifications sent on**: Select the operations that can trigger email notifications. When you select an operation, the appliance sends a notification each time that operation occurs. By default, all operations are selected.
        - **Approval Required**: The appliance sends an email notification each time an approval is required.
        - **Task Approved**: The appliance sends an email notification each time a task is approved.
        - **Task Rejected**: The appliance sends an email notification each time a task is rejected.
        - **Task Succeeded**: The appliance sends an email notification each time a task is completed successfully.
        - **Task Failed**: The appliance sends an email notification each time the execution of a task fails.
        - **Task Rescheduled**: The appliance sends an email notification each time a task is being rescheduled.
    - **Notifications sent to**: For each operation, select whether the **Approver**, **Submitter**, or **Both** are notified when the operation occurs. The default value is **Both** for all operations. For information about email notifications, see Viewing Approval Tasks below.

4. Optionally, click **Next** to add extensible attributes to the approval workflow. For information, see *About Extensible Attributes*.
5. Save the configuration.

Viewing Approval Workflows

Grid Manager lists all approval workflows in the **Approval Workflows** tab. Only superusers can view approval workflows defined for the Grid. Limited-access users cannot view approval workflows.
To view approval workflows:

1. From the **Administration** tab, select the **Workflow** tab -> **Approval Workflows** tab.
2. Grid Manager displays the following for each approval workflow:

- **Submitter Group**: The name of the admin group whose tasks require approvals.
- **Approver Group**: The name of the admin group that can approve tasks submitted by members of the submitter group.
- **Ticket Number**: Displays whether the submitter is required to enter a ticket number when submitting tasks that require approvals. Possible values are **Not Used**, **Optional**, and **Required**.
- **Submitter Comment**: Displays whether the submitter is required to enter a comment when submitting tasks that require approvals. Possible values are **Not Used**, **Optional**, and **Required**.
- **Approver Comment**: Displays whether the approver is required to enter a comment when approving tasks. Possible values are **Not Used**, **Optional**, and **Required**.
- **Site**: Values that were entered for this predefined extensible attribute.

You can do the following in this tab:

- Modify some of the data in the table. Double click a row, and either modify the data in the field or select an item from a drop-down list. Click **Save** to save the changes. Note that some fields are read-only.
- Sort the data in ascending or descending order by column.
- Select an approval workflow and click the Edit icon to modify data, or click the Delete icon to delete it.
- Use filters and the **GoTo** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information about using quick filters, see *Finding and Restoring Data*.
- Print and export the data in this tab.

Modifying Approval Workflows

You can modify information in an approval workflow, except for the submitter group. To modify approval workflow configuration:

1. From the **Administration** tab, select the **Workflow** tab -> **Approval Workflows** tab.
2. Select an approval workflow and click the Edit icon.
3. Grid Manager provides the following tabs from which you can modify information:

- **General** tab: You can modify the approver group and decide whether the ticket number, submitter comment, and approver comment are required, but you cannot change the submitter group.
- **Approval Notifications** tab: You can modify when and to whom email notifications are sent.
- **Extensible Attributes** tab: You can add or modify values of extensible attributes. For information, see *About Extensible Attributes*.

4. Save the configuration.

Deleting Approval Workflows

You can delete an approval workflow any time after you have created it. Note that when you delete a workflow that has associated tasks that are pending approvals, the tasks will be rejected after you delete the workflow.
To delete an approval workflow:

1. From the **Administration** tab, select the **Workflow** tab -> **Approval Workflows** tab.
2. Select an approval workflow and click the Delete icon.
3. Click **Yes** in the *Delete Confirmation* dialog.

Viewing Approval Tasks

If you belong to an approver admin group, you can view, approve, or reject tasks that are pending your approval in the **Task Manager** tab. For information, see *Viewing Tasks*. Submitter's can view all pending and completed tasks they have submitted.

Viewing Workflow Notifications

When a submitter and approver receives an email notification about their tasks, the appliance lists the approval status and workflow related information such as task ID, submitter name, execution time, object type and action in the email notification.
Following is a sample email notification:

```
Notification:
 =============

Message: Task 32 submitted by subm has been approved The following task has
been approved:
 Task details

    Task ID: 32 Submitter: subm Approver: jdoe
     Submit time: 2012-10-09 05:55:01 (UTC) Coordinated Universal Time
    Execution time: N/A
     Object type: NS Record Action: Add
     Affected object: corp1.com Ticket number: MKTG245
     Submitter comment: Create an NS record. Approver comment: Approved.
```

```
Click here to go to the task management tab - https://192.168.1.2/ui/?
contextId=taskmanager
```

> **Note**
>
> When you can click the hyperlink displayed in the notification, you can log in to **Grid Manager** and access the **Task Manager** tab in a separate browser tab or window.

Unsupported Operations for Submitters

When admins are part of a submitter group in an approval workflow, there are certain operations they cannot perform even though they may have the permissions to do so. Following is the list of operations that submitters cannot perform:

- Reclaim IPv4 or IPv6 addresses
- Expand networks
- Resize networks
- Split networks
- Sign (DNSSEC) zones
- Unsign DNSSEC signed zones
- Import DS to DNSSEC signed zones
- Perform KSK rollovers on a DNSSEC signed zones
- Copy records from one DNS zone to another
- Clear all discovered data
- Clear discovered timestamps
- Clear unmanaged addresses
- Resolve discovery conflicts
- Update extensible attributes on multiple objects at a the same time
- Delete or modify several objects at a time (using the "Select all objects in this dataset" option from Grid Manager)
- Order DHCP Ranges inside a network (feature is available only when used with Sophos)
- Configure member DHCP Captive Portal through the wizard
- Restore objects from the Recycle Bin
- Delete non-native NIOS DNS resource records. These objects can only be synchronized from a Microsoft DNS server
- Copy rules from one Response Policy Zone to another
- Order Response Policy Zones

Administering NIOS

This section provides information about configuring admin groups, roles, and accounts, and defining the appropriate permissions. It explains how to configure and manage a Grid or an independent appliance, and set operational parameters. It also describes the file distribution services (TFTP, FTP, and HTTP) and the bloxTools environment. It includes the following topics:

- *Appliance Administration*
- *IP Address Management*
- *Configuring Super Hosts*
- *DNS*
- *DHCP*
- *Configuring Microsoft Windows Servers*
- *Monitoring*
- *Infoblox Reporting and Analytics*
- *Infoblox Infrastructure Security*
- *Infoblox Subscriber Services*
- *VLAN Management*

Appliance Administration

This section provides information about configuring admin groups, roles, and accounts, and defining the appropriate permissions. It explains how to configure and manage a Grid or an independent appliance, and set operational parameters. It also describes the file distribution services (TFTP, FTP, and HTTP) and the bloxTools environment. It includes the following chapters:

- *Managing Administrators*
- *Deploying a Grid*
- *Deploying Independent Appliances*
- *Deploying Cloud Network Automation*
- *Managing Appliance Operations*
- *File Distribution Services*
- *bloxTools Environment*
- *RIR Registration Updates*

Managing Administrators

This section describes the various tasks associated with setting up admin groups, admin roles, admin accounts, and permissions. It contains the following sections:

- *About Admin Groups*
- *About Admin Roles*
- *Managing Admin Groups and Admin Roles*
- *About Administrative Permissions*
- *Authenticating Administrators*
- *Authenticating Admins Using Two-Factor Authentication*
- *About Remote Admins*
- *Authenticating Admins Using RADIUS*
- *Creating Local Admins*
- *Authenticating Admin Accounts Using TACACS+*

About Admin Groups

All administrators must belong to an admin group. The permissions and properties that you set for a group apply to all administrators assigned to that group. You can assign a dashboard template to an admin group. A dashboard template specifies the tasks an admin group can access through the **Tasks Dashboard** tab when they log in to Grid Manager. For information about dashboard templates, see *Configuring Dashboard Templates*. You can also restrict certain user groups to manage specific tasks in the **Tasks Dashboard** tab only. These users cannot manage other core network services through Grid Manager. For information about how to apply this restriction, see Limited-Access Admin Groups below.

To define admins who can perform specific core network service tasks, you can set up admin groups and assign them permissions for those tasks. To control when and whether certain tasks should be performed, you can add an admin group to an approval workflow and define the admins as submitters or approvers. A submitter is an admin whose tasks require approvals before execution, and an approver is an admin who can approve the submitted tasks. When you add submitter and approver groups to an approval workflow, you have control over who can perform which mission critical tasks and whether and when the tasks should be executed. For more information about how to create and configure approval workflows, see *Configuring Approval Workflows*.

There are three types of admin groups:

- **Superuser** – Superuser admin groups provide their members with unlimited access and control of all the operations that a NIOS appliance performs. There is a default superuser admin group, called **admin-group**, with one superuser administrator, **admin**. You can add users to this default admin group and create additional admin groups with superuser privileges. Superusers can access the appliance through its console, GUI, and API. In addition, only superusers can create admin groups.
- **Limited-Access** – Limited-access admin groups provide their members with read-only or read/write access to specific resources. These admin groups can access the appliance through the GUI, API, or CLI. They cannot access the appliance through the console.
- **Default** – When upgrading from previous NIOS releases, the appliance converts the ALL USERS group to the Default Group when the ALL USERS Group contains admin accounts. The appliance does not create the Default Group if there is no permission in the ALL USERS group. The permissions associated with the ALL USERS group are moved to a newly created role called Default Role. Supported in previous NIOS releases, the ALL USERS group was a default group in which you defined global permissions for all limited-access users. This group implicitly included all limited-access users configured on the appliance.

All limited-access admin groups require either read-only or read/write permission to access certain resources, such as Grid members, and DNS and DHCP resources, to perform certain tasks. Therefore, when you create an admin group, you must specify which resources the group is authorized to access and their level of access.

Only superusers can create admin groups and define their administrative permissions. There are two ways to define the permissions of an admin group. You can create an admin group and assign permissions directly to the group, or you can create roles that contain permissions and assign the roles to an admin group.

You must create admin groups and assign them access to the cloud API and applicable permissions so they have authority over delegated objects. When you assign permissions for objects that have not been delegated, these admin groups or admin users assume applicable permissions to these un-delegated objects. For example, you can create an admin group that can access a specific set of networks while another can access another set of networks. Note that you cannot create a new admin group using the same name. For information about Cloud Network Automation, see *Deploying Cloud Network Automation*.

Complete the following tasks to assign permissions directly to an admin group:

1. Create an admin group, as described in Creating Limited-Access Admin Groups below.
2. Assign permissions to the admin group, as described in *About Administrative Permissions.* Complete these tasks to assign admin roles to an admin group:
3. Create an admin role, as described in *About Admin Roles*.
4. Define permissions for the newly created admin role, as described in Creating Admin Roles, see *About Admin Roles*.
5. Create an admin group and assign the role to the group, as described in Creating Limited-Access Admin Groups below.

After you have created admin groups and defined their administrative permissions, you can assign administrators to the group.

- For local admins, see *Creating Local Admins.*
- For remote admins, see *About Remote Admins*.

Creating Superuser Admin Groups

Superusers have unlimited access to the NIOS appliance. They can perform all operations that the appliance supports. There are some operations, such as creating admin groups and roles, that only superusers can perform.

Note that there must always be one superuser admin account, called "admin", stored in the local database to ensure that at least one administrator can log in to the appliance in case the NIOS appliance loses connectivity to the remote admin databases such as RADIUS servers, AD domain controllers, TACACS+ servers, LDAP servers, or OCSP responders.

NIOS comes with a default superuser admin group (**admin-group**). It also automatically creates a new admin group, **fireeye-group**, when you add the first FireEye RPZ (Response Policy Zone). Infoblox recommends that you do not add another admin group with the same name as the default or FireEye admin group. Note that the FireEye admin group is read-only and you cannot assign permissions to it. For more information about FireEye RPZs, see *About FireEye Integrated RPZs*.

When you install valid licenses and configure your Grid for Cloud Network Automation, NIOS enables the **cloud-api-only** admin group. You can assign admin users to this group so they are authorized to send cloud API requests to the Cloud Platform Appliances. Note that you cannot delete this admin group or create a new admin group using the same name. For information about Cloud Network Automation, see *Deploying Cloud Network Automation*.

You can create additional superuser admin groups, as follows:

1. From the **Administration** tab, select the **Administrators** tab -> **Groups** tab, and then click the Add icon.
2. In the *Add Admin Group* wizard, complete the following:
    - **Name:** Enter a name for the admin group.
    - **Comment:** Enter useful information about the group, such as location or department. For **fireeye-group,** NIOS displays **Group used to receive FireEye alerts** in this field.

- **Disable:** Select this to retain an inactivated profile for this admin group in the configuration. For example, you may want to define a profile for recently hired administrators who have not yet started work. Then when they do start, you simply need to clear this checkbox to activate the profile.

3. Click **Next** and complete the following:
Superusers: Select this to grant the admin accounts that you assign to this group full authority to view and configure all types of data and perform all tasks.

- **Allowed Interfaces**: Superusers admin groups are automatically granted access to the Infoblox GUI (Grid Manager), API, and CLI. You can specify which API the superusers group can access. Note that you must have the Cloud Network Automation or Cloud Platform license installed to configure access to the cloud API.
GUI: This is selected by default. The superusers admin group automatically has full access to Grid Manager.
API: This is selected by default. Note that the following options are displayed only if a cloud license is installed in the Grid.
CLI: This is selected by default. The superusers admin group automatically has full access to the NIOS CLI.
- **API (WAPI/PAPI only)**: The superusers admin group has full access to the RESTful API and the Infoblox API by default.
- **Cloud API:** Select this to allow the superusers admin group to use the cloud API. This option is available only if a cloud license is installed in the Grid. Select one of the following:
  - **Cloud API only (no PAPI)**: Select this to allow the admin group to use WAPI (RESTful API) to send cloud API requests. Note that the Cloud API uses WAPI exclusively. The group has no access to the Infoblox API.
  - **Cloud API and PAPI (No WAPI)**: Select this to allow the admin group to send API requests and have access to the Infoblox API. However, the group cannot use WAPI to send cloud API calls.

> ⚠ Note
>
> When you assign cloud API access to an admin group, the group assumes full authority over all delegated objects. You must however specifically assign object permissions to the admin group for the group to gain authority over non-delegated objects. For information about how to assign object permissions, see *About Administrative Permissions*.

4. Click **Next** and complete the following to define the dashboard template:

- **Dashboard Template**: From the drop-down list, select the dashboard template you want to assign to this superuser group. When you apply a dashboard template to an admin group, the template applies to all users in the group. The default is **None**, which means that users in this group can access all licensed tasks in the **Tasks Dashboard** tab if they have the correct permissions to the task-related objects. Note that if you want to delete a template, you must first unassign the template from an admin group, or select **None**, before you can delete it. For more information about dashboard templates, see *About Dashboards*.

5. Click **Next** to add admin email addresses if you want the appliance to send approval workflow notifications to a list of email addresses for the admin group. Complete the following in the Email Address table:

Click the Add icon and Grid Manager adds a row to the table. Enter the email address of the admin who should receive workflow notifications. You can click the Add icon again to add more email addresses. You can also select an email address and click the Delete icon to delete it. To modify an email address, click the **Email Address** column and modify the existing address.

> ⚠ Note
>
> When you configure an approval workflow and select **Group Email Address(es)** as the approver notification addresses, the appliance sends workflow notifications to all email addresses you have added to this table. For information, see *Configuring Approval Workflows .*

6. Optionally, click **Next** to add extensible attributes to the admin group. For information, see *About Extensible Attributes.*

7. Save the configuration and click **Restart** if it appears at the top of the screen. You can do one of the following after you create a superuser admin group:

- Add local admins to the superuser group. For information, see *Creating Local Admins*.
- Assign the superuser group to remote admins. For information, see *About Remote Admins*.

Creating Limited-Access Admin Groups

When you create a limited-access admin group, you can assign roles to it. The group then inherits the permissions of its assigned roles. In addition, you can assign permissions directly to the group. Only superusers can create admin groups.

To create a limited-access admin group:

1. From the **Administration** tab, select the **Administrators** tab -> **Groups** tab, and then click the Add icon.
2. In the *Add Admin Group* wizard, complete the following:
    - **Name:** Enter a name for the admin group.
    - **Comment:** Enter useful information about the group, such as location or department.
    - **Disable:** Select this to retain an inactivated profile for this admin group in the configuration. For example, you may want to define a profile for recently hired administrators who have not yet started work. Then when they do start, you simply need to clear this checkbox to activate the profile.
3. Click **Next** and complete the following:
    - **Superusers:** Clear this checkbox to create a limited-access admin group.
    - **Roles**: Optionally, click the Add icon to add an admin role to the admin group. In the *Role Selector* dialog box, select the roles you want to assign to the admin group, and then click the Select icon. Use Shift+click and Ctrl+click to select multiple admin roles. You can assign up to 21 roles to an admin group. The appliance displays the selected roles in the list box. When an admin group is assigned multiple roles, the appliance applies the permissions to the group in the order the roles are listed. Therefore if there are overlapped permissions among the roles, the appliance uses the permission from the role that is listed first and ignores the others. You can reorder the list by selecting a role and clicking the arrow keys to move the role up and down the list. To delete a role, select it and click the Delete icon.
    - **Allowed Interfaces**: Specify whether the admin group can use the Infoblox GUI (Grid Manager) and the API (application programming interface) to configure the appliance. Note that you must have the Cloud Network Automation or Cloud Platform license installed to configure access to the cloud API.

      GUI: Select this to allow the admin group to use the Infoblox GUI, Grid Manager.

      CLI: Select this to allow the admin group access to the Infoblox CLI. You can select all the commands that you want the group to execute by selecting the command group from the drop-down list. You can then select individual commands from the command group that the admin group can execute . For example, if you want to grant access to the admin group to run all commands related to the Grid command group, select **Grid** from the drop-down list and select all the commands. You can also select individual commands from the Grid command group that you want the admin group to execute.

      API: Select this to allow the admin group access to the Infoblox API. The following options are available only if a Cloud Network Automation or Cloud Platform license is active in the Grid. You must first select this option to enable the following options.
        - **API (WAPI/PAPI only)**: Select this to allow the admin group to use only the RESTful API and Infoblox API.
        - **Cloud API:** Select this to allow the admin group to use the cloud API. This option is available only if a Cloud Network Automation or Cloud Platform license is installed in the Grid. Select one of the following:
            - **Cloud API only (No PAPI)**: Select this to allow the admin group to use WAPI (RESTful API) to send cloud API requests. Note that the Cloud API uses WAPI exclusively. The group has no access to the Infoblox API.
            - **Cloud API and PAPI (No WAPI)**: Select this to allow the admin group to send API requests and have access to the Infoblox API. However, the group cannot use RESTful API to send cloud API calls.

Notes

- When you assign cloud API access to an admin group, the group assumes full authority over all delegated objects. You must however specifically assign object permissions to the admin group for the group to gain authority over non-delegated objects. For information about how to assign object permissions, see *About Administrative Permissions*.
- The GUI permission that you assign to the admin group is independent of the CLI permission that you assign. That is, you have to assign each of these permissions separately to non-super users. You can track actions and commands of non-super-users in the audit.log file.
- If you enable CLI commands for reporting users, they will not be able to login to the CLI unless they log in to the **Reporting** tab in Grid Manager.
- SAML-only users will not be able to run CLI commands, because such users are created dynamically and hence do have the password. However, users belonging to the saml_local group can run the `set` series of commands.
- Cloud users will not be able to run CLI commands because they are delegated users.

4. Click **Next** and complete the following to define the dashboard template:

- **DashboardTemplate**: From the drop-down list, select the dashboard template you want to assign to this superuser group. When you assign a dashboard template to an admin group, the template applies to all users in the group. The default is **None**, which means that users in this group can perform all licensed tasks in the **TasksDashboard** tab if they have the correct permissions to the task-related objects. Note that if you want to delete a template, you must first unassign the template from an admin group, or select **None**, before you can delete it. For more information about dashboard templates, see *About Dashboards*.
- **Display Task flow Dashboards Only**: Select this checkbox if you want to restrict this admin group to access only the Tasks Dashboard in Grid Manager. Note that when you select this checkbox, users in this admin group have access to the tasks you specified in the selected dashboard template, if applicable. They cannot perform any other tasks or manage any core network services in Grid Manager the next time they log in to the system.

5. Click **Next** to add admin email addresses if you want the appliance to send approval workflow notifications to a list of email addresses for the admin group. Complete the following in the Email Address table:

Click the Add icon and Grid Manager adds a row to the table. Enter the email address of the admin who should receive workflow notifications. You can click the Add icon again to add more email addresses. You can also select an email address and click the Delete icon to delete it. To modify an email address, click the **Email Address** column and modify the existing address.

Note

When you configure an approval workflow and select **Group Email Address(es)** as the approver notification addresses, the appliance sends workflow notifications to all email addresses you have added to this table. For information, see *Creating Approval Workflows*.

6. Optionally, click **Next** to add or delete extensible attributes for this admin group. For information, see *About Extensible Attributes*.

7. Save the configuration and click **Restart** if it appears at the top of the screen.

About Admin Roles

An admin role is a group of permissions that you can apply to one or more admin groups. Roles allow you to quickly and easily apply a suite of permissions to an admin group. You can define roles once and apply them to multiple admin groups. The appliance contains the following system-defined admin roles:

- **DHCP Admin:** Provides read/write access to all network views, all DHCP MAC filters, all Grid members, and all Microsoft servers that are managed by the Grid. It also provides read-only access to all DHCP templates and DHCP lease history.
- **DNS Admin**: Provides read/write access to all Grid members, all Microsoft servers that are managed by the Grid, all shared record groups, and all DNS views.
- **DTC Admin**: Provides read/write access to all DTC objects, such as LBDNs, LBDN records, pools, servers, monitors, certificates, GeoIP, and topologies.
- **File Distribution Admin**: Provides read/write access to Grid file distribution properties.
- **Grid Admin**: Provides read/write access to all DNS views, all shared record groups, all members, all Microsoft servers that are managed by the Grid, all network views, all DHCP MAC filters, all DHCP templates, DHCP lease history, Grid File distribution properties, network discovery, task scheduling, and all Dashboard tasks.
- **Load Balancer Admin**: Provides read/write access to all load balancer resources.
- **PKI Admin**: Provides read/write access to all HSM groups, all certificate authentication services, and all CA certificates.
- **DHCP Fingerprint**: Provides read/write access to all DHCP fingerprint related objects.
- **Super Host Admin**: Provides read/write access to all super host objects.
- **VLAN Admin**: Provides read/write access to all VLAN views, ranges, and objects.

You can assign these system-defined roles to admin groups and create additional roles based on the job functions in your organization. If you are creating a role that has similar permissions to an existing role, you can copy the role and then make the necessary modifications to the new role. Thus you do not have to create each new role from scratch.

You can assign up to 21 roles to an admin group, and you can assign a role to more than one admin group. When you make a change to a role, the appliance automatically applies the change to that role in all admin groups to which the role is assigned.

Creating Admin Roles

There are two ways to create an admin role. You can create a new role and define its permissions, or you can copy an existing role and redefine the configuration for the new role.

To create a new role from scratch:

1. From the **Administration** tab, select the **Administrators** tab -> **Roles** tab, and then click the Add icon.
2. In the *Add Role* wizard, complete the following:
    - **Name:** Enter a name for the role.
    - **Comment:** Enter useful information about the role. For example, if you are creating a role for IT personnel, you can put the information here.
    - **Disable:** Select this to retain an inactivated profile for this admin role in the configuration.
3. Optionally, click **Next** to add extensible attributes to this role. For information, see *About Extensible attributes*.
4. Click **Next** and select one of the following:
    - **Save & Add Permissions**: Save the entry and add permissions to the role. Grid Manager displays the **Permissions** tab with the newly created role selected. You can then add permissions to this role. For information, see *About Administrative Permissions*.
    - **Save & Close**: Save the entry and close the wizard.
    - **Save & Edit**: Save the entry and continue to edit.
    - **Save & New**: Save the entry and open a new wizard.

To copy an existing role:

1. From the **Administration** tab, select the **Administrators** tab -> **Roles** tab -> *admin_role* checkbox, and then click **Clone** from the Toolbar.
2. The *Copy Role* editor provides the following tabs from which you can modify data for the new role:
    - ***General***: Enter the name and information about the new role. You can also disable the role in this tab.
    - ***Admin Groups***: Displays a list of admin groups that are currently using this role. You cannot modify the list.
    - ***Extensible Attributes***: Add and delete extensible attributes that are associated with the admin role. You can also modify the values of the extensible attributes. For information, see *About Extensible Attributes*.
3. Save the configuration and click **Restart** if it appears at the top of the screen. The appliance displays the new role in the **Roles** tab.

After you create roles, you can do the following:

- Define their permissions. For information and guidelines on defining permissions, see *About Administrative Permissions*.
- Assign roles to admin groups, as described in creating limited-access admin groups, see *About Admin Groups*.

Managing Admin Groups and Admin Roles

After you create an admin group or an admin role, you can view, modify, and delete it.

Modifying Admin Groups and Roles

To modify an admin group:

1. From the **Administration** tab, select the **Administrators** tab -> **Groups** tab -> *admin_group* checkbox, and then click the Edit icon.
2. The *Admin Group* editor provides the following tabs from which you can modify data:

- **General**: You can modify the following data.
  - **Name:** Modify the name of the admin group.
  - **Comment:** Enter useful information about the group, such as location or department.
  - **Disable:** Select this to retain an inactivated profile for this admin group in the configuration. For example, you may want to define a profile for recently hired administrators who have not yet started work. Then when they do start, you simply need to clear this checkbox to activate the profile.
  - **Allow Access from**: To control access to the GUI and API, select one of the following. You can restrict access using a named ACL or define individual ACEs. For information about named ACLs, see *Configuring Access Control*.
    Note this group-based authentication is applicable for Grid-wide settings only. NIOS authenticates user credentials only after it authenticates the Grid-wide settings.
  - **Any**: Select this to allow any clients to access the GUI and API. This is selected by default.
  - **Named ACL**: Select this and click **Select Named ACL** to select a named ACL that contains only IPv4 and IPv6 addresses and networks. When you select this, the appliance allows GUI and API access for all ACEs in the named ACL. You can click **Clear** to remove the selected named ACL.
  - **Set of ACEs**: Select this to configure individual access control entries (ACEs). You can define ACEs for selected admin groups from which users can log in to the application. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding.
  - **IPv4 Address and IPv6 Address**: Select this to add an IPv4 address or an IPv6 address. The **Type** column displays either IPv4 address or IPv6 address based on the item you select from the drop-down list. Click the **Value** field and enter the IP address. The appliance allows this client to access the GUI and API and restricts others.
  - **IPv4 Network and IPv6 Network**: Select this to add an IPv4 network or IPv6 network. The **Type** column displays either IPv4 address or IPv6 address based on the item you select from the drop-down list. Click the **Value** field and enter the network. The appliance allows this network to access the GUI and API and restricts others.
- After you have added access control entries, you can do the following:
  - Select the ACEs that you want to consolidate and put into a new named ACL. Click the **Create new named ACL** icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
  - Reorder the list of ACEs using the up and down arrows next to the table.Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.
- **Roles**: Modify the data as described in Creating Limited-Access Admin Groups, see *About Admin Groups*.
- **Extensible Attributes**: Add and delete extensible attributes that are associated with the admin group. You can also modify the values of the extensible attributes. For information, see *About Extensible Attributes.*

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring Account Lockout for Admin Groups

You can enable password security such that if a group user tries to log in to Grid Manager by using an incorrect password, NIOS locks the account for a configured time period after the configured number of failed login attempts. Only superusers can enable and configure this feature.

To configure account lockout for admin groups:

1. From the **Administration** tab, select the **Administrators** tab -> **Groups** tab -> *admin_group* checkbox, and then click the Edit icon
2. In the *Admin Group* editor, select the **Security** tab -> **Basic** tab.
3. NIOS automatically populates some field values based on account lockout configurations for the Grid. For more information, see *Managing Security Operations*. Click the **Override** button to modify the following data:
    - **Enable Account Lockout:** Select the checkbox to enable account lockout for the group user. This option is disabled by default.
    - **Maximum number of attempts:** Enter the maximum number of invalid login attempts to Grid Manager after which NIOS locks the account. You can specify a value from **1** to **99.** The default value is **5**.
    - **Lockout duration:** Enter the time duration in minutes for which the account must be locked. You can specify a value from **1** to **1440**. The default value is **5**.
    - **Never Unlock:** Select the checkbox to permanently lock a group user account, which is already locked. Only a superuser can clear the checkbox to unlock the account. This option is not applicable to superuser accounts because you cannot permanently lock a superuser account. This option is disabled by default.

Note

NIOS displays an error on **Save & Close**, if the **Never Unlock** option is enabled for superusers.

Deleting Admin Groups and Roles

You can remove any default or custom admin group as long as it is not your own admin group or the last admin group. You can also delete any default or custom admin role. The appliance puts the deleted roles in the Recycle Bin, if enabled.

Note

You cannot delete the **cloud-api-only** and **splunk-reporting-group** admin groups. These admin groups are automatically created when you configure your Grid for Cloud Network Automation and Reporting and Analytics respectively. For information about Cloud Network Automation and Reporting and Analytics, see *Deploying Cloud Network Automation* and *Infoblox Reporting and Analytics* .

To delete an admin group:

1. From the **Administration** tab, select the **Administrators** tab -> **Groups** tab -> *admin_group* checkbox, and then click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes**.
   To delete an admin role:
3. From the **Administration** tab, select the **Administrators** tab -> **Roles** tab -> *admin_role* checkbox, and then click the Delete icon.
4. In the *Delete Confirmation* dialog box, click **Yes**.

Configuring Password Duration for Admin Groups

You can set a time duration for the password for each admin group such that the password is valid only for that duration. After the specified duration expires, the password for the users of the group expires.

> **Warning**
>
> The password expiry settings are applicable only to local users.

To set the time duration for a password for each admin group:

1. Go to the **Administration** tab, **Administrators** tab -> **Groups** tab, and select the checkbox next to the group for which you want to set the password time duration, and then click the Edit icon.
2. Click the **Password** tab.
3. Click the **Override** button if you want the time duration that specify here to override the time duration you set when *specifying admin passwords using Grid Properties Editor*.
   Note that the options in the screen are enabled only if you click the **Override** button. If you do not click **Override**, the time duration you set when *specifying admin passwords using Grid Properties Editor* applies.
4. Select the **Password must expire** checkbox.
5. In the **Password must expire every _ days** field, enter the number of days for which the password must be valid. For example, if you enter 11, the password is valid for 11 days.
6. In the **Reminder _ days prior to expiration** field, enter the number of days before the expiry that NIOS sends a reminder. The range of days is from 1 to 30. The number that you enter here must always be lower than the number you enter in the **Password must expire every _ days** field.
7. Click **Save & Close**.

> **Note**
>
> - If you click the Override button and do not select the Password must expire checkbox, it means that the password for the admin group will never expire.
> - The time duration that you set here does not apply to the saml_group and splunk-reporting groups.

Viewing Admin Groups

You can view the list of admin groups that are currently in the Grid. To view admin groups, from the **Administration** tab, select the **Administrators** tab -> **Groups** tab.

Grid Manager displays the following information:

- **Name**: The name of the admin group.
- **Superuser**: Indicates whether the admin accounts that you assign to this group have full authority to view and configure all types of data. The value can be **Yes** or **No**.
- **Comment**: The information about the admin group.
  You can select the additional fields, **Disabled** and **Site**, for display.
  You can also do the following:
- Sort the data in ascending or descending order by column.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information about using quick filters, see *Finding and Restoring Data.*
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *About the Grid Manager Interface.*
- Print or export the data.

Viewing Admin Roles

You can view the list of admin roles that are currently in the Grid. To view admin roles, from the **Administration** tab, select the **Administrators** tab -> **Roles** tab.

Grid Manager displays the following information:

- **Name**: The name of the admin role.
- **System**: Indicates whether the admin role is system defined or not. The value can be **Yes** or **No**.
- **Comment**: The information about the admin role.

You can select the additional fields, **Disabled** and **Site**, for display. You can also do the following:

- Sort the data in ascending or descending order by column.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information about using quick filters, see *Finding and Restoring Data.*
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *About the Grid Manager Interface*.
- Print or export the data.

Viewing Admin Group Assignments

After you define permissions for an admin role, you can assign it to multiple admin groups. You can view the list of admin groups to which an admin role is assigned, as follows:

1. From the **Administration** tab, select the **Administrators** tab -> **Roles** tab -> *admin_group* checkbox, and then click the Edit icon.
2. In the *Role* editor, select the **Admin Groups** tab.

Grid Manager displays the list of admin groups to which the role is assigned.

Disabling Multiple Login Sessions

You can disallow multiple logins for the same NIOS session. That is, if one user in the group has logged on to a NIOS session, for example https://255.255.255.0, no other users in the group can log on to the same IP address from another browser or from another system.

> **Warning**
>
> Disabling multiple login sessions is possible only for local users.

To do this:

1. Go to the **Administration** tab, **Administrators** tab -> **Groups** tab, and select the checkbox next to the group for which you want to disallow multiple logins and click the Edit icon.
2. Click the **Security** tab.
3. Click the **Override** button if you want the override the multiple login sessions setting that you *specified for the Grid*.
4. Select the **Disable Concurrent Login** checkbox to disallow a member of the group to log on to multiple sessions of the same NIOS system; that is to disallow multiple login sessions per user.
   Note that Before you disable multiple logins for a group in a NIOS system, ensure that all existing sessions (if any) of members of that group in that NIOS system are logged out. If not, the existing sessions will continue to remain active even after you disable multiple logins.
5. Click **Save & Close**.

Disabling Inactive Users

You can disable a group of users who have not logged in to NIOS for a specified duration of time.

> **Warning**
>
> Disabling inactive users is possible only for local users.

To do this:

1. Go to the **Administration** tab, **Administrators** tab -> **Groups** tab, and select the checkbox next to the group for which you want to disable users.
2. Click the **Security** tab.
3. Click the **Override** button if you want to override the disable setting that you *specified for the Grid*.
4. Select the **Disable Inactive Users** checkbox.
5. In the **Disable account if user has not logged in for <time period> days** field, specify the time period (in days) after which users who have not logged in must be disabled. The range of days is from 2 to 9999. You can also specify a reminder to be sent in the **Remind <days> prior to expiration** field. The range of days is from 1 to 30. The number of days you specify in this field is the time from which users start getting daily email reminders that their account will be disabled. NIOS sends the email reminder only if an email address has been configured for the user.
6. Select the **Allow user to reactivate account via serial console** and **Allow user to reactivate account via remote console** checkboxes if you want users to activate their account after it has been disabled. To reactivate using the serial console, see *Deploying a Single Independent Appliance*. To reactivate using the remote console, type `ssh <user name>@<ip address>`.
   Note that reactivating the account using the serial console or the remote console is possible only for superusers.
7. Click **Save & Close**.

About Administrative Permissions

You can assign permissions to admin roles which you then assign to admin groups, or you can assign permissions directly to an admin group. The following are permissions you can grant admin groups and roles:

- Read/Write (RW): Allows admins to add, modify, delete, view, and search for a resource.
- Read-Only (RO): Allows admins to view and search for a resource. Admins cannot add, modify, or delete the resource.
- Deny: Prevents admins from adding, modifying, deleting, and viewing a resource. This is the default permission level for all resources.

By default, the superuser group (**admin-group**) has full access to all resources on the appliance. Superusers can create limited-access admin groups and grant them permissions to resources at the global and object levels.
Limited-access admin groups must have either read-only or read/write permissions assigned in order to view information or perform tasks on any supported objects.
When you assign permissions at the global level, the permissions apply to all objects that belong to the specified resource. For example, when you define a read/write permission to all DHCP networks, the permission applies to all DHCP ranges and fixed addresses in the networks. For information about global permissions, see Defining Global Permissions below.
You can also define permissions at a more granular level, such as for a specific Grid member, DNS zone, Response Policy Zone, network, and even an individual database object, such as a resource record or fixed address. When you define a permission at the object level, admins with this permission can only manage the specified object and its associated objects. For information about object permissions, see Defining Object Permissions below.
You can use global and object permissions to restrict admins to specific DNS and DHCP resources on specific Grid members by assigning the appropriate permissions. You can use this feature to separate DNS and DHCP administration on selected Grid members. For more information, see Defining DNS and DHCP Permissions on Grid Members below.
You can configure global permissions, object permissions, and member DNS and DHCP permissions for default and custom admin groups and roles. You cannot however define permissions for the factory default roles, such as DHCP Admin.

The appliance supports the following permissions:

Permissions	Description
Grid permissions	Includes Grid DNS properties, Grid DHCP properties, all Grid members, Microsoft servers that are managed by the Grid, network discovery, task scheduling, CSV imports, and all dashboard tasks.
IPAM permissions	Includes network views, IPv4 and IPv6 networks, and host records.
DHCP permissions	Includes Grid DHCP properties, network views, IPv4 networks, host records, DHCP ranges, DHCP fixed addresses/reservations, DHCP enabled host addresses, Mac filters, shared networks, DHCP templates, lease history, and roaming hosts.
DNS permissions	Includes Grid DNS properties, DNS views, DNS zones, Response Policy Zones, host records, bulk hosts, all DNS resource records, all shared records, and adding a blank A/AAAA record.
File distribution permissions	Includes Grid-level file distribution properties.
Reporting permissions	Includes Grid-level reporting properties.
Administration permissions	Includes all certificate authentication services, CA certificates and object change tracking.
GLB (Global Load Balancer) permissions	Includes all NIOS managed GLB objects.
DHCP fingerprint permissions	Includes all DHCP fingerprint related objects.
Named ACL permissions	Includes all named ACLs (access control lists).
Cloud permissions	Includes all tenant objects.
Super Host Permissions	Includes all super host objects.

NIOS applies permissions hierarchically in a parent-child structure. When you define permissions for a resource, all objects within that resource inherit the same permissions. For example, when you grant an admin group read/write permission for a network, the admin group automatically has read/write permission for objects in that network. To override permissions set at a higher level, you define permissions at a more specific level. For example, you can override the read/write network-level permission by setting read-only or deny permission for a fixed address or a DHCP-enabled host address. To define permissions for a more specific level, see the following:

- Permissions for common tasks, as described in *Administrative Permissions for Common Tasks*.
- Permissions for the Grid and Grid members, as described in *Administrative Permission for the Grid*.
- Permissions for IPAM resources, such as IPv6 networks, as described in *Administrative Permissions for IPAM Resources.*
- Permissions for DNS resources, such as DNS views and A records, as described in *Administrative Permissions for DNS Resources*.
- Permissions for DNS resource with associated IP addresses in networks and ranges, as described in *Administrative Permissions for DNS Resources with Associated IP addresses in Networks and Ranges*.

- Permissions for DHCP resources, such as network views and fixed addresses, as described in *Administrative Permissions for DHCP Resources*.
- Permissions for file distribution services, as described in *Administrative Permissions for File Distribution Services.*
- Permissions for certificate authentication services and CA certificates, as described in *Administrative Permissions for Certificate Authentication Services and CA Certificates*.
- Permissions for object change tracking, as described in *Administrative Permissions for Object Change Tracking*
- Permissions for GLB and GLB objects, as described in *Administrative Permissions for Load Balancers*.
- Permissions for Cloud objects, as described in *Administrative Permissions for Cloud Objects*.

When you set permissions that overlap with existing permissions, Grid Manager displays a warning about the overlaps. You can view detailed information and find out which permissions the appliance uses and which ones it ignores. For information, see Applying Permissions and Managing Overlaps below.

Defining Global Permissions

You can define permissions at a global level for an admin group or admin role. To define global permissions:

1. For an admin group: From the **Administration** tab, select the **Administrators** tab -> **Permissions** tab -> *admin_group* in the Groups table, and then click the Add icon -> **Global Permissions** from the Create New Permission area or select Add -> **Global Permissions** from the Toolbar.
   or
   For an admin role: From the **Administration** tab, select the **Administrators** tab -> **Permissions** tab -> *admin_role* in the Roles table, and then click Add icon -> **Global Permissions** from the Create New Permission area or select Add -> **Global Permissions** from the Toolbar.
2. Grid Manager displays the *Manage Global Permissions* editor. For an admin group, the appliance displays the selected admin group in the **Group Permission** field. For an admin role, the appliance displays the selected admin role in the **Role Permission** field. You can also select a different group or role from the drop-down list.
3. Select the resources that you want to configure from the **Permission Type** drop-down list. Depending on your selection, Grid Manager displays the corresponding resources for the selected permission type in the table.
4. Select **Read/Write**, **Read-Only**, or **Deny** for the resources you want to configure. By default, the appliance denies access to resources if you do not specifically configure them.
5. Optionally, select additional resources from the **Permission Type** drop-down list. Grid Manager appends the new resources to the ones that you have already configured. Define the permissions for the resources you select.
6. Save the configuration and click **Restart** if it appears at the top of the screen.

The below Global Permissions table lists global permissions you can assign to admin groups or admin roles:

Global Permissions

Permissions (Read/Write, Read-Only, or Deny)		
Administration Permissions	All Certificate Authentication Services	For more information, see *Administrative Permissions for Certificate Authentication Services and CA Certificates*.
	All CA Certificates	
	Object Change Tracking	For more information, see *Administrative Permissions for Object Change Tracking.*
Cloud Permissions	All Tenants	For more information, see *Administrative Permissions for Cloud Objects*.

Permissions (Read/Write, Read-Only, or Deny)		
Named ACL Permissions	Named ACL	For more information, see *Administrative Permissions for Named ACLs*.
DHCP Permissions	Grid DHCP Properties	For more information, see *Administrative Permissions for Common Tasks*.
	All Network Views	For more information, see *Administrative Permissions for DHCP Resources*.
	All IPV4/IPv6 Networks	For more information, see *Administrative Permissions for IPv4 and IPv6 Networks and Shared Networks*.
	All Hosts	For more information, see *Administrative Permissions for IPAM Resources*.
	All DHCP Fingerprints	For more information, see *Administrative Permissions*.
	All DHCP MAC Filters	For more information , see *Administrative Permissions for DHCP Resources*.
	All IPv4/IPv6 DHCP Fixed Addresses/ Reservations	For more information, see *Administrative Permissions for IPv4 or IPv6 Fixed Addresses and IPv4 Reservations*.
	All IPv4/IPv6 Host Addresses	For more information, see *Administrative Permissions for DHCP Resources*.
	All IPv4/IPv6 Ranges	For more information, see *Administrative Permissions for IPv4 and IPv6 DHCP Ranges*.
	All IPv4/IPv6 Shared Networks	For more information, see *Administrative Permissions for IPv4 and IPv6 Networks and Shared Networks*.
	All IPv4/IPv6 DHCP Templates	For more information, see *Administrative Permissions for IPv4 or IPv6 DHCP Templates*.
	All Microsoft Superscopes	For more information, see *Administrative Permissions for IPv4 or IPv6 DHCP Templates*.
	All Roaming Hosts	For more information, see *Administrative Permissions for Roaming Hosts*.
	DHCP IPv4/IPv6 Lease History	For more information, see *Administrative Permissions for the IPv4 and IPv6 DHCP Lease Histories*.
DNS Permissions Grid	DNS Properties	For more information, see *Administrative Permissions for Common Tasks*.

Permissions (Read/Write, Read-Only, or Deny)		
	All DNS Views	For more information, see *Administrative Permissions for Common Tasks*.
	All DNS Zones	For more information, see *Administrative Permissions for Common Tasks*.
	All Hosts	For more information, see *Administrative Permissions for Hosts*.
	All IPV4/IPV6 Host Addresses	For more information, see *Administrative Permissions for DNS Resources with Associated IP addresses in Networks and Ranges*.
	All Resource Records (A, AAAA, CAA, CNAME, DNAME, NAPTR, MX, PTR, SRV, TXT, TLSA and Bulkhost)	For more information, see *Administrative Permissions for Common Tasks*.
	All Shared Record Groups	For more information, see *Administrative Permissions for Shared Record Groups*.
	All Shared Records (A, AAAA, MX, SRV and TXT)	For more information, see *Administrative Permissions for Common Tasks*.
	All Rulesets (BLACK List Rulesets and NXDOMAIN Rulesets)	For more information, see *Administrative Permissions for DHCP Resources*.
	All DNS64 Synthesis Groups	For more information, see *Administrative Permissions for DNS64 Synthesis Groups*.
	All Response Policy Zones	For more information, see *Administrative Permissions for Zones*and *License Requirements and Admin Permissions*.
	All Response Policy Rules	For more information, see *Administrative Permissions for Zones*and *License Requirements and Admin Permissions*.
	All DTC Objects (LBDN Records, LBDNs, Pools, Servers, Monitors, Certificates, GeoIP and Topologies)	For more information, see *Administrative Permissions for Zones*and *License Requirements and Admin Permissions*.
	Adding a blank A/AAAA record	For more information, see *Administrative Permissions for Common Tasks*.
File Distribution Permissions	Grid File Distribution Permissions	For more information, see *Administrative Permissions for File Distribution Services*.

Permissions (Read/Write, Read-Only, or Deny)		
Grid Permissions	All Members	For more information, see *Administrative Permissions for Common Tasks*.
	Network Discovery	For more information, see *Administrative Permissions for Discovery*.
	Schedule Tasks	For more information, see *Administrative Permissions for Scheduling Tasks*.
	CSV Import	For more information, see *Administrative Permissions for Named ACLs*.
	All Microsoft Servers	For more information, see *Administrative Permissions for Microsoft Servers*.
	All Dashboard Tasks	For more information, see *Administrative Permissions for Dashboard Tasks*.
	All Kerberos keys	For more information, see *Configuring GSS-TSIG keys*.
	All Active Directory Domains	For more information, see *Managing Active Directory Sites*.
IPAM Permissions	All Network Views	For more information, see *Administrative Permissions for Common Tasks*.
	All IPv4 Networks	For more information, see *Administrative Permissions for IPv4 and IPv6 Networks and Shared Networks*.
	All IPv6 Networks	For more information, see *Administrative Permissions for IPv4 and IPv6 Networks and Shared Networks*.
	All Hosts	For more information, see *Administrative Permissions for Hosts*.
	All IPv4 Host Addresses	For more information, see *Administrative Permissions for DNS Resources with Associated IP addresses in Networks and Ranges*.
	All IPv6 Host Addresses	For more information, see *Administrative Permissions for DNS Resources with Associated IP addresses in Networks and Ranges*.
	Port Control	For more information, see *Administrative Permissions for Discovery*.

Permissions (Read/Write, Read-Only, or Deny)		
SAML Permissions	SAML Authentication Services	For more information, see *Administrative Permissions for SAML*.
Super Host Permissions	Super Host Permissions	For more information, see *About Administrative Permissions for Super Hosts*.
Security Permissions	Grid Security Permissions	For more information, see *Administrative Permissions*.
Reporting Permissions	Grid Reporting Permissions	For more information, see *Administrative Permissions for Common Tasks*.
	Reporting Dashboard	For more information, see *Administrative Permissions for Reporting*.
	Reporting Search	For more information, see *Administrative Permissions for Reporting*.
VLAN Permissions	VLAN views, VLAN ranges, and VLAN objects	For more information, see *Administrative Permissions for VLAN Management*.

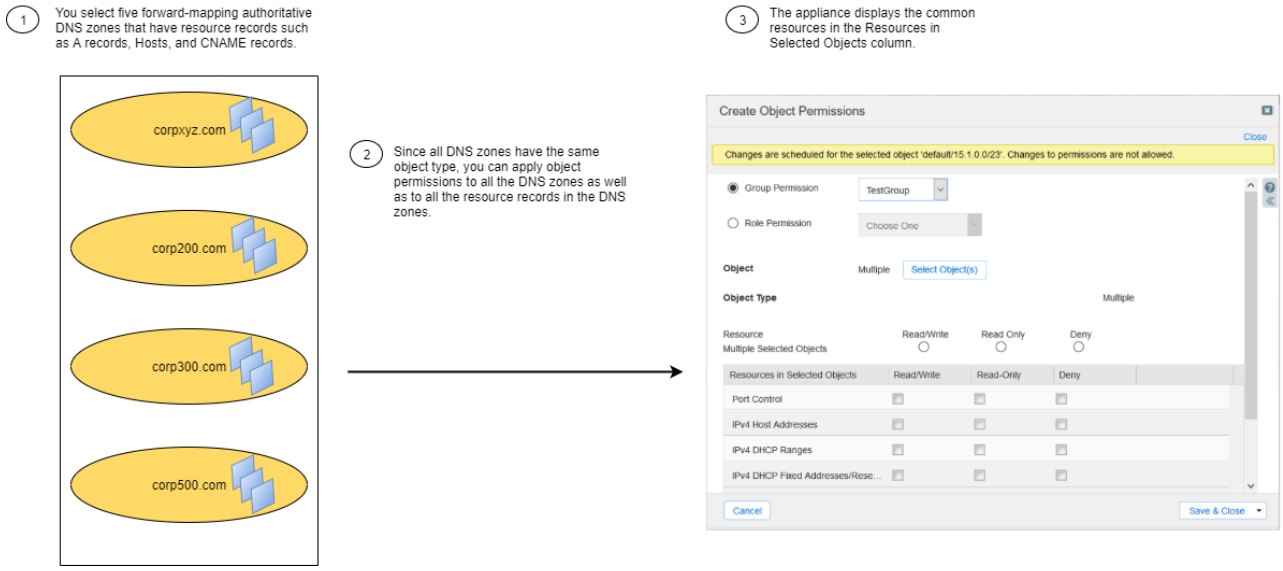
Defining Object Permissions

You can add permissions to specific objects for selected admin groups or roles. When you add permissions to objects, you can select multiple objects with the same or different object types. When you select multiple objects with the same object type, you can apply permissions to the selected objects as well as the sub object types that are contained in the selected objects. As described in the below figure *Selecting Multiple Objects with the Same Object Type*, when you select five DNS forward-mapping authoritative zones, the appliance displays the object type "AuthZone" for all the zones. Since all five DNS zones are of the same object type, you can also apply permissions to all the resource records in these zones. The appliance displays the resources in the resource section of the *Create Object Permissions* editor. You can choose one or more of the resources to which you want to apply permissions.

In Cloud Network Automation, admin groups and admin users who have cloud API access have full permissions to delegated. However, you must specifically assign permissions for objects that have not been delegated in order for any admin groups or admin users to gain permission to these objects. Therefore, an admin group that has access to the cloud API would have full permissions to all delegated objects but limited permissions to non-delegated objects.

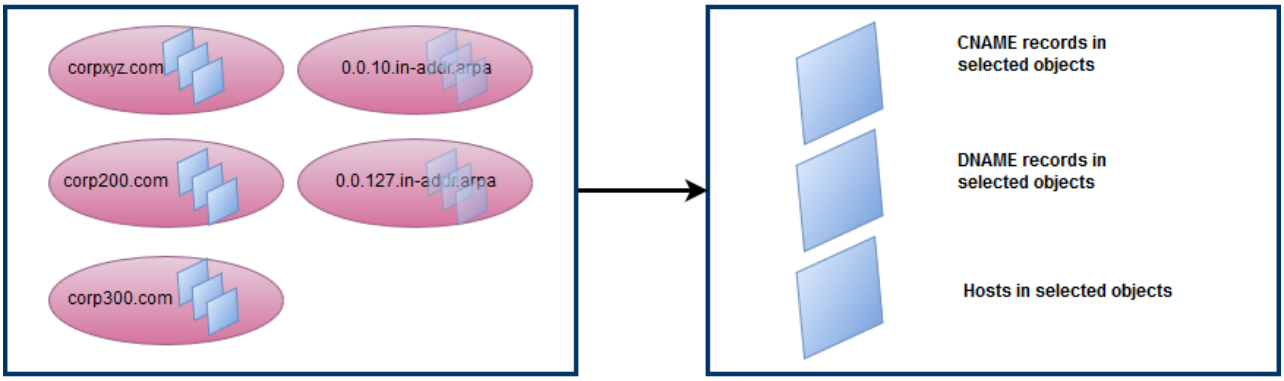
For information about how to allow cloud API access to an admin group, see *Creating Limited-Access Admin Groups*. For information about guidelines for authority delegation, see *About Authority Delegation*.

Selecting Multiple Objects with the Same Object Type



When you select multiple objects with more than one object type, you can add permissions to the selected objects as well as to the sub object types that are common among the selected objects. For example, when you select three DNS forward-mapping authoritative zones and two DNS IPv4 reverse-mapping authoritative zones as illustrated in the below figure Multiple Objects with Common Sub Object Types, you can apply permissions to all the five DNS zones as well as to the CNAME, DNAME, and host records in these zones because CNAME, DNAME, and host records are the common sub object types in these zones.

Multiple Objects with Common Sub Object Types
When you select three DNS forward-mapping authoritative zones and two IPv4 reverse-mapping authoritative zones, you can apply object permissions to all the DNS zones as well as the CNAME, DNAME and Host records in these DNS zones.



To define object permissions for an admin group or role:

1. For an admin group: From the **Administration** tab, select the **Administrators** tab -> **Permissions** tab -> *admin_group* in the Groups table, and then click the Add icon -> **Object Permissions** from the Create New Permission area or select **Add** -> **Object Permissions** from the Toolbar.
   or
   For an admin role: From the **Administration** tab, select the **Administrators** tab -> **Permissions** tab -> *admin_role* in the Roles table, and then click Add icon -> **Object Permissions** from the Create New Permission area or select Add -> **Object Permissions** from the Toolbar.

2. Grid Manager displays the *Create Object Permissions* wizard. For an admin group, the appliance displays the selected group in the **Group Permission** field. For an admin role, the appliance displays the selected admin role in the **Role Permission** field. You can also select a different group or role from the drop-down list.
3. Click **Select Object(s)**. Grid Manager displays the *Object Selector* dialog box.
4. In the *Object Selector* dialog box, complete the following:
    - Enter a value or partial value of an object in the first field. This field is not case-sensitive. For example, if the object to which you want to define permissions contains "Infoblox", enter Infoblox here.
    - Select the object type for which you are searching in the **Type** drop-down list. By default, the appliance searches all object types.
    - In the operator drop-down list, select an operator for the filter criteria. Depending on what you select in the first filter field, this list displays the relevant operators for the selection.
    - In the value field, enter or select the attribute value for the first filter field. Depending on what you select for the first two filter fields, you can either enter a value or select a value from a drop-down list.
5. Click **Search**. The appliance lists all matching objects in the table. You can select multiple object types by clicking the Add icon to add more filter criteria. You can also click **Reset** to clear all entries.
6. Select the checkboxes of the objects to which you are defining permissions, and then click the Select icon.
7. In the *Create Object Permissions* wizard, do the following:
    - **Object**: Displays the name of the selected object. When you select multiple objects, the appliance displays **Multiple** here. Mouse over to the information icon to view the list of objects to which you are defining permissions.
    - **Object Type**: Displays the object type of the selected object. When you select more than one object type, the appliance displays **Multiple** here.
    - **Resource**: Displays the selected objects. When you select more than one object type, the appliance displays **Multiple Selected Objects** here. Mouse over to the information icon to view the list of objects to which you are defining permissions. Grant the resources an appropriate permission: **Read/Write**, **Read-Only,** or **Deny**.
8. Save the configuration and click **Restart** if it appears at the top of the screen.

Grid Manager displays a warning message when the permissions you define here overlap with other permissions in the system. Click **See Conflicts** to view the overlapping permissions in the *Permissions Conflict* dialog box. For information, see Applying Permissions and Managing Overlaps below.
You can also set permissions for specific objects from the objects themselves. For example, to define permissions for a particular Grid member, navigate to that Grid member and define its permissions.
To define the permissions of a specific object:

1. Navigate to the object. For example, to define permissions for a particular network, from the **Data Management** tab, select the **IPAM** tab -> *network* checkbox, and then click the Edit icon.
2. In the editor, select the **Permissions** tab, and then do one of the following:
    - Click the Add icon to add permission to the object. In the **Admin Group / Role Selector** dialog box, select an admin group or role to which you want to assign the permission, and then click the Select icon.
    - Modify the permission and resource type of a selected admin group or role.
    - Select an admin group or role and click the Delete icon to delete it.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Defining DNS and DHCP Permissions on Grid Members

You can restrict certain admin groups or roles to perform specific DNS and DHCP tasks on specific Grid members by assigning the correct global and object permissions. You can use this feature to separate the DNS and DHCP administration on different Grid members. For example, you can create an admin group or role that can only create, modify, and delete DHCP ranges in a specific network on a specific member in the Grid. This admin group or role is restricted to the specified tasks on the selected Grid member. It cannot perform other DNS or DHCP tasks on this member, and it cannot perform the specified tasks on other Grid members.
For example, you can define permissions that allow admins to create, modify, and delete DHCP ranges in network 10.0.0.0/8 on Grid member "sales.infoblox.com" by granting read/write object permissions to all DHCP ranges, network 10.0.0./8, and member DHCP on sales.infoblox.com. Admins with these permissions can only add, modify, and delete DHCP ranges in network 10.0.0.0/8 on Grid member sales.infoblox.com. They cannot perform other DHCP or DNS tasks on the member, and they cannot perform these tasks on other Grid members.
For information about required permissions for specific DNS and DHCP tasks, see *Administrative Permissions for*

Common Tasks.
You can define the following DNS and DHCP permissions for an admin group or role:

- Grid DNS or Grid DHCP: Admins with read/write permissions can manage any DNS or DHCP resources on any Grid members. They can also modify Grid DNS or Grid DHCP properties and any member DNS and member DHCP properties. Admins with read-only permissions can only view DNS or DHCP resources. They cannot modify any DNS or DHCP resources or restart related services.
- Member DNS or Member DHCP: Admins with read/write permissions can perform the defined DNS or DHCP tasks only on the specified Grid member, not any other members. They can also modify DNS or DHCP properties on the specified member. Admins with read-only permission cannot assign the Grid member to any DNS or DHCP resources.
- Restart DNS or Restart DHCP on member: Admins with read/write permissions can restart the DNS or DHCP service on the specified Grid member, not any other members. However, they cannot modify DNS or DHCP properties on the member. They can assign the specified Grid member to any DNS or DHCP resources, but they cannot assign any other Grid members to DNS or DHCP resources.

To specify member DNS and DHCP permissions, define DNS or DHCP permissions at the global or object level for an admin group or admin role, as described in Defining Global Permissions and Defining Object Permissions above. Ensure that you include the Grid member object to which you want to restrict DNS or DHCP administration. You can assign valid permissions to administrators to manage kerberos keys. For more information, see *Configuring GSS-TSIG keys*.
You can also control whether the admins can modify DNS or DHCP properties on a member, as described in Modifying Permissions on a Grid Member below.

Modifying Permissions on a Grid Member

Admins can perform different tasks on a Grid member based on the permissions they have. The following table Member Permissions and Tasks outlines the permissions and the tasks admins can perform on a Grid member:

Member Permissions and Tasks

After you add permissions to an admin group or role for a specific Grid member, you can modify the member permissions and resources. Note that when you modify the member permissions and resources, the appliance updates the permissions of the admin group or role accordingly.

	Grid Member	Member DNS or DHCP Properties	Restart DNS or DHCP on Grid Member
Read/Write	• Modify member properties • Restart, reboot, and shutdown member • Modify member DNS and DHCP properties • Restart member DNS and DHCP services • Assign and un-assign member to DNS and DHCP objects	• Modify member DNS or DHCP properties • Restart member DNS or DHCP service • Assign and un-assign member to DNS or DHCP objects	• Restart member DNS or DHCP service • Assign and un-assign member to DNS or DHCP objects
Read-only	• View member DNS and DHCP properties	• View member DNS or DHCP properties	• N/A (You cannot define a read-only permission)

	Grid Member	Member DNS or DHCP Properties	Restart DNS or DHCP on Grid Member
Deny	• Cannot modify member, DNS, and DHCP properties • Cannot restart related services • Cannot assign member to DNS and DHCP objects	• Cannot modify member, DNS, and DHCP properties • Cannot restart related services • Cannot assign member to DNS and DHCP objects	• Cannot modify member, DNS, and DHCP properties • Cannot restart related services • Cannot assign member to DNS and DHCP objects

To modify Grid member permissions:

1. From the **Data Management** tab, select the **DHCP** or **DNS** tab -> **Members** tab -> *Grid_member*, and then click the Edit icon.
2. In the *Member DHCP Properties* or *Member DNS Properties* editor, select the **Permissions** tab.
3. Click a permission in the Permissions table, select a different permission from the **Permissions** drop-down list or select a different resource from the **Resources** drop-down list. Note that when you select **Restart DNS** or **Restart DHCP**, the admins with this permission can only restart the DNS or DHCP service on the selected member. They cannot modify DNS or DHCP properties of this member.
4. Save the configuration. Note that the appliance automatically updates the permissions of the corresponding admin group or role in the **Administration** tab.

Applying Permissions and Managing Overlaps

When an admin tries to access an object, the appliance checks the permissions of the group to which the admin belongs. Because permissions at more specific levels override those set at a higher level, the appliance checks object permissions hierarchically—from the most to the least specific. In addition, if the admin group has permissions assigned directly to it and permissions inherited from its assigned roles, the appliance checks the permissions in the following order:

1. Permissions assigned directly to the admin group.
2. Permissions inherited from admin roles in the order they are listed in the **Roles** tab of the *Admin Group* editor.

For example, an admin from the DNS1 admin group tries to access the a1.test.com A record in the test.com zone in the Infoblox default view. The appliance first checks if the DNS1 admin group has a permission defined for the a1.test.com A record. If there is none, then the appliance checks the roles assigned to DNS1. If there is no permission defined for the a1.test.com A record, the appliance continues checking for permissions in the order listed in the Permission Checking table. The appliance uses the first permission it finds.
Permission Checking

The appliance checks object permissions from the most to the least specific, as listed.	For each object, the appliance checks permissions in the order listed.
1. a1.test.com A record 2. A records in test.com 3. test.com 4. All zones in the default view 5. Default view 6. All A records 7. All zones 8. All DNS views	a. DNS1 admin group b. Role 1, Role 2, Role 3…

An admin group that is assigned multiple roles and permissions can have overlaps among the different permissions. As stated earlier, the appliance uses the first permission it finds and ignores the others. For example, as shown in the below Directly-Assigned Permissions and Roles table, if an admin group has read/write permission to all A records in the test.com zone and a role assigned to it is denied permission to test.com, the appliance provides read/write access to A

records in the test.com zone, but denies access to the test.com zone and all its other resource records.
Directly-Assigned Permissions and Roles

Permission assigned to the admin group	Read/Write to all A records in the test.com zone
Permission inherited from an admin role	Deny to the test.com zone
Effective permissions	Deny to the test.com zone Read/Write to all A records in test.com zone Deny to all other resource records in test.com zone

If the group has multiple roles, the appliance applies the permissions in the order the roles are listed. If there are overlaps in the permissions among the roles, the appliance uses the permission from the role that is listed first. For example, as shown in the Multiple Roles table, the first role assigned to the admin group has read-only permission to all A records in the test.com zone and the second role has read/write permission to the same records. The appliance applies the permission from the first admin role.
Multiple Roles

Role 1 permission	Read-only to all A records in the test.com zone
Role 2 permission	Read/Write to all A records in test.com zone Read/Write to all MX records in test.com zone
Effective permissions	Deny to the test.com zone Read-only to all A records in the test.com zone Read/Write to all MX records in test.com zone

You can check for overlapped permissions when you add permissions to roles and to admin groups, and when you assign roles to an admin group. When you create a permission that overlaps with existing permissions, Grid Manager displays a warning message and the **SeeConflicts** link on which you click to view the overlapped permissions. For information, see Viewing Overlapping Permissions below. You can also use the quick filter **Overlaps** to filter overlapped permissions, the appliance lists permissions that overlap with other permissions. If you want to change the permission the appliance uses, you must change the order in which the roles are listed or change the permissions that are directly assigned to the admin group. For information about Creating Limited-Access Admin Groups, see *About Admin Groups*.

Viewing Overlapping Permissions

When you click **See Conflicts** to view overlapping permissions, Grid Manager displays the following information in the *Permission Overlap* dialog box:

1. **Resource**: The name of the object or resource.
2. **Type**: The object type.
3. **Permission**: The permission granted. This can be Read/Write, Read-Only, or Deny.
4. **Inherited From**: Indicates the source from which the permission is inherited.
5. **Conflict Status**: Indicates whether the permission is being used or ignored. In a permission overlap, the group permission always overrides the role permission if both permissions are set at the same level (global or object). However, if the permissions are set at different levels, the permission at a more specific level overrides that set at a higher level.
6. **Role/Group Name**: The name of the admin group or admin role.

You can click the arrow key next to the resource to view the permission that is being ignored in the overlap.

Managing Permissions

After you define permissions for an admin group and role, you can do the following:

- View the permissions, as described in Viewing Permissions below.
- Modify the permissions, as described in Modifying Permissions below.
- Delete the permission, as described in Deleting Permissions below.

Viewing Permissions

Only superusers can view the permissions of all admin groups.
To view the permissions of an admin group or role:

1. From the **Administration** tab, select the **Administrators** tab -> **Permissions** tab.
2. For an admin group: Select an admin group in the Groups table.
   or
   For an admin role: Select an admin role in the Roles table.
3. Grid Manager displays the following information in the Permissions table:

- **Group/Role**: The name of the admin group or role.
- **Permission Type**: The type of permissions. This can be Administration Permissions, Analytics Permissions, Cloud Permissions, Named ACL Permissions, DHCP Permissions, DNS Permissions, File Distribution Permissions, Grid Permissions, IPAM Permissions, Reporting Permissions, or Security Permissions.
- **Resource**: The name of the object. For example, this field displays **All Hosts** if you have defined permissions for all the hosts in the Grid.
- **Resource Type**: The object type. For example, this can be Host, PTR record, or Shared Network.
- **Permission**: The defined permission for the resource.

When you click **Show All** for Admins, Groups, and Roles, Grid Manager displays all the admin accounts, admin groups, and admin roles in their respective tables.

Filtering the List of Permissions

You can filter the permissions you want to view by selecting one of the following from the quick filter menu:

- **Effective Permissions**: Select to view only the permissions that the appliance is using for this group. The permissions that were ignored due to overlaps are not listed in this view.
- **Overlaps**: Select to view only the overlapped permissions.
- **All Configured Permissions**: Select to view all permissions.

Modifying Permissions

You can modify the permissions of user-defined admin roles and admin groups. You cannot modify the permissions of system-defined admin roles. When you change the permissions of a role that has been assigned to multiple admin groups, the appliance automatically applies the change to the role in all admin groups to which it is assigned.
To modify the existing permissions of a role or an admin group:

1. From the **Administration** tab, select the **Administrators** tab -> **Permissions** tab.
2. For an admin group: Select an admin group in the Groups table. or
3. For an admin role: Select an admin role in the Roles table.
4. In the Permissions table, select the resource that you want to modify, and then click the Edit icon.
5. In the *Mange Global Permissions* or *Create Object permissions e*ditor, select the new permission: **Read/Write**, **Read-Only** or **Deny** for the resource.
6. Save the configuration and click **Restart** if it appears at the top of the screen.

Deleting Permissions

You can remove permissions from user-defined admin roles and admin groups. You cannot remove permissions from system-defined admin roles. When you remove permissions from a role, they are removed from the role in all admin groups to which the role is assigned. You can remove a permission from a group as long as it is not inherited from a role.

You cannot remove permissions that are inherited from a role.
To delete a permission:

1. From the **Administration** tab, select the **Administrators** tab -> **Permissions** tab.
2. For an admin group: Select an admin group in the Groups table.
   or
   For an admin role: Select an admin role in the Roles table.
3. In the Permissions table, select the resource that you want to modify, and then click the Delete icon.
4. In the *Delete Permission Confirmation* dialog box, click **Yes**.

Authenticating Administrators

The NIOS appliance supports the following authentication methods: local database, RADIUS, Active Directory, LDAP, TACACS+, and SAML. The appliance can use any combination of these authentication methods. It authenticates admins against its local database by default. Therefore, if you want to use local authentication only, you must configure the admin groups and add the local admin accounts, as described in *Creating Local Admins*.

Depending on where admin user credentials are stored, you can configure the NIOS appliance to authenticate admins locally or remotely or using SAML. When you configure the authentication type as "local," NIOS authenticates admins against its local database. When you configure the authentication type as "remote," NIOS authenticates admins whose user credentials are stored remotely on authentication servers, such as RADIUS servers, AD domain controllers, LDAP servers, or TACACS+ servers. When you configure the authentication type as "SAML Only," NIOS authenticates admins against their user credentials in the IDP (Identity Provider).

Note the following when you configure remote authentication type for local admins:

- You cannot define two local admins that have the same name and belong to different authentication server groups.
- Only superusers can modify the authentication type for other admin accounts.
- At least one superuser account must use the remote authentication type.

To authenticate admins using RADIUS, Active Directory, TACACS+, or LDAP in addition to local authentication, you must define those services on the appliance and define the admin authentication policy. For information, see *About Remote Admins*. To authenticate admins using SAML, see *Authenticating Admins Using SAML*.

NIOS also supports two-factor authentication where it authenticates the following:

1. Administrators through the admin authentication policy.
2. Admin client certificates through the certificate authentication service.

For more information about two-factor authentication and how to configure it, see *Defining the Authentication Policy*.

Note

If you are using remote authentication, you must always have at least one local admin in a local admin group to ensure connectivity to the NIOS appliance in case the remote servers become unreachable.

Authenticating Admins Using Two-Factor Authentication

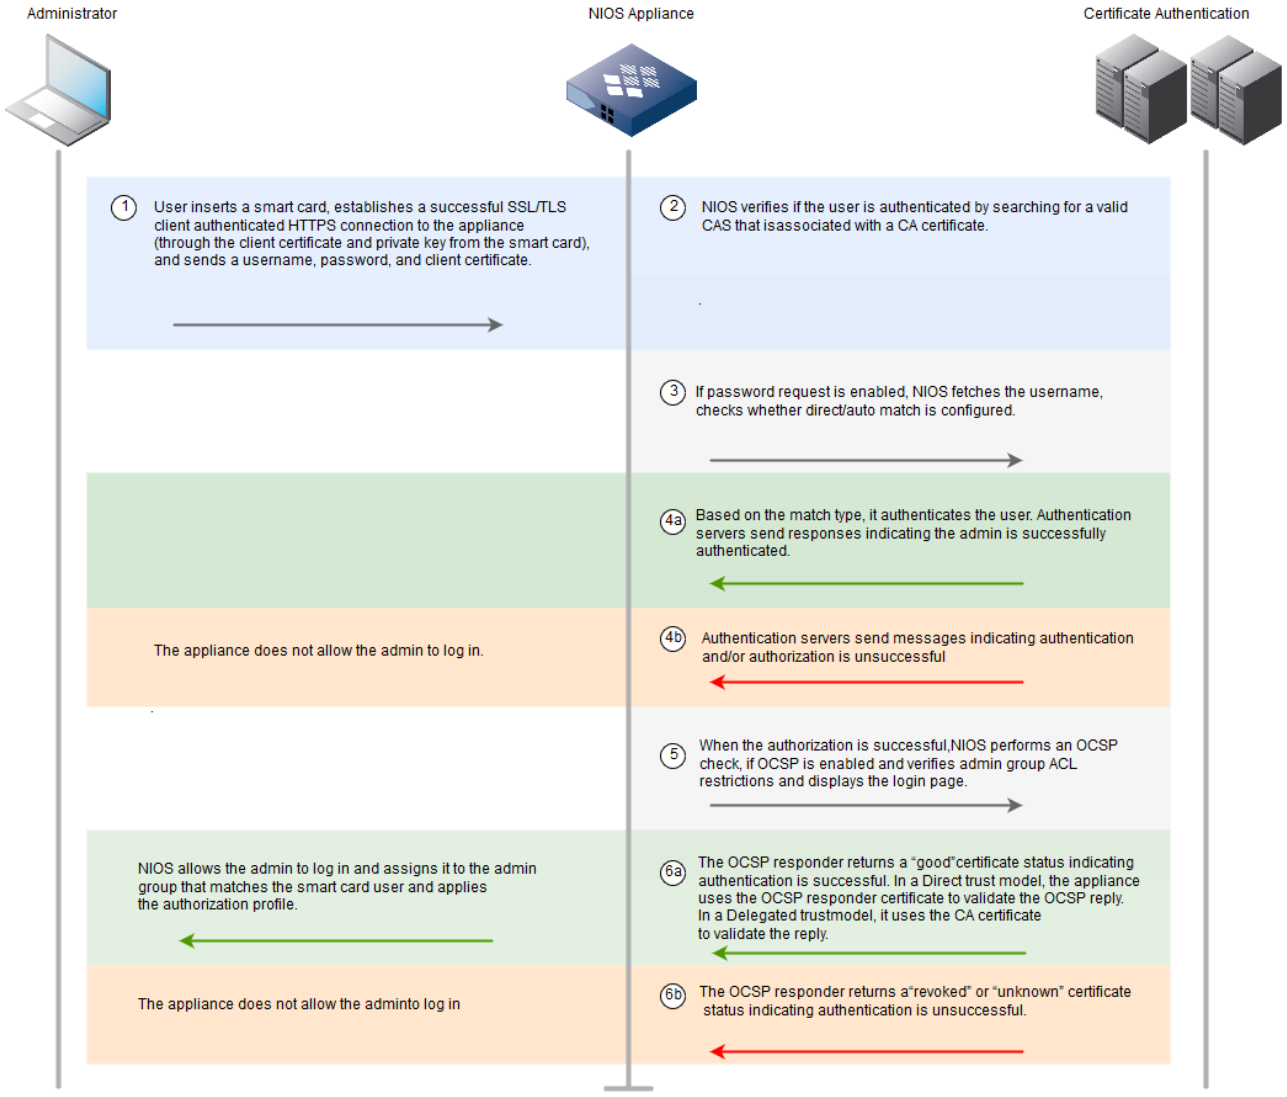
You can configure NIOS to use the two-factor authentication method to authenticate users based on X.509 client certificates. In two-factor authentication, NIOS first negotiates SSL/TLS client authentication to validate client certificates. It then authenticates the admins based on the configured authentication policy. You must first configure an authentication policy, and then configure and enable the certificate authentication service for the two-factor authentication to take effect. NIOS uses certificate authentication service as the authentication policy. For information about how to set up an authentication policy, see *Defining the Authentication Policy.*
Using the certificate authentication service, you can choose how the client certificate associates with the CA certificate. NIOS allows you to associate the client certificate manually and automatically. With manual certificate binding option, you must associate a certificate for a particular user manually, which is verified with the CA certificate. With automatic match

policy, NIOS extracts the username from the client certificate, which is then matched with the certificate authentication service. When you configure certificate authentication service, NIOS searches the CA certificates associated with each admin group to detect a valid certificate authentication service for the client's certificate. You can either select a direct match or an automatic match for a certificate authentication service.
The Infoblox certificate authentication service uses the OCSP, which is an internet protocol that validates certificate status for X.509 digital certificates that are assigned to specific admins. NIOS allows you to choose Authority Information Access (AIA) extension from a certificate as a source of OCSP configuration or define OCSP servers manually. You can also disable OCSP check for a particular certificate authentication service. For more information about OCSP, refer to RFC 2560 at *https://tools.ietf.org/html/rfc2560*.
The status of these client certificates is stored on OCSP responders to which NIOS sends requests about certificate status. A certificate status can be "good," revoked," or "unknown." After a successful SSL/TLS client authentication, NIOS authenticates the admin based on the configured authentication policy. If the authentication fails at this point, the appliance denies access to the admin. If the authentication policy has passed, the appliance sends a request to the OCSP responder for client certificate status about the admin. If the appliance receives a "good" status from the OCSP responder, the two-factor authentication is successful. The admin can now access the appliance. If the appliance receives a "revoked" or "unknown" status from the OCSP responder, the two-factor authentication fails. The admin cannot access the appliance even though the admin authentication policy has passed.
When there are multiple OCSP responders configured, the appliance contacts the responders based on their configured order. For the same client certificate, the appliance always takes the status reported by the first responder on the list that actually responds, even when there are different OCSP replies from different responders. When the appliance cannot contact the first responder or if the first responder does not reply, the appliance then takes the OCSP reply from the second responder and so on.

Note

- Authentication for both the admin authentication policy and OCSP validation must be successful on NIOS.
- Certificate-based authentication does not work on Cloud Platform members for WAPI calls.

Figure 4.7 illustrates the two-factor authentication and authorization process.



Best Practices for Configuring Two-Factor Authentication

Only superusers and limited-access users with the correct permissions can configure two-factor authentication. For information about admin roles and permissions, see *Managing Admin Groups and Admin Roles*. To configure two-factor authentication, consider the following:

- You must first set up an certificate authentication service and enable it.
- You can configure only one certificate authentication service that contains one or multiple OCSP responders to which NIOS sends requests about client certificate status. The appliance supports IPv4 and IPv6 OCSP responders.
- When you configure multiple OCSP responders, you can put them in an ordered list. The appliance contacts the first responder on the list. If the connection fails, it moves on to the second one, and so on. The result of the status check for a client certificate is based on the status reported by the first responder that replies.
- You can configure the timeout value and retry attempts that the appliance waits and tries before it moves on to the next OCSP responder.
- You can upload server certificates for each responder for OCSP response validation. You must upload an OCSP server certificate if you select the direct trust model.
- You can disable a specific responder if the server is out of service for a short period of time.
- Before you add an OCSP responder to the server group, you can test the server credentials.

To configure and enable two-factor authentication, complete the following tasks:

1. For local and remote authentication, ensure that the admin names for smart card users match the CNs (Common Names) used in the client certificates. For information about local and remote authentication, see *About Admin Accounts*.
2. Upload the CA (Certificate Authority) certificate, as described in About CA Certificates ,see *Managing Certificates*. The CA-signed certificates are used to validate OCSP server certificates and admin OCSP client certificates. Ensure that the CA certificate is in .PEM format. The .PEM file can contain more than one certificate.

   Note that the uploaded CA certificates must be the ones that issued the client certificates to be authenticated. Otherwise, clients such as browsers, cannot establish a successful SSL/TLS client authenticated HTTPS session to the appliance.

3. Configure a certificate authentication service and enable it, as described in Configuring Certificate Authentication Services below.
4. View certificate authentication services, as described in Viewing Certificate Authentication Services below.
5. Modify certificate authentication services, as described in Modifying Certificate Authentication Services below.
6. Delete certificate authentication services, as described in Deleting Certificate Authentication Services below.

Note that once you save the certificate authentication service configuration, the appliance terminates administrative sessions for all admin users. After you enable the certificate authentication service, you can verify whether two-factor authentication is enabled. Go to the **Administration** -> **Administrators** -> **Authentication Policy** tab, Grid Manager displays the "Two-Factor Authentication Enabled" banner in this tab.

Configuring Certificate Authentication Services

To configure and enable the certificate authentication service, complete the following:

1. From the **Administration** tab, click the **Authentication Server Groups** tab.
2. Click the **Certificate Authentication Services** subtab and click the Add icon.
3. In the *Add Certificate Authentication Service* wizard, complete the following:
   - **Name**: Enter a name for the certificate authentication service.
   - **Username/password request**: Select the checkbox if the certificate authentication service must request username and password from the user. When you select this checkbox, NIOS populates the username from the certificate and requests password from the user. If you do not select the checkbox, only the certificate is necessary to log in to the appliance. The appliance ignores the username and password when the user provides both. You can only see the login button and do not have to provide the password. The appliance displays the username when you click the login button.
   - **Auto-populate username**: Select a value from the drop-down list. You can define how the appliance must authenticate a particular user and its associated group. The values in the list are **Auto-match** and **Direct-match**. When you select **Direct-match**, NIOS searches for users with directly assigned certificates, which contains issuer details and serial attributes, in the local database. Users with directly assigned certificates can use certificate based authentication only.
   - **Auto match by**: Select a value from the drop-down list. This field is enabled only when you select **Auto-match** for **Auto-populate username**. NIOS extracts the username from the certificate and searches for it in effective authorization policies based on the configured match policies. The values in the list are:
     - **AD Issuer Subject**: Select this from the drop-down list to authenticate the user based on the Active Directory mentioned by the user.
     - **SAN Email**: Select this from the drop-down list to authenticate the user based on the email address in the SAN (Subject Alternative Name).
     - **SAN UPN**: Select this from the drop-down list to authenticate the user based on the UPN (User Principal Name) in the SAN (Subject Alternative Name).
     - **Serial Number**: Select this from the drop-down list to authenticate the user based on the serial number.
     - **Subject DN Common Name**: Select this from the drop-down list to authenticate the user based on the subject DN (Distinguished Name) common name. A Subject DN can include information about the user who is being authenticated, including common name, name of the organization, country code, and so on.
     - **Subject DN Email**: Select this from the drop-down list to authenticate a user based on the subject DN email address.

- **Enable remote lookup for user membership:** Select the checkbox to enable lookup on remote servers. NIOS performs lookup against local users by default. For a remote lookup, you must specify the username and password for the authentication service. You can perform a look up for a user membership only if the remote service admin that is configured for remote lookup has enough permissions to read other user's membership information. You must also select the remote service that must be used for lookup. Note that NIOS supports remote lookup for Active Directories only.
  Note that You can select the above checkbox, **Authentication Service** and **Service Account Credentials** fields only when you select **Auto-match** for **Auto-populate username.** You must not select the **Username/password request** checkbox when you select the checkbox for **Enable remote lookup for user membership.**
- **Authentication Service**: Select an authentication service from the drop-down list.
- **Service Account Credentials**: Enter a username and password for authenticating lookup on remote servers.

- **Comment**: Optionally, enter additional information about the certificate authentication service.
- **Disable**: Select this checkbox to disable the record. Clear the checkbox to enable it.

4. Click **Next** to save the configuration and add OCSP responders to the table.
5. You can add multiple OCSP responders for failover purposes.

- **OCSP Check Type**: Select a value from the drop-down list to perform OCSP checks. The values in the drop-down list are:
  - **AIA and Manual**: Select this from the drop-down list to use AIA (Authority Information Access) extension of X.509 certificate, when it is present, to authenticate the user. Note that AIA points to the certificate authentication service that is used to verify the certificate. If AIA is not available, then the authentication fails. If the certificate does not contain AIA, then the appliance uses manual OCSP for authentication.
  - **AIA only**: Select this from the drop-down list to use AIA only to authenticate the user. AIA points to the certificate authentication service that is used to verify the certificate. By selecting this option you restrict NIOS to use AIA only. If the certificate does not contain AIA or it is not complete, then the authentication fails.
  - **Disabled**: Select this from the drop-down list if you do not want to perform an OCSP check.
  - **Manual**: Select this from the drop-down list to define OCSP settings and upload CA certificates manually. When you select this option, NIOS ignores AIA even though it is present.
- **OCSP Responders**: Click the Add icon and complete the following in the **Add OCSP Responder** section:
  - **Server Name or IP Address**: Enter the FQDN or the IP address of the OCSP responder that is used for authentication. The appliance supports IPv4 and IPv6 OCSP responders.
  - **Comment**: Enter useful information about the OCSP responder.
  - **Port**: Enter the port number on the OCSP responder to which the appliance sends authentication requests. The default is 80.
  - **Server Certificate**: Click **Select** to upload a server certificate. In the *Upload* dialog box, click **Select** to navigate to the certificate, and then click **Upload**. The appliance validates the certificate when you save the configuration. A server certificate is required for the direct trust model.
  - **Disable Server**: Select this checkbox to disable the OCSP responder if, for example, the connection to the server is down and you want to stop the NIOS appliance from trying to connect to this server.
    Note that you cannot save the OCSP configuration when you disable all OCSP responders, thus the certificate authentication service is disabled and two-factor authentication is no longer in effect. You cannot add OCSP responders when you select **AIA only** or **Disabled** from the drop-down list for **OCSP Check Type**.

  Click **Add** to save the configuration and add the responder to the table. You can add multiple OCSP responders for failover purposes. You can use the up and down arrows to place the responders in the order you desire. The appliance tries to connect with the first responder on the list. If the connection fails, it tries the next responder on the list, and so on. Grid Manager displays the following for each responder:

- **Responder**: The FQDN or the IP address of the OCSP responder.
- **Comment**: Information you entered about the OCSP responder.
- **Port**: The port number on the OCSP responder to which the appliance sends authentication requests.
- **Disabled**: Indicates whether the OCSP responder is disabled or not. Note that you must enable at least one responder to enable the certificate authentication service.

You can also click **Test** to test the configuration. If the appliance connects to the responder using the configuration you entered, it displays a message confirming the configuration is valid. If it is unable to connect to the responder, the appliance displays a message indicating an error in the configuration.

- **Response Timeout (s)**: Enter the time the appliance waits for a response from the specified OCSP responder.

  The default is 1 second. You can select the time unit from the drop-down list.

- **Retries**: Enter the number of times the appliance tries to connect to the responders after a failed attempt. The default is 5.
- **Recovery Interval**: Enter the time the appliance waits to recover from the last failed attempt in connecting to an OCSP responder. Select the time unit from the drop-down list. The default is 30 seconds. This is the time interval that NIOS waits before it tries to contact the responder again since the last attempt when the appliance could not connect with the responder or when the responder did not send a reply within the configured response timeouts and retry attempts.
- **Trust Model**: Select **Direct** or **Delegated** from the drop-down list as the trust model for OCSP responses. In a direct trust model, OCSP responses are signed with an explicitly trusted OCSP responder certificate. You must upload the OCSP responder certificate if you select **Direct**. In a delegated trust model, OCSP responses are signed with a trusted CA certificate. A server certificate is not required when you select **Delegated**. The default is **Direct**.

6. Click **Next** to save the configuration and associate CA Certificates with the respective certificate authentication service. You can associate multiple CA certificates with the service.

Note that enabling the certificate authentication service terminates administrative services for all users. Ensure that you have uploaded the correct CA certificates before enabling the service. Your login names must also match the common name used in the certificate. When you configure multiple OCSP responders, ensure that you place them in the correct order because the status check for a client certificate is based on the OCSP reply sent by the first OCSP responder that replies.

NIOS detects a valid certificate authentication service for a client's certificate by searching through the assigned CA certificates for each group. NIOS matches issuer field in the client's certificate with the CA certificate to find the appropriate match. Note that the subject in CA certificate must match the issuer in the client's certificate and corresponding certificate authentication service.

Note the following about the certificate authentication service:

- You cannot assign the same CA certificate to the same group twice or to a different certificate authentication service. However, different certificate authentication services can contain CA certificates with the same subject. To distinguish such groups you can use **Client Subject name** to determine which certificate must match the CA certificate to be associated with the certificate authentication service. If the client certificate does not match any certificate authentication service, then the authentication fails. A CA certificate verifies the client certificate.

7. Click **Add** to associate CA certificates with the certificate authentication service. The following information is displayed when you associate a CA certificate:

- **Subject**: The name of the certificate.
- **Issuer**: The name of the trusted CA that issued the certificate.
- **Valid From**: The date from which the certificate becomes valid.
- **Valid To:** The date until which the certificate is valid. You can do the following:
- Select a certificate and click the Delete icon to delete it.
- Print the data or export it in .csv format.

You can also do the following for a certificate authentication service:

- Use **Global Search** to search for certificate authentication services. For information about Global search, see *About the Grid Manager Interface.*
- View audit log entries for the certificate authentication service. For information about viewing the audit log, see *Monitoring Tools.*
- Select a certificate authentication service and click the Delete icon to delete it. In the *Delete Confirmation* dialog box, click **Yes** to confirm deletion.
- Modify a certificate authentication service as mentioned in Modifying Certificate Authentication Services below.
- Print the data or export it in .csv format.

Enabling Certificate Authentication Service for a User

You can restrict users to use certificate based authentication only. Note that certificate authentication service with a direct-match searches only for users with certificate authentication service enabled. Such users are successfully authenticated by the certificate authentication service using auto-match.

1. From the **Administration** tab, click the **Administrators** tab -> **Admins** tab -> *admin_account* checkbox, and then click the Edit icon.
2. In the *Administrator* editor, click the **General** tab, and then click the **Advanced** tab.
3. In the **General Advanced** tab, complete the following:

- **Enable Certificate Authentication**: Select this checkbox to enable certificate authentication for the selected user. You must configure certificate authentication service and associate a valid client CA certificate with the selected user. This is disabled by default.
- **Client Certificate Number**: You can specify a client certificate number only when you select the **Enable Certificate Authentication** checkbox. This is disabled by default. Enter the serial number as mentioned in the certificate. Examples: 397F9435000100000032 (hexadecimal format), 123 (decimal format), and so on.
- **Client CA Certificate**: You must associate a CA certificate that signs the client certificate. Click **Select** to associate a CA certificate. When you select a CA certificate from the list, NIOS displays the subject of the selected CA certificate. The *CA Certificate Selector* dialog box displays the following information about CA certificates:
    - **Issuer**: The name of the trusted CA that issued the certificate.
    - **Valid From**: The date from which the certificate becomes valid.
    - **Valid To**: The date until which the certificate is valid.
    - **Subject**: The name of the certificate.
      Click **OK** to select and associate the client CA certificate with the selected admin user.

4. Save the configuration.

Viewing Certificate Authentication Services

To view the certificate authentication service, complete the following:

1. From the **Administration** tab, click the **Authentication Server Groups** tab.
2. Click the **Certificate Authentication Services** subtab.
3. Grid Manager displays the following about the certificate authentication service:
    - **Name**: The name of the certificate authentication service.
    - **Comment**: Comments about the certificate authentication service.

You can also display the following column:

- **Disabled**: Indicates if the certificate authentication service is enabled or disabled.

You can do the following in this tab:

- Sort the data in ascending or descending order by column.
- Select the certificate authentication service and click the Edit icon to modify data, or click the Delete icon to delete it.
- Print and export the data in this tab.

Modifying Certificate Authentication Services

To modify a certificate authentication service:

1. From the **Administration** tab, click the **Authentication Server Groups** tab -> **Certificate Authentication Services** subtab -> select a certificate authentication service, and then click the Edit icon.
2. The *Certificate Authentication Service* editor provides the following tabs from which you can modify data:
    - **General**: In this tab, modify certificate authentication service data, as described in Configuring Certificate Authentication Services above.
    - **OCSP**: Modify associated OCSP responders.
    - **CA**: Add and delete CA certificates that are associated with the certificate authentication service.
3. Save the configuration.

Deleting Certificate Authentication Services

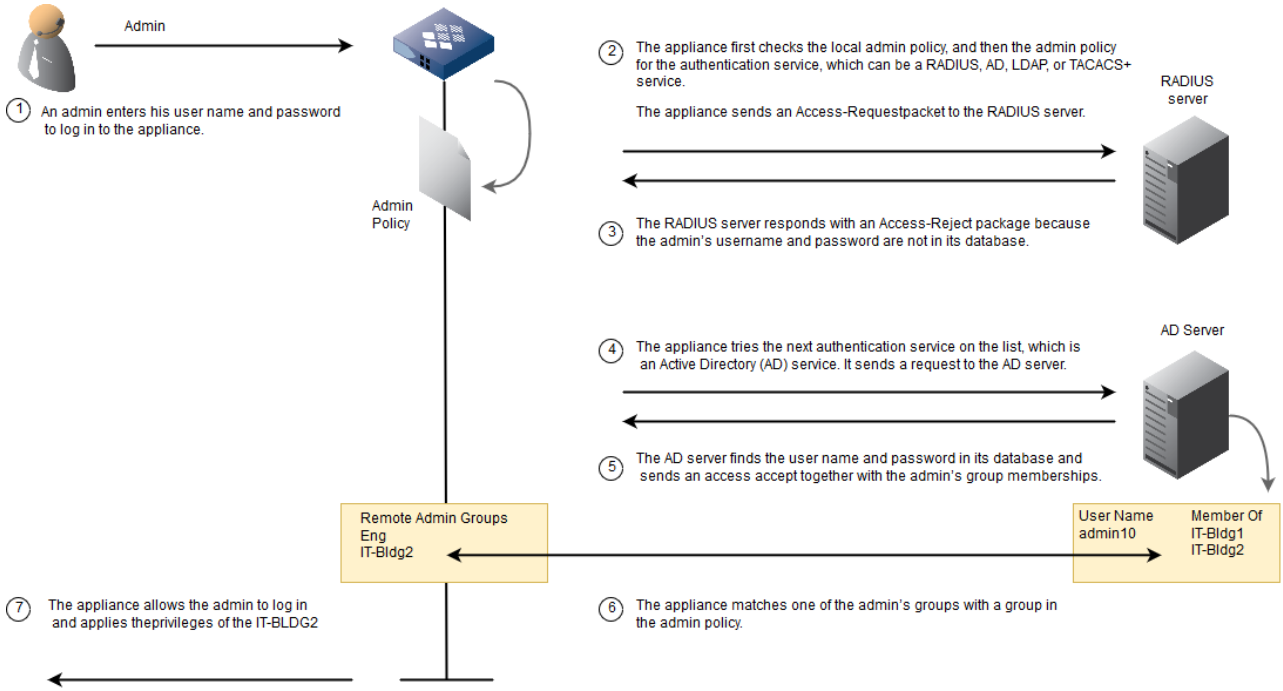
You can delete a certificate authentication service any time after you have created it. To delete a certificate authentication service:

1. From the **Administration** tab, click the **Authentication Server Groups** tab -> **Certificate Authentication Services** subtab, select a certificate authentication service and then click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes**.

About Remote Admins

NIOS can authenticate admins whose user credentials are stored remotely on RADIUS servers, AD domain controllers, LDAP servers, or TACACS+ servers. You can configure authentication server groups for each type of server to which NIOS sends authentication requests. For example, you can create a server group for RADIUS servers and another server group for AD domain controllers. Then in the admin authentication policy, you can list which authentication server groups to use and in what order.
In addition, if admin groups are configured on the remote authentication server, you can configure admin groups with the same names on the NIOS appliance and list them in the authentication policy as well. Then if the remote authentication server provides the admin group name while authenticating an admin, NIOS can automatically assign the admin to the matching admin group specified in the authentication policy. You can also create a default admin group for all admins that are authenticated through a remote authentication service.
Managing Administrators illustrates the authentication and authorization process for remote admins. In the example, two authentication server groups are configured—a RADIUS server group and an AD server group. When an admin logs in with a user name and password, the appliance uses the first service listed in the admin policy to authenticate the admin. If authentication fails, the appliance tries the next service listed, and so on. It tries each service on the list until it is successful or all services fail. If all services fail, then the appliance denies access and generates an error message in syslog.
If authentication succeeds, the NIOS appliance tries to match the admin group names in the admin policy to any groups received from the remote server. If it finds a match, the NIOS appliance applies the privileges of that group to the admin and allows access. If the appliance does not find a match, then it applies the privileges of the default group. If no default group is defined, then the appliance denies access.

Authenticating Remote Admins



Only superusers can perform the following tasks to configure NIOS to authenticate admins using remote authentication servers:

- Configure the authentication server groups. You can create multiple RADIUS, LDAP, and AD server groups, and certificate authentication services, but only one TACACS+ server group.
  - For information about RADIUS authentication, see *Authenticating Admins Using RADIUS.*
  - For information about AD authentication, see *Authenticating Admins Using Active Directory.*
  - For information about TACACS+ authentication, see *Authenticating Admin Accounts Using TACACS+.*
  - For information about LDAP authentication, see *Authenticating Admins Using LDAP*.
  - For information about the certificate authentication service, see *Authenticating Admins Using Two-Factor Authentication*.
- Configure admin groups with names that match those on the remote server. For information about admin groups, see *About Admin Groups*.
- Configure the admin policy, as described in *Defining the Authentication Policy*.

> **Note**
>
> Infoblox strongly recommends that even if you are using remote authentication, you always have at least one local admin in a local admin group to ensure connectivity to the appliance in case the remote servers become unreachable. Also, when you delete an authentication server group, the appliance removes it from the system. Deleted authentication server groups are not moved to the Recycle Bin. Once deleted, the authentication server groups no longer exist in the system.

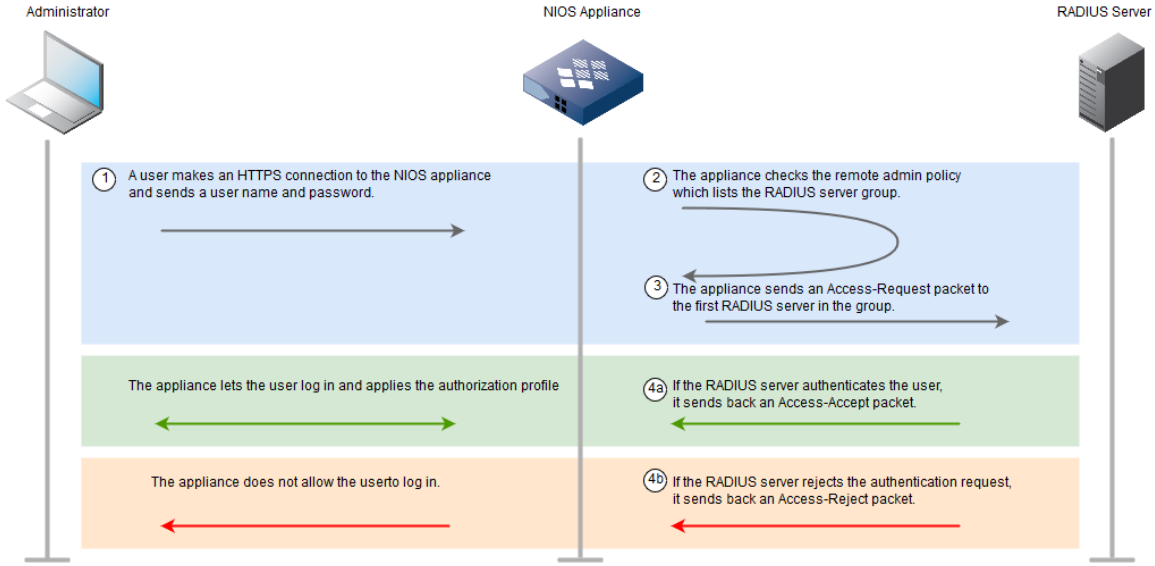
When remote authentication is successful, the appliance creates a remote admin user object in the NIOS database, which stores user preferences such as time zone, table size, and active Dashboard widgets for the remote user. If the remote user does not log in to the appliance for more than 180 days, the appliance removes the corresponding admin user object from the database. Although the remote user can still log in to the appliance, user preferences are lost. The Grid Master performs this clean up action once a day.
You can also authenticate users based on X.509 client certificates. You can configure NIOS to authenticate these admins

through the two-factor authentication method. For more information about two-factor authentication and how to configure it, see *Defining the Authentication Policy*.

Authenticating Admins Using RADIUS

RADIUS provides authentication, accounting, and authorization functions. The NIOS appliance supports authentication using the following RADIUS servers: FreeRADIUS, Microsoft, Cisco, and Funk.
When NIOS authenticates administrators against RADIUS servers, NIOS acts similarly to a network access server (NAS), which is a RADIUS client that sends authentication and accounting requests to a RADIUS server. The following figure illustrates the RADIUS authentication process.

Authentication using a RADIUS server



Authentication Protocols

When you configure the NIOS appliance to authenticate admins against a RADIUS server group, you must specify the authentication protocol of each RADIUS server, which can be either PAP (Password Authentication Protocol) or CHAP (Challenge Handshake Authentication Protocol).
PAP tries to establish the identity of a host using a two-way handshake. The client sends the user name and password in clear text to the NIOS appliance. The appliance uses a shared secret to encrypt the password and sends it to the RADIUS server in an Access-Request packet. The RADIUS server uses the shared secret to decrypt the password. If the decrypted password matches a password in its database, the user is successfully authenticated and allowed to log in.
With CHAP, when the client tries to log in, it sends its user name and password to the NIOS appliance. The appliance then creates an MD5 hash of the password together with a random number that the appliance generates. It then sends the random number, user name, and hash to the RADIUS server in an Access-Request package. The RADIUS server takes the password that matches the user name from its database and creates its own MD5 hash of the password and random number that it received. If the hash that the RADIUS server generates matches the hash that it received from the appliance, then the user is successfully authenticated and allowed to log in.
You can configure one of the following modes to send the authentication request to the RADIUS server:

- Ordered: In this mode, the authentication request is sent to the first server in the list. The authentication request is sent to the next server only when the first server is out of service or unavailable.
- Round Robin: In this mode, the first authentication request is sent to a server chosen randomly in a group. If there is no response from the server, continued attempts are performed sequentially until it selects the last server in the list. Then it starts with the first server in the list and continues the selection process until all the servers have been attempted.

Accounting Activities Using RADIUS

You can enable the accounting feature on the RADIUS server to track whether an administrator has initiated a session. After an administrator successfully logs in, the appliance sends an Accounting-Start packet to the RADIUS server.

Configuring Remote RADIUS Servers

For NIOS to communicate with a RADIUS server, you must also set up the remote RADIUS server to communicate with the NIOS appliance.

> **Note**
>
> If you have two Infoblox appliances in an HA pair, enter both the members of the HA pair as separate access appliances and use the LAN or MGMT IP address of both appliances (not the VIP address), if configured.

Depending on your particular RADIUS server, you can configure the following RADIUS server options to enable communication with the NIOS appliance:

- Authentication Port
- Accounting Port
- Domain Name/IP Address of the NIOS appliance
- Shared Secret Password
- Vendor Types

Configuring Admin Groups on the Remote RADIUS Server

Infoblox supports admin accounts on one or more RADIUS servers.
On the remote RADIUS server, do the following to set up admins and associate them with an admin group:

- Import Infoblox VSAs (vendor-specific attributes) to the dictionary file on the RADIUS server
- For third-party RADIUS servers, import the Infoblox vendor file (the Infoblox vendor ID is 7779)
- Define the admin group
- Associate one or more remote admin accounts with the admin group
- Add and activate a policy for the admin accounts, but do not associate the policy with a policy group that contains an infoblox-group-info attribute.

Refer to the documentation for your RADIUS server for more information.

Configuring RADIUS Authentication

To configure NIOS to use one ore more RADIUS server groups to authenticate administrators, you must do the following:

- Configure at least one RADIUS authentication server group. For more information, see Configuring a RADIUS Authentication Server Group below.
- Define admin groups for the admins that are authenticated by the RADIUS servers and specify their privileges and settings. The group names in NIOS must match the admin group names on the RADIUS server. See *About Admin Groups* for information about defining admin groups.
- In the authentication policy, add the RADIUS server groups and the admin groups that match those on the RADIUS server. You can also designate an admin group as the default group for remote admins. NIOS assigns admins to this group when it does not find a matching group for a remote admin. See *Defining the Authentication Policy* for more information about configuring the policy.

Configuring a RADIUS Authentication Server Group

You can add multiple RADIUS servers to the group for redundancy. When you do, the appliance tries to connect to the first RADIUS server on the list and if the server does not respond within the maximum retransmission limit, then it tries the next RADIUS server on the list. NIOS tries to connect to each RADIUS server in the order the servers are listed. If it

does not receive a response within the configured timeout period and has tried to connect the specified retry value, then it tries the next RADIUS server on the list. It logs an error to syslog when it fails to connect to any of the servers in the group.
After you add a RADIUS server to the NIOS appliance, you can validate the configuration. The appliance uses a pre-defined username and password when it tests the connection to the RADIUS server. The pre-defined user name is "Infoblox_test_user" and the password is "Infoblox_test_password". Do not use these as your administrator username and password.
To configure a RADIUS authentication server group :

1. From the **Administration** tab, click the **Authentication Server Groups** tab.
2. Click the Add icon in the **RADIUS Services** subtab.
3. In the *Add RADIUS Authentication Service* wizard, complete the following:
    - **Name**: Enter the name of the server group.
    - **RADIUS Servers**: Click the Add icon and enter the following:
        - **Server Name or IP Address:** Enter the FQDN or the IP address of the RADIUS server that is used for authentication.
        - **Comment:** Enter additional information about the RADIUS server.
        - **Authentication Port**: The destination port on the RADIUS server. The default is 1812. This field is required only if you do not enable accounting on the RADIUS server. This field is not required if you enable accounting to configure an accounting-only RADIUS server.
        - **Authentication Type:** Select either PAP or CHAP from the drop-down list. The default is PAP.
        - **Shared Secret:** Enter the shared secret that the NIOS appliance and the RADIUS server use to encrypt and decrypt their messages. This shared secret is a value that is known only to the NIOS appliance and the RADIUS server.
        - **Enable Accounting**: Select this to enable RADIUS accounting for the server so you can track an administrator's activities during a session. When you enable accounting, you must enter a valid port number in the **Accounting Port** field.
        - **Accounting Port**: The destination port on the RADIUS server. The default is 1813.
        - **Connect through Management Interface:** Select this so that the NIOS appliance uses the MGMT port for administrator authentication communications with just this RADIUS server.
        - **Disable server:** Select this to disable the RADIUS server if, for example, the connection to the server is down and you want to stop the NIOS appliance from trying to connect to this server.
        - Click **Test** to test the configuration. If the NIOS appliance connects to the RADIUS server using the configuration you entered, it displays a message confirming the configuration is valid. If it is unable to connect to the RADIUS server, the appliance displays a message indicating an error in the configuration.
        - Click **Add** to add the server to the list.

When you add multiple RADIUS servers, the appliance lists the servers in the order you added them. This list also determines the order in which the NIOS appliance attempts to contact a RADIUS server. You can move a server up or down the list by selecting it and clicking the up or down arrow.
You can also delete a RADIUS server by selecting it and clicking the Delete icon.

- **Authentication**: Optionally, modify the authentication settings. These settings apply to all RADIUS servers that you configure on the NIOS appliance.
- **Timeout(s):** Specify the number of seconds that the appliance waits for a response from the RADIUS server.
- **Retries:** Specify how many times the appliance attempts to contact an authentication RADIUS server.

The default is 5.
If you have configured multiple RADIUS servers for authentication and the NIOS appliance fails to contact the first server in the list, it tries to contact the next server, and so on.

- **Accounting**: Optionally, modify the Accounting settings.
    - **Timeout(s):** Specify the number of seconds that the appliance waits for a response from the RADIUS server.
    - **Retries:** Specify how many times the appliance attempts to contact an accounting RADIUS server. The default is 1000.
- **Mode:** Specifies how the appliance contacts the RADIUS servers. The default is Ordered List.
    - **Ordered List:** The Grid member always selects the first RADIUS server in the list when it sends an authentication request. It queries the next server only when the first server is considered down.

- **Round Robin:** The Grid member sends the first authentication request to a server chosen randomly in a group. If there is no response from the server, the Grid member selects the next server in the group.Continued attempts are performed sequentially until it selects the last server in the group. Then it starts with the first server in the group and continues the selection process until all the servers have been attempted.
- **Comment**: Enter useful information about the RADIUS service.
- **Disable**: Select this to disable RADIUS authentication for the servers listed in the table.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Note that the following fields in the wizard do not apply to this feature: **Enable NAC Filter**, **Cache Time to Live**, and **Recovery Interval**. They are used with the NAC Integration feature described in *Authenticated DHCP*.

Creating Local Admins

When you create an admin account, you must specify the authentication type, name, password, and admin group of the administrator. You can also control in which time zone the appliance displays the time in the audit log and the DHCP and IPAM tabs of Grid Manager, such as the *DHCP Lease History* and *DHCP Leases* panels. The appliance can use the time zone that it automatically detects from the management system that the admin uses to log in.

Alternatively, you can override the time zone auto-detection feature and specify the time zone. To create an admin account and add it to an admin group:

- Log in as a superuser.
- From the **Administration** tab, select the **Administrators** tab -> **Admins** tab, and then click the Add icon.
  or
  From the **Administration** tab, select the **Administrators** tab -> **Groups** tab -> *admin_group*, and then click the Add icon.
- In the *Add Administrator* wizard, complete the following:
  - **Authentication Type:** The default is **Local**. When you select **Local**, NIOS authenticates admins against the local database.
    Local: The following fields are displayed when you select **Local** authentication type. Enter the following:
    - **Login:** Enter a name for the administrator. This is the user name that the administrator uses to log in to the appliance. This user name is stored in the NIOS local database.
    - **Password:** Enter a password for the administrator. This is the password that the administrator uses to log in to the appliance. This password is stored in the NIOS local database.
    - **Confirm Password:** Enter the same password.
      Note In NIOS 8.5.2 or later, when you set up the account for a Grid Master or a standalone vNIOS instance that is deployed on AWS, the minimum password length must be four characters. The password must consist of at least one uppercase character, one lowercase character, one numeric character, and one symbol character. Example: Infoblox1!
      If the symbol character is at the beginning of the password, then include the password within quotes ('). Example: '@Infoblox123'.
  - **Use AWS SSH authentication keys**: To prevent CLI login failures after upgrading, you will need to enable **Use AWS SSH authentication keys** for each user that needs CLI access to AWS appliances. When you select **Use AWS SSH authentication keys**, NIOS allows you to access the CLI either by using a key pair and entering a password, or only by using the key pair which means the password-only authentication is blocked for the user. You can upload the SSH key by using the **Manage SSH Public Keys** field. It is mandatory to upload a valid SSH public key if you select the **Use AWS SSH authentication keys** option.
    If you use the **User data** field in the AWS console to install a NIOS license, the **Use AWS SSH authentication key** option is enabled by default. For more information about the **User data** field, see the *Initializing New Infoblox vNIOS for AWS Instances with the AWS User Data Field* section in the *Installation Guide for vNIOS for AWS documentation*.
    Note for a TE-V4025 appliance, if you use the **User data** field to install the TE-4025 license, the **Use AWS SSH authentication key** option will not be enabled by default. Therefore, Infoblox recommends that you first deploy the vNIOS instance without specifying the IB-4025 license, and then install the license from the NIOS CLI.

- **Authentication Method**: You can choose **Key pair** or **Key pair + Password** methods from the **Authentication Method** drop-down list. A server generates two distinct, but related keys: a public key that you upload and a corresponding private key that is stored in the system. A Key pair is the combination of these two related keys and is the default authentication method. If you select **Key pair** as the authentication method, then a user can access the CLI with a valid key pair. If you select **Key pair + Password** as the authentication method, the user must provide a password to access the CLI even after a successful key pair authentication. For information on defining and managing passwords, see Managing Passwords below.
- **Manage SSH Public Keys**: You need to upload a valid SSH public key file. The supported key types are RSA, EDSA, and ED25519. The**Key Type**and**Key Value**fields in the**MANAGE SSH PUBLIC KEYS** are automatically updated once you upload a valid SSH key.

Note that from NIOS 8.5.2 onwards, the **Use AWS SSH authentication keys**, **Authentication Method**, and **Manage SSH Public Keys** fields are not available for the **Remote** and **SAML Only** authentication types. That is, you cannot use the CLI to access vNIOS for AWS if you are a remote user or a SAML user.

- **Remote:** When you select **Remote**, NIOS authenticates admins based on the user credentials stored remotely on authentication servers, such as RADIUS servers, AD domain controllers, LDAP servers, or TACACS+ servers. The **Login** field is displayed when you select **Remote** authentication type. Enter a name for the administrator that is stored in the database of the remote server. This is the user name that the administrator uses to log in to the appliance.
- **SAML Only**: When you select **SAML Only**, NIOS authenticates admins based on the user credentials stored in the IDP (Identity Provider). An admin can log in to NIOS only by clicking the **SSO Login** button and if the user credentials exist in the IDP account.
- **SAML/Local**: When you select **SAML/Local**, NIOS authenticates admins based on the user credentials stored in the IDP, when the SSO Login button is clicked or against the local database when the User name and Password is supplied and the Login button is clicked. For **SSO Login**, the user name and password need not be supplied in the NIOS GUI, rather it should be supplied in the **IDP's** login prompt. For information about SAML authentication, see *Authenticating Admins Using SAML*.

> **Note**
>
> You cannot configure the **Remote** authentication type for NIOS admin users who belong to the **fireeye-group** admin groups.

Email Address: Enter the email address for this administrator. The appliance uses this email address to send scheduling notifications.

- **Admin Group:** Click **Select** to specify an admin group. If there are multiple admin groups, Grid Manager displays the *Admin Group Selector* dialog box from which you can select one. An admin can belong to only one admin group at a time.

NIOS appliance creates a new group, **fireeye-group**, when you add the first FireEye zone. The FireEye admin group is read-only and you cannot assign permissions to it. Select **fireeye-group** for the admin group and add users to this group. For more information, see *About FireEye Integrated RPZs.*

> You cannot add a NIOS admin user that uses the Remote authentication type to the **fireeye-group** admin group.

- **Comment:** Enter useful information about the administrator.
- **Disable:** Select this checkbox to retain an inactive profile for this administrator in the configuration. For example, you might want to define a profile for a recently hired administrator who has not yet started work. Then when he or she does start, you simply need to clear this checkbox to activate the profile.
- **Status**: Displays the status of the administrator. The status can be one of the following:
  - **Active**: The administrator account is active. This is the default status.
  - **Disabled**: The administrator account is disabled.
  - **Locked**: The administrator account is locked because the password has been entered incorrectly a specified number of times.
  - **Inactive**:The administrator account is inactive because the account has not been logged in to for a specified period of time. For more information about configuring security features , see *Managing Security Operations*.

4. Optionally, click **Next** to add extensible attributes to the admin account. For information, see *About Extensible Attributes*.

5. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing Passwords

Superusers can define requirements for the passwords of local admins according to your organization's policies. In addition to specifying the minimum password length, you can define rules that specify the character types that are allowed in the password. You can also specify whether passwords expire, their duration, and when reminders are sent to the users. Additionally, you can specify whether the history of used password needs to be stored, and you can require admins to change their passwords when they first log in or after their passwords are reset.

You set the requirements at the Grid level, so they apply to all local admins who log in to the Grid. You can also set the requirements at the standalone system level. The requirements that you define appear in the User Profile of all local admins and when users are required to change their password.

To define the password requirements for local admins:

1. **Grid:** From the **Grid** tab, select the **Grid Manager** tab. Expand the Toolbar and select **Grid Properties** -> **Edit**.
   or,
   Standalone system: From the **System** tab, select the **System Manager** tab. Expand the Toolbar and select **System Properties Editor**.
2. In the editor, select the **Password** tab and complete the following:
   - **Minimum Password Length:** Specify the minimum number of characters that are required in a password.
   - **Password Complexity:** You can set up some requirements around how users compose a password by specifying the category and the number of characters and/or symbols the password must contain. The default is 0 for all categories, which means the password is not required to contain those characters. Specify the minimum number of characters the password must contain for the following:
     - **lowercase characters [a-z]**
     - **uppercase characters [A-Z]**
     - **numeric characters [0-9]**
     - **symbol characters**. Allowed characters are: **! @ # $ % ^ & * ( )**
     - **character changes from previous passwords**. To discourage users from reusing previous passwords, you can require a minimum change of characters from previous passwords.
     - **password encryption**. Passwords with more than 64 characters are not encrypted.
   - **Password must expire:** Specify the number of days after which the password must expire and the number of days before which NIOS must send a reminder to the user that the password will expire.
   - **Enforce Password History:** Select this checkbox to store the history of used passwords in the NIOS database. This option is disabled by default.
     - In the **Remember last passwords** field, specify the number of passwords to be stored. You can specify a value from 1 to 20. The default value is 5.
   - **Minimum password age:** Specify the minimum number of days the password must be active before the user can attempt to change it. You can specify a value between 0 to 9998. The recommended value is 2.

     Note that if the **Password must expire** checkbox is enabled, you must set the **Minimum password age** to a value less than the password expiration interval value. Superusers can override the **Minimum password age** and reset the passwords of local admins.
   - **Force password change at next login:** Select this checkbox to force all new users to change their passwords when they log in for the first time, and to force existing users whose passwords were reset by superusers or whose passwords were just reset to change their passwords.

⚠ The "force password change at next login" feature does not apply to admin users in the **fireeye-group**. These users will not be prompted to change their passwords at the next login. Their original passwords continue to work. For information about FireEye integrated RPZs, see *About FireEye Integrated RPZs.*

3. Click **Save & Close**.

Modifying and Deleting Admin Accounts

You can modify and delete admin accounts that you create, but you can only partially modify the default superuser account "admin"—and only when you are logged in as a superuser account. Furthermore, because there must always be a superuser account on the appliance, you can only remove the default "admin" account after you create another superuser account.

To modify an admin account:

1. From the **Administration** tab, select the **Administrators** tab -> **Admins** tab -> *admin_account* checkbox, and then click the Edit icon.
   or
   From the **Administration** tab, select the **Administrators** tab -> **Groups** tab -> *admin_group* -> *admin_account* checkbox, and then click the Edit icon.
2. The *Administrator* editor provides the following tabs from which you can modify data:
   - **General**: In the **General Basic** tab, modify the data of the admin account.

     > **Note**
     >
     > If the **Use AWS SSH authentication keys** option was previously disabled and is allowed when modifying an existing admin account, then password-only authentication is blocked. If the **Use AWS SSH authentication keys** option was earlier enabled and is now disabled, then password-only authentication is allowed.

     Note that if the **Use AWS SSH authentication keys** option was previously disabled and is allowed when modifying an existing admin account, then password-only authentication is blocked. If the **Use AWS SSH authentication keys** option was earlier enabled and is now disabled, then password-only authentication is allowed.
     On the **General Advanced** tab, complete the following:
     - **Time Zone**: Select a time zone from the drop-down list if you want to specify the time zone for the administrator. By default, the appliance automatically detects the time zone from the management system that the administrator uses to connect to the appliance. The appliance uses this time zone when it displays the timestamps for relevant data.
     - **Enable Certificate Authentication**: Select the checkbox to enable the certificate authentication service. You must also specify the serial number of the client certificate and associate a CA certificate that signs the client certificate. For more information, see *Enabling Certificate Authentication Service for a User.*
   - **Extensible Attributes**: Add and delete extensible attributes that are associated with the admin account. You can also modify the values of the extensible attributes. For information, see *About Extensible Attributes.*
3. Save the configuration and click **Restart** if it appears at the top of the screen.

To delete an admin account:

1. From the **Administration** tab, select the **Administrators** tab -> **Admins** tab -> *admin_account* checkbox, and then click the Delete icon.
   or
   From the **Administration** tab, select the **Administrators** tab -> **Groups** tab -> *admin_group* -> *admin_account* checkbox, and then click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes**.

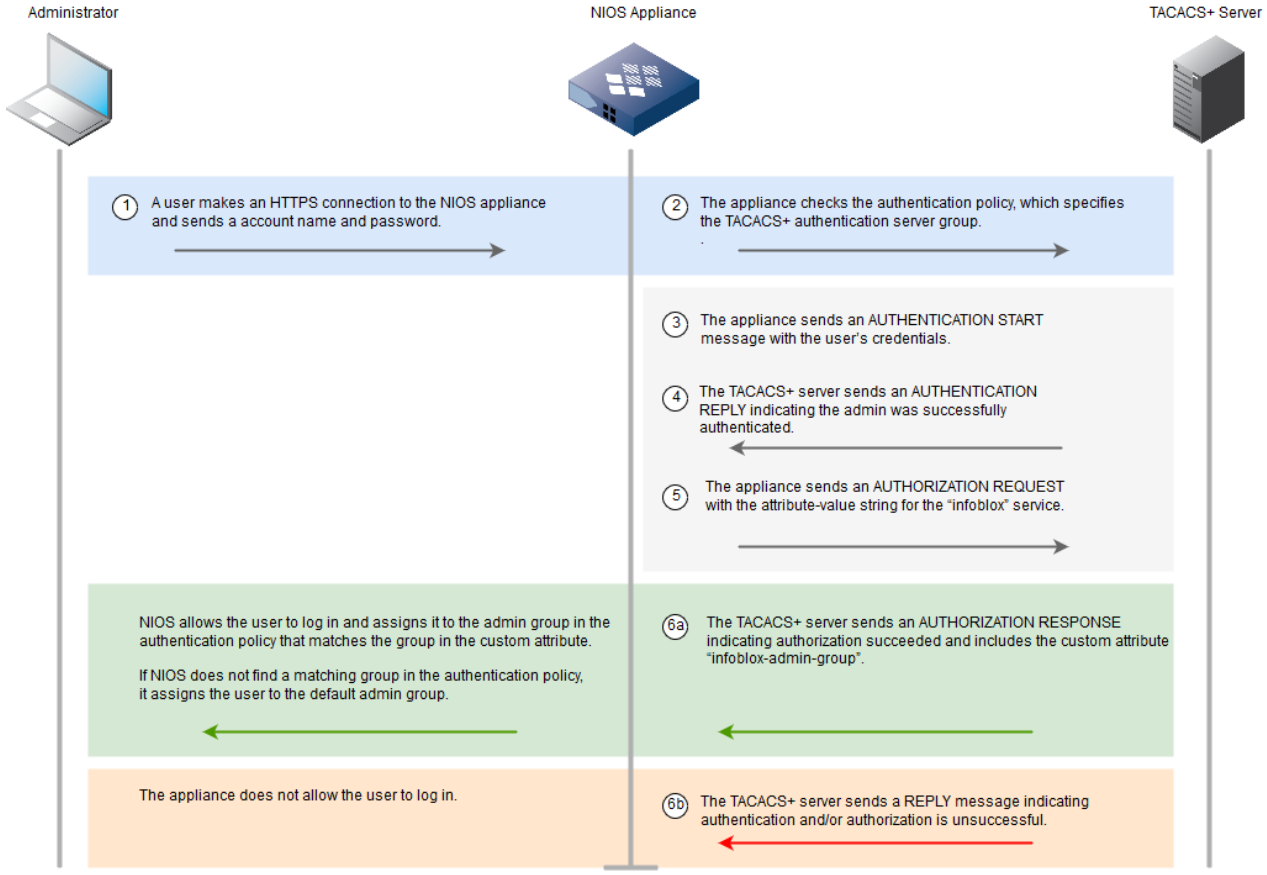
When you remove a Grid member from the Grid, local admin accounts are not removed and you will still be able to see these admin accounts.

Authenticating Admin Accounts Using TACACS+

You can configure NIOS to authenticate admins against TACACS+ (Terminal Access Controller Access-Control System Plus) servers. TACACS+ provides separate authentication, authorization, and accounting services. To ensure reliable delivery, it uses TCP as its transport protocol, and to ensure confidentiality, all protocol exchanges between the

TACACS+ server and its clients are encrypted. For detailed information about TACACS+, refer to the Internet draft *https://tools.ietf.org/html/draft-grant-tacacs-02*.
In addition, you can configure a custom service, infoblox, on the TACACS+ server, and then define a user group and specify the group name in the custom attribute infoblox-admin-group. Ensure that you apply the user group to the custom service infoblox. On NIOS, you define a group with the same name and add it to the authentication policy.
Then when the TACACS+ server responds to an authentication and authorization request and includes the infoblox-admin-group attribute, NIOS can match the group name with the group in the authentication policy and automatically assign the admin to that group.
The following figure illustrates the TACACS+ authentication and authorization process when PAP/CHAP authentication is used.

TACACS+ Authentication



TACACS+ Accounting

When you enable TACACS+ accounting, NIOS sends the TACACS+ accounting server a TACACS+ accounting event with the same information that it sends to the Audit Log for any user command/event. NIOS sends an accounting start packet when a user first logs in successfully using TACACS+ authentication, and it sends an accounting STOP packet when a user logs out of the GUI or CLI or when a GUI or CLI session times out. If a product restarts or software failure occurs, NIOS drops any outstanding accounting packets. Note that audit log entries that are greater than 3,600 characters are truncated in accounting events sent to TACAS+ servers.

Configuring TACACS+

Complete the following tasks to enable NIOS and the TACACS+ servers to communicate. On each TACACS+ server that you are adding to the authentication server group:

- For Windows TACACS+ servers, add the NIOS appliance as an AAA client. This step is not required for LINUX TACACS+ servers.
- Determine which user group on the TACACS+ server is used to match the admin group in NIOS, and then configure the following settings for the user group:
    - Add "infoblox" as a custom service.
    - Define the custom attribute for the group, in the format: **infoblox-admin-group=** *group_name*. For example, **infoblox-admin-group=remoteadmins1**. The group name can have a maximum of 64 characters.

On the NIOS appliance:

- Create a TACACS+ authentication server group. You can create only one TACACS+ server group. For more information, see Configuring a TACACS+ Authentication Server Group below.
- Create the local admin group in NIOS that matches the user group on the TACACS+ server. Note that the NIOS admin group name must match the group name specified in the TACACS+ server and in the custom attribute. For example, if the custom attribute is **infoblox-admin-group=remoteadmins1**, then the admin group name must be **remoteadmins1**. In addition, you can designate a default admin group for remote admins. For information about configuring group permissions and privileges, see *About Admin Groups*.
- In the authentication policy, add the newly configured TACACS+ server group and the TACACS+ admin group name. See *Defining the Authentication Policy* for more information about configuring an admin policy.

Configuring a TACACS+ Authentication Server Group

You can add multiple TACACS+ servers to the TACACS+ authentication server group. NIOS sends authentication requests to the TACACS+ servers in the order they are listed. NIOS sends authentication requests to the first server on the list. If that server is unreachable or generates an error, then NIOS sends the request to the next server in the list that has not been previously queried, and so on. NIOS logs an error message in syslog if all servers have been queried and they all generate errors or are unreachable.
To configure a TACACS+ authentication server group:

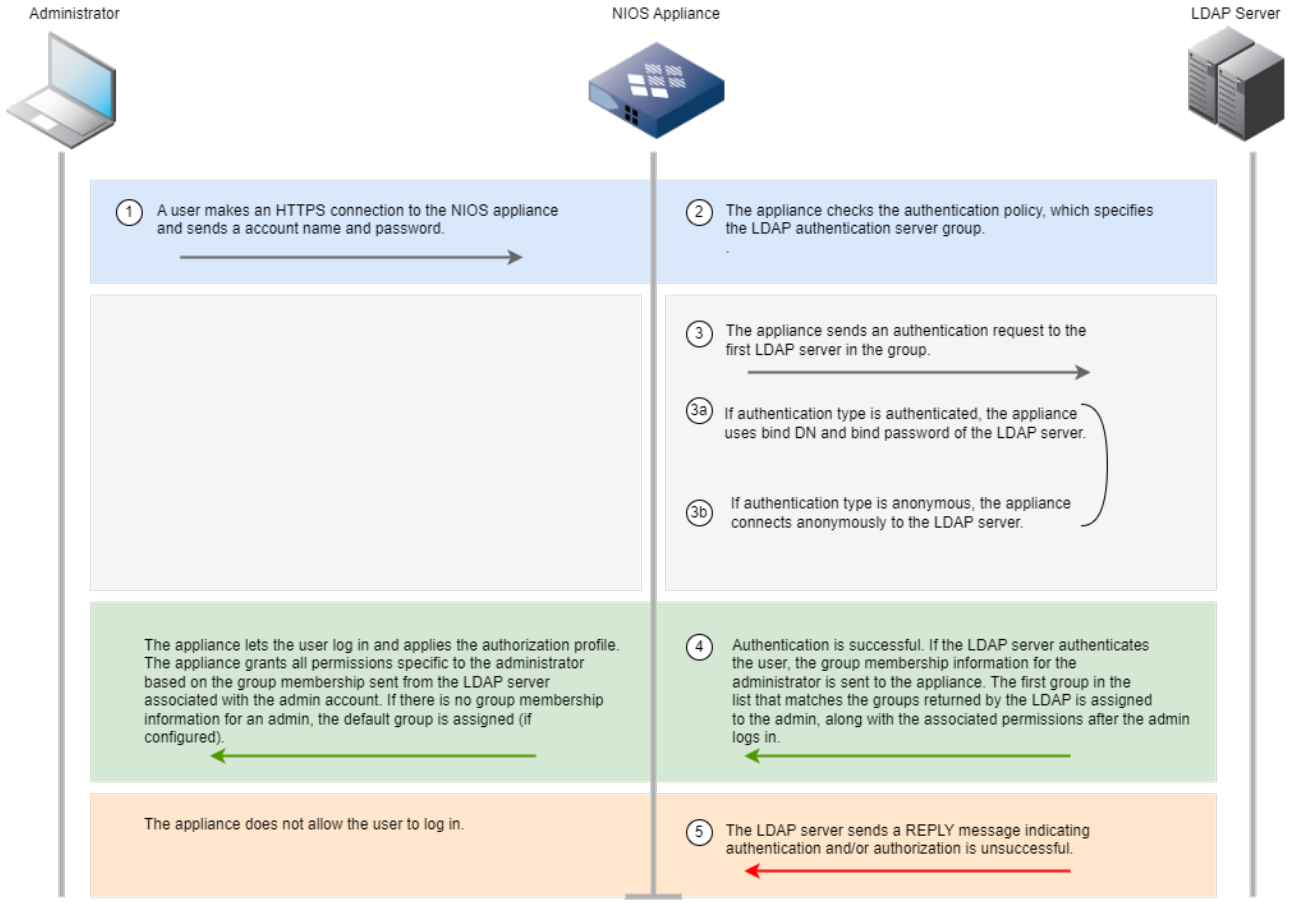
1. From the **Administration** tab, click the **Authentication Server Groups** tab.
2. Click the **TACACS+ Services** subtab and click the Add icon.
3. In the *Add TACACS+ Service* wizard, complete the following:
    - **Name:** Enter a name for the server group.
    - **TACACS+ Servers:** Click the Add icon and complete the following:
        - **Server Name or IP address:** The name or IP address of the TACACS+ server.
        - **Comment:** You can enter additional information about the server.
        - **Port:** The TCP destination port for TACACS+ communication. This port is used for authentication, accounting and authorization packets. The default is port 49.
        - **Authentication Type:** Select **ASCII**, **PAP** or **CHAP**. The default is **CHAP**.
        - **Shared Secret:** The shared key that the NIOS appliance and the TACACS+ server use to encrypt and decrypt messages.
        - **Enable Accounting:** Select this to enable NIOS to send accounting information to the TACACS+ server.
        - Connect through Management Interface: Select this checkbox to enable the appliance to use the MGMT port to communicate with the TACACS+ server. Ensure that the MGMT port is configured. Otherwise, the appliance will use the LAN interface
        - **Disable Server:** Select this to prevent queries from being sent to this server. You can retain the configuration, but disable the service.
          Click **Test** to test the configuration. Click **Add** to add the TACACS+ server to the list.
          When you add multiple TACACS+ servers, the appliance lists the servers in the order you added them. This list also determines the order in which the NIOS appliance attempts to contact a TACACS+ server. You can move a server up or down the list by selecting it and clicking the up or down arrow.
        - **Authentication/Authorization:** Optionally, modify the authentication and authorization settings. These settings apply to all TACACS+ servers that you configure on the NIOS appliance.
            - **Timeout(s):** Specify the number of seconds or milliseconds that the appliance waits for a response from the TACACS+ server before it tries to contact it again. The amount of time before the server is retried. The default and minimum is 5000, and the maximum is 60000.

        - **Retries:** Specify how many times NIOS attempts to contact a TACACS+ server and fails before it tries to contact the next server on the list. The default is 0. The maximum is 5.
    - **Accounting**: Optionally, modify the Accounting settings.
        - **Timeout(s):** Specify the number of seconds or milliseconds that the appliance waits for a response from the TACACS+ server. The amount of time before the server is retried. The default and minimum is 1000, and the maximum is 30000.
        - **Retries:** Specify how many times the appliance attempts to contact an accounting TACACS+ server and fails before it tries to contact the next accounting server on the list. The default is 0. The maximum is 5.
    - **Comment:** Enter additional information about the service.
    - **Disable**: Select this to retain an inactive TACACS+ authentication service profile.
4. Save the configuration.

Authenticating Admins Using LDAP

LDAP (Lightweight Directory Access Protocol) is an internet protocol for accessing distributed directory services. The NIOS appliance can authenticate admin accounts by verifying user names and passwords against LDAP. The NIOS appliance queries the LDAP server for the group membership information of the admin. The appliance matches the group names from the LDAP server with the admin groups in its local database. It then authorizes services and grants the admin privileges, based upon the matching admin group on the appliance. The following figure illustrates the LDAP authentication process.

Authenticating using an LDAP server



Authentication Protocols

When you configure the NIOS appliance to authenticate admins against an LDAP server group, you must specify the authentication protocol of each LDAP server, which can be either anonymous or authenticated. The NIOS appliance connects anonymously to the LDAP server when the authentication type is anonymous. With authenticated type, the

NIOS appliance connects using the bind DN and bind password defined for that server.
You can configure one of the following modes to send the authentication request to the LDAP server:

- Ordered: In this mode, the authentication request is sent to the first server in the list. The authentication request is sent to the next server only when the first server is out of service or unavailable.
- Round Robin: In this mode, the first authentication request is sent to a server chosen randomly in a group. If there is no response from the server, continued attempts are performed sequentially until it selects the last server in the list. Then it starts with the first server in the list and continues the selection process until all the servers have been attempted.

You can also specify the authentication type, for admins who belong to specific groups. The NIOS appliance uses the selected group authentication type to query the LDAP server and retrieve the group names to which the admin belongs. In LDAP, you can group users by any custom object classes. Example: objectclass groupofNames, objectclass posixGroup, etc. In NIOS, when you select Member Group Attribute as the group authentication type, the appliance uses custom LDAP group attributes to query the LDAP server and retrieve the group names for authentication. Example: memberOf, isMemberOf, etc. When you select Posix Group as the authentication type, the appliance uses "memberuid" and "objectClass" to query the server and retrieve the group names for authentication.

Configuring LDAP

Do the following to configure NIOS to use one or more LDAP server groups to authenticate administrators:

- Configure at least one LDAP authentication server group. For more information, see Configuring an LDAP Server Group below.
- Define admin groups for the admins that are authenticated by the LDAP servers and specify their privileges and settings. The group names in NIOS must match the admin group names on the LDAP server. For more information about defining admin groups, see *About Admin Groups*.
- In the authentication policy, add the LDAP server groups and the admin groups that match those on the LDAP server. You can also designate an admin group as the default group for remote admins. NIOS assigns admins to this group when it does not find a matching group for a remote admin. For more information about configuring the policy, see *Defining the Authentication Policy*.

Configuring an LDAP Server Group

You can add one or more LDAP servers to an LDAP group for redundancy. The NIOS appliance tries to connect with the LDAP server based on the method you configure for the authentication request. If it does not receive a response within the configured timeout period and has tried to connect the specified retry value, then it tries the next LDAP server on the list. The appliance makes a syslog entry when it fails to connect to any of the servers in the group and sends an SNMP trap and an email notification if configured.
To configure an LDAP server group on the NIOS appliance:

1. From the **Administration** tab, click the **Authentication Server Groups** tab.
2. Click the Add icon in the **LDAP Services** subtab.
3. In the *Add LDAP Authentication Service* wizard, complete the following:
    - **Name**: Enter the name of the server group.
    - **LDAP Servers**: Click the Add icon and enter the following:
        - **Server Name or IP Address:** Enter the FQDN (fully-qualified domain name) of the server or enter the IPv4/IPv6 address.
        - **LDAP Version**: Select the LDAP version. The NIOS appliance supports both LDAPv2 and LDAPv3. The default LDAP version is v3.
        - **Base DN**: Enter the base DN (Distinguished Name) value. All entries stored in an LDAP directory have a unique DN.
        - **Authentication Type:** Select the authentication type from the drop-down list. The supported authenticated types are as follows:
            - **Anonymous:** Select this to connect to the LDAP server anonymously. This is selected by default.
            - **Authenticated**: Select this to connect using the bind DN and bind password defined for that server.
                - **Bind User DN**: Enter the bind user DN.

        - **Bind Password**: Enter the bind password.
    - **Encryption:** Select the encryption type from the drop-down list.
        - **SSL**: This is selected by default. All the network traffic is encrypted through an SSL (Secure Sockets Layer) protocol. The appliance automatically updates the authentication port to 636 for SSL. You must upload a CA certificate that verifies the LDAP server certificate. Click **CA Certificates** to upload the certificate. In the *CACertificates* dialog box, click the Add icon, and then navigate to the certificate to upload it.
        - **NONE**: Select this to unencrypt the connection. Note that Infoblox strongly recommends that you select the SSL option to ensure the security of all communications between the server and the member.
    - **Network Port**: Enter the authentication port number on the LDAP server to which the appliance sends authentication requests. The default value is 636. When you select NONE from the Encryption drop-down list, the appliance automatically updates the authentication port to 389.
    - **Comment**: Enter useful information about the LDAP server.
    - **Connect through Management Interface:** Select this so that the NIOS appliance uses the MGMT port for administrator authentication communications with just this LDAP server.
    - **Disable Server:** Select this to disable the LDAP server if, for example, the connection to the server is down and you want to stop the NIOS appliance from trying to connect to this server. You cannot disable the only server in a group if it is already being used by the remote authentication policy.
    - Click **Test** to test the configuration. If the NIOS appliance connects to the LDAP server using the configuration you entered, it displays a message confirming the configuration is valid. If it is unable to connect to the server, the appliance displays a message indicating an error in the configuration.
    - Click **Add** to add the LDAP server to the group.
      When you add multiple LDAP servers, the appliance lists the servers in the order you added them. This list also determines the order in which the NIOS appliance attempts to contact an LDAP server. You can move a server up or down the list by selecting it and clicking the up or down arrow.
      You can also delete a server by selecting it and clicking the Delete icon.
- **Server Timeout(s):** Specify the number of seconds that the appliance waits for a response from the LDAP server. The default value is 5 seconds.
- **Retries:** Specify how many times the appliance attempts to contact an authentication LDAP server. The default value is 5.
  If you have configured multiple LDAP servers for authentication and the NIOS appliance fails to contact the first server in the list, it tries to contact the next server after completing the specified number of attempts, and so on.
- **Mode:** Specifies the order in which a Grid member connects to an LDAP server.
    - **Ordered List:** The Grid member always selects the first LDAP server in the list when it sends an authentication request. It queries the next server only when the first server is considered down. This is the default.
    - **Round Robin:** The Grid member sends the first authentication request to a server chosen randomly in a group. If there is no response from the server, the Grid member selects the next server in the group. Continued attempts are performed sequentially until it selects the last server in the group. Then it starts with the first server in the group and continues the selection process until all the servers have been attempted.
- **Recovery Interval**: Specify the number of seconds that the appliance waits to recover from the last failed attempt in connecting to an LDAP server. Select the time unit from the drop-down list. The default is 30 seconds. This is the time interval that NIOS waits before it tries to contact the server again since the last attempt when the appliance could not connect to the LDAP server or when the LDAP server did not send a reply within the configured response timeouts and retry attempts.
- **Group Authentication Type**: Select the group authentication type for LDAP authentication service from the drop-down list. By default, **Member Group Attribute** authentication type is selected.When you select **Member Group Attribute**, you can specify custom LDAP group attribute in the **Group Membership Attribute** field. For example, memberOf, isMemberOf, etc. The appliance uses this attribute to retrieve the group names to which the admin belongs. When you select **Posix Group**, the appliance uses "memberuid" and "objectClass" to retrieve the group names to which the admin belongs.
- **Group Membership Attribute**: Specify the LDAP group attribute (such as "memberOf" and "isMemberOf"). This is used to query the server and retrieve the group names to which the admin belongs. This field is enabled only when you select Member Group Attribute in the **Group Authentication Type** drop-down list. The default value is **memberOf**.

- **LDAP Search Scope**: To search for an admin user name in the LDAP directory, select one of the following LDAP search scope:
    - **Base**: Specify Base to perform search only on base in the LDAP directory. This is the top level of the LDAP directory tree.
    - **One Level**: Specify One Level to perform search on base DN and one level below the base in the LDAP directory.
    - **Subtree**: Specify Sub tree to perform search on base and all the entries below the base DN in the LDAP directory.
      The default value is One Level.
- **User ID:** Specify the attribute associated with the user object in the LDAP server, such as "uid" and "cn". This attribute is used to match the NIOS user name.
- **Map LDAP Field to Extensible Attribute (for Captive Portal Users only)**: If you configure the LDAP authentication server group to authenticate the captive portal users, you can map an LDAP attribute value to an existing extensible attribute. This mapping is optional. By doing so, the LDAP attribute value will be queried from the LDAP server once the captive portal user authentication is successful. The attribute value received from the LDAP server is mapped to the corresponding extensible attribute. NIOS updates or creates a MAC address filter depending on the captive portal user or the client's hardware and name. Click the Add icon and enter the following:
    - **LDAP Field**: Enter the LDAP attribute. This attribute is queried in the LDAP directory server.
    - **Extensible Attributes**: Select an attribute from the drop-down list. The drop-down list displays only the extensible attributes configured with attribute type as string. Infoblox recommends that you avoid confidential data while mapping extensible attribute to an LDAP attribute because this data is visible in the extensible attribute field of the corresponding MAC address filter.
      Note that mapping an extensible attribute to an LDAP attribute must be unique for a given LDAP server. Attribute not defined in the LDAP directory for a given user is considered as null and is mapped to the corresponding extensible attribute with a default value. The default value of extensible attribute is Not Found. This default value is not configurable and they do not cause the authentication to fail.
- Comment: Enter useful information about the LDAP server group.
- **Disable**: Select this to disable the LDAP authentication server group. Note that you cannot disable an LDAP group if it is already being used to authenticate one or more administrators and/or captive portal users.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

About Admin Accounts

A user must have an admin account to log in to the NIOS appliance. Each admin account belongs to an admin group, which contains roles and permissions that determine the tasks a user can perform. For information, see *About Admin Groups*.

When an admin connects to the appliance and logs in with a username and password, the appliance starts a two-step process that includes both authentication and authorization. First, the appliance tries to authenticate the admin using the username and password. Second, it determines the authorized privileges of the admin by identifying the group to which the admin belongs. It grants access to the admin only when it successfully completes this process.

The NIOS appliance can authenticate users that are stored on its local database as well as users stored remotely on an Active Directory domain controller, a RADIUS server, a TACACS+ server or an LDAP server. The group from which the admin receives privileges and properties is stored locally.

NIOS can authenticate users based on X.509 client certificates irrespective of the client certificate source. For example, smart card holders such as U.S. Department of Defense CAC users and PIV card holders. The status of these certificates is stored remotely on OCSP (Online Certificate Status Protocol) responders. NIOS uses two-factor authentication to validate these users. For more information about two-factor authentication and how to configure it, see *Authenticating Admins Using Two-Factor Authentication*.

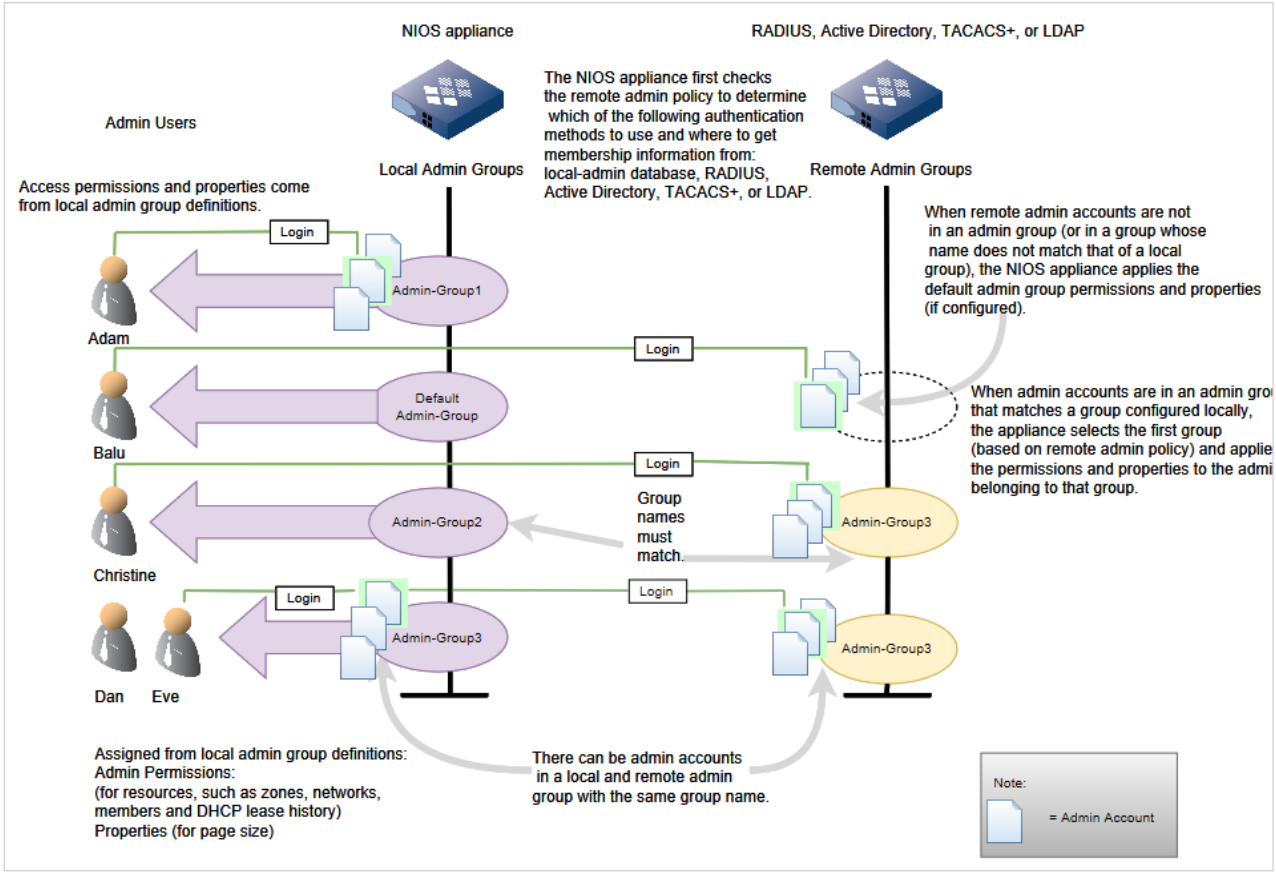
The tasks involved in configuring administrator accounts locally and remotely are listed in *Storing Admin Accounts Locally and Remotely* table

	NIOS Appliance	RADIUS server/AD Domain Controller/TACAS+ server/ LDAP server/Certificate authentication service
To store admin accounts locally	• Use the default admin group ("admin-group") or define a new group • Set the privileges and properties for the group • Add admin accounts to the group	
To store admin accounts remotely	• Configure communication settings with a RADIUS server, an Active Directory domain controller, TACACS+ server, or LDAP server If you use admin groups on the RADIUS server, Active Directory domain controller, TACACS+ server, or LDAP server: • Configure admin groups that match the remote admin groups • Set the privileges and properties for the groups If you do not use admin groups on the RADIUS server, Active Directory domain controller, TACACS+ server, or LDAP server: • Assign an admin group as the default	• Configure communication settings with the NIOS appliance If you use admin groups: • Import Infoblox VSAs (vendor-specific attributes) (if RADIUS) • Define an admin group with the same name as that on the NIOS appliance • Define admin accounts and link them to an admin group If you do not use admin groups: • Define admin accounts

The admin policy defines how the appliance authenticates the admin: with the local database, RADIUS, Active Directory, TACACS+, or LDAP. You must add RADIUS, Active Directory, TACACS+, or LDAP as one of the authentication methods in the admin policy to enable that authentication method for admins. See *Defining the Authentication Policy* for more information about configuring the admin policy.

> **Note**
>
> Local passwords are stored in the database as part of the user object. Values for passwords are stored after applying a random salt and hashed with SHA-128.

The following figure illustrates the relationship of local and remote admin accounts, admin policy, admin groups, and permissions and properties.
Privileges and Properties Applied to Local and Remote Admin Accounts



Complete the following tasks to create an admin account:

1. Use the default admin group or create an admin group. See *About Admin Groups*.
2. Define the administrative permissions of the admin group. See *About Administrative Permissions*.
3. Create the admin account and assign it to the admin group.
    - To add the admin account to the local database, see *Creating Local Admins*.
    - To configure the appliance to authenticate the admin account stored remotely, see *About Remote Admins*.

Defining the Authentication Policy

The authentication policy defines which authentication server groups the appliance uses to authenticate admins and lists the local admin groups that map to the remote admin groups.

By default, the appliance provides the "Local Admin" service for authenticating users against the local database. You cannot modify or delete this default service.

Configuring a List of Authentication Server Groups

To enable NIOS to use multiple authentication server groups, define a prioritized list as follows:

1. From the **Administration** tab, select the **Administrators** tab -> **Authentication Policy** tab.
2. From the **Authenticate users against these services in this order** section, click the Add icon to add an authentication server group.
3. Select one of the following in the *Add Authentication Service* section:
    - **Active Directory**: Select this to add an AD authentication server group, and then select a group from the drop-down list.

- **RADIUS**: Select this to add a RADIUS authentication server group, and then select a group from the drop-down list.
- **TACACS+:** Select this to add the TACACS+ authentication server group, and then select a group from the drop-down list.
- **LDAP**: Select this to add the LDAP authentication server group, and then select a group from the drop-down list.
- **Certificate Authentication Service**: Select this to add a certificate authentication service, and then select a service from the drop-down list.
- **SAML**: Select this to use SAML SSO as the authentication service.

4. Click **Add**.

You can reorder the list by selecting an authentication server group and moving it up or down the list using the arrow keys.

> ⚠ Note
>
> Using a remote authentication service causes high memory utilization on discovery members. However, this does not affect the operation of other processes.

Configuring a List of Remote Admin Groups

In order for NIOS to assign a remote admin to the correct group, you must list the admin groups in the local database that match the remote admin groups. You can also define a default admin group to which NIOS assigns remote users with no admin groups listed.

The appliance matches a remote admin to a group in the order the groups are listed. When the appliance receives information that an admin belongs to one or more groups, the appliance assigns the user to the first group in the list that matches. It assigns the admin to the default group, if specified, if no groups are returned by the authentication server, or if the appliance does not find a group in the local database that matches the group returned by the authentication server.

To configure the remote admin group list:

1. From the **Administration** tab, select the **Administrators** tab -> **Authentication Policy** tab.
2. In the **Authentication Server Groups is the authority for** section, select one of the following:
   - **Remote users, their passwords and their groups ownership**: Select this to use the authentication server groups to define the list of remote users, their passwords and their group ownerships. This is selected by default. You can add the list of admin groups to map the remote admin group to a local group in the **Map the remote admin group to the local group in this order** section.
   - **Passwords of Local users**: Select this to authenticate a remote user when you do not know to which remote admin group the user belongs.
   - **Map the remote admin group to the local group in this order**: In order for the appliance to assign a remote admin to the correct group, you must list the admin groups in the local database that match the remote admin groups. The appliance matches a remote admin to a group in the order the groups are listed. You can also define a default admin group to which NIOS assigns remote users with no admin groups listed. This section is disabled when you select **Passwords of Local users** in the **Authentication Server Groups is the authority for** section.
     When the appliance receives information that the admin belongs to one or more groups, the appliance selects the first group in the list that matches, and assigns that group to the admin. If no groups are returned by the authentication server, the default group is assigned (if specified).

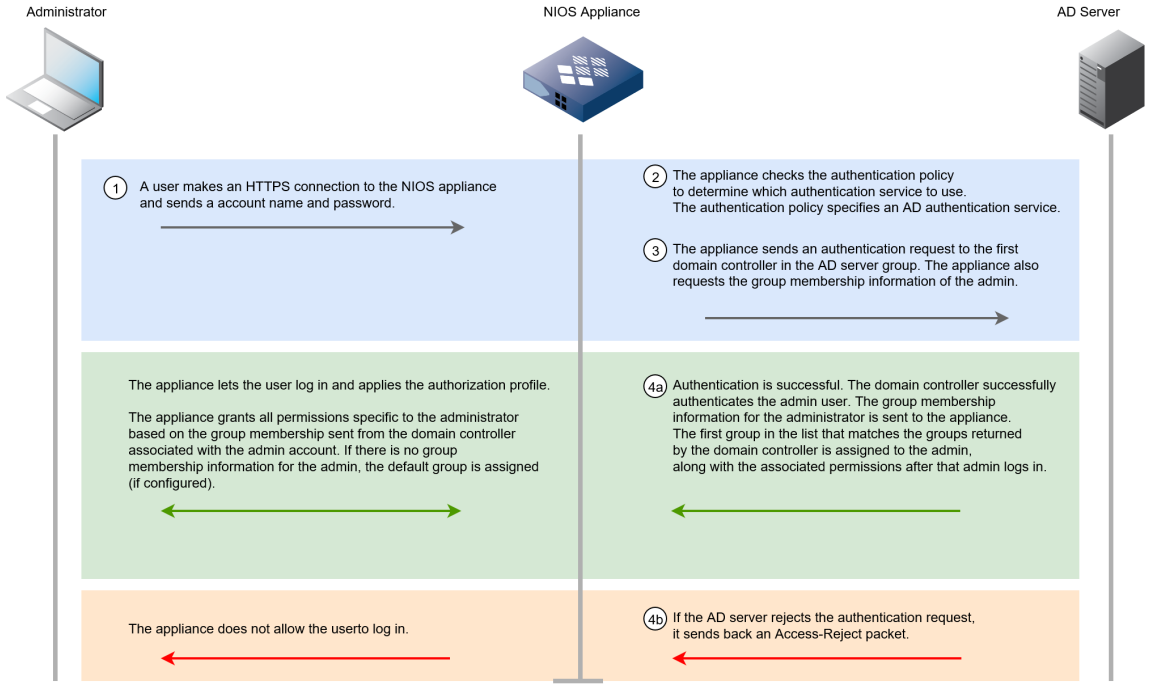
     Complete the following to configure the remote admin group list:
     - Click the Add icon to add an admin group to the list. In the *Admin Group Selector* dialog box, select an admin group. Use Shift+click and Ctrl+click to select multiple admin groups.
     - You can reorder the list by selecting an admin group and using the arrow keys to move it up or down the list.
     - **Assign user to this group if remote admin group cannot be found**: Click **Select** to assign a user to a specific admin group if the remote admin group is not found. In the *Admin Group Selector* dialog

box, select an admin group. You can also click **Clear Selection** to clear the displayed member and select a new one.

Authenticating Admins Using Active Directory

Active Directory™ (AD) is a distributed directory service that is a repository for user information. The NIOS appliance can authenticate admin accounts by verifying user names and passwords against Active Directory. In addition, the NIOS appliance queries the AD domain controller for the group membership information of the admin. The appliance matches the group names from the domain controller with the admin groups on its local database. It then authorizes services and grants the admin privileges, based upon the matching admin group on the appliance.
The following figure illustrates the Active Directory authentication process.

Authentication Using a Domain Controller



To configure NIOS to authenticate administrators using Active Directory domain controller groups, you must first configure user accounts on the domain controller.

> **Note**
>
> Do not create Microsoft user accounts with the following characters: "", +, ,, ;, <, =, >, \. Microsoft does not allow creating users with these characters and such characters will be replaced by an underscore _.

Then, on the NIOS appliance, do the following:

- Configure one or more AD authentication server group on the appliance and add AD domain controllers to the group. For information about configuring an AD authentication service group for admins, see *Configuring an Active Directory Authentication Service Group*.
- If you configured admin groups on the AD controller, you must create those same groups on the NIOS appliance and specify their privileges and settings. Note that the admin group names must match those on the AD domain controller. You can specify a default group as well. The NIOS appliance assigns admins to the default group if none of the admin groups on the NIOS appliance match the admin groups on the AD domain controller or if there are no other admin groups configured. For information about configuring group permissions and privileges, see *About Admin Groups*.

- Add the newly configured Active Directory service to the list of authentication services in the admin policy, and add the admin group names as well. See *Defining the Authentication Policy* for more information about configuring an admin policy.

Configuring an Active Directory Authentication Service Group

You can add multiple domain controllers to an AD authentication server group for redundancy. The NIOS appliance tries to connect with the first domain controller on the list. If it is unable to connect, it tries the next domain controller on the list, and so on.
To configure an Active Directory authentication server group on the NIOS appliance:

1. From the **Administration** tab, click the **Authentication Server Groups** tab.
2. Click the **Active Directory Services** subtab and click the Add icon.
3. In the *Add Active Directory Authentication Service* wizard, complete the following:
    - **Name:** Enter a name for the service.
    - **Active Directory Domain**: Enter the AD domain name.
    - **Domain Controllers**: Click the Add icon and complete the following to add an AD domain controller:
        - **Server Name or IP Address:** Enter the FQDN or the IP address of the AD server that is used for authentication.
        - **Comment:** Enter additional information about the AD server.
        - **Authentication Port**: Enter the port number on the domain controller to which the appliance sends authentication requests. The default is 389.
        - **Encryption:** Select **SSL** from the drop-down list to transmit through an SSL (Secure Sockets Layer) tunnel. When you select SSL, the appliance automatically updates the authentication port to 636. Infoblox strongly recommends that you select this option to ensure the security of all communications between the NIOS appliance and the AD server. If you select this option, you must upload a CA certificate from the AD server. Click **CA Certificates** to upload the certificate. In the *CA Certificates* dialog box, click the Add icon, and then navigate to the certificate to upload it.
        - **Connect through Management Interface:** Select this so that the NIOS appliance uses the MGMT port for administrator authentication communications with just this AD server.
        - **Disable server:** Select this to disable an AD server if, for example, the connection to the server is down and you want to stop the NIOS appliance from trying to connect to this server.
        - Click **Test** to test the configuration. If the NIOS appliance connects to the domain controller using the configuration you entered, it displays a message confirming the configuration is valid. If it is unable to connect to the server, the appliance displays a message indicating an error in the configuration.
        - Click **Add** to add the domain controller to the group.

          When you add multiple domain controllers, the appliance lists the servers in the order you added them. This list also determines the order in which the NIOS appliance attempts to contact a domain controller. You can move a server up or down the list by selecting it and clicking the up or down arrow.
          You can also delete a domain controller by selecting it and clicking the Delete icon.
        - **Timeout(s):** The number of seconds that the NIOS appliance waits for a response from the specified authentication server. The default is 5.
        - **Comment:** Enter additional information about the service.
        - **Disable**: Select this to retain an inactive AD authentication service profile.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Enabling Active Directory Authentication for Nested Groups

Windows servers support nesting groups in which you can add a group of admin users as a member of another group. Nested groups consolidate admin accounts and help reduce the number of permissions required for individual users or groups. In NIOS, you can enable a nested group query so the appliance can recursively look up and use the AD authentication service to authenticate members or admin accounts. These members or admin accounts can be part of the default nested group, outside of the default nested group, or located within a non-default custom organizational unit.

When an admin belongs to multiple paths of hierarchy, you can enable nested group query in order to apply the AD authentication service hierarchically in a parent-child structure. This enables the NIOS appliance to apply the AD

authentication service to all the groups of which an admin is a member. For example, if User 1 is a member of the default nested Group C, and Group C is a member of Group B, and Group B is a member of Group A, then the authentication service is applicable to all the groups of which User 1 is a member. In this example, the appliance performs a recursive lookup in Group C, Group B, and Group A while authenticating User 1.

You can also define multiple organizational units and add non-default AD admins and groups to these units.

Note

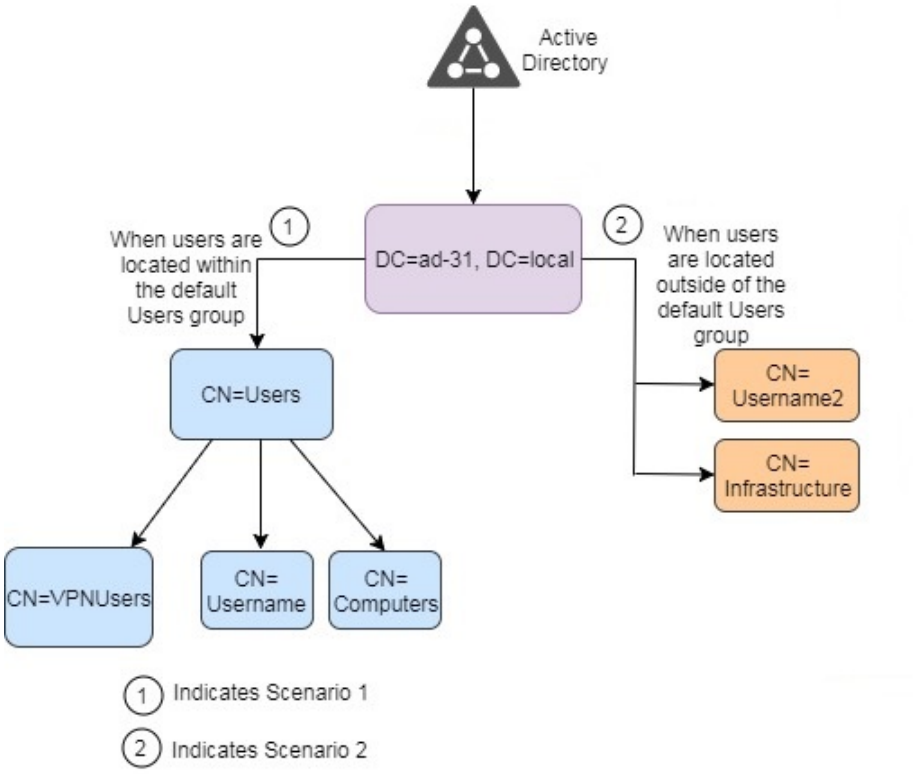
- Microsoft recommends that you create all non-default users and groups in different organizational units to apply Group Policy Objects and prevent corruption or misuse of critical default accounts and groups.
- In Active Directory, objects are referred to by the DN (Distinguished Name), which contains CN (Common Name), OU (Organizational Unit), and DC (Domain Component) that are delimited by commas and indicate where the object resides in an AD hierarchy.

Infoblox supports AD authentication for nested groups in the following scenarios:

- **Scenario 1**: When the user is located within the default **Users** group.
  In this example, the DC ad-31.local contains CN=Users that is the default user group or the container. Users Username, VPNUsers, and Computers are located within the default user group. When you enable a nested group query, the appliance uses the AD authentication service to authenticate the admin accounts that are within the default nested group CN=Users. The DN for users within the default user group are as follows:
  - DN: CN=Username, CN=Users, DC=ad-31, DC=local
  - DN: CN=VPNUsers, CN=Users, DC=ad-31, DC=local
  - DN: CN=Computers, CN=Users, DC=ad-31, DC=local
- **Scenario 2**: When the user is located outside the default **Users** group.
  In this example, users CN=Username2 and CN=Infrastructure are not located within the default user group or the container. The DN for users within the DC ad-31.local are as follows:
  - DN: CN=Username2, CN=Users, DC=ad-31, DC=local
  - DN: CN=Infrastructure, CN=Users, DC=ad-31, DC=local

The following figure illustrates how you can configure default and non-default nested groups and add users to these groups in a Windows Active Directory. It contains a DC ad-31.local that can contain default users group, organizational units or individual users. When you select the **Disable Default Search Path** checkbox, the AD authentication service authenticates the admin account that is mentioned in the additional search path for a non-default organizational unit.

Active Directory Authentication for Nested Groups



To enable AD authentication for nested groups on the NIOS appliance:

1. From the **Administration** tab, click the **Authentication Server Groups** tab.
2. Click the **Active Directory Services** subtab and click the Add icon.
3. In the *Add Active Directory Authentication Service* wizard, complete the following:
   Nested Group Query: This checkbox is not selected by default, meaning the nested group query is disabled. When nested group query is disabled, AD authentication service is applied to only one group of which the AD admin is a member. When you select this checkbox, AD authentication service is applied to all the nested groups of which an AD admin is a member. This setting is applicable to all the AD servers configured for the Active Directory authentication service.
4. Save the configuration.

Changing Password Length Requirements

Password length requirements control how long a password must be for a NIOS appliance admin account. Increasing this value reduces the likelihood of hackers gaining unauthorized access.
To change password length requirements:

1. From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar.
2. In the *Grid Properties* editor, select the **Password** tab.
3. Enter a number from 4 to 64 in the **Minimum Password Length** field.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Notifying Administrators

You can notify individual administrators about system status through email, or notify a group of people using an alias email address. If you have configured DNS resolution on your network, the **E-mail relay configuration** function is not

required. If you did not configure the settings on the **DNS Resolver** section, you must enter a static IP address of the target system in the **Relay Name/IP Address** field. The appliance sends e-mail to administrators when certain events occur. This functionality supports both IPv4 and IPv6 networks. Here is a list of events that trigger e-mail notifications:

- Changes to link status on ports and online/offline replication status
- Events that generate traps, except for upgrade failures (ibUpgradeFailure). For a list of events and Infoblox MIBs, see *SNMP MIB Hierarchy.*

The appliance attempts to send the email notification once after an event. It does not try to send the notification again, if the first attempt fails. Infoblox recommends that you use the **Test Email settings** button to test the email settings and to verify that the recipient received the notification.
You can define the email settings at the Grid and member levels.

Grid Level

To notify an administrator of an independent appliance or a Grid:

1. From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar.
2. In the *Grid Properties* editor, select the **Email** tab, and then complete the following:
    - **Enable Email notification:** Select this for NIOS to send email notifications.
        - **From Email Address:** Enter the email address from which to send email notifications. If this field is blank, the member host name is used by default. For example, no-reply@member_host_name
        - **To Email Address:** Enter the email address of the administrator. Use an email alias to notify multiple people.
    - **Use SMTP Relay:** Select this if the NIOS appliance must send email to an intermediary SMTP (Simple Mail Transfer Protocol) server that relays it to the SMTP server responsible for the domain name specified in the email address. Some SMTP servers only accept email from certain other SMTP servers and might not allow email from the NIOS appliance. In this case, specify the DNS name or IP address of a different SMTP server that does accept email from the NIOS appliance and that will then relay it to the SMTP server that can deliver it to its destination.
      Clear this if it is unnecessary to use an email relay server.
        - **SMTP Relay Name or Address:** If you have configured DNS resolution, enter the DNS name of the relay server.
          If DNS resolution is not configured, enter the IP address of the relay server.
3. Optionally, click **Test Email settings** to confirm this feature is operating properly.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Member Level

To define email settings for a member:

1. From the **Grid** tab, select the **Grid Manager** tab -> *member* checkbox, and then select the Edit icon.
2. In the *Grid Member Properties* editor, select the **Email** tab, and then click **Override** to override Grid-level settings.
3. Complete the email configuration as described in Grid Level above.

Administrative Permissions for Common Tasks

Permissions for Common Tasks table lists some of the common tasks admins can perform and their required permissions. *Permission for Network Discovery* table lists tasks related to device discovery, with their required permissions.
All the permission tables in this chapter use the following definitions:

RW = Read/Write permission

RO = Read-only permission

Permissions for Common Tasks

Tasks	All Grid Members	Grid DNS Properties	Grid DHCP Properties	Specific Grid Member(s)	Member DNS Properties	Member DHCP Properties	Restart Member DNS	Restart Member DHCP	All DNS Views	All DNS Zones	All Shared Record Groups	All Resource Records	All Network Views	All Networks	Specific Network(s)	DHCP Range(s)	Fixed Addresses	Scheduling Task	Network Discovery	Adding a blank A/AAAA record

Tasks	All Grid Members	Grid DNS Properties	Grid DHCP Properties	Specific Grid Member(s)	Member DNS Properties	Member DHCP Properties	Restart Member DNS	Restart Member DHCP	All DNS Views	All DNS Zones	All Shared Record Groups	All Resource Records	All Network Views	All Networks	Specific Network(s)	DHCP Range(s)	Fixed Addresses	Scheduling Task	Network Discovery	Adding a blank A/AAAA record
Create, modify, and delete fixed addresses in a specific network without assigned members															RW		RW			
Assign member to DHCP objects								RW												

Administrative Permission for the Grid

By default, the Grid Master denies access to Grid members when a limited-access admin group does not have defined permissions. You can grant an admin group read-only or read/write permission, or deny access to all Grid members or you can grant permission to specific Grid members, as described in Applying Permissions and Managing Overlaps, see *About Administrative Permissions*.

> **Note**
>
> Only superusers can modify DNS and DHCP Grid properties.

The following sections describe the types of permissions that you can set with Grid permissions:

- Administrative Permissions for Grid Members
- Administrative Permissions for Network Discovery
- Administrative Permissions for Scheduling Tasks
- Administrative Permissions for Microsoft Servers

Administrative Permissions for Grid Members

Grid Member Permissions table below lists the tasks admins can perform and the required permissions for Grid members.

Grid Member Permissions

Tasks	Grid Member(s)	Member DNS Properties	Member DHCP Properties	Restart Member DNS	Restart Member DHCP	DNS Views	DNS Zones	Networks	DHCP Ranges
Assign member to DNS zones				**RW**			**RW**		
Assign member to networks					**RW**			**RW**	
Assign member to DHCP ranges									**RW**
Configure member properties	**RW**								
Add a member to a Match Members list of a DNS view	**RW**								
Delete a view with members in a Match Members list						**RO**			
View DNS and DHCP member properties		**RO**	**RO**						
View and download syslog	**RO**								
View DNS and DHCP configuration file		**RO**	**RO**						

Tasks	Grid Member(s)	Member DNS Properties	Member DHCP Properties	Restart Member DNS	Restart Member DHCP	DNS Views	DNS Zones	Networks	DHCP Ranges
View network statistics	**RO**								
Restart DNS service on the member				**RW**					
Restart DHCP service on the member					**RW**				

Administrative Permissions for Network Discovery

Limited-access admin groups can initiate a discovery and manage discovered data based on their administrative permissions.
You can set global permissions for network discovery as described in Defining Global Permissions, see *About Administrative Permissions*. The following table lists the tasks admins can perform and the required permissions for network discovery.
Permissions for Network Discovery

Tasks	Network Discovery	DNS Zones	Networks Selected for Discovery	Port Control
Initiate and control a discovery on selected networks	**RW**		**RW**	
View discovered data			**RO**	
Add unmanaged data to existing hosts, and resolve conflicting IP addresses			**RW**	
Convert unmanaged data to a host, fixed address, reservation, A record, or PTR record		**RW**	**RW**	
Configure device interfaces, provision networks on interfaces, de-provision networks	**RW**			**RW**

Administrative Permissions for Scheduling Tasks

You can schedule tasks, such as adding hosts or modifying fixed addresses, for a future date and time. To schedule tasks, you must first enable the scheduling feature at the Grid level, and then define administrative permissions for admin groups and admin roles. For information, see *Scheduled Tasks*. Only superusers can enable and disable this feature and grant scheduling permissions to admin groups. Limited-access admin groups can schedule tasks only when they have scheduling permissions.
Superusers can do the following:

- Enable and disable task scheduling at the Grid level

- Grant and deny scheduling permissions to admin groups and admin roles
- Schedule tasks for all supported object types
- Reschedule and delete any scheduled task

You can set global permissions to schedule tasks as described in Defining Global Permissions, see *About Administrative Permissions*. The following table lists the tasks admins can perform and the required permissions. Users with read/write permission to scheduling can view, reschedule, and delete their own scheduled tasks.

Table 4.10 Scheduling Task Permissions

Tasks	Scheduling Task	All Networks	All DNS Views	All Shared Record Groups
Schedule the addition, modification, and deletion of all supported object types	RW	RW	RW	RW
View, reschedule, and delete scheduled tasks	RW	RW	RW	RW
Convert unmanaged data to a host, fixed address, reservation, A record, or PTR record	RW	RW	RW	

To schedule tasks for specific resources, admins must have Read/Write permission to scheduling tasks, plus the required permissions to the supported resources. For information about permissions for specific resources, see the following:

- Grid members—See Administrative Permission for the Grid.
- DNS resources—See *Administrative Permissions for DNS Resources*.
- DHCP resources—See *Administrative Permissions for DHCP Resources*.

Note that the appliance deletes all pending scheduled tasks when superusers disable task scheduling at the Grid level. The appliance deletes an admin's scheduled tasks when superusers do the following:

- Set the scheduling permission of admin groups and roles to "Deny"
- Delete or disable an admin group or an admin role
- Delete or disable local admins
- Delete the scheduling permission from any admin group or admin role that contains users with pending scheduled tasks
- Change the admin group of a limited-access admin

Administrative Permissions for Microsoft Servers

By default, only superusers can add Microsoft servers as managed servers to the Grid. Limited-access admins can add and manage Microsoft servers from the Grid based on their administrative permissions.
The following table lists the tasks admins can perform and the required permissions. Note that only superusers can add a Microsoft server to a name server group.

Microsoft Server Permissions

Tasks	Microsoft Server(s)	Grid Member (s)	Network Views	DNS Views	DNS Zones	Resource Records	Networks	DHCP Ranges	Superscopes
Assign Microsoft server to member	RW	RW							
Assign a network view to the Microsoft server	RW	RW	RW						
Assign a DNS view to the Microsoft server	RW	RW		RW					
Assign Microsoft server as primary or secondary to DNS zones	RW			RW	RW				
Remove a Microsoft server as the primary or secondary server of a zone					RW				
Remove a zone from a Microsoft server					RW				
Edit zones and resource records of Microsoft servers					RW	RW			
Assign a Microsoft server to a network	RW						RW		
Assign a Microsoft server to a DHCP range	RW							RW	
Remove a network served by a Microsoft server	RW						RW		
Remove a DHCP range (scope) from a Microsoft server							RW	RW	
Add, modify and remove Microsoft superscopes	RW							RW	RW
Clear leases from Microsoft server	RW							RW	
Edit Microsoft server properties	RW								
View Microsoft server properties	RO								
View and download Microsoft logs	RO								
Start/Stop DNS or DHCP on the Microsoft server	RW								
Remove a Microsoft server from the Grid	RW								

Administrative Permissions for IPAM Resources

Limited-access admin groups can access certain IPAM resources only if their administrative permissions are defined. By default, the appliance denies access when a limited-access admin group does not have defined permissions. You can grant admin groups read-only or read/write permission, or deny access to the following IPAM resources:

- Network views
- IPv4 networks
- IPv6 networks
- Hosts

The appliance applies permissions for IPAM resources hierarchically. Permissions to a network view apply to all networks and resources in that view. You can also grant an admin group broad permissions to IPAM resources, such as read/write permission to all IPv4 networks and IPv6 networks in the database. In addition, you can grant permission to a specific host in a network. Permissions at more specific levels override global permissions.

The following sections describe the types of permissions that you can set for IPAM resources:

- For more information about Administrative Permissions for Network Views, see *Administrative Permissions for DHCP Resources*.
- Administrative Permissions for IPv4 and IPv6 Networks, see below
- Administrative Permissions for Hosts, see below.

Administrative Permissions for IPv4 and IPv6 Networks

Limited-access admin groups can access IPv4 and IPv6 networks only if their administrative permissions are defined. Permissions for a network apply to all its DNS and DHCP resources, if configured. To override network-level permissions, you must define permissions for specific objects within the networks. You can also define permissions for specific DHCP objects and Grid member to restrict admins to perform only the specified DHCP tasks on the specified member. For more information about Defining DNS and DHCP Permissions on Grid Members, see *About Administrative Permissions*.
You can grant read-only or read/write permission, or deny access to networks, as follows:

- All IPv4 or IPv6 networks—Global permission that applies to all networks in the database.
- A specific network—Network permissions apply to all objects in the network. This overrides global permissions.
- A specific network on a specific member—Network permissions apply to all objects in the network and member permissions apply to the specific member. For information about member permissions and modifying permissions on a Grid Member, see *About Administrative Permissions*.

Administrative Permissions for Hosts

A host record can contain both DNS and DHCP attributes if you configure them. When applying administrative permissions to host records, the permissions apply to all relevant DNS and DHCP resources within the host records. You can define global permissions to all hosts. To override global permissions, you must define permissions for specific hosts.
You can grant read-only or read/write permission, or deny access to host records, as follows:

- All hosts—Global permission that applies to all host records in the Grid.
- A specific host—Object permission that applies only to a selected host.

Administrative Permissions for DHCP Fingerprint Permissions

NIOS provides a global permission for all All DHCP Fingerprints; however, it does not support object level permissions for fingerprints. To use fingerprint filters, you must have superuser privileges.

Administrative Permissions for Network Insight Tasks

The below table summarizes the permissions you need to perform various tasks related to device discovery.
Permissions for Network Discovery

Tasks	Network Discovery	DNS Zones	Networks Selected for Discovery	Port Control	All Network Views/ All IPv4 Networks/ All IPv6 Networks	Permissions for Object
Initiate and control a discovery on selected networks	**RW**		**RW**			
View discovered data			**RO**			
Resolve conflicting IP addresses			**RW**			
Convert unmanaged objects to a host, fixed address, reservation, A record, or PTR record		**RW**	**RW**			
Configure device interfaces, provision networks on interfaces	**RW**			**RW**		
Configure a Blackout schedule for networks or DHCP ranges	**RW**				**RO**	
Creating/editing port reservations for a Grid member, host, fixed address, reservation, A record, or PTR record				**RW**		**RO**

Administrative Permissions for DNS Resources

You can grant roles and admin groups read-only or read/write permission, or deny access to the following DNS resources:

- DNS Views
- DNS Zones
- Response Policy Zones
- All RPZ Rules
- Hosts
- Bulk Hosts
- A records
- AAAA records
- CNAME records
- DNAME records
- MX records
- PTR records
- SRV records
- TXT records

- Hosts
- Bulk Hosts
- Shared Record Groups
- Shared A records
- Shared AAAA records
- Shared CNAME records
- Shared MX records
- Shared SRV records
- Shared TXT records
- DNS64 synthesis groups
- Adding a blank A/AAAA record

The appliance applies permissions for DNS resources hierarchically. Permissions to a DNS view apply to all zones and resource records in that view. Permissions for a zone apply to all its subzones and resource records, and resource record permissions apply to those resource records only. To override permissions set at higher level, you must define permissions at a more specific level. To assign permissions, see *About Administrative Permissions*.
You can also define permissions for specific DNS objects and Grid member to restrict admins to perform only the specified DNS tasks on the specified member. For more information about defining DNS and DHCP permissions on Grid Members, see *About Administrative Permissions*.
The following sections describe the different types of permissions that you can set for DNS resources:

- Administrative Permissions for DNS Views
- Administrative Permissions for Zones
- Administrative Permissions for Resource Records

Administrative Permissions for DNS Views

Limited-access admin groups can access DNS views, including the default view, only if their administrative permissions are defined. Permissions to a DNS view apply to all its zones and resource records. To override view-level permissions, you must define permissions for its zones and resource records. For example, you can grant an admin group read-only permission to a view and read/write permission to all its zones. This allows the admins to display the view properties, but not edit them, and to create, edit and delete zones in the view.
You can grant read-only or read/write permission, or deny access to DNS views, as follows:

- All views—Global permission that applies to all DNS views in the database.
- A specific view—Applies to its properties and its zones, if you do not define zone-level permissions. This overrides the global view permissions.
- All zones in a view—If you do not define permissions for zones, they inherit the permissions of the view they are in.

For information on setting permissions for a view and its zones, see *About Administrative Permissions*.
The following table lists the tasks admins can perform and the required permissions for DNS views.

Permissions for DNS Views

Tasks	Grid Member(s)	All DNS Views	Specific DNS View	All DNS Zones
Create, modify, and delete DNS views		**RW**		
Create, modify, and delete DNS zones with assigned members	**RW**			**RW**
Create, modify, and delete DNS zones without assigned members				**RW**
Modify and delete a specific DNS view			**RW**	

Tasks	Grid Member(s)	All DNS Views	Specific DNS View	All DNS Zones
Create, modify, and delete DNS zones, subzones, and resource records in a specific DNS view			**RW**	**RW**
Add Grid members to a Match Members list of a DNS view	**RW**		**RW**	
Delete a DNS view with Grid members in a Match Members list	**RW**		**RW**	
View DNS view properties, DNS zones, and resource records		**RO**		
View DNS zone properties, subzones, and resource records				**RO**
Restart services from the DNS tab	**RO**		**RW**	

Administrative Permissions for Zones

By default, zones inherit administrative permissions from the DNS view in which they reside. You can override view-level permissions by setting permissions for specific zones. Permissions set for a zone are inherited by its subzones and resource records. To override zone-level permissions, set permissions for specific subzones and resource records. For example, you can grant an admin group the following permissions:

- Read-only to a zone and to all its A, AAAA, and PTR records (in reverse and forward-mapping zones)
- Read/Write permission to all MX and SRV records in the zone
- Deny to all the other resource records—CNAME, DNAME, TXT, host, and bulk host You can grant read-only or read/write permission, or deny access to zones as follows:
- All zones —Global permission that applies to all zones in all views.
- All zones in a view—Permissions at this level override the global permissions.
- A specific zone—Applies to the zone properties and resource records, if you do not define permissions for its resource records. This overrides global and view-level permissions. If you delete a zone and reparent its subzone, the subzone inherits the permissions of the new parent zone.
- All Response Policy Zones—Global permission that applies to all the Response Policy Zones.
- All Response Policy Rules—Global permission that applies to all the local Response Policy Zone rules.

  > **Note**
  >
  > Object permissions are not applicable to Response Policy Zone rules.

- Each resource record type in a zone—For example, you can define permissions for all A records and for all PTR records in a zone. if you do not define permissions for resource records, they inherit the permissions of the zone in which they reside.

For information on setting permissions for zones and resource records, see *About Administrative Permissions*. The following table lists the tasks admins can perform and the required permissions for zones.

DNS Zone Permissions

Tasks	Grid Member(s)	Specific DNS View	All DNS Zones	Specific DNS Zone	Resource Records	Shared Record Group
Create, modify, and delete zones, subzones and resource records with assigned members	**RW**		**RW**			

Tasks	Grid Member(s)	Specific DNS View	All DNS Zones	Specific DNS Zone	Resource Records	Shared Record Group
Create, modify, and delete zones, subzones and resource records without assigned members			**RW**			
Lock and unlock a zone				**RW**		
Delete a zone with assigned Grid members	**RW**			**RW**		
Create, modify, and delete all zones, subzones, and resource records in a specific view		**RW**	**RW**			
Assign a name server group (member) to a zone	**RW**			**RW**		
Delete a zone with name server groups assigned	**RW**			**RW**		
Assign a shared record group to a zone				**RW**		**RW**
View zone properties, subzones, and resource records of a specific zone				**RO**		
Search for zones, subzones, and resource records in a specific DNS view		**RO**	**RO**			
Copy resource records from one zone to another: Source zone				**RO**	**RO**	
Copy resource records from one zone to another: Destination Zone				**RW**	**RW**	

Administrative Permissions for Resource Records

Resource records inherit the permissions of the zone to which they belong. You can override zone-level permissions by setting permissions for specific resource records.
You can grant read-only or read/write permission, or deny access to resource records as follows:

- Each resource record type in all zones and in all views—Global permission that applies to all resource records of the specified type; for example, all A records in the database.
- Each resource record type in a zone— Permissions at this level override global permissions.
- A specific resource record—Overrides zone-level permissions.

For information on setting permissions for resource records, see *About Administrative Permissions*. The following table lists the tasks admins can perform and the required permissions for resource records.

DNS Resources

Tasks	Resource Record Type	Specific Resource Record
Create, modify, and delete resource records for a specified type, such as all A records or all PTR records	**RW**	
View resource records for a specified type only	**RO**	
Search for records of a specified type	**RO**	
View a specific resource record		**RO**
View, modify, and delete a specific resource record		**RW**

The following are additional guidelines:

- Only admins with read/write permission to bulk host records and read/write permission to reverse zones can create bulk host records and automatically add reverse-mapping zones.
- To create host records, admins must have read/write permission to the network and zone of the host.
- Admins must have read-only permission to the host records in a zone to view the Host Name Compliance Report. Admins must have read/write permission to the resource records in a zone to modify host names that do not comply with the host policy.

Administrative Permissions for Adding Blank A or AAAA Records

By default, only superusers can add and edit A, AAAA, shared A, and shared AAAA records with a blank name. Limited-access admin groups can add and edit A, AAAA, shared A, and shared AAAA records with a blank name, only if their administrative permissions are defined. You can grant read/write or deny permission to **Adding a blank A/AAAA record** for specific admin groups, which applies to all admin roles in the group. You can define global permissions for specific admin groups and roles to allow limited-access users to add and edit blank A, AAAA, shared A, and shared AAAA records, as described in Defining Global Permissions.

Administrative Permissions for Shared Record Groups

By default, only superusers can add, edit, and delete shared record groups. Limited-access admin groups can access shared record groups, only if their administrative permissions are defined.
You can set different permissions for a shared record group and for each type of shared resource record in the group. For example, you can grant a role or an admin group the following permissions:

- Read-only to a shared record group and to all its shared A, AAAA, and CNAME records
- Read/Write permission to all the shared MX and SRV records in the shared record group
- Deny to the TXT records

You can grant read-only or read/write permission, or deny access to shared record groups, as follows:

- All shared record groups—Global permission that applies to all shared record groups in the database.
- A specific shared record group—Overrides global permissions.
- Each shared record type in all shared record groups — The shared resource record types include shared A records, shared AAAA records, shared CNAME records, shared MX records, shared SRV records, and shared TXT resource records.
- Each shared record type in a shared record group— Permissions at this level override global permissions.
- A specific shared record—Overrides zone-level permissions. Note the following guidelines:
- Shared record group permissions override zone permissions.
- Even if a zone is locked, superusers and limited-access users with read/write access can still edit or delete a shared record in the zone.

For information on setting permissions for shared record groups, see . The following table lists the tasks admins can perform and the required permissions for shared record groups.

Permissions for Shared Record Groups

Tasks	All Shared Record Groups	Specific Shared Record Group	Shared Record Type	Specific DNS Zone	Specific Shared Record
Create, modify, and delete shared record groups	**RW**				
Modify and delete a shared record group		**RW**			
View a shared record group		**RO**			
Create, modify, and delete shared records for a specific type			**RW**		
View or search for shared records of a specific type			**RO**		
Create, modify, and delete shared records for a specific type in a specified shared record group		**RW**	**RW**		
View shared records for a specific type in a specified shared record group only		**RO**	**RO**		
Create, modify, and delete a shared record					**RW**
View a specific shared record					**RO**
Assign a shared record group to DNS zones		**RW**		**RW**	
Change the DNS zones associated with a shared record		**RW**		**RW**	
Delete zones with a shared record group assigned. Before you delete a shared record group, you must remove all zones associated with it.		**RW**		**RW**	

Administrative Permissions for DNS64 Synthesis Groups

By default, only superusers can add, edit, and delete DNS64 synthesis groups. Limited-access admin groups can access synthesis groups, only if their administrative permissions are defined.
You can grant read-only or read/write permission, or deny access to synthesis groups, as follows:

- All synthesis groups—Global permission that applies to all shared record groups in the database.
- A specific synthesis group—Overrides global permissions.

For information on setting permissions for synthesis groups, see *About Administrative Permissions*. The following table lists the tasks admins can perform and the required permissions for synthesis groups.

Permissions for DNS64 Synthesis Groups

Tasks	All Synthesis Groups Specific Synthesis Group	Specific Shared Record Group	Grid	Specific Member	Specific DNS View
Create, modify, and delete synthesis groups	**RW**				

Tasks	All Synthesis Groups Specific Synthesis Group	Specific Shared Record Group	Grid	Specific Member	Specific DNS View
Modify and delete a specific synthesis group		**RW**			
View a synthesis group		**RO**			
Apply a synthesis group to the Grid		**RO**	**RW**		
Apply a synthesis group to a member		**RO**		**RW**	
Apply a synthesis group to a DNS view		**RO**			**RW**

Administrative Permissions for DNS Resources with Associated IP addresses in Networks and Ranges

You can further control permissions for DNS resources that have associated IP addresses in a network container, network, or address range. These DNS resources include A records, AAAA records, PTR records, and DNS hosts. Permissions for these resources have been added so you now have more control over who can perform which tasks for these DNS resources without affecting permissions defined for the networks and ranges to which the resources belong. For example, if you want to allow an admin to add, modify, and delete A records associated with IP addresses within a specific network but you do not want the same admin to modify or delete the network, you can grant the admin read-only permission for the specified network and read/write permission for A records in that network.
Similar behavior applies to AAAA records, PTR records, and DNS hosts.
As a superuser, you can now grant permissions to admin groups for more granular access to the following resources:

- IPv4 and IPv6 DHCP fixed addresses and IPv4 reservations in a range
- IPv4 and IPv6 host addresses in a range
- A and AAAA records in a network container, network, or range
- IPv4 and IPv6 PTR records in a network container, network, or range

For information about how to configure new permissions for these resources, see Configuring Permissions for DNS Resources in Networks and Ranges below.

Best Practices for Configuring Permissions in Networks and Ranges

Before using permissions for DNS resources in networks and ranges, consider the following:

- You can enable and disable these permissions using the set dns_perm_for_nw_range CLI command. When you disable permissions after you have enabled and defined them, the appliance retains the permissions in an inactive mode. Inactive permissions are not verified nor displayed in Grid Manager. When you re-enable the permissions, the appliance activates them and displays them in Grid Manager. You can also use the show dns_perm_for_nw_range CLI command to verify the status of new permissions.

Note that permissions for fixed addresses and reservations are not controlled by the CLI command; they are always enabled.
You can also enable and disable permissions for DNS Resources in Networks and Ranges through Grid Manager, as described in Enabling Permissions for DNS Resources in Networks and Ranges below.

- When you switch between enabling and disabling these permissions, changes take effect immediately and a service restart in Grid Manager is not required. However, you may need to refresh Grid Manager to view the changes.

- You can assign these permissions when DNS, DHCP, or Microsoft Management licenses are installed. If you remove all of these licenses after you have configured relevant permissions for supported resources, the appliance retains the permissions, but you will not be able to see the permissions nor configure them.

Changes to Default Behavior

This section describes changes to the default behavior when you enable permissions for DNS resources with associated IP addresses in networks and ranges. The following table lists behavior in previous releases and changes made in this release for supported resources. Review these changes before you configure permissions for these resources.

Resources	Behavior in Previous NIOS Releases	Changes in NIOS 6.10.4

A Records
AAAA Records
PTR Records
DNS Hosts
	• Admins can add, modify, and delete A, AAAA, PTR records and DNS hosts that have associated IP addresses in a network or range when they have read/ write permission for the respective zone or a higher level DNS parent object (even if they have deny or read-only permission for the network to which the DNS resources belong).	• When you enable new permissions, you can define the following permissions for the admins to add, modify, and delete A, AAAA, PTR records and DNS hosts that have associated IP addresses in a network container, network, or range:
		  • Read/write permission for the specific records in the zone or a higher level DNS parent object.
		  and
		  • Read/write permission for the records in the specified network container, network, or range to which the resources belong.
		
		Note: Fields for A, AAAA, PTR records and DNS hosts in a zone or a higher level DNS parent object, except **Name**, **IP Address**, **MAC Address**, **DUID** and **Disabled**, can be modified by admins who do not have write permission for the same records in the specified network container, network, or range.
		
		• You cannot define read-only permission for A, AAAA, and PTR records in a range. The read operation for A, AAAA, PTR, and host records is based on DNS permission hierarchy. In other words, read-only permission for a parent DNS zone allows you to view DNS objects, regardless of the permission you have defined for these resources in their associated ranges.

Resources	Behavior in Previous NIOS Releases	Changes in NIOS 6.10.4
DHCP-enabled Hosts	• Admins can add, modify, and delete DHCP-enabled host addresses when they have read/write permission for hosts in the specified zone and read/write permission for the network to which the IP addresses belong. (This behavior stays the same in NIOS 6.10.4.)	• When you enable new permissions and you want to allow the admin to add, modify, and delete DHCP-enabled hosts that fall within a specific address range, define read/write permission for hosts in that specified range. Note that if the admin has read/write permission for the network, they can add, modify, and delete hosts that do not fall within a specific address range. **Note:** Fields for DHCP-enabled host addresses, except **Name**, **Enable in DNS**, **IPv4/IPv6 Address**, **MAC Address**, **DUID**, and **Disabled**, can be modified by admins who do not have write permission for the same addresses in the specified network container, network, or range. • Regardless of whether new permissions are enabled, DHCP-enabled host addresses always appear in their respective network containers or networks. However, host addresses in a range appear in the range only when new permissions are enabled.
Fixed Addresses/ Reservations	• Admins can add, modify, and delete fixed addresses and reservations in an address range when they have read/write permission for DHCP fixed addresses for the network to which the range belongs.	• When you enable new permissions and you want to allow the admin to add, modify, and delete fixed addresses and reservations in a specific address range, define read/write permission for fixed addresses or reservations in that specified range. Note that if the admin has read/write permission for the network, they can add, modify, and delete fixed addresses and reservations that do not fall within a specific address range. • Fixed addresses appear in their respective network containers, networks, and ranges regardless of whether new permissions are enabled.

Enabling Permissions for DNS Resources in Networks and Ranges

To enable permission for DNS Resources in Networks and Ranges:

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Expand the Toolbar and select **Grid Properties** -> **Edit**.
3. In the *Grid Properties* editor, select the **General** tab -> **Advanced** tab, and then complete the following:
    - **Enable DNS Object Permissions in Networks and Ranges**: Select this checkbox to enable DNS object permissions in networks and ranges. When you enable this, admins with Read/Write permission for specific records in a zone or a higher-level DNS parent object, and admins with Read/Write permission for

resource records in specified network containers, networks, or ranges can add, modify, and delete A, AAAA, PTR records, and DNS hosts that have associated IP addresses in the network containers, networks, or ranges.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring Permissions for DNS Resources in Networks and Ranges

To define permissions for resources that are associated with IP addresses in a network container, network, or address range, complete the following:

1. Log in to the appliance through the Infoblox CLI and use the `set dns_perm_for_nw_range` command to enable new permissions, as follows:
   ```
   Infoblox > set dns_perm_for_nw_range on
   ```
   You can also enable permission for DNS resources in networks and ranges through the Infoblox GUI, as described in Enabling Permissions for DNS Resources in Networks and Ranges.
2. Log in to Grid Manager and depending on which permission you want to define, do one of the following:
   Network View: From the **Administration** tab, select the **Networks View** tab -> *network_view* checkbox and click the Edit icon.
   Network Container: From the **Data Management** tab, select the **IPAM** tab -> *network_container* checkbox and click the Edit icon.
   Network: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon.
   DHCP Range: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> **network** -> *addr_range* checkbox, and then click the Edit icon.
   Fixed Address: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> **network** -> *fixed_address* checkbox, and then click the Edit icon.
   Reservation: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> **network** -> *reservation* checkbox, and then click the Edit icon.
   Zone: From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and then click the Edit icon.
   Note that you cannot assign permissions for zones that are auto-created.
3. In the editor, click the **Permissions** tab, and select the supported permission from the **Permissions** drop-down list for the admin group or role.
4. Select a resource from the drop-down list in the **Resources** column.
5. Save the configuration.

Permission Examples

The following table lists examples for configuring new permissions for fixed addresses (or reservations) in network 10.1.2.0/24 and range 10.1.2.1-10.1.2.10.

Action	Permission for network 10.1.2.0/24	Permission for range 10.1.2.1-10.1.2.10	Action Allowed? (Yes/ No)	Comment
Add, modify, or delete fixed address 10.1.2.5	No	No	No	N/A
Add, modify, or delete fixed address 10.1.2.5	No	Read/write for "Fixed addresses in 10.1.2.1-10.1.2.10 Range"	Yes	Read/write permission at the range level is sufficient for creating a fixed address that falls within the range.

Action	Permission for network 10.1.2.0/24	Permission for range 10.1.2.1-10.1.2.10	Action Allowed? (Yes/ No)	Comment
Add, modify, or delete fixed address 10.1.2.100	Read/write for "Fixed addresses in 10.1.2.0/24 Network"	Deny for "Fixed addresses in 10.1.2.1-10.1.2.10 Range"	Yes	Since fixed address 10.1.2.100 does not belong to the 10.1.2.1-10.1.2.10 range, read/write permission for "Fixed addresses in 10.1.2.0/24 Network" is sufficient for the operation.

The following table lists some examples for configuring DNS resources that have associated IP addresses in a network or range:

Action	Permission for DNS zone corpxyz.com	Permission for network 10.1.2.0/24	Permission for range 10.1.2.1-10.1.2.10	Action Allowed? (Yes/No)	Comment
Add, modify, or delete an A record with IP address 10.1.2.8	Read/write permission for corpxyz.com	No	No	No	Read/write permission for "A Records in 10.1.2.1-10.1.2.10 range" is also required.
Add, modify, or delete an A record with IP address 10.1.2.8	Read/write permission for corpxyz.com	No	Read/write for "A Records in 10.1.2.1-10.1.2.10	Yes	Since 10.1.2.8 falls within the 10.1.2.1-10.1.2.10 range, read/ write permission for "A Records in 10.1.2.1-1 0.1.2.10 Range" and read/write for corpxyz.com are both required.
Add, modify, or delete an A record with IP address 10.1.2.8, and modify or delete a network	Read/write permission for corpxyz.com	Read-only permission for network 10.1.2.0/24	Read/write for "A Records in 10.1.2.1-10.1.2.10 Range	Yes for A record No for network	Admins can add, modify, and delete A records because they have read/write permissions for the zone and range; but they cannot modify or delete networks because they have read-only permission for network 10.1.2.0/24.
Add, modify or delete DHCP-enabled host address 10.1.2.22	Yes if the host is a DNS host. N/A if the host is a DHCP host.	Read/write permission for "IPv4 Hosts in 10.1.2.0 network"	No	Yes	Host address 10.1.2.22 is within the 10.1.2.0 network but outside of the 10.1.2.1- 10.1.2.10 range, so read/write permission for "IPv4 Hosts in 10.1.2.0 network" is sufficient.
Add, modify, or delete DHCP-enabled host address 10.1.2.8, and modify or delete a network	Yes if the host is a DNS host. N/A if the host is a DHCP host.	Read-only permission for network 10.1.2.0/24	Read/write for "Hosts in 10.1.2.1-10.1.2.10 Range	Yes for A record No for network	Admins can add, modify, and delete DHCP-enabled hosts because they have read/write permissions for "Hosts in 10.1.2.1010.1.2.10 range"; but they cannot modify or delete networks because they have read-only permission for network 10.1.2.0/24.

The following table list an example for permissions required to configure PTR records that have associated IP addresses in a network:

Action	Permission for DNS zone corpxyz.com	Permission for network 10.1.2.0/24	Permission for reverse zone 0.0.10.in-addr.arpa	Action Allowed? (Yes/No)	Comment
Add, modify, or delete a PTR record with IP address 5.0.0.10. **Note**: You can also add, modify, or delete PTR records in the IPv6 reverse-mapping zone.	Read/write permission for corpxyz.com	No	Yes	Yes	Read/write permission for "PTR Records in corpxyz.com and 0.0.10.in-addr.arpa" is required.

Administrative Permissions for DHCP Resources

Limited-access admin groups can access certain DHCP resources only if their administrative permissions are defined. By default, the appliance denies access when a limited-access admin group does not have defined permissions. You can grant admin groups read-only or read/write permission, or deny access to the following DHCP resources:

- Network views
- IPv4 networks
- Hosts
- IPv4 DHCP ranges
- IPv4 DHCP fixed addresses
- IPv4 DHCP reservations
- MAC address filters
- IPv4 shared networks
- IPv4 network templates
- IPv4 DHCP range templates
- IPv4 fixed address templates
- IPv4 DHCP enabled host addresses
- IPv4 DHCP lease history
- Roaming hosts
- IPv6 networks
- IPv6 DHCP ranges
- IPv6 DHCP fixed addresses
- IPv6 DHCP enabled host addresses
- IPv6 shared networks
- IPv6 network templates
- IPv6 DHCP range templates
- IPv6 fixed address templates
- IPv6 DHCP lease history

You can grant an admin group broad permissions to DHCP resources, such as read/write permission to all IPv4 or IPv6 networks and shared networks in the database. In addition, you can grant permission to specific resources, such as a specific IPv4 or IPv6 network or DHCP range, or an individual address in an IPv4 or IPv6 network. Permissions at more specific levels override global permissions.
You can also define permissions for specific DHCP objects and Grid member to restrict admins to perform only the specified DHCP tasks on the specified member. For more information about defining DNS and DHCP permissions on Grid Members, see *About Administrative Permissions*.
The following sections describe the different types of permissions that you can set for DHCP resources:

- Administrative Permissions for Network Views
- Administrative Permissions for IPv4 and IPv6 Networks and Shared Networks
- Administrative Permissions for IPv4 or IPv6 Fixed Addresses and IPv4 Reservations
- Administrative Permissions for IPv4 and IPv6 DHCP Ranges
- Administrative Permissions for IPv4 or IPv6 DHCP Templates
- Administrative Permissions for Roaming Hosts
- Administrative Permissions for MAC Address Filters

- Administrative Permissions for the IPv4 and IPv6 DHCP Lease Histories

Administrative Permissions for Network Views

Limited-access admin groups can access network views, including the default network view, only if they have read-only or read/write permission to a specific network view or to all network views. Permissions granted to a network view apply to all its IPv4 and IPv6 networks, shared networks, DHCP ranges and fixed addresses.
You can grant admin groups read-only or read/write permission, or deny access to network views as follows:

- All network views—Global permission that applies to all network views in the database.
- A specific network view—Permission to a specific network view applies to the properties you set in the *Network View* editor, and to all the IPv4 and IPv6 networks and shared networks in the network view. This overrides the global permission to all network views. When you configure permissions for a network view, you can also set permissions for the following:
    - All IPv4 and IPv6 networks in the selected network view—If you do not define permissions for IPv4 or IPv6 networks, they inherit the permissions of their network view.
    - All IPv4 and IPv6 shared networks in a specific network view—If you do not define permissions for IPv4 or IPv6 shared networks, they inherit the permissions of their network view.

Note that you can grant an admin group read-only or read/write permission to specific IPv4 or IPv6 networks in a network view, without granting them permission to that network view. For information, see Permissions for IPv4 and IPv6 Networks and Shared Networks below.
For information on how to define permissions for network views, see *About Administrative Permissions*.
The following table lists the tasks admins can perform and the required permissions for network views.

Network View Permissions

Tasks	All DNS Views	Specific DNS View	All Network Views	Specific Network View	All IPv4 or IPv6 Networks	All IPv4 or IPv6 Shared Networks
Create and delete network views and their associated DNS views	**RW**		**RW**			
Create and delete a network view and its associated DNS views		**RW**		**RW**		
Create, modify, and delete IPv4 and IPv6 networks and shared networks in all network views			**RW**			
Create, modify, and delete IPv4 and IPv6 networks and shared networks in a network view				**RW**		

Tasks	All DNS Views	Specific DNS View	All Network Views	Specific Network View	All IPv4 or IPv6 Networks	All IPv4 or IPv6 Shared Networks
View the properties of all network views			**RO**			
View network statistics of all network views			**RO**			
View and search for all IPv4 and IPv6 networks and shared networks			**RO**			
View the properties of a network view				**RO**		
View and search for IPv4 and IPv6 networks and shared networks in a network view				**RO**		
Expand and join IPv4 and IPv6 networks			**RW**			
Expand and join IPv4 and IPv6 networks in a specific network view				**RW**		
Create, modify, and delete IPv4 and IPv6 networks, DHCP ranges and fixed addresses in a specific network view				**RW**		
View network statistics and properties of all networks in a network view				**RO**		
Search for IPv4 and IPv6 networks in a network view				**RO**		

Tasks	All DNS Views	Specific DNS View	All Network Views	Specific Network View	All IPv4 or IPv6 Networks	All IPv4 or IPv6 Shared Networks
Create, modify, and delete all IPv4 or IPv6 shared networks						**RW**
View the properties of all IPv4 or IPv6 shared networks						**RO**
View and search for IPv4 and IPv6 shared networks in a network view				**RO**		
Restart services from the DHCP tab	**RO**			**RW**		

Administrative Permissions for IPv4 and IPv6 Networks and Shared Networks

Limited-access admin groups can access IPv4 and IPv6 networks, including shared networks, only if their administrative permissions are defined. Permissions for a network apply to all its DHCP ranges and fixed addresses. To override network-level permissions, you must define permissions for specific DHCP ranges and fixed addresses. For example, you can grant an admin group read-only permission to a network, read/write permission to its DHCP ranges, and read-only permission to its fixed addresses.
You can grant read-only or read/write permission, or deny access to networks, as follows:

- All IPv4 or IPv6 networks—Global permission that applies to all IPv4 or all IPv6 networks in the database.
- All IPv4 or IPv6 shared networks—Global permission that applies to all IPv4 or all IPv6 shared networks in the database.
- A specific IPv4 or IPv6 network—Network permissions apply to its properties and to all DHCP ranges, fixed addresses and hosts in the network, if they do not have permissions defined. This overrides global permissions.
- All IPv4 or IPv6 DHCP ranges in a network—If you do not define permissions for DHCP ranges, they inherit the permissions of the network in which they reside.
- All IPv4 or IPv6 fixed addresses in a network—If you do not define permissions for fixed addresses, they inherit the permissions of the network in which they reside.

To define permissions for a specific IPv4 or IPv6 network and its DHCP ranges and fixed addresses, see *About Administrative Permissions*.
The following table lists the tasks admins can perform and the required permissions for IPv4 and IPv6 networks.

Network Permissions

Tasks	Grid Member(s)	All IPv4 or IPv6 Networks	Specific IPv4 or IPv6 Network	All IPv4 or IPv6 Shared Networks	Specific DNS Zone	All IPv4 or IPv6 DHCP Ranges	All IPv4 or IPv6 Fixed Addresses	IPv4 or IPv6 Network Template

Create, modify, and delete IPv4 or IPv6 networks, DHCP ranges, and fixed addresses without assigned Grid members		**RW**						
Create, modify, and delete IPv4 or IPv6 networks, DHCP ranges, and fixed addresses with assigned Grid members	**RW**	**RW**						
Assign a Grid member to a specific IPv4 or IPv6 network and its DHCP ranges	**RW**		**RW**					
Expand and join IPv4 or IPv6 networks		**RW**						
Create IPv4 or IPv6 networks from templates		**RW**						**RO**
Create, modify, and delete an IPv4 or IPv6 network		**RW**						
View IPv4 or IPv6 network properties and statistics, and search for DHCP ranges and fixed addresses in a specific network			**RO**					
Create, modify, and delete IPv4 or IPv6 DHCP ranges and fixed addresses in a specific network			**RW**					

Create and split an IPv4 or IPv6 network and automatically create a reverse DNS zone			**RW**		**RW**			
Create, modify, and delete IPv4 or IPv6 shared networks				**RW**				
View IPv4 or IPv6 shared networks				**RO**				
Create, modify, and delete IPv4 or IPv6 DHCP ranges with an assigned member in a specific network	**RW**		**RW**					
Create, modify, and delete IPv4 or IPv6 DHCP ranges						**RW**		
View and search for IPv4 or IPv6 DHCP ranges in a specific network			**RO**					
Create, modify, and delete IPv4 or IPv6 fixed addresses							**RW**	
View and search for IPv4 or IPv6 fixed addresses in a specific network			**RO**					

Administrative Permissions for IPv4 or IPv6 Fixed Addresses and IPv4 Reservations

IPv4 and IPv6 fixed addresses and IPv4 reservations inherit the permissions of the networks in which they reside. You can override network-level permissions by defining permissions for fixed addresses.
You can grant read-only or read-write permission, or deny access to fixed addresses, as follows:

- All IPv4 fixed addresses/reservations—Global permission that applies to all IPv4 fixed addresses and reservations in the database.
- All IPv6 fixed addresses—Global permission that applies to all IPv6 fixed addresses in the database.
- All IPv4 fixed addresses/reservations in a network— Permissions at this level override global permissions. If you do not define permissions for fixed addresses and reservations, they inherit the permissions of the network in which they reside.

- All IPv6 fixed addresses in a network— Permissions at this level override global permissions. If you do not define permissions for IPv6 fixed addresses, they inherit the permissions of the network in which they reside.
- A single IPv4 fixed address/reservation—Overrides global and network-level permissions.
- A single IPv6 fixed address—Overrides global and network-level permissions.

For information on setting permissions for fixed addresses, see *About Administrative Permissions*.
The following table lists the tasks admins can perform and the required permissions for IPv4 and IPv6 fixed addresses.

Permissions for Fixed Addresses/Reservations

Tasks	Specific IPv4 or IPv6 Network	All IPv4 or IPv6 fixed Addresses/ IPv4 Reservations	Specific IPv4 or IPv6 Fixed Address/ IPv4 Reservation
Create, modify, and delete IPv4 fixed addresses/reservations or IPv6 fixed addresses		**RW**	
Create, modify, and delete IPv4 fixed addresses/reservations or IPv6 fixed addresses in a specific network	**RW**		
Modify and delete an IPv4 fixed address/reservation or IPv6 fixed address			**RW**
View and search for all IPv4 fixed addresses/reservations or IPv6 fixed addresses		**RO**	
View and search for IPv4 fixed addresses/reservations or IPv6 fixed addresses in a network	**RO**	**RO**	
View and search for an IPv4 fixed address/reservation or IPv6 fixed address			**RO**

Administrative Permissions for IPv4 or IPv6 DHCP Enabled Host Addresses

A read-write permission to IPv4 or IPv6 Host Address gives limited-access users the ability to create, modify, and delete IPv4 and IPv6 DHCP enabled host addresses in a specified network. Admin users with a read-write permission can create, modify, and delete IPv4 or IPv6 DHCP enabled host addresses only in the specified network. They do not have the ability to create, modify or delete any networks or objects, such as fixed addresses, in those networks.
You can also grant admin users read-only permission or deny access to the following:

- IPv4 Host Address—Object permission that applies to all IPv4 DHCP enabled host addresses in a specified network.
- IPv6 Host Address—Object permission that applies to all IPv6 DHCP enabled host addresses in a specified network.

For information about setting permissions for DHCP enabled host addresses, see *About Administrative Permissions*.
The following table lists tasks that admins can perform and the required permissions for IPv4 and IPv6 DHCP enabled host addresses.

Permissions for DHCP Enabled Host Addresses

Tasks	Specific IPv4 or IPv6 Network	All IPv4 or IPv6 DHCP enabled host Addresses
Create, modify, and delete IPv4 or IPv6 DHCP enabled host addresses in a specified network		**RW**
Modify and delete a specific IPv4 or IPv6 DHCP enabled host address		**RW**
View and search for all IPv4 or IPv6 DHCP enabled host addresses		**RO**
View and search for IPv4 or IPv6 DHCP enabled host addresses in a specified network		**RO**

Administrative Permissions for IPv4 and IPv6 DHCP Ranges

DHCP ranges inherit the permissions of the networks in which they reside. You can override network-level permissions by defining permissions for DHCP ranges. You can read-only or read/write permission, or deny access to DHCP address ranges, as follows:

- All IPv4 or IPv6 DHCP ranges—Global permission that applies to all IPv4 or IPv6 DHCP ranges in the database.
- All IPv4 or IPv6 DHCP ranges in a network—Permissions at this level override global permissions. If you do not define permissions for DHCP ranges, they inherit the permissions of the network in which they reside.
- A single IPv4 or IPv6 DHCP range—Overrides global and network-level permissions.

For information on setting permissions for DHCP ranges, see *About Administrative Permissions*. The following table lists the tasks admin can perform and the required permissions for DHCP ranges.

DHCP Ranges

Tasks	Grid Member(s)	Specific IPv4 or IPv6 Network	All DHCP IPv4 or IPv6 Ranges	Specific IPv4 or IPv6 DHCP Range	MAC Address Filter
Create, modify, and delete IPv4 or IPv6 DHCP ranges with an assigned member or a failover association	**RW**		**RW**		
Create, modify, and delete IPv4 or IPv6 DHCP ranges in a network with assigned members	**RW**	**RW**			
Modify and delete an IPv4 or IPv6 DHCP range with an assigned member	**RW**			**RW**	
View and search for all IPv4 or IPv6 DHCP ranges with an assigned member	**RO**			**RO**	
View and search for IPv4 or IPv6 DHCP ranges in a network with assigned members	**RO**	**RO**			

Tasks	Grid Member(s)	Specific IPv4 or IPv6 Network	All DHCP IPv4 or IPv6 Ranges	Specific IPv4 or IPv6 DHCP Range	MAC Address Filter
View and search for an IPv4 or IPv6 DHCP range with an assigned member	**RO**			**RO**	
View and search for an IPv4 or IPv6 DHCP range without an assigned member				**RO**	
Apply relay agent and option filters to an IPv4 DHCP range				**RW**	
Apply a MAC address filter to an IPv4 DHCP range				**RW**	**RO**

Administrative Permissions for IPv4 or IPv6 DHCP Templates

There are three types of DHCP templates for IPv4 and IPv6 objects—network, DHCP range, and fixed address/ reservation templates. To access any of these templates, a limited-access admin group must have read-only permission to the template. Limited-access admin groups cannot have read/write permission to the templates. Only superusers can create, modify and delete network, DHCP range, and fixed address templates. An admin group with read-only permission to the DHCP templates can view them and use them to create networks, DHCP ranges and fixed addresses, as long as they have read/write permissions to those DHCP resources as well.
You can set global read-only permission that applies to all DHCP templates, and you can set permissions to specific templates as well.
For information on setting permissions, see *About Administrative Permissions*. The following table lists the tasks admins can perform and the required permissions for DHCP templates.

Permissions for DHCP Templates

Tasks	IPv4 or IPv6 DHCP Templates	All IPv4 or IPv6 Networks	All IPv4 or IPv6 DHCP Ranges	All IPv4 or IPv6 Fixed Addresses/ IPv4 Reservations
Create IPv4 or IPv6 networks from templates	**RO**	**RW**		
Create IPv4 or IPv6 DHCP ranges from templates	**RO**		**RW**	
Create IPv4 fixed addresses/ reservations or IPv6 fixed addresses from templates	**RO**			**RW**
View templates	**RO**			

Note the following additional guidelines:

- DHCP range templates and fixed address templates do not inherit their permissions from network templates. You must set permissions for each type of template.
- An admin group can create a network using a network template that includes a DHCP range template and a fixed address template, even if it has no permission to access the DHCP range and fixed address templates.

Administrative Permissions for Roaming Hosts

Limited-access admin groups can access roaming hosts only if their administrative permissions are defined. The appliance denies access to roaming hosts for which an admin group does not have defined permissions. You can grant read-only or read/write permission, or deny access to roaming hosts as follows:

- All roaming hosts in the database—Global permission that applies to all the roaming hosts in the database.
- A specific roaming host—Permissions that applies to specific roaming host.

For information on setting permissions, see *About Administrative Permissions*. The following table lists the tasks admins can perform and the required permissions for roaming host.

Permissions for Roaming Hosts

Tasks	Grid DHCP Properties	Specific IPv4 or IPv6 Roaming Host	All Roaming Host
Enable roaming hosts	**RW**		
View roaming host	**RO**	**RO**	**RO**
Create, modify, and delete roaming hosts	**RO**		**RW**
Modify and delete roaming host	**RO**	**RW**	

Administrative Permissions for MAC Address Filters

Limited-access admin groups can access MAC address filters only if their administrative permissions are defined. The appliance denies access to MAC address filters for which an admin group does not have defined permissions. You can grant read-only or read/write permission, or deny access to MAC address filters as follows:

- All MAC address filters in the database
- A specific MAC address filter

For information on setting permissions, see *About Administrative Permissions*. The following table lists the tasks admins can perform and the required permissions for MAC address filters.

Permissions for MAC Filters

Tasks	All MAC Address Filters	Specific MAC Address Filter	Specific IPv4 DHCP Ranges
Create, modify, and delete MAC address filters	**RW**		
Create, modify, and delete MAC address entries for a MAC address filter		**RW**	
Modify and delete a MAC address filter		**RW**	
Apply a MAC address filter to an IPv4 DHCP range		**RO**	**RW**
Delete a MAC address filter from an IPv4 DHCP range		**RO**	**RW**

Tasks	All MAC Address Filters	Specific MAC Address Filter	Specific IPv4 DHCP Ranges
View MAC address filters and their MAC address entries	**RO**		
View a MAC address filter and its MAC address entries		**RO**	

Administrative Permissions for the IPv4 and IPv6 DHCP Lease Histories

A limited-access admin group can view and export the IPv4 and IPv6 DHCP lease histories if it has read-only permission to the IPv4 and IPv6 DHCP lease history. Permissions to the IPv4 and IPv6 DHCP lease histories are different from the network permissions. Therefore, an admin group can access the IPv4 and IPv6 DHCP lease histories, regardless of its network permissions. Note that only superusers can import a DHCP lease history file.
To define permissions for the IPv4 and IPv6 DHCP lease histories:

1. For an admin group: From the **Administration** tab, select the **Administrators** tab -> **Permissions** tab -> *admin_group* in the Groups table, and then click the Add icon -> **Global Permissions** from the Create New Permission area or select Add -> **Global Permissions** from the Toolbar.
   or
   For an admin role: From the **Administration** tab, select the **Administrators** tab -> **Permissions** tab -> *admin_role* in the Roles table, and then click Add icon -> **Global Permissions** from the Create New Permission area or select Add -> **Global Permissions** from the Toolbar.
2. Complete the following in the *Manage Global Permissions* dialog box:
   - **Permission Type**: Select **DHCP Permissions** from the drop-down list.
   - In the table, select **Read/Write**, **Read-only**, or **Deny** for **All IPv4 DHCP Lease History** and **All IPv6 DHCP Lease History.**
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Administrative Permissions for File Distribution Services

You can restrict access to the TFTP, HTTP and FTP services provided by the appliance. By default, the appliance denies access to the TFTP, HTTP and FTP services, unless an admin group has their administrative permissions defined.
You can grant read-only or read/write permission, or deny access to the following resources:

- Grid File Distribution Properties—Applies to the Grid and its members, directories, and files. You can set this from the Administrators perspective only.
- Member File Distribution Properties—Applies to the Grid member properties only.
- A specific directory—Applies to the directory and its files.

For information on setting permissions, see *About Administrative Permissions*. The following table lists the tasks admins can perform and the required permissions for file distribution services.

Permissions for File Distribution Services

Tasks	Grid File Distribution Properties	Member Distribution Properties	Specific Directory
Create and remove directories and files	**RW**		
Modify the Grid and member file distribution properties	**RW**		
View the Grid and member file distribution properties, directories, and files	**RO**		

Tasks	Grid File Distribution Properties	Member Distribution Properties	Specific Directory
Modify the member file distribution properties		**RW**	
View the member file distribution properties		**RO**	
Add and delete a directory, subdirectories, and files in the directory			**RW**
View a directory and its subdirectories and files			**RO**

Administrative Permissions for Dashboard Tasks

Limited-access admin groups can configure IPAM tasks on the Tasks Dashboard only if their administrative permissions are defined. The appliance denies access to IPAM tasks for which an admin group does not have defined permissions.
You can grant read-only or read/write permission, or deny access to IPAM tasks as follows:

- All IPAM tasks on the Tasks Dashboard
- A specific IPAM task

When you deny access to an IPAM task for an admin group, uses cannot configure the task on their dashboards. Users must have at lease read-only permission to a specific task to see it in the task pack. To perform a specific task, users must also have read/write permission to the objects associated with the task. For information about specific permissions for IPAM, DNS, and DHCP objects, see *Administrative Permissions for IPAM Resources*, *Administrative Permissions for DNS Resources*, and *Administrative Permissions for DHCP Resources*. For information about setting permissions, see *About Administrative Permissions*. The following table lists the tasks admins can perform and the required permissions for configuring IPAM tasks on the Tasks Dashboard.

Permissions for IPAM Tasks

Tasks	All Dashboard Tasks	Add Networks	Add Hosts	Add Fixed Addresses	Add CNAME Record	Add TXT Record	Add MX Record
Configure all tasks in the IPAM task pack	**RO RW**						
Configure the Add Networks task		**RO RW**					
Configure the Add Hosts task			**RO RW**				
Configure the Add Fixed Addresses task				**RO RW**			
Configure the Add CNAME Record task					**RO RW**		

Tasks	All Dashboard Tasks	Add Networks	Add Hosts	Add Fixed Addresses	Add CNAME Record	Add TXT Record	Add MX Record
Configure the Add TXT Record task						**RO RW**	
Configure the Add MX Record task							**RO RW**

Administrative Permissions for Certificate Authentication Services and CA Certificates

Limited-access admins can configure certificate authentication services and CA certificates only if their administrative roles and permissions are defined. If you want to allow admins to configure two-factor authentication, you can assign the PKI Admin role to limited-access admins or grant them read/write permissions to the following:

- All certificate authentication services
- All CA Certificates

For information about setting permissions, see *About Administrative Permissions*. The following table lists the admin tasks and required permissions for configuring certificate authentication services and managing CA certificates.

Administration Permissions

Tasks	Grid Member(s)	All Certificate Authentication Services	All CA Certificates
Create, modify, and delete certificate authentication services		**RW**	
Create, modify, and delete CA certificates	**RW**		**RW**

Administrative Permissions for Object Change Tracking

Infoblox stores updated objects in the NIOS database. Users with read-only permission can query and view these objects. Grid Manager allows you to grant the following permissions:

- Read-only permission to view deleted objects information. If the users have a read-only permission and the **exclude_deleted** flag is not set, then they will receive information about the deleted objects only.
- Deny to prevent the users from accessing updated objects information. If the users have a Deny permission, then they cannot query for any object updates even if the **exclude_deleted** flag is not set.

Users with a read-only permission must have permissions on all the objects to perform a full or an incremental synchronization. For example, consider that a user, user1, has read-only permission on DNS views, but does not have permission on network views. If user1 performs a full synchronization, NIOS does not include network views in the response as user1 does not have permission to view these objects. Hence, Infoblox recommends that you give permissions to all the objects in the NIOS database.

Administrative Permissions for Load Balancers

Limited-access admins can view and manage GLBs (Global Load Balancers), load balancer synchronization groups, and their associated objects if their administrative roles and permissions are defined. If you want to allow admins to manage GLB objects, assign the Load Balancer Admin role to limited-access admins and grant them the following permissions:

- Read/write, read-only, or deny permission to NIOS managed GLB groups and independent load balancers

- Read/write, read-only, or deny permission to NIOS managed GLB objects
- Read-only or deny permission to GLB objects, such as DNS profiles and iRules, that are synchronized from the GLB but cannot be managed through NIOS

For information about setting permissions, see *About Administrative Permissions*. The following table lists the admin tasks and required permissions for configuring GLBs, load balancer synchronization groups, and their associated objects.

Administration Permissions for Load Balancers and Load Balancer Synchronization Groups

Tasks	Grid Member(s)	All Load Balancer Objects	All Load Balancers	All Load Balancer Groups
View load balancer objects	**RO**	**RO**		
Add and modify synchronized load balancer objects	**RW**	**RW**		
Add, modify, and delete synchronized load balancer objects	**RW**	**RW**	**RW**	**RW**
Modify and delete synchronized load balancer groups	**RW**		**RW**	**RW**

Authenticating Admins Using SAML

NIOS uses SAML (Security Assertion Markup Language) 2.0 authentication support for Single-Sign-On in NIOS. SAML provides a standard vendor-independent grammar and protocol for transferring information about a user from one web server to another independent of the server DNS domains. SAML enables IT administrators to manage user access rights in a single place. By enabling SAML, user management is delegated to an external application, thus relieving IT administrators the complexity of maintaining user accounts in all the applications (also known as Service Providers) being used by the organization. Instead, IT administrators need to maintain one account in the Identity Provider (IdP) which can be used across Service Providers (SPs). IdP is the application server that maintains the user accounts of the entire organization. IT administrators can manage users access rights at one place. User can login to the IdP directly and once logged in, they can be traverse towards the required SP without being prompted for the user ID and password. SAML helps NIOS delegate Identity Management to a third-party SSO application (IdP) and thereby eases administrative efforts.

> ⚠ Note
>
> You need super user permissions to perform SAML-related configurations.

SAML Login Use Cases

The following is a list of use cases and the outcome of NIOS users trying to log in using SAML authentication and not using SAML authentication:

- If SAML is enabled and users have already logged in to the IdP account and the corresponding user account is present in NIOS, users can directly start using Grid Manager without logging in to NIOS.
- If a user has logged in to the IdP account and the corresponding IdP account is not present in NIOS, if the **Auto Create User** checkbox is selected, the user can directly start using Grid Manager without logging in to NIOS. For information about the **Auto Create User** checkbox, see *Auto Creating SAML Users in NIOS*.
- If a NIOS user who is not SAML-authorized tries to log in to NIOS using the **SSO Login** button, the login fails. However, the user can log in using the **Login** button.

Prerequisites for Configuring SAML Authentication

Ensure that you meet the following prerequisites before you configure SAML for NIOS:

- When adding the NIOS application in IdP, specify the Grid Manager URL in the https://<Grid Manager IP address>:8765/?acs format. This is referred to as the Assertion Consumer Service URL or ACS URL. The 8765 port is opened for SAML services.
- After you add NIOS to the IdP, either copy the metadata or the metadata URL or specify it in the SAML configuration screen.
- Ports 443 (HTTPS) and 80 (HTTP) must be allowed on the firewall to allow NIOS to communicate with IdP.
- Ensure that the group that you specify in the IdP also exists in NIOS with the same users as that in the IdP. If you did not specify a group attribute in IdP, SAML authenticated users are added to the default SAML group: **saml-group**.
- SAML authentication in NIOS requires configuring an Identity Provider (IdP) for authentication. Infoblox-verified named IdPs are listed in the **IDP Type** drop-down list. The **IDP Type** drop-down list also contains the **Others** option for users who wish to configure an IdP that is not listed. Due to the lack of compliance to SAML standards and widely varying IdP vendor implementations, Infoblox is unable to provide configuration support if you select the **Others** option. Infoblox recommends that you contact the IdP vendor for support if you use this option.

SAML Qualified IDPs and Response Format

The qualified SAML IDPs are:

- Azure SSO
- Ping Identity
- Shibboleth SSO
- OKTA

IDP's response is as following:

For example:

```
<saml2:NameID Format="urn:oasis:names:tc:SAML:1.1:nameid-
format:unspecified">arunchurimanjunath@gmail.com</saml2:NameID>
```

NameID is the mandatory parameter in the IDP response format.

Enabling SAML Authentication

To enable SAML authentication for NIOS users, perform the following steps:

1. Login as a super user.
2. Click the **SAML Authentication Services** tab.
3. From the Toolbar, click **Add** -> **SAML Service**.
4. In the *Add SAML Authentication Service* wizard:
    - **Name**: Enter a name for the authentication service.
    - **IDP Type**: Select the IdP type that you want to configure for the authentication service. NIOS supports the following IdP types: Azure SSO, Okta, Ping Identity, Shibboleth SSO, Others.
    - **SSO Metadata URL**: Enter the metadata URL of the IdP. Alternatively, copy the metadata into a file and upload the file. For information on obtaining the metadata, see *Obtaining Metadata*.
    - **SSO Redirect IP Address/FQDN**: Enter the IP address or the FQDN of Grid Master. If you enter a value other than the IP address or FQDN, the SAML service will not work. A best practice is to enter the FQDN because it is used by the IdP for the SAML response.
    - **Session Timeout**: Enter the amount of time that a SAML user can be idle after which the session must terminate. The time that you specify here supersedes the session timeout time specified in the **Grid Properties** - > **Security** - > **Session Timeout(s)** field. For more information about session timeout in the Grid, see *Managing Security Operations*.
    - **IDP Group Attribute**: Enter a group attribute name. The group attribute name that you enter must have the same value as the **Group Attribute** in your IdP configuration. If the value in NIOS is different from what is configured in the IdP, or if the value is missing, the incoming SAML user is placed in the default SAML

group **saml-group**. If the value matches, the IdP's group attribute filter passes the user's group membership to NIOS. If there is a NIOS group that exactly matches a group name from the list of groups from the IdP, and the NIOS group is configured for SAML, the user get placed into that NIOS group. If there is no matching NIOS group, the user gets placed in the default SAML group **saml-group**.
    - **Comment**: Enter additional comments if any.
5. Click **Save & Close**.

Now, if you log out and try to relogin, the **SSO Login** button is displayed.

When SAML authorized users try to login for the first time by clicking the **SSO Login** button, they are directed to their IdP login page. If the user credentials they specified exist in the IdP, they are redirected to the NIOS home page.

Note

- If there are any IdP or metadata changes following a Grid Master Candidate promotion, it is necessary to delete the configuration and re-configure.
- After HA failover, ensure that you reload the Grid Manager after 3 to 5 seconds, to view the SSO login button.

Obtaining Metadata

This section explains how to obtain the metadata URL of the IdP. The procedures in this section may vary a little depending on the type of IdP that you select. The procedure in this section uses Okta as an IdP example. If you are using an IdP other than Okta, contact your IT administrator for the metadata URL.

To obtain the metadata URL of Okta:

1. Log in to your Okta account.
2. Go to **My Applications** and click the URL of your Grid Manager.
3. You can either copy the XML metadata for the Grid Manager into a file or use the URL of the metadata.

Auto Creating SAML Users in NIOS

After enabling SAML authentication, you can configure NIOS such that users who belong to a particular group in IdP are automatically created in NIOS. Once the users are automatically created in NIOS, if they log in to their IdP account, they can directly access Grid Manager.

1. Login as a super user.
2. Create a group by the same name as that of the group in the IdP account. For information about creating groups, see *About Admin Groups*.
3. Click the **Administration** → **Administrators** tab.
4. Select the group that you created and click the Edit icon. The out-of-the-box group for SAML authenticated users is **saml-group**.
5. Click the **SAML** tab.
6. Select **Auto Create User** for users in the IdP group to be automatically created in NIOS. When a new IdP user logs in to NIOS, that user is created in NIOS.
7. Select **Persist Auto Created User after logout** if you want to retain the SAML user accounts in NIOS even after the session times out. The session timeout value is specified in the **Session Timeout** field when you enabled SAML authentication. For more information, see *Enabling SAML Authentication*. If you do not select the **Persist Auto Created User after logout** checkbox, if the session times out, users for whom the **SAML Only** option was selected in the **Authentication Type** field, are deleted from NIOS. Not selecting the **Persist Auto Created User after logout** checkbox also deletes the user account along with all the scheduled tasks associated with the user account when the user logs out of NIOS. For information about the Authentication Type field, see *Creating Local Admins*.
8. Click **Save & Close**.

> **Note**
>
> If you select the **Persist Auto Created User after logout** checkbox and the session times out, you must manually verify whether the user account exists in IdP or not. If the user account is deleted from IdP, then you must manually delete the account in NIOS.

Authenticating SAML Users

When you create administrators, you can authenticate them either as a SAML-only administrator or as a SAML/local administrator. Depending on the authentication type, administrators can log in using either the SSO Login button or the Login button. For more information see *Creating Local Admins*.

Administrative Permissions for Named ACLs

Only superusers and limited-access users with Read/Write permission to All Named ACLs and Read/Write permission to the corresponding objects and operations can manage named ACLs and their ACEs.
For information about access control and named ACLs, see *Configuring Access Control*. The following table lists the operations and required permissions for managing named ACLs.

Administration Permissions

Tasks	Grid Member(s)	All Named ACLs	DNS Views	Related DNS objects	File Distribution
Create, modify, and delete named ACLs for all supported operations	**RW**	**RW**	**RW**	**RW**	**RW**
View named ACLs and ACEs	**RW**	**RO**	**RO**	**RO**	**RO**

Administrative Permissions for DNS Threat Protection

You can grant read-only or read/write permission, or deny access to the following resources:

- Grid Security Properties—Applies to the Grid and its members.
- Member Security Properties—Applies to the Grid members only.

For information about setting permissions, see *About Administrative Permissions*. The following table lists the tasks admins can perform and the required permissions for the threat protection service.

Permissions for hardware-based Threat Protection Service

Tasks	Grid Security Properties	Member Security Properties
View Grid security properties	**RO**	
Update Grid Security properties	**RW**	
View member security properties for specific Grid members	**RO**	**RO**
Update member security properties for specific Grid members	**RW**	**RW**

Tasks	Grid Security Properties	Member Security Properties
Start and stop threat protection service for a Grid member	**RW**	**RW**
Publish rules for a Grid member	**RW**	**RW**
View rule categories and rules for the Grid	**RO**	
Enable and disable rules for the Grid	**RW**	
Update rule versions for any rules on the Grid	**RW**	
Revert to a previous rule version for any rules on the Grid	**RW**	
Modify configuration parameters, such as action and severity, for rules on the Grid	**RW**	
Create custom rules from rule templates for the Grid	**RW**	
Delete custom rules for the Grid	**RW**	
View rule categories and rules on a Grid member	**RO**	**RO**
Enable and disable rules on a Grid member	**RW**	**RW**
Update rule versions for any rules on a Grid member	**RW**	**RW**
Revert to a previous rule version for any rules on a Grid member	**RW**	**RW**
Modify configuration parameters, such as action and severity, for rules on a Grid member	**RW**	**RW**
View threat protection related event statistics on a Grid member	**RO**	**RO**
Upgrade rulesets for a Grid	**RW**	

Permissions for Software ADP

Tasks	Grid Security Properties	Member Security Properties
View the list of Threat Protection profiles in the Profiles Viewer	**RO**	**RO**

Tasks	Grid Security Properties	Member Security Properties
View profile settings in the Threat Protection Profile Editor	**RO**	
Create a Threat Protection profile	**RW**	
Clone a Threat Protection profile from an existing profile (This also clones all settings for the ruleset from an old profile.)	**RW**	
Clone a Threat Protection profile from an existing member settings	**RW**	
Update the profile settings (name, comment, events per second, disable multiple TCP DNS request, list of members)	**RW**	
Change the ruleset that is assigned to a profile (This internally merges all customizations for an old ruleset to a new ruleset.)	**RW**	
View the profile rules and rule settings	**RO**	
Enable/disable rules in the profile	**RW**	
Change the rule parameters for rules in the profile (action, log severity, events per second etc.)	**RW**	
Merge two profiles	**RW**	
Assign/remove a profile from Member Security properties	**RW**	**RW**
Delete a profile	**RW**	

Administrative Permissions for DNS Threat Analytics

Only superusers and limited-access users with Read/Write permission can manage Threat Analytics service. You can grant read-only or read/write permission, or deny access to the following:

- Grid Threat Analytics Properties—Applies to the Grid and its members.

For information about setting permissions, *Managing Permissions*. The following table lists the tasks admins can perform and the required permissions for the threat analytics service.

Permissions for Threat Analytics Service

Tasks	Grid Threat Analytics Properties	RPZ Zones	Grid Members	DNS Views
View Grid Threat Analytics properties	**RO**		**RO**	

Tasks	Grid Threat Analytics Properties	RPZ Zones	Grid Members	DNS Views
Update Threat Analytics properties	**RW**	**RW**	**RW**	**RW**
Start and stop Threat Analytics service	**RW**		**RW**	
Create an RPZ and use it as mitigation blacklist feed	**RW**	**RW**	**RW**	**RW**
View whitelisted domains	**RO**		**RO**	
Move blacklisted domains to the whitelist	**RW**	**RW**		
Update Threat Analytics module and whitelist sets	**RW**			
Viewing threat analytics module and whitelist versions	**RO**			
Define the Threat Analytics Update policy	**RW**			
Manually Upload Threat Analytics Updates	**RW**			

Administrative Permissions for All Rulesets

You can grant permissions for individual ruleset objects to admin users. NIOS provides a global permission ALL Rulesets for admin groups. To perform operations on an NXDOMAIN ruleset, a blacklist rule, or an RPZ ruleset, you must have permission to the rule or ruleset to which the ruleset object belongs.

Administrative Permissions for Cloud Objects

You can grant read-only or read/write permission, or deny access to the following cloud related objects:

- All tenant—Applies to all tenants.
- Per tenant object—Applies to selected tenants only.

You need appropriate permissions to make changes to all tenants or a specific tenant object through Grid Manager. Note that following:

- Update the tenant object: You must have permission on all tenant objects or the specific tenant object that is being updated. When you modify any tenant object associated with a tenant, it requires explicit Read/Write permission on the specific tenant object, whether permission on the associated tenant exists or not.
- Read-Only: This operation returns all tenant objects if you have the all tenant permission, or returns only specific tenant objects for which you have access.
- Permission for a tenant object implicitly gives the read permission to any object that is associated with the tenant.
- Note that creating and deletion operations do not need any permission.

Administrative Permissions for CSV Import

The following CSV import permissions are applicable to local users on the NIOS appliance. They are not valid for AD or RADIUS users.

- When you delete a user, CSV import tasks associated with the respective user are not deleted. Superusers can access these tasks. Pending CSV import tasks will not be executed due to authentication failure.
- If you change user permissions, the pending and running CSV import tasks are executed, but may finish with errors. Note that the appliance re-establishes database transaction after every 500 lines are imported. If you delete or modify the respective user entry between these transactions, the rest of the import may fail.
- Superusers can manage any stopped, failed, or completed CSV import tasks belonging to a deleted user.

Administrative Permissions for Reporting

NIOS supports global and object permissions for reporting: Reports and Searches. Consider the following when applying permissions for reports and searches:

- When you view a DNS report, DHCP report, or search options, you can view all the data in the corresponding report or search results, even if you do not have permissions to view the DNS or DHCP objects.
- A limited-access user needs relevant permissions to view any report or search.
- When you grant a read-only permission for a specific report to a user, the user receives read-only access to everything the report displays.
- A user can view report data returned by a search operation even when the user is denied access to the search operation.
- You can only view pre-defined reports, global reports and customized reports or searches. A user, including superuser, cannot view customized reports or searches of other users.
- You cannot edit pre-defined reports.
- Only a superuser can edit global reports or searches.
- Only an owner of the customized report or search operation can modify the report.
- Superuser may create reports up to system wide limit.
- A limited-access admin can create up to five reports by default. You can configure this limitation through Grid Manager.

Administrative Permissions for VLAN Management

A superuser has RW access for all VLAN related objects.

Global permissions and object permissions are supported for VLAN views, ranges, and objects. Permissions set at specific levels override global permissions for VLAN ranges, views, and objects. For more information see *About Administrative Permissions*.

A user who belongs to the VLAN Admin role has the following permissions set:

Permission Type	Object	Task	Permission
VLAN Permissions	VLAN view	Creating VLAN views	RW
		Editing VLAN views	RW
		Deleting VLAN views	RW
VLAN Permissions	VLAN range	Creating VLAN ranges	RW
		Editing VLAN ranges	RW

Permission Type	Object	Task	Permission
		Deleting VLAN ranges	RW
VLAN Permissions	VLAN object	Creating VLAN objects	RW
		Editing VLAN objects	RW
		Deleting VLAN objects	RW
IPAM Permissions	Network view	Creating network views	RO
		Editing network views	RO
		Deleting network views	RO
IPAM Permissions	IPv4/IPv6 network		RW

For information about VLAN management, see *VLAN Management*.

Administrative Permissions for SAML

A user who belongs to the SAML Admin role has the following permissions set:

Permission Type	Resource Type	Permission
SAML Permissions	SAML Admin group	RW
SAML Permissions	SAML Authentication Services	RW

For information about SAML authentication, see *Authenticating Admins Using SAML*.

Deploying a Grid

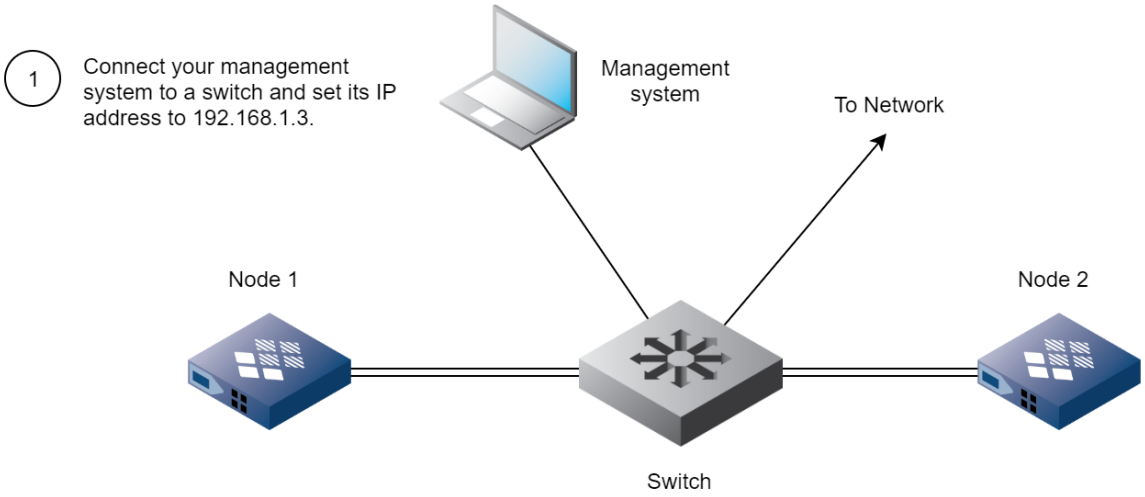
To deploy a Grid, it is important to understand what a Grid is, how to create a Grid Master and add members, and how to manage the Grid. This section explains in detail about a grid and covers the topics:

- *Creating a Grid Master*
- *About Grids*
- *About HA Pairs*
- *Adding Grid Members*
- *Configuring an IPv6-only Grid*
- *Auto-Provisioning NIOS Appliances*
- *Pre-Provisioning NIOS and vNIOS Appliances*
- *Configuring a Grid*
- *Managing a Grid*
- *Grid Bandwidth Considerations*
- *Automatic Software Version Coordination*
- *NAT Groups*

Creating a Grid Master

To create a Grid, you first create a Grid Master, and then add members. Although the Grid Master can be a single appliance (a "single master"), a more resilient design is to use an HA pair (an "HA master") to provide hardware redundancy. For information about HA pairs, see *About HA Pairs*. The basic procedure for forming two appliances into an HA master is shown in the Initially Configuring a Pair of Appliances as a Grid Master figure. You can create a Grid Master in either IPv4, IPv6, or dual mode (IPv4 and IPv6). An IPv4 Grid Master uses IPv4 as the Grid communication protocol, so it supports IPv4 and dual mode Grid members. An IPv6 Grid Master uses IPv6 as the Grid communication protocol, so it supports IPv6 and dual mode Grid members. A dual mode Grid Master supports IPv4, IPv6, and dual mode Grid members. You can set either IPv4 or IPv6 as the communication protocol. All Infoblox hardware platforms, except for appliances with a 50 GB disk, support configuration as a Grid Master or Grid Master candidate. For information about which vNIOS appliance supports configuration as a Grid Master, see *vNIOS Appliances*.

Initially Configuring a Pair of Appliances as a Grid Master



2 Connect Node 1 to the switch, log in to its default IP address (192.168.1.2), check that a Grid license is installed, and then configure the following:

- VIP address, netmask, gateway
- Hostname
- HA and LAN1 addresses of Node 1
- HA and LAN1 addresses of Node 2
- VRID (virtual router ID)
- NTP settings
- Grid name
- Shared secret

3 After you configure Node 1, it listens for three seconds for VRRP advertisements containing its VRID number. When it does not receive any, it assumes the active role in the HA pair and starts sending advertisements.

Note:
For more information about VRRP advertisements, see VRRP Advertisements page

4 Connect Node 2 to the switch, log in to its default IP address (192.168.1.2), check that a Grid license is installed, and then configure the following:

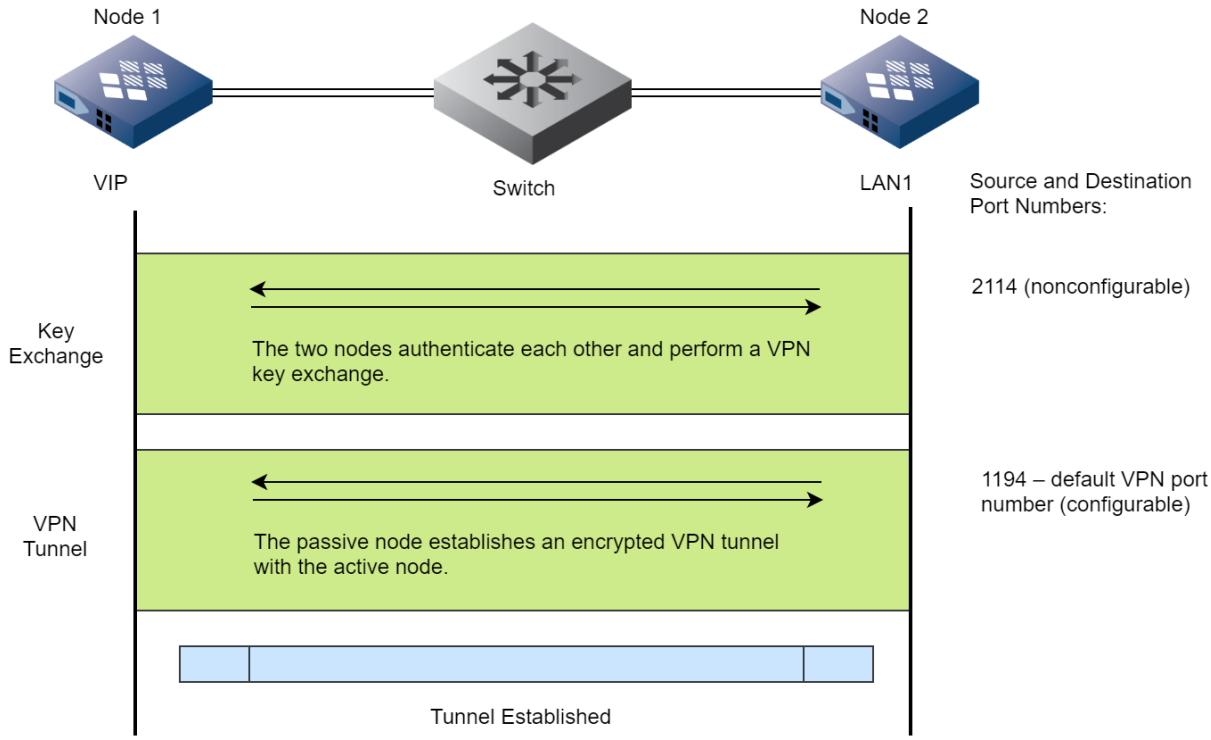
- VIP address (for Node 1)
- LAN1 address, netmask, gateway
- Hostname
- Grid name
- Shared secret

Note:
Because you do not set the VRID for Node 2, it cannot listen for VRRP advertisements yet. It learns its VRID after it joins the Grid and downloads the database from Node 1. Then, when Node 2 receives an advertisement containing its VRID from Node 1, it assumes the passive role in the HA pair.

5 After you configure Node 2, it contacts the VIP address on Node 1 and initiates a mutual authentication of the nodes using the shared secret. The nodes then construct an encrypted VPN tunnel to secure Grid communications.

After the two nodes form an HA pair, Node 2 initiates a key exchange and creates an encrypted VPN tunnel with Node 1. The two nodes communicate between the VIP interface linked to the HA port on Node 1 and the LAN1 port on Node 2. The initialization of VPN communications between the two nodes is shown in the below figure.

Establishing a VPN Tunnel for Grid Communications

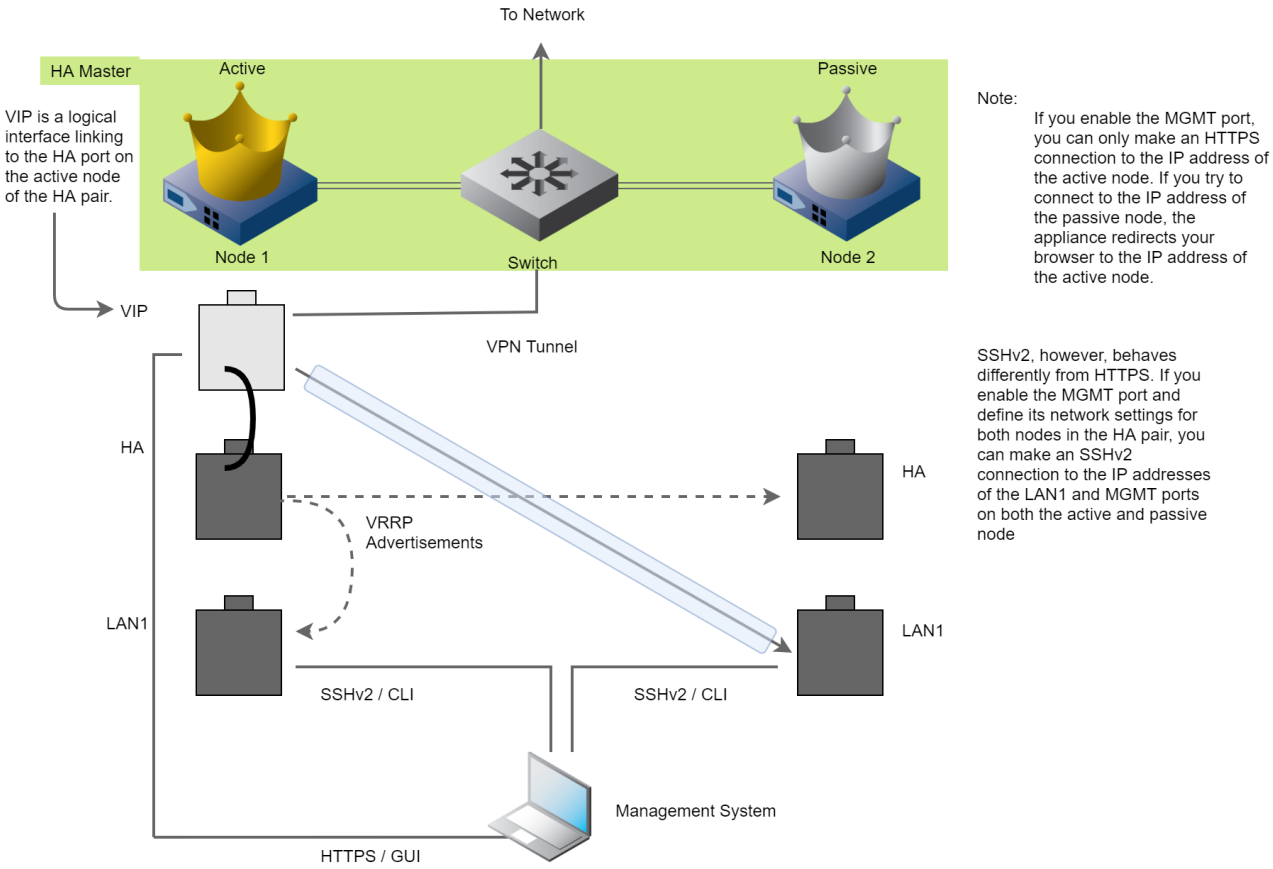


After the nodes establish a VPN tunnel between themselves, Node 1 sends Node 2 its entire database (its configuration settings and service data). Since the configuration contains the VRID (virtual router ID) for the HA pair, Node 2 starts listening for VRRP advertisements containing that VRID number. Also, since Node 1 is already sending such advertisements, Node 2 receives one and assumes the passive role in the HA pair.

After the initial transmission of its database, Node 1 continues to send Node 2 real-time database updates through the VPN tunnel.

Node 1 maintains the synchronization of the database throughout the Grid—which, at this point, has no other members—sends VRRP advertisements indicating its physical and network health, and—if configured to do so— provides network services. Node 2 maintains a state of readiness to assume the mastership in the event of a failover. You can see the flow of HA and Grid-related traffic from ports on the active node to ports on the passive node in the Traffic and Ports that an HA Grid Master Uses figure. This illustration also shows the ports that you can use for management traffic and network service.

Traffic and Ports that an HA Grid Master Uses



From the management system, you can manage the active node of the HA Master by making an HTTPS connection to the VIP interface and using the GUI, and by making an SSHv2 connection to the LAN1 port (and MGMT port, if enabled) and using the CLI. If you enable the MGMT port on an HA pair, you can make an HTTPS connection through the MGMT port on the active node, and you can make an SSHv2 connection through the LAN1 or MGMT port on the active and passive nodes.

> **Note**
>
> For information about enabling and using the MGMT port, SSH, and the Infoblox GUI, see *Using the MGMT Port, Restricting GUI/API Access*, and *Logging on to the NIOS UI*.

Port Numbers for Grid Communication

If connectivity between Grid members must pass through a firewall, the firewall policies must allow the initial key exchange and subsequent VPN traffic to pass. The key exchange uses UDP with a source and destination port of 2114. VPN traffic uses UDP with a default source and destination port of 1194. The VPN port number is configurable.

To configure the VPN port number, complete the following:

1. On the **Grid** tab -> **Grid Manager** tab, expand the Toolbar, and then select **Grid Properties** -> **Edit**.
2. On the **General** tab of the *Grid Properties* editor, type a new port number in the **VPN Port** field.
3. Save the configuration.
4. When Grid Manager displays a warning indicating that a product restart is required, click **Yes** to continue. The product automatically restarts.

A member and master first perform a handshake to authenticate each other and exchange encryption keys. Then, they build an encrypted VPN tunnel between themselves. The member typically initiates both of these connections. The

master only initiates a key exchange if you manually promote a member to the role of master, (see *Promoting a Master Candidate*). The figure *Establishing a VPN Tunnel for Grid Communications* shows the typical connection exchange and default port usage not only between the two nodes forming an HA pair but also between a member and master when the member joins a Grid.

The member and master key exchange occurs when an appliance joins a Grid, during master promotion, and when a member reconnects to a Grid after becoming disconnected. At all other times, Grid-related communications occur through encrypted VPN tunnels.

Grid Setup Wizard

The *Grid Setup Wizard* simplifies configuring a Grid. You can use it to configure an HA or single Grid Master and to join appliances to a Grid. The *Grid Setup Wizard* appears when you first log in to the appliance. After that, you can access it at any time as follows:

1. On the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
2. Expand the Toolbar and select **Grid Properties** -> **Setup (Grid Setup Wizard)**.

Creating an HA Grid Master

To create a Grid, you first create a Grid Master and then add members. Although you can define a single appliance as a Grid Master, using an HA pair provides hardware redundancy for this vital component of a Grid. You can create an HA Master in either IPv4, IPv6, or in dual mode. An IPv4 HA Master uses IPv4 as the communication protocol between the two nodes and for Grid communication. An IPv6 HA pair uses IPv6 as the communication protocol between the two nodes and for Grid communication. But in a dual mode HA pair, you can select either IPv4 or IPv6 as the communication protocol between the two nodes and for Grid communication. The following procedure explains how to put two NIOS appliances on the network and use the *Grid Setup Wizard* to configure them as Nodes 1 and 2 to form an HA Grid Master. For information about which vNIOS appliance supports configuration as an HA Grid Master, see *vNIOS Appliances*.

Configuring the Connecting Switch

To ensure that VRRP (Virtual Router Redundancy Protocol) works properly, configure the following settings at the port level for all the connecting switch ports (HA, LAN1, and LAN2):

- **Spanning Tree Protocol**: Disable this or enable this with Portfast. For vendor specific information, search for "HA" in the Infoblox Knowledge Base system at *https://support.infoblox.com*.
- **Trunking**: Disable.
  Note that if VLAN tagging is enabled on an Infoblox HA appliance, you must enable trunking at the port level.
  EtherChannel: Disable.
- **IGMP Snooping**: Disable.
- **DHCP Snooping**: Disable or Enable Trust Interface.
  Note that you must disable DHCP Snooping to successfully run DHCP services on the Grid. For more information about DHCP services, see *About Infoblox DHCP Services*.
- **Port Channeling**: Disable.
- **Speed and Duplex settings**: Match these settings on both the Infoblox appliance and switch.
- Disable other dynamic and proprietary protocols that might interrupt the forwarding of packets.

> ⚠ Note
> By default, a NIOS appliance automatically negotiates the optimal connection speed and transmission type (full or half duplex) on the physical links between its LAN1 or LAN1 (VLAN), HA, and MGMT ports and the Ethernet ports on the connecting switch. If the two appliances fail to auto-negotiate the optimal settings, see *Modifying Ethernet Port Settings* for steps you can take to resolve the problem.

Placing Both Appliances on the Network

1. Connect the power cable from each NIOS appliance to a power source and turn on the power. If possible, connect the appliances to separate power circuits. If one power circuit fails, the other might still be operative.
2. Connect Ethernet cables from the LAN1 port and the HA port on each appliance to a switch on the network.
3. Use the LCD on one appliance or make a console connection to it and configure the network settings of its LAN1 port so that it is on the local subnet and you can reach it on the network. LCD supports only IPv4 addressing and not IPv6 addressing. You can configure IPv6 address for the appliance through CLI or GUI. IPv4 addressing is supported on the LCD; ensure that you have the correct network address values before configuration of the appliance.
   Note that for details about using the LCD and console, refer to the installation guide that shipped with your product.
4. Similarly, configure the LAN1 port on the other appliance so that it is in the same subnet as the first appliance.
5. Connect your management system to the network so that it can reach the IP addresses of the LAN1 ports on both appliances.

HA Master – Node 1

1. On your management system, open a browser window, and connect to https://*ip_addr*, where *ip_addr* is the IP address of the LAN1 port on Node 1. IPv4 and IPv6 values are valid, based on the LAN1 port configuration.
2. Log in using the default username and password: **admin** and **infoblox**. For detailed information about logging in to the GUI, see *Logging on to the NIOS UI*.
3. Read the Infoblox *End-User License Agreement* (EULA), and then click **I Accept**.
   Note that if you want to view the privacy policy of Infoblox, then on the EULA screen, click **Infoblox Privacy Policy**. Grid Manager displays the policy on a new browser tab.
4. Click **OK**. The *Grid Setup* wizard appears.
5. On the first screen, select **Configure a Grid Master** and click **Next**.
6. On the next screen, specify the Grid properties and click **Next**:
   - **Grid Name**: Enter a text string that the two appliances use to authenticate each other when establishing a VPN tunnel between them. The default Grid name is **Infoblox**.
   - **Shared Secret**: Enter a text string that both appliances use as a shared secret to authenticate each other when establishing a VPN tunnel between them. The default shared secret is **test**.
   - **Confirm Shared Secret**: Enter the shared secret again.
   - **Hostname**: Enter a valid domain name for the appliance.
   - **Type of Network Connectivity**: Select the type of network connectivity from the drop-down list:
     - **IPv4 and IPv6**: Select this to configure a dual mode HA Master.
     - **IPv4**: Select this to configure an IPv4 HA Master.
     - **IPv6**: Select this to configure an IPv6 HA Master.
   - **Is the Grid Master an HA pair?**: Select **Yes**.
     - **Send HA and Grid Communication over**: This field is displayed only when you are configuring a dual mode HA pair. Select either **IPv4** or **IPv6** as the communication protocol for VRRP advertisements.

   Notes
   - Infoblox recommends that you back up the configuration after you convert a Grid to a different mode.
   - Restoring the old backup by performing a forced restore, may prevent the Grid members from rejoining the Grid Master after the restore.
7. On the next screen, specify the network properties and click **Next**:
   - **Virtual Router ID**: Enter the VRID (virtual router ID). This must be a unique VRID number—from 1 to 255—for this subnet.
   - **Ports and Addresses**: This table lists the network interfaces based on the type of network connectivity of the HA Master.
     For IPv4 HA Master, specify the network information for VIP (IPv4), Node1 HA (IPv4), Node2 HA (IPv4), Node1 LAN1 (IPv4), and Node2 LAN1 (IPv4) interfaces.
     For IPv6 HA Master, specify the network information for VIP (IPv6), Node1 LAN1 (IPv6), and Node2 LAN1 (IPv6) interfaces.
     For a dual mode HA Master, if you select **IPv4** in the **Send HA and Grid Communication over** field, specify the network information for the following interfaces: VIP (IPv4), Node1 HA (IPv4), Node1 LAN1 (IPv4),

Node2 HA (IPv4), Node2 LAN1 (IPv4), VIP (IPv6), Node1 LAN1 (IPv6), and Node2 LAN1 (IPv6) interfaces.
For a dual mode HA Master, if you select **IPv6** in the **Send HA and Grid Communication over** field, specify the network information for the following interfaces: VIP (IPv4), Node1 LAN1 (IPv4), Node2 LAN1 (IPv4), VIP (IPv6), Node1 LAN1 (IPv6), and Node2 LAN1 (IPv6) interfaces.
Enter correct information for the following by clicking the field:

- **Interface**: Displays the name of the interface. You cannot modify this.
- **Address**: Type the IPv4 or IPv6 address depending on the type of interface.
- **Subnet Mask (IPv4) or Prefix Length (IPv6)**: Specify an appropriate subnet mask for IPv4 address or prefix length for IPv6 address. The prefix length ranges from 2 to 127.
- **Gateway**: Type the IPv4 or IPv6 address of the default gateway depending on the type of interface. For the IPv6 interface, you can also type **Automatic** to enable the appliance to acquire the IPv6 address of the default gateway and the link MTU from router advertisements.
  Note
  You can now define a link-local address as the default IPv6 gateway and isolate the LAN segment so that the local router can provide global addressing and access to the network and Internet. This is supported for both LAN1, LAN2, and VLAN interfaces, as well as LAN1, LAN2, VLAN in the failover mode. However, the link-local address does not support the following:
  - IPv6 link local gateway for the MGMT interface.
  - IPv6 link local is not supported for addresses. It supported only for gateways.
- **VLAN Tag**: For a VLAN, enter the VLAN tag or ID. You can enter a number from 1 to 4094. Ensure that you configure the corresponding switch accordingly.
- **Port Settings**: From the drop-down list, choose the connection speed that you want the port to use. You can also choose the duplex setting. Choose **Full** for concurrent bidirectional data transmission or **Half** for data transmission in one direction at a time. Select **Automatic** to instruct the NIOS appliance to negotiate the optimum port connection type (full or half duplex) and speed with the connecting switch automatically. This is the default setting. You cannot configure port settings for vNIOS appliances.

8. Optionally, enter a new password and click **Next**. The password must be a single string (no spaces) that is at least four characters long.
9. Select the time zone of the Grid Master and indicate whether the Grid Master synchronizes its time with an NTP (Network Time Protocol) server.
   - If you choose to enable NTP, click the Add icon and enter the IP address of an NTP server. Entries may be an IPv4 or IPv6 address. You can enter IP addresses for multiple NTP servers.
   - If you choose to disable NTP, set the date and time for the appliance.
   - Click **Next**.
10. The last screen displays the settings you specified in the previous panels of the wizard. Verify that the information is correct and click **Finish**. The application restarts after you click **Finish**.
    Note that the *Grid Setup Wizard* provides options such as not changing the default password and manually entering the time and date. However, changing the password and using an NTP server improves security and accuracy (respectively), and so these choices are presented here.
    Record and retain this information in a safe place. If you forget the shared secret, you need to contact Infoblox Technical Support for help. When you add an appliance to the Grid, you must configure it with the same Grid name, shared secret, and VPN port number that you configure on the Grid Master.
11. Close the management window. The configuration for Node 1 is complete.

HA Master – Node 2

1. On your management system, open a new browser window, and connect to https://*ip_addr*, where *ip_addr* is the IP address of the LAN1 port on Node 2. IPv4 or IPv6 values are valid.
   When you enter an IPv6 address, enclose the address in square brackets (as in https://[ip_addr] or https://[2001:db8::256:ABCD:EF12:34:1].
2. Log in using the default username and password **admin** and **infoblox**.
3. Read the Infoblox *End-User License Agreement* (EULA), and then click **I Accept**.
   Note that if you want to view the privacy policy of Infoblox, then on the EULA screen, click **Infoblox Privacy Policy**. Grid Manager displays the policy on a new browser tab.
4. Click **OK**. The *Grid Setup* wizard appears.
5. On the first screen, select **Join Existing Grid** and click **Next**.

6. On the next screen, specify the Grid properties and click **Next**.
    - **Grid Name**: Enter a text string that the two appliances use to authenticate each other when establishing a VPN tunnel between them. This must match the Grid name you entered for Node 1.
    - **Grid Master's IP Address**: Enter the same VIP you entered for Node 1.
    - **Shared Secret**: Enter a text string that both appliances use as a shared secret to authenticate each other when establishing a VPN tunnel between them. This must match your entry in Node 1.
7. On the next screen verify the IP address settings of the member and click **Next**.
   The last screen displays the settings you specified in the previous panels of the wizard.
8. Verify that the information is correct and click **Finish**.
   The setup of the HA master is complete. From now on, when you make an HTTPS connection to the HA pair, use the VIP address.

The communication protocol for all the services in a dual mode (IPv4 and IPv6) HA Master is the same protocol as the one used for VRRP advertisements. For example, if you select **IPv4** in the **Send HA and Grid Communication over** field in step 2 of the *Grid Setup* wizard, then IPv4 is set as the communication protocol for all the services. However, you can override the communication protocol for all the services in a dual mode HA Master. For more information, see *Changing the Communication Protocol for a Dual Mode Appliance*.

Creating a Single Grid Master

Although using an HA master is ideal because of the hardware redundancy it provides, you can also use a single appliance as the Grid Master. You can create a single Grid Master in either IPv4, IPv6, or dual mode (IPv4 and IPv6). Infoblox recommends frequent backups if the Grid Master is a single appliance, and there is no Master Candidate. For information about which vNIOS appliance supports configuration as a single Grid Master, see *vNIOS Appliances*.

Setting up an appliance as a single Grid Master is very easy. If the appliance has the DNSone package with the Grid upgrade, it is already a Grid Master. You simply need to define the network settings for its LAN1 port. The various procedures for defining the network settings for the LAN1 port of a single independent appliance apply here as well. Therefore, you can use any of the following procedures to define the network settings for the LAN1 port of the appliance that you want to make a single Grid Master:

- **LCD**: See *Method 1 – Using the LCD*. (LCD configuration does not support IPv6 address entry.)
- **Console port**: See –*Method 2 – Using the CLI.*

You can also use the NIOS *Grid Setup Wizard* to create a single Grid Master. In addition to providing a simple method accompanied by helpful information, the setup wizard allows you to change the admin password and configure time settings for the appliance.

Using the Setup Wizard

To create a single Grid Master using the *Grid Setup Wizard,* complete the following:

1. Connect the power cable from the NIOS appliance to a power source and turn on the power.
2. Connect an Ethernet cable from the LAN1 port on the appliance to a switch on the network.
3. If you have not changed the default IP address (192.168.1.2/24) of the LAN1 port through the LCD or CLI—and the subnet to which you connect the appliance does not happen to be 192.168.1.0/24—put your management system in the 192.168.1.0/24 subnet and connect an Ethernet cable between your management system and the NIOS appliance.
4. Open a web browser and make an HTTPS connection to the IP address of the LAN1 port. To reach the default IP address, enter: **https://192.168.1.2*** .
   Several certificate warnings appear during the login process. This is normal because the preloaded certificate is self-signed (and, therefore, is not in the trusted certificate stores in your browser) and has the host name *www.infoblox.com,* which does not match the destination IP address you entered in step 3. To stop the warning messages from occurring each time you log in to the GUI, you can generate a new self-signed certificate or import a third-party certificate with a common name that matches the FQDN (fully qualified domain name) of the appliance. For information about certificates, see *Managing Certificates.*
5. Log in using the default username **admin** and password **infoblox**.
6. Read the Infoblox *End-User License Agreement*, and then click **I Accept**. Note that if you want to view the privacy policy of Infoblox, then click **Infoblox Privacy Policy**. Grid Manager displays the policy on a new browser tab.

7. Click **OK**. The *Grid Setup Wizard* appears.
8. On the first screen, select **Configure a Grid Master** and click **Next**.
9. On the next screen, specify the Grid properties and click **Next**:
    - **Grid Name**: Enter a text string that the Grid Master and appliances joining the Grid use to authenticate each other when establishing a VPN tunnel between them. The default Grid name is **Infoblox**.
    - **Shared Secret**: Enter a text string that the Grid Master and appliances joining the Grid use as a shared secret to authenticate each other when establishing a VPN tunnel between them. The default shared secret is **test**.
    - **Confirm Shared Secret**: Enter the shared secret again.
    - **Hostname:** Enter a valid domain name for the appliance.
    - **Type of Network Connectivity**: Select the type of network connectivity for the Grid Master from the drop-down list:
        - **IPv4 and IPv6**: Select this to configure a dual mode Grid Master.
        - **IPv4**: Select this to configure an IPv4-only Grid Master.
        - **IPv6**: Select this to configure an IPv6-only Grid Master.
          Note:
            - Infoblox recommends that you back up the configuration after you convert a Grid to a different mode.
            - Restoring the old backup by performing a forced restore, may prevent the Grid members from rejoining the Grid Master after the restore.
    - **Is the Grid Master an HA pair?**: Select **No**.
10. On the next screen, configure the network settings and click **Next**:
    a. **Ports and Addresses**: This table lists the network interfaces based on the type of network connectivity of the Grid Master. For IPv4 Grid Master, specify the network information for LAN1 (IPv4) port and for IPv6 Grid Master, specify the network information for LAN1 (IPv6) port. For a dual mode Grid Master, specify the network information for both LAN1 (IPv4) and LAN1 (IPv6).
    Enter correct information for the following by clicking the field:
        - **Interface**: Displays the name of the interface. You cannot modify this.
        - **Address**: Type the IPv4 or IPv6 address depending on the type of interface. An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight 16-bit groups of hexadecimal digits separated by colons (example: 2001:db8:0000:0123:4567:89ab:0000:cdef or 2001:db8::123:4567:89ab:0:cdef).
        - **Subnet Mask (IPv4) or Prefix Length (IPv6)**: Specify an appropriate subnet mask for the IPv4 address or prefix length for the IPv6 address. The prefix length ranges from 2 to 127.
        - **Gateway:** Type the IPv4 or IPv6 address of the default gateway depending on the type of interface. For the IPv6 interface, you can also type **Automatic** to enable the appliance to acquire the IPv6 address of the default gateway and the link MTU from router advertisements.
          Note that you can now define a link-local address as the default IPv6 gateway and isolate the LAN segment, so the local router can provide global addressing and access to the network and Internet. For information about the link-local address limitations, see the **Gateway** field description in the *HA Master – Node 1* section.
        - **VLAN Tag**: For a VLAN, enter the VLAN tag or ID. You can enter a number from 1 to 4094. Ensure that you configure the corresponding switch accordingly.
        - **Port Settings**: From the drop-down list, choose the connection speed that you want the port to use. You can also choose the duplex setting. Choose **Full** for concurrent bidirectional data transmission or **Half** for data transmission in one direction at a time. Select **Automatic** to instruct the NIOS appliance to negotiate the optimum port connection type (full or half duplex) and speed with the connecting switch automatically. This is the default setting. You cannot configure port settings for vNIOS appliances.
11. Optionally, enter a new password and click **Next**. The password must be a single alphanumeric string (no spaces) that is at least four characters long. The password is case-sensitive.
12. Select the time zone of the Grid Master and indicate whether the Grid Master synchronizes its time with an NTP (Network Time Protocol) server, and then click **Next**.
    - If you choose to enable NTP, click the Add icon and enter the IP address of an NTP server. Entries may be an IPv4 or IPv6 address. You can enter IP addresses for multiple NTP servers.
    - If you choose to disable NTP, set the date and time for the appliance.
13. The last screen displays the settings you specified in the previous panels of the wizard. Verify that the information is correct and click **Finish**. The application restarts after you click **Finish**.

Note
The *Grid Setup* wizard provides options such as not changing the default password and manually entering the time and date. However, changing the password and using an NTP server improves security and accuracy (respectively), and so these choices are presented here.

Record and retain this information in a safe place. If you forget the shared secret, you need to contact Infoblox Technical Support for help. When you add an appliance to the Grid, you must configure it with the same Grid name, shared secret, and VPN port number that you configure on the Grid Master.

The last screen of the setup wizard states that the changed settings require the appliance to restart. When you click **Finish**, the appliance restarts.

The setup of the single master is complete. From now on, when you make an HTTPS connection to the appliance, use its new IP address.

In a dual mode Grid Master, the communication protocol for all the services is set to IPv4, by default. You can change the default communication protocol for the services. For information, see *Changing the Communication Protocol for a Dual Mode Appliance*.

About Grids

A Grid is a group of two or more NIOS appliances that share sections of a common, distributed, built-in database and which you configure and monitor through a single, secure point of access: the Grid Master. A Grid can include Infoblox appliances and vNIOS appliances. A vNIOS appliance is a non-Infoblox hardware platform running the vNIOS software package. For supported vNIOS platforms, see *vNIOS Appliances*.
Infoblox appliances support both IPv4 and IPv6 networks and you can configure a Grid in one of the following modes:

- **IPv4-only**: An IPv4-only Grid uses IPv4 as the Grid communication protocol and it includes an IPv4 Grid Master and the Grid members, which can be either IPv4 or dual mode (IPv4 and IPv6) independent and HA appliances. Note that when you add a dual mode HA member to an IPv4-only Grid, the communication protocol between the two nodes of an HA pair must be IPv4.
- **IPv6-only**: An IPv6-only Grid uses IPv6 as the Grid communication protocol and it includes an IPv6 Grid Master and the Grid members, which can be either IPv6 or dual mode (IPv4 and IPv6) independent and HA appliances. Note that when you add a dual mode HA member to an IPv6-only Grid, the communication protocol between the two nodes of an HA pair must be IPv6.
- **IPv4 and IPv6 (Dual mode)**: A dual mode Grid can use either IPv4 or IPv6 as the Grid communication protocol. A dual mode Grid includes a dual mode Grid Master and the Grid members, which can be either IPv4, IPv6, or dual mode independent and HA appliances.

Note

Infoblox appliances support IPv4 and IPv6 networking configurations in most deployments cited in this chapter. You can set the LAN1 port to an IPv6 address and use that address to access Grid Manager. All HA (high availability) operations can be applied across IPv6. Topics in this and following chapters generally use IPv4 examples. Also note that the LAN2, MGMT, and VLAN ports also support IPv6. DNS services are fully supported in IPv6 for the LAN1, LAN2, MGMT, and VLAN ports. DHCP services are fully supported in IPv6 for the LAN1 and LAN2 ports. Examples throughout this chapter use IPv4 addressing. Interfaces on NIOS appliances support both IPv4 and IPv6 transports and intra-Grid communication is based on the type of IP address used by the Grid member to join the Grid.

The following table summarizes the possible setups of a Grid configuration:

Possible Setups of Grid configuration

Grid Configuration	VRRP Protocol for HA Pair	Grid Communication Protocol	Grid Connection via MGMT	Additional IPv4 Addresses	Additional IPv6 Addresses
IPv4 Grid Master	IPv4	IPv4	NA	Yes	Yes
IPv6 Grid Master	IPv6	IPv6	NA	Yes	Yes
Dual mode Grid Master	IPv4 or IPv6	IPv4 or IPv6	NA	Yes	Yes
IPv4 Grid member	IPv4	IPv4	IPv4	Yes	Yes
IPv6 Grid member	IPv6	IPv6	IPv6	Yes	Yes
Dual mode Grid member	IPv4 or IPv6	IPv4 or IPv6	IPv4 or IPv6	Yes	Yes

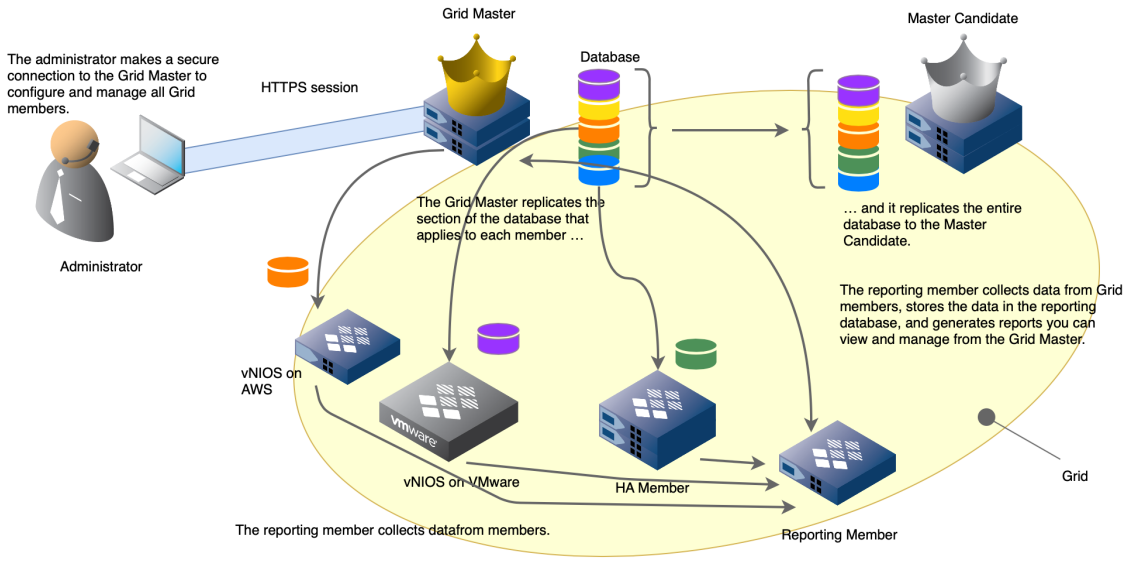
> ⚠ Note
>
> Infoblox recommends that appliances with disk sizes below 250 GB must not be configured as Grid Masters.

You can also add supported Reporting platforms as a logging and reporting devices in your Grid. Infoblox provides a few Infoblox platforms that you can use as the logging and reporting device. For information about the supported appliances, see *Configuring Reporting Clustering*. Infoblox reporting solution supports both IPv4 and IPv6 networks and you can configure a reporting member in either IPv4, IPv6, or in dual mode (IPv4 and IPv6) network environment. An IPv4-only Grid uses IPv4 as the Grid communication protocol, so you can add an IPv4 or dual mode reporting member to an IPv4-only Grid. An IPv6-only Grid uses IPv6 as the Grid communication protocol, so you can add an IPv6 or dual mode reporting member to an IPv6-only Grid. However, a dual mode Grid can use either IPv4 or IPv6 as the Grid communication protocol, so you can add an IPv4, IPv6, or a dual mode reporting member to a dual mode Grid. The reporting appliance collects data from members in the Grid and stores the data in the database. It then uses the data to generate predefined and user-defined reports that you can access through Grid Manager. These reports provide useful information about the IPAM, DNS, DHCP, and system activities and usage in your Grid. For more information about reporting, see *Infoblox Reporting and Analytics*.

Instead of manually provisioning IP addresses and DNS name spaces for network devices and interfaces, you can add Cloud Platform Appliances to leverage DNS and DHCP features of the Grid to manage your CMPs (Cloud Management Platforms). For information about the Infoblox Cloud Network Automation solution and supported Grid configurations, see *Deploying Cloud Network Automation*.

The following figure shows the basic concept of a Grid, database distribution (or "replication"), and reporting.

Grid and Partitioned Database Replication

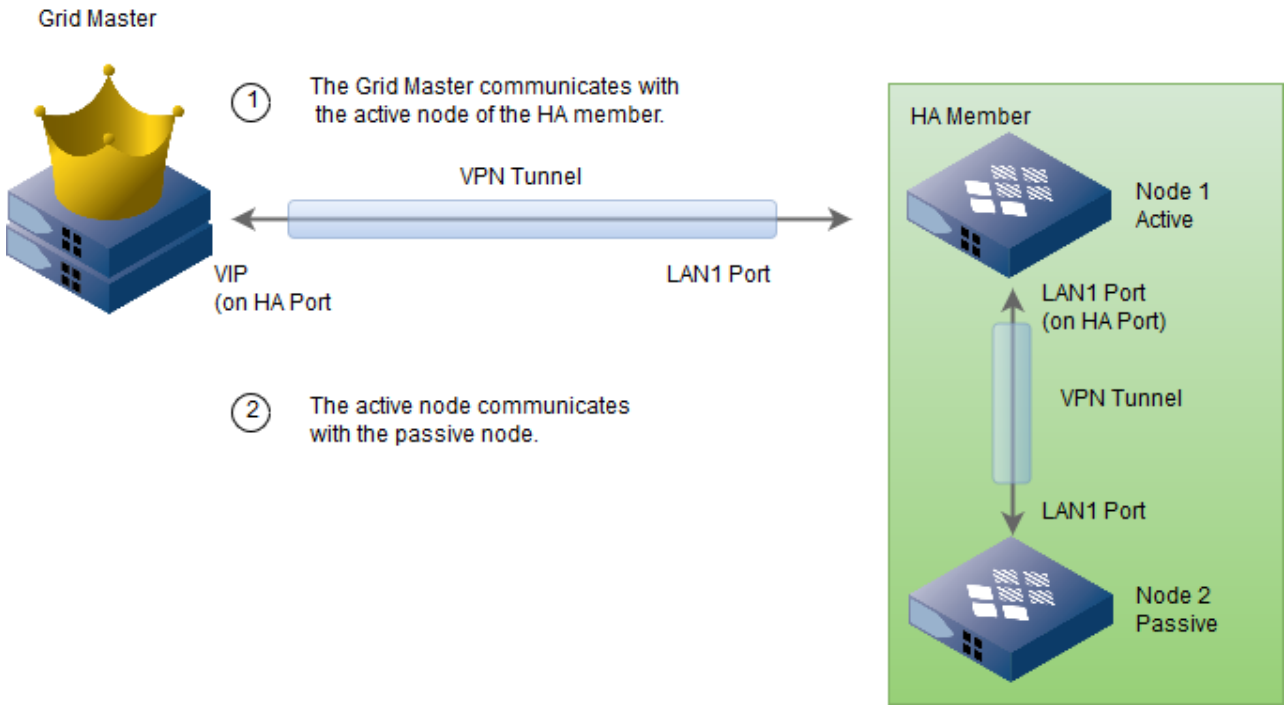


Note: In addition to the HTTPS session securing administrative traffic to theGrid Master, all Grid communications between the Grid Master and Grid members pass through encrypted VPN tunnels (not shown).

The Grid Master can be either an HA master or a single master; that is, an HA (high availability) pair or a single appliance. Similarly, a Grid member can be either a single member or an HA member. You can add single appliances and HA pairs to a Grid, forming single members and HA members respectively. A single Grid member can be either an Infoblox appliance or a vNIOS appliance. An HA Grid member can be a pair of Infoblox appliances or vNIOS appliances. For information, see *vNIOS Appliances*.

The Grid Master communicates with every Grid member in a hub-and-spoke configuration. Intra-Grid communication is based on the type of IP address used by the Grid member to join the Grid Master. An IPv4-only Grid Master uses IPv4 and an IPv6-only Grid Master uses IPv6 for intra-Grid communication. However, a dual mode Grid Master uses either IPv4 or IPv6 depending on the IP address type used by the Grid member to join the Grid Master. For an HA member, the Grid Master communicates with the active node, which in turn communicates with the passive node, as shown in the following figure.

Grid Communications to an HA Member



When adding vNIOS appliances to a Grid, you centralize the management of core network services of the virtual appliances through the Grid Master. vNIOS appliances support most of the features of the Infoblox NIOS software, with some limitations as described in *vNIOS Appliances*.

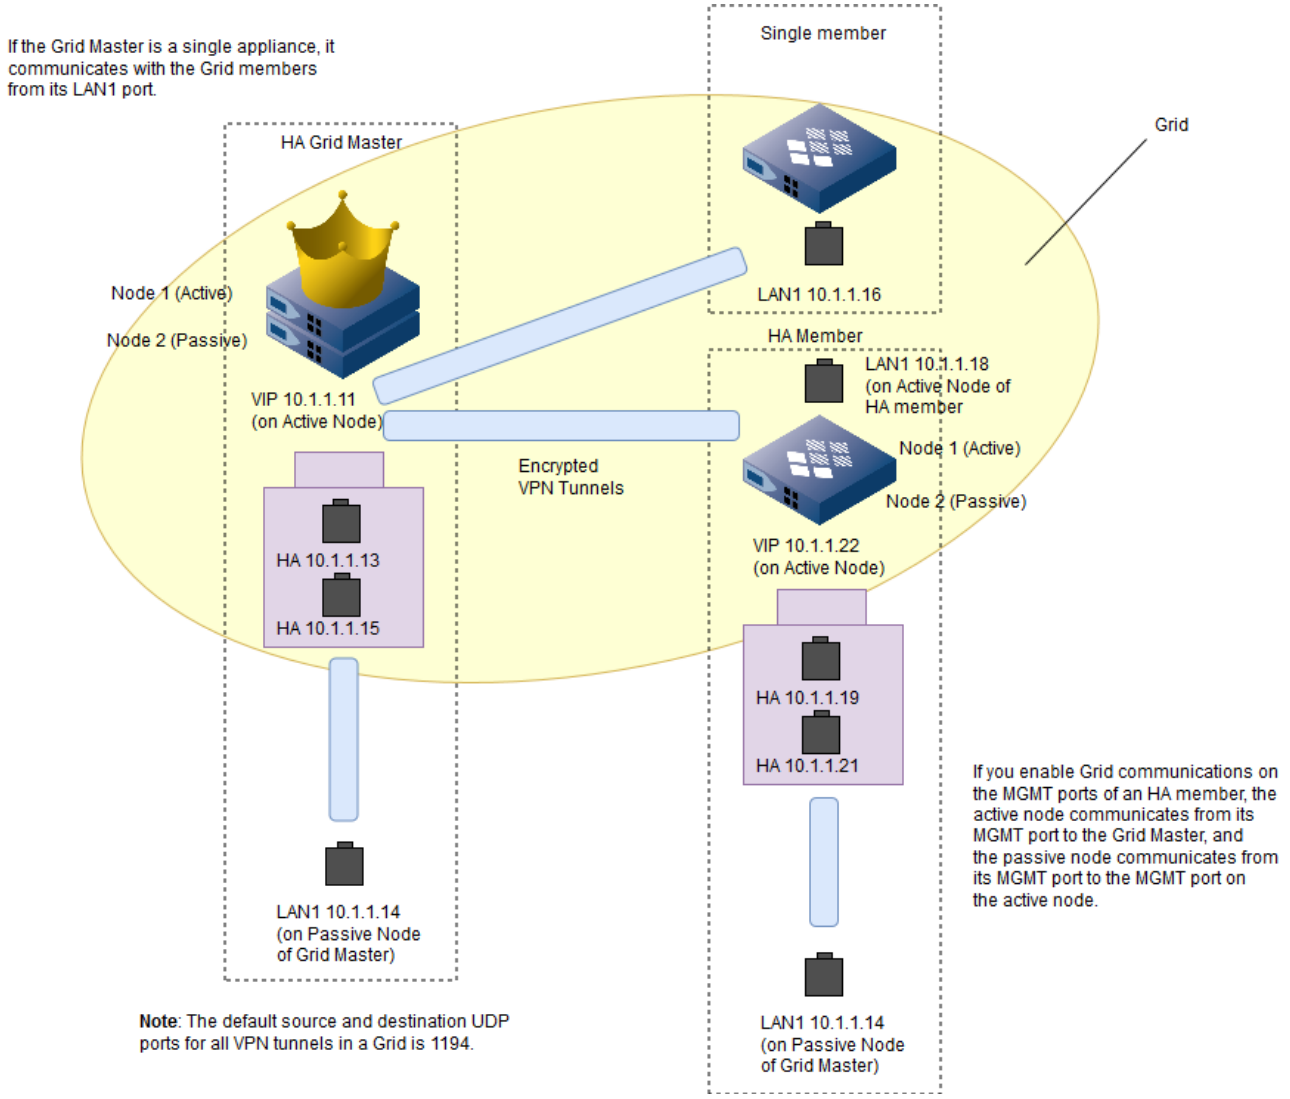
By default, Grid communications use the UDP transport with a source and destination port of 1194. This port number is configurable. For a port change to take effect, one of the following must occur: the HA master fails over, the single master reboots, or the Grid restarts services.
After adding an appliance or HA pair to a Grid, you no longer access the Infoblox GUI on that appliance. Instead, you access the GUI running on the Grid Master. Although you can create multiple administrator accounts to manage different services on various Grid members, all administrative access is through the Grid Master. So even if someone has administrative privileges to a single Grid member, that administrator must access the GUI running on the Grid Master to manage that member.
You can access the Infoblox GUI through an HTTPS connection to one of the following IP addresses and ports on the Grid Master:

- The VIP address, which links to the HA port on the active node of an HA Grid Master
- The IP address of the LAN1 port on a single Grid Master
- The IP address of the MGMT port (if enabled) of the active node of an HA or single Grid Master. See *Using the MGMT Port*.

Grid Communications

The Grid Master synchronizes data among all Grid members through encrypted VPN tunnels. The default source and destination UDP port number for VPN tunnels is 1194. You can continue using the default port number or change it. For example, if you have multiple Grids, you might want each Grid to use a different port so that you can set different firewall rules for each. Whatever port number you choose to use for the VPN tunnels in a Grid, all the tunnels in that Grid use that single port number.
Before an appliance or HA pair forms a tunnel with the master, they first authenticate each other using the Challenge-Response Authentication Mechanism (CRAM). The source and destination port number for this traffic is 2114. During the CRAM handshake, the master tells the appliance or HA pair what port number to use when building the subsequent VPN tunnel.

VPN Tunnels within a Grid



Another type of traffic, which flows outside the tunnels, is the VRRP (Virtual Router Redundancy Protocol) advertisements that pass between the active and passive nodes in an HA pair. The VRRP advertisements act like heartbeats that convey the status of each node in an HA pair. If the active node fails, the passive node becomes active. The VIP (virtual IP) address for that pair then shifts from the previously active node to the currently active node.

Master Grids

A Master Grid provides centralized management of multiple Grids. When a Grid is managed by a Master Grid, the Master Grid icon appears on the left side of the top panel of Multi-Grid Manager. Assuming you have permission, you can click this icon to access Multi-Grid Manager. In addition, the Toolbar provides several functions for joining the Master Grid, editing its properties and leaving the Master Grid. For more information about the Master Grid and these functions, refer to the *Multi-Grid Manager Administrator Guide*.

About HA Pairs

You can configure two appliances as an HA (high availability) pair to provide hardware redundancy for core network services and Infoblox Advanced DNS Protection. For more information, see *About Infoblox Advanced DNS*

Protection. An HA pair can be a Grid Master, a Grid Master candidate, a Grid member, or an independent appliance. An HA pair can also comprise a physical appliance and a virtual appliance, two physical appliances, or two virtual appliances. The two nodes that form an HA pair—identified as Node 1 and Node 2—are in an active/passive configuration. The active node receives, processes, and responds to all service requests. The passive node constantly keeps its database synchronized with that of the active node, so it can take over services if a failover occurs. A failover is the reversal of the active/passive roles of each node; that is, when a failover occurs, the previously active node becomes passive and the previously passive node becomes active. You can configure an HA pair in either IPv4, IPv6, or in dual mode. An IPv4 HA pair uses IPv4 as the communication protocol between the two nodes and an IPv6 HA pair uses IPv6 as the communication protocol between the two nodes. But in a dual mode HA pair, you can select either IPv4 or IPv6 as the communication protocol between the two nodes. Note that when you add a dual mode HA member to a Grid, the communication protocol between the two nodes of an HA pair must the same as the Grid communication protocol.

⚠ Note

HA Grid Master and HA Grid Master Candidate configurations are not supported when Threat Protection licenses are installed on the appliance.

When you configure an HA pair using the IB-4030-10GE (Rev-1 or Rev-2) appliance for DNS cache acceleration, the passive node does not operate with a pre-loaded cache or hot cache during a failover; it builds up the DNS cache over time. For more information about HA and other limitations for the IB-4030-10GE appliances, refer to the *Infoblox DNS Cache Acceleration Application Guide*. For Infoblox , only the active node in an HA pair handles DNS traffic. The passive node is in a standby mode ready to take over if a failover occurs.
The appliance uses the following components in the HA functionality:

- bloxSYNC: An Infoblox proprietary mechanism for secure, real-time synchronization of the database that maintains the data, system configuration, and protocol service configuration between the two nodes. With bloxSYNC, the nodes continuously synchronize changes of their configurations and states. When a failover occurs, the passive node can quickly take over services. For information, see About HA Failover below.
- VRRP (Virtual Router Redundancy Protocol): An industry-standard, MAC-level HA failover mechanism. VRRP utilizes the concept of an active and passive node that share a single VIP (virtual IP) address. When the active node that owns the VIP becomes unavailable, the passive node takes over the VIP and provides network core services. For information about VRRP, refer to *RFC3768,Virtual Router Redundancy Protocol (VRRP)* and see VRRP Advertisements below.

Using bloxSYNC and VRRP combined, if the active node fails or is taken offline for maintenance purposes, the passive node assumes the VIP and continues to respond to requests and services with minimal interruption. You can deploy an HA pair as a Grid Master, a Grid member, or an independent HA. To deploy an independent HA pair, see *Deploying an Independent HA Pair*. To deploy an HA Grid Master, see *Creating a Grid Master*.

Planning for an HA Pair

To achieve high availability, the HA and LAN1 (or VLAN) ports on both the active and passive nodes are connected to switches on the same network or VLAN. Both nodes in an HA pair share a single VIP address and a virtual MAC address so they can appear as a single entity on the network. You can also assign IPv6 addresses for each of the active and passive nodes, in addition to the IPv6 VIP address.

⚠ Note

- Infoblox uses VRRP advertisements for the active and passive HA design. Therefore, all HA pairs must be located in the same location connected to the highly available switching infrastructure. Any other deployment is not supported without a written agreement with Infoblox. Contact Infoblox Technical Support for more information about other deployment support.
- You can enable ARP on the passive node of an HA pair and monitor its status externally. To enable ARP on the passive node of an HA pair, see Enabling ARP on the Passive Node of an HA Pair below.

In HA, each node must configure two addresses: the VRRP public address on the LAN1 interface and the VRRP HA address on the HA interface. An HA pair consists of a set of five IP addresses, all of which must belong to the same subnet. Each device in an HA pair joins the multicast address on both the HA and public interfaces.

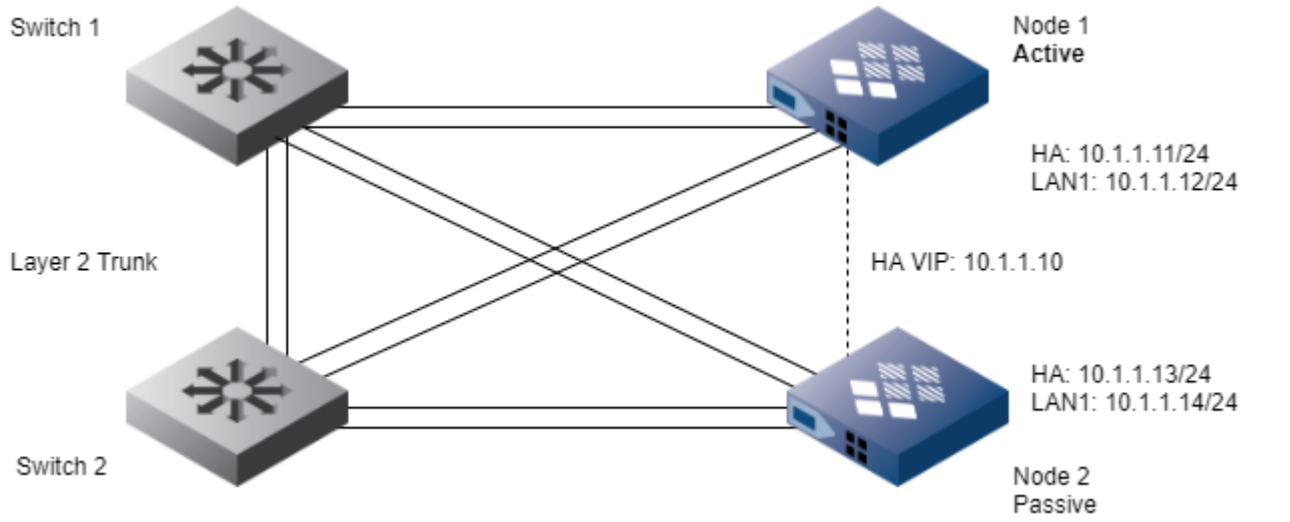
As illustrated in the following figure, the VIP and virtual MAC addresses link to the HA port on each node. Select five IP addresses on the same network before you configure an HA pair, as follows:

- VIP: For core network services and for management purposes when the MGMT port is disabled. Both nodes share the same VIP. The VIP is the true public address in which services and daemons are active.
- Node 1 HA (active): Source IP for the VIP and VRRP advertisements. Listens on both its LAN and HA ports. For an active HA node, both the LAN interface/address and the HA interface/address belong to the VRRP multicast group.
- Node 1 LAN1 (active): For management through SSHv2 and listens for VRRP advertisements from the HA port.
- Node 2 HA (passive): Listens for VRRP advertisements on the LAN port. For a passive HA node, only the LAN interface/address belongs to the VRRP multicast group (using the LAN port's MAC address).
- Node 2 LAN1 (passive): Source IP for SSL VPN to the VIP of the active node and receives bloxSYNC from the VIP.

> **Note**
>
> An HA member connecting to the GRID Master over the Management port should have the LAN1 or HA ports connected to different physical switches to make sure the VRRP packets are exchanged correctly between the active and passive nodes. If the LAN1 or HA ports are connected to the same physical switch, you must configure the LAN1/LAN2 bonding to exchange the VRRP packets between the active and passive nodes.

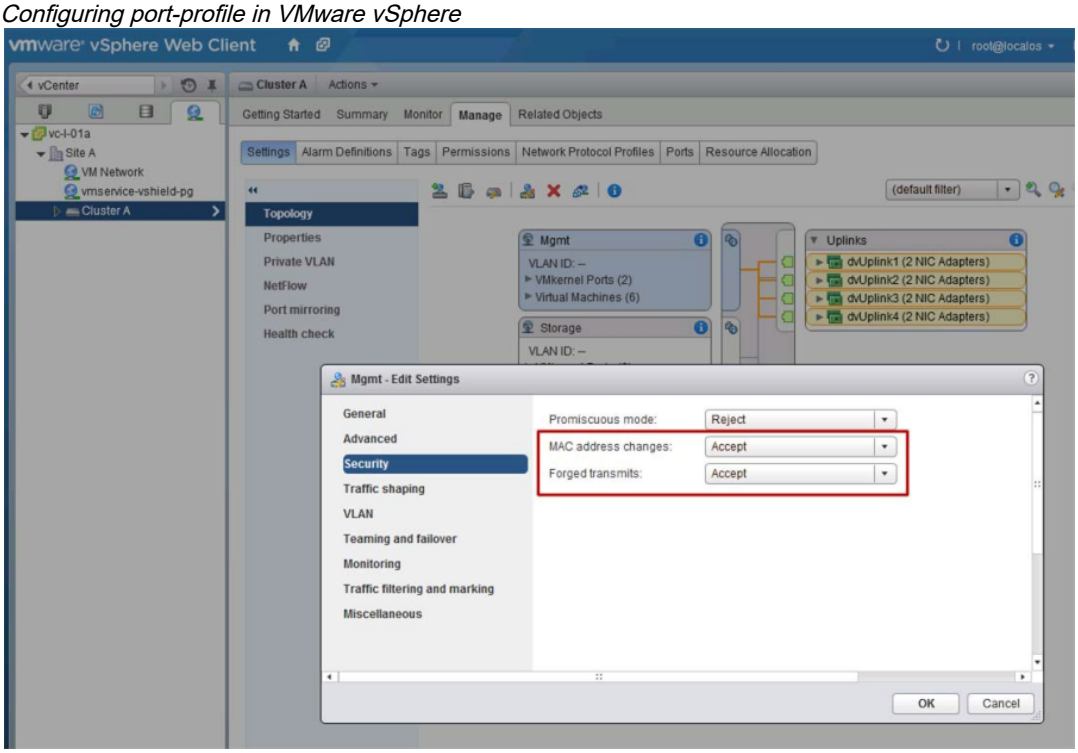
The above configuration holds good only for IPv4 VRRP configurations. IPv6 VRRP configurations require only three addresses: the VIP and the LAN1 interfaces. For the IPv6 dedicated HA interfaces, NIOS uses the link local IPv6 address which you do not need to provide.

HA Pair



When you deploy a vNIOS HA pair, ensure that the port connection allows for more than one MAC address per vNIC. For example, if you deploy a vNIOS HA pair in VMware vSphere, the port-profile to which the vNIOS HA and LAN ports connect should allow for more than one MAC address per vNIC. You can do this by changing the security settings of the port-group to accept "MAC address changes" and "Forged transmits," as illustrated in the following figure.

Configuring port-profile in VMware vSphere



Limitations of Using a Combination of a Physical Appliance and a Virtual Appliance for HA

Although you can use a combination of a physical and virtual appliance for an HA pair, using the deployment has the following limitations:

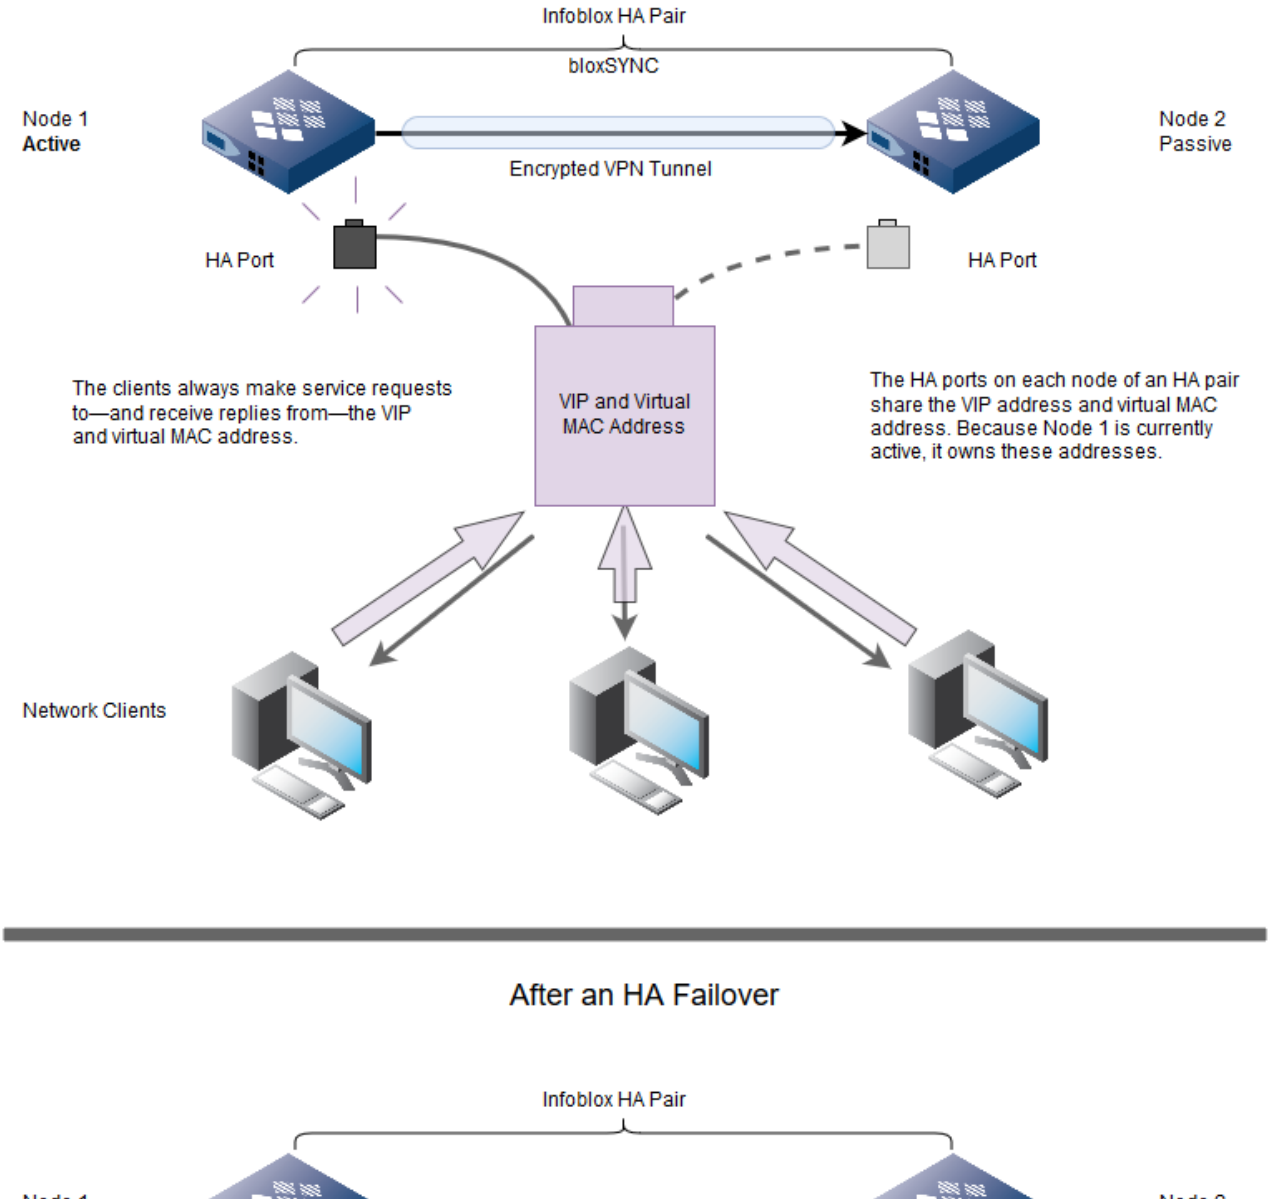
- Check whether the NIOS licenses that you subscribed to support both physical and virtual appliances.
- Ensure that the same licenses are installed on both the physical appliance and the virtual appliance.
- You cannot have tagged and untagged interfaces on the same subnet on VMware ESXi hypervisors.
- Virtual appliances do not support tagging.
- LOM (Lights Out Management) is not supported in a hybrid HA setup.
- DSCP (Differentiated Services Code Point) services are not supported on virtual appliances. Therefore, you cannot configure the DSCP value in an HA setup.
- Because port settings are not available for virtual appliances, you cannot join a node if the port settings are overridden.
- You cannot combine a platform on which Advanced DNS Protection hardware is running with a platform on which Advanced DNS Protection Software is running.
- You cannot configure MTU (Maximum Transmission Unit) in a hybrid HA setup.
- You cannot have a combination of an IB-FLEX and a non IB-FLEX appliance.
- Auto-provisioning is not supported on virtual appliances; therefore, you cannot use the auto-provisioning feature in a hybrid HA setup.
- A hybrid HA setup may cause some performance impact because hybrid HA performance depends on many factors such as the hardware on which the VM is running, the number of VMs contending for the same CPU, RAM, input/output resources, and the overhead generated by the virtualisation layer.
- Minor performance differences are expected between the two nodes of a hybrid HA pair. Hybrid HA performance may vary, and it depends on the hardware components on which different virtualization platforms are running and the performance delivered by Infoblox hardware appliances. Different use cases will produce different numbers (slightly increased or decreased CPU usage, disk access time, and so on). Such performance variation is expected and is not a cause of concern.

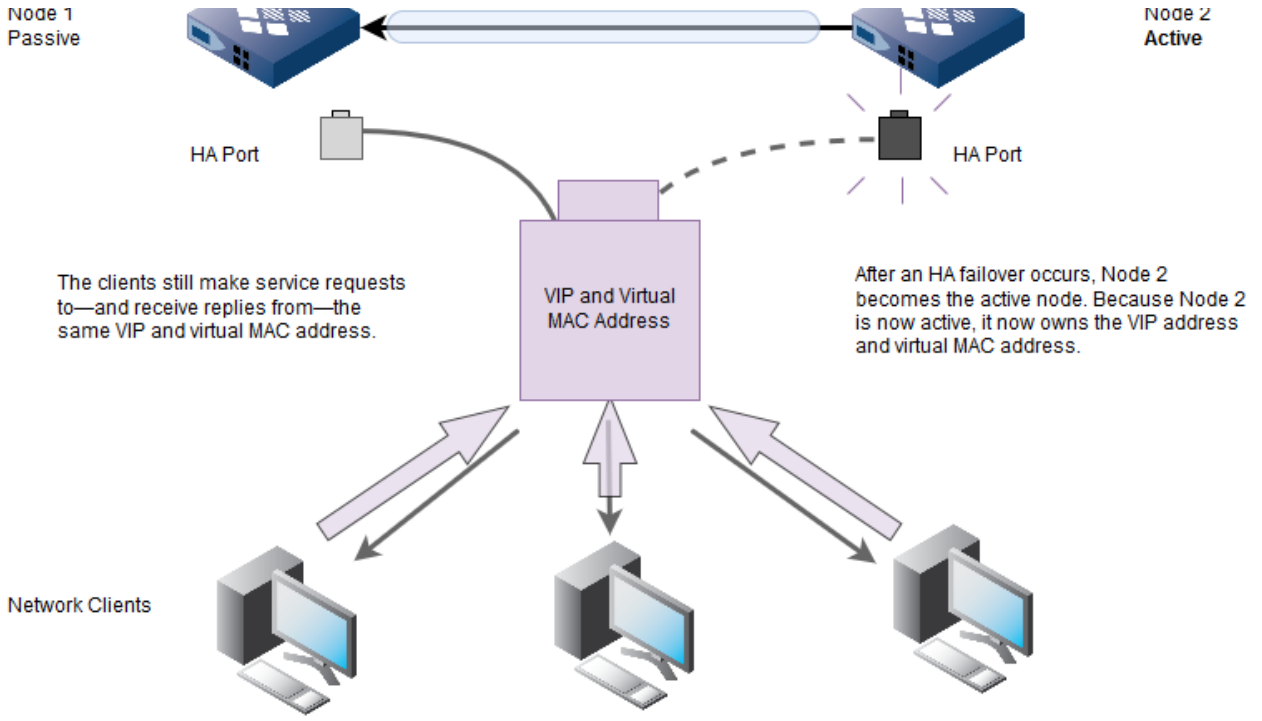
About HA Failover

The appliance supports HA through bloxHA™, which provides a robust failover mechanism. As described in Planning for an HA Pair, both nodes in an HA pair share a single VIP address and a virtual MAC address. The node that is currently active is the one whose HA port owns the VIP address and virtual MAC address. When a failover occurs, these addresses shift from the HA port of the previous active node to the HA port of the new active node, as illustrated in the figure below.

> **Note**
> For a vNIOS HA pair, you must configure both LAN1 and HA interfaces to operate. When there is a notification about failure in any one of the port, make sure that both of these ports are working. If one of the port is down and another port is still working, the HA pair believes its peer is active. But, there will be connectivity issues as one of the port is down. An HA failover occurs on vNIOS appliances only when both of these ports are down. For details about configuring these virtual NICs, refer to the *Infoblox Installation Guide* vNIOS *for VMware*.

VIP Address and Virtual MAC Address and HA Failover





Enabling ARP on the Passive Node of an HA Pair

You can enable ARP (Address Resolution Protocol) on the passive node of an HA pair and monitor its status externally. For example, when the active node of an HA pair fails over to the passive node, you can ping the passive node from an external location and monitor its status. By default, ARP is disabled on the passive node of an HA pair. ARP settings on an HA member are preserved during a system restart or reboot, HA switch over, and upgrade. In addition, you do not need to restart the appliance when you modify ARP settings. When the active node becomes passive during an HA failover, ARP on an HA member inherits the settings configured in the database.

You can view detailed status for both nodes of an HA pair through the *Detailed Status* panel. To view the *Detailed Status* panel, from the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox -> Detailed Status icon in the horizontal navigation bar. In the *Detailed Status* panel, you can view ARP connectivity status for the passive node of an HA pair (Green = The passive HA node is connected to the local router; Yellow = The passive HA node fails to connect to the local router; Gray = ARP is disabled on the passive node of an HA pair). The passive HA node uses arping to test the ARP connectivity with the local router. If the local router is not configured, you may see false warnings even if the ARP connectivity is fine. In case of an ARP connectivity failure, the appliance sends an SNMP trap and an email notification, if configured.
Note that the ARP setting is not preserved on a passive HA node when you reset the appliance using the CLI command reset all or reset the database using the CLI command reset database.

To enable ARP on an HA passive node:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
2. Select an HA member and click the Edit icon.
3. In the *Grid Member Properties* editor, select the **Network** tab -> **Advanced** tab and complete the following:
    - **Enable ARP on HA Passive Node?**: Select one of the following:
        - **Disable (default)**: Select this to disable ARP on an HA passive node. This is selected by default.
        - **Enable (not recommended)**: Select this to enable ARP on an HA passive node.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

⚠ Note

For the Grid having an HA Grid Master and the **Enable ARP on HA Passive Node?** option enabled, if you try to restore from the HA Grid Master to a single node Grid Master the Grid breaks the configuration and if you try to recover the configuration the system becomes unusable. However, you can recover the configuration by resetting the database.

Warning
Enabling ARP on the passive node of an HA interface might affect VRRP on the local network and could cause the firewall to send false alerts.

HA failover on DNS Nameservers

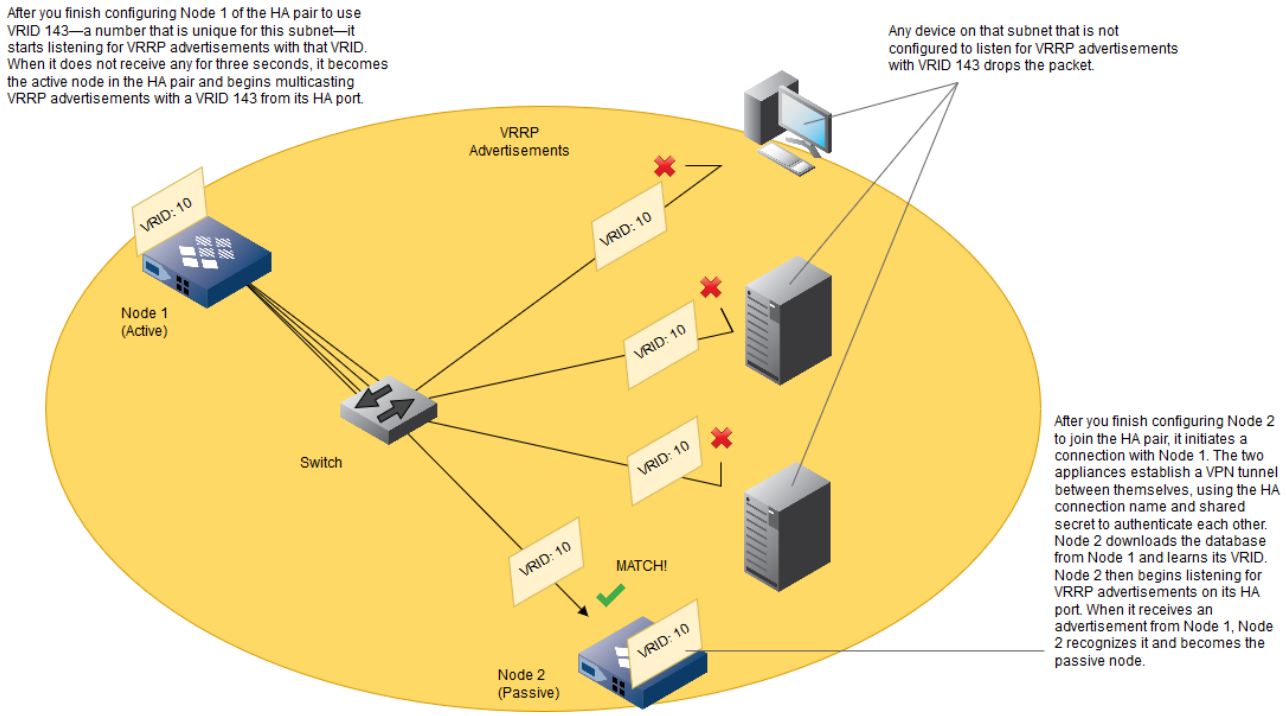
When an HA failover occurs on NIOS, there is an approximate 4-5 second time interval in which the network is adjusted for the new active node and the new passive node. During this failover period, the active node becomes unresponsive. After the new active node comes up on the network, the DNS service loads all Response Policy Zone (RPZ) files if RPZ is configured. The larger the RPZ files, the longer it takes to load them, and the longer it takes the DNS service to start serving DNS. For example, on a TE-1425 with RPZs that contain 15 million resource records, it can take approximately one and a half minutes to start serving DNS.

If your nameserver uses Grid replication to keep internal zones up to date and is not configured to use RPZ, then the delay before the DNS service starts serving DNS is slightly longer that it is for the HA failover itself.

VRRP Advertisements

VRRP advertisements are periodic announcements of the availability of the HA node linked to the VIP. The two nodes in an HA pair include a VRID (virtual router ID) in all VRRP advertisements and use it to recognize VRRP advertisements intended for themselves. Only another appliance on the same subnet configured to use the same VRID responds to the announcements. The active node in an HA pair sends advertisements as multicast datagrams every second. It sends them from its HA port using the source IP address of the HA port (not from the VIP address) and the source MAC address 00:00:5e:00:01:vrrp_id. The last two hexadecimal numbers in the source MAC address indicate the VRID number for this HA pair. For example, if the VRID number is 143, then the source MAC address is 00:00:5e:00:01:8f (8f in hexadecimal notation = 143 in decimal notation).
The destination MAC and IP addresses for all VRRP advertisements are 00:00:5e:00:01:12 and 224.0.0.18 (00:00:5e:00:02:12 and FF02::12 for IPv6 only configurations). Because a VRRP advertisement is a multicast datagram that can only be sent within the immediate logical broadcast domain, the nodes in an HA pair must be in the same subnet together.
As illustrated in the figure below, when you configure an HA pair, only the appliance configured to listen for VRRP advertisements with the same VRID number processes the datagrams, while all other appliances ignore them. The passive node in an Infoblox HA pair listens for these on its HA port and the active node listens on its LAN1 or LAN1 (VLAN) port. If the passive node does not receive three consecutive advertisements or if it receives an advertisement with the priority set to 0 (which occurs when you manually perform a forced failover or request the active node to restart, reboot, or shut down), it changes to the active state and assumes ownership of the VIP address and virtual MAC address.
If both nodes go offline, the one that comes online first becomes the active node. If they come online simultaneously, or if they enter a dual-active state—that is, a condition arises in which both appliances assume an active role and send VRRP advertisements, possibly because of network issues—then the appliance with the numerically higher VRRP priority becomes the active node. The priority is based on system status and events.
If both nodes have the same priority, then the appliance whose HA port has a numerically higher IP address becomes the active node. For example, if the IP address of the HA port on Node 1 is 10.1.1.80 and the IP address of the HA port on Node 2 is 10.1.1.20, then Node 1 becomes the active node.
For more information about VRRP, see *RFC 3768, Virtual Router Redundancy Protocol (VRRP)*.

VRRP Advertisements with a Unique VRID



> **Note**
>
> For a dual mode (IPv4 and IPv6) HA Master or HA member, you can set either IPv4 or IPv6 for VRRP advertisements.
> The Grid members may restart all the services after the Grid Master has recovered from the dual-active state.

Adding Grid Members

Note

> You may provision a Port Reservation for the new Grid Member. When doing so, you select the device to which you expect the new Grid Member to connect; In the context of a Grid member, this device type is usually an Ethernet Switch or Switch-Router. The Add Grid Member Wizard provides a step in which you define the port reservation settings, as described in the following section Adding a Single Member. The process also can be applied when defining an HA pair, as described in the sections *Creating an HA Grid Master* and Adding an HA Member see below.

You can add single appliances and HA pairs to a Grid, forming single members and HA members, respectively. A single Grid member can be either an Infoblox appliance or a vNIOS appliance. You can configure Grid members in either IPv4, IPv6, or dual mode (IPv4 and IPv6). For information about which vNIOS appliance supports configuration as an HA Grid member, see *vNIOS Appliances*.
You can also define an HA member on the Grid Master and then add two individual NIOS appliances to the Grid as Node 1 and Node 2 to complete the HA member you defined on the master.
New members inherit all settings that you create at the Grid level unless you override them at the member level. You can also define port reservations for the network infrastructure devices to which the Grid members will connect.
The process for adding either a single appliance or HA pair to a Grid involves the following steps:

1. Adding and configuring Grid members on the Grid Master. In addition to defining the network and appliance settings for a member, you can also configure service settings before you join the member or HA pair to the Grid.

2. Reserving a port on a switch or switch-router for connectivity to the Grid member.
3. Joining the appliance or HA pair to the Grid. This includes defining the VIP or IP address of the Grid Master, the Grid name, and the shared secret on the single appliance or HA pair. If an appliance or HA pair cannot join the Grid because of MTU (maximum transmission unit) limitations on its network link, you can reduce the MTU that the master uses when communicating with it. See *Setting the MTU for VPN Tunnels*. If the Grid Master is behind a NAT device and there are members on both sides of that NAT device, you must create a NAT group, as described in *NAT Groups*.

In a large-scale deployment of Grids across multiple sites, consider remotely provisioning your Grid members before joining them to the Grid. For more information about this feature, see Auto-Provisioning NIOS Appliances.
In situations where you want to define certain configurations on an offline Grid member and associate DNS and DHCP data to the member before deploying it, you can use the pre-provisioning feature to accomplish this. For more information, see *Pre-Provisioning NIOS and vNIOS Appliances*.

Adding a Single Member

The basic steps necessary to add a single member are as follows:

1. Define the network settings of the LAN1 port of the single appliance on the Grid Master.
2. Initiate the join Grid operation during which you specify the VIP or IP address of the Grid Master, the Grid name, and the shared secret on the single appliance. For information, see Joining Appliances to the Grid below.

On the Grid Master, you can configure any service settings such as DNS zones and records, DHCP networks and address ranges, and other services for a member before or after you join the appliance to the Grid. The basic steps for adding a single member are presented in the following section.
For information on how to configure a vNIOS appliance as a Grid member, refer to the *Quick Start Guide for Installing vNIOS Software on VMware Platforms*.

Configuring a Single Member on the Grid Master

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
2. Expand the Toolbar and click **Add** -> **Add Grid Member**.
3. In the *Add Grid Member* wizard, enter the following and click **Next**:
    - **Member Type**: Specify the appliance type of the Grid member. If the member is an Infoblox appliance, select **Infoblox**, which is the default. For a vNIOS appliance, select **Virtual NIOS** for vNIOS virtual appliances, including cloud virtual appliances.
    - **Host Name**: Type the FQDN (fully qualified domain name) of the appliance that you are adding to the Grid. Ensure to use a host name containing characters (A-Z or a-z), numbers (0–9), ".", "-", and "_". Additional special characters cannot be used.
    - **Time Zone**: If the Grid member is in a different time zone from the Grid, click **Override** and select a time zone.
    - **Comment**: Type a comment that provides some useful information about the appliance, such as its location.
    - **Master Candidate**: Select this option to designate this appliance as a Master Candidate. For supported vNIOS appliances, see *vNIOS Appliances*.
4. Enter the following information about the member that you are adding to the Grid and click **Next**:

- **Type of Network Connectivity**: Select the type of network connectivity for the Grid member from the drop-down list:
    - **IPv4 and IPv6**: Select this to configure a dual mode Grid member.
    - **IPv4**: Select this to configure an IPv4 Grid member.
    - **IPv6**: Select this to configure an IPv6 Grid member.

  Note that Infoblox recommends that you back up the configuration after you convert a Grid to a different mode. Restoring the old backup by performing a forced restore, may prevent the Grid members from rejoining the Grid Master after the restore.
- **Standalone Member**: Select this option.
- **Required Ports and Addresses**: This table lists the network interfaces based on the type of network connectivity of the Grid member. For IPv4 Grid member, specify the network information for LAN1 (IPv4) port and for IPv6

Grid member, specify the network information for LAN1 (IPv6) port. For a dual mode Grid member, specify the network information for both LAN1 (IPv4), and LAN1 (IPv6).

Enter correct information for the following by clicking the field:

- **Interface**: Displays the name of the interface. You cannot modify this.
- **Address**: Type the IPv4 or IPv6 address depending on the type of interface. An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight 16-bit groups of hexadecimal digits separated by colons (example: 2001:db8:0000:0123:4567:89ab:0000:cdef or 2001:db8::123:4567:89ab:0:cdef).
- **Subnet Mask (IPv4) or Prefix Length (IPv6)**: Specify an appropriate subnet mask for IPv4 address or prefix length for IPv6 address. The prefix length ranges from 2 to 127.
- **Gateway:** Type the IPv4 or IPv6 address of the default gateway depending on the type of interface. For IPv6 interface, you can also type **Automatic** to enable the appliance to acquire the IPv6 address of the default gateway and the link MTU from router advertisements.
- **VLAN Tag**: For a VLAN, enter the VLAN tag or ID. You can enter a number from 1 to 4094. Ensure that you configure the corresponding switch accordingly.
- **Port Settings**: From the drop-down list, choose the connection speed that you want the port to use. You can also choose the duplex setting. Choose **Full** for concurrent bidirectional data transmission or **Half** for data transmission in one direction at a time. Select **Automatic** to instruct the NIOS appliance to negotiate the optimum port connection type (full or half duplex) and speed with the connecting switch automatically. This is the default setting. You cannot configure port settings for vNIOS appliances.
- **DSCP Value**: Displays the Grid DSCP value, if configured. To modify, click Override and enter the DSCP value. You can enter a value from 0 to 63. For information about DSCP, see *Configuring Ethernet Ports*.

5. In the Port Reservation page, do the following:

Begin by checking the Reserve Port checkbox. Note that reserving a switch port does not guarantee its availability once the device must connect. The port is automatically assigned for connectivity to the LAN1 port on the appliance.

Optionally, you can skip connecting port configuration by clicking Next. Click the **Clear** button to remove the selected device from the configuration.

- Click the Select Device button to choose the device for which the port reservation will be associated. You should know the identity of the device to which the Infoblox appliance will connect before taking this step. For Grid member connectivity, the chosen device should be either a switch or a switch-router.
- After choosing the device, choose the Interface with which the reservation will be bound. The drop-down list shows only interfaces that are most recently found to be available by Grid Manager during the last Discovery cycle. This list will not include any ports that are Administratively Up and Operationally Up or that are otherwise already assigned to other networks or Objects.
- The Wizard page also shows a list of any VLANs that are currently configured in the chosen device (**The following VLANs are configured**). This Wizard page does not allow the definition of new VLANs for port configuration–only the assignment of an existing VLAN in the device to your new port reservation. (Recall that you may specify the **VLAN Tag** across which Grid member traffic will travel, when you specified the Grid member information in Step 2 of the Wizard.)
- Check the Configure Port checkbox to define specific Port Control settings for the port reservation.
- Choose the Data VLAN and/or the Voice VLAN settings you may need for the port assignment. Depending on the selected device, the **Voice VLAN** field may or may not appear.
- Set the Admin Status to Up if you need to activate the port after assignment in the current task.
    - All Port Control operations require CLI credentials to be entered into Grid Manager. Because some IPAM and DHCP Objects will use Port Control features as part of object creation, CLI credentials are automatically leveraged as part of discovery. Ensure you have the correct sets of CLI credentials for devices in your network.
- Enter a Description for the port assignment. Infoblox recommends doing so to help other technicians to recognize the port assignment event.
- When finished, click Next to continue in the wizard.

6. Optionally, define extensible attributes. For information, see *About Extensible Attributes*.

7. The final step for adding a Grid member is to define when the associated Port Configuration task executes. You may execute it immediately or schedule it for another time and date.

- To create the new port configuration immediately, select Now. The port control task is automatically synchronized to take place at the same time as the activation of the new Grid member.
- You can choose to have Grid Manager execute the port control task at a later time. To do so, select Later. Choose a Selected time by entering or selecting a Start Date (click the calendar icon to choose a calendar date) and a Start Time, and choose a Time Zone.

8. Choose one of the following from the **Save &...** drop-down button menu:

- Click **Save & Close** to add the single member to the Grid and close the wizard (this is the default).
- Click **Save & Edit** to add the single member to the Grid and launch the editor. You can configure additional properties, such as the MTU size, or add the member to a NAT group.
- Click **Save & New** to add the single member to the Grid and launch the wizard again to add another member.

The communication protocol for all the services in a dual mode (IPv4 and IPv6) Grid member is set to IPv4, by default. You can change the default communication protocol for all the services. For information, see Communication Protocol for a Dual Mode Appliance below.

Adding an HA Member

The basic steps necessary to add an HA member are as follows:

1. Define the network settings of the HA pair on the Grid Master.
2. Initiate the join Grid operation, during which you specify the VIP or IP address of the Grid Master, the Grid name, and the shared secret on the HA pair. For information, see Joining Appliances to the Grid below.

In addition, on the Grid Master you can configure the service settings such as DNS zones and records, DHCP networks and address ranges, and so on for a member before or after you join the HA pair to the Grid. The basic steps for adding an HA member are presented below.

> ⚠ Note
>
> The procedure for adding an HA pair to a Grid when it uses the MGMT port of the active node for Grid communications differs slightly from that described below. See *Grid Communications.*

Configuring an HA Member on the Grid Master

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
2. Expand the Toolbar and click **Add** -> **Add Grid Member**.
3. In the *Add Grid Member* wizard, enter the following and click **Next**:
    - **Member Type**: Specify the appliance type of the Grid member. If the member is an Infoblox appliance, select Infoblox, which is the default. For a vNIOS appliance on VMware, select **Virtual NIOS**.
    - **Host Name:** Type the FQDN (fully qualified domain name) for the HA member. Ensure to use a host name containing characters (A-Z or a-z), numbers (0–9), ".", "-", and "_". Additional special characters cannot be used.
    - **Time Zone**: If you want the Grid member to have a different time zone, click **Override** and select a time zone.
    - **Comment**: Type a comment that provides some useful information about the appliance, such as its location.
    - **Master Candidate**: select this checkbox to designate this appliance as a Master Candidate. For supported vNIOS appliances, see *vNIOS Appliances*.
4. Enter the following information about the member that you are adding to the Grid and click **Next**:
    - **Type of Network Connectivity**: Select the type of network connectivity for the HA member from the drop-down list:
        - **IPv4 and IPv6**: Select this to configure a dual mode HA member.
        - **IPv4**: Select this to configure an IPv4 HA member.
        - **IPv6**: Select this to configure an IPv6 HA member.
    - **High Availability Pair**: Select this option.
        - **Virtual Router ID**: Enter a unique VRID number—from 1 to 255—for the local subnet.

- **Send HA and Grid Communication Over**: This field is displayed only when you are configuring a dual mode HA member. Select either **IPv4** or **IPv6** as the communication protocol for VRRP advertisements and for joining the Grid Master.
  Note that Infoblox recommends that you back up the configuration after you convert a Grid to a different mode.
  Restoring the old backup by performing a forced restore, may prevent the Grid members from rejoining the Grid Master after the restore.

- **Required Ports and Addresses**: This table lists the network interfaces based on the type of network connectivity. For IPv4 HA member, specify the network information for VIP (IPv4), Node1 HA (IPv4), Node2 HA (IPv4), Node1 LAN1 (IPv4), and Node2 LAN1 (IPv4) interfaces. For IPv6 HA member, specify the network information for VIP (IPv6), Node1 LAN1 (IPv6), and Node2 LAN1 (IPv6) interfaces.
  For a dual mode HA member, if you select **IPv4** in the **Send HA and Grid Communication over** field, specify the network information for the following interfaces: VIP (IPv4), Node1 HA (IPv4), Node1 LAN1 (IPv4), Node2 HA (IPv4), Node2 LAN1 (IPv4), VIP (IPv6), Node1 LAN1 (IPv6), and Node2 LAN1 (IPv6) interfaces.
  For a dual mode HA member, if you select **IPv6** in the **Send HA and Grid Communication over** field, specify the network information for the following interfaces: VIP (IPv4), Node1 LAN1 (IPv4), Node2 LAN1 (IPv4), VIP (IPv6), Node1 LAN1 (IPv6), and Node2 LAN1 (IPv6) ports.
  Enter correct information for the following by clicking the field:
- **Interface**: Displays the name of the interface. You cannot modify this.
- **Address**: Type the IPv4 or IPv6 address depending on the type of interface. An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight 16-bit groups of hexadecimal digits separated by colons (example: 2001:db8:0000:0123:4567:89ab:0000:cdef or 2001:db8::123:4567:89ab:0:cdef).
- **Subnet Mask (IPv4) or Prefix Length (IPv6)**: Specify an appropriate subnet mask for IPv4 interface or prefix length for IPv6 interface. The prefix length ranges from 2 to 127.
- **Gateway**: Type the IPv4 or IPv6 address of the default gateway depending on the type of interface. For IPv6 interface, you can also type **Automatic** to enable the appliance to acquire the IPv6 address of the default gateway and the link MTU from router advertisements.
- **VLAN Tag**: For a VLAN, enter the VLAN tag or ID. You can enter a number from 1 to 4094. Ensure that you configure the corresponding switch accordingly.
- **Port Settings**: From the drop-down list, choose the connection speed that you want the port to use. You can also choose the duplex setting. Choose **Full** for concurrent bidirectional data transmission or **Half** for data transmission in one direction at a time. Select **Automatic** to instruct the NIOS appliance to negotiate the optimum port connection type (full or half duplex) and speed with the connecting switch automatically. This is the default setting. You cannot configure port settings for vNIOS appliances.
- **DSCP Value**: Displays the Grid DSCP value, if configured. To modify, click **Override** and enter the DSCP value. You can enter a value from 0 to 63. For information about DSCP, see *Implementing Quality of Service Using DSCP*.
  Note that when the system operates in HA mode, should the IPv6–addressed VIP value be deleted, the IPv6 address of the HA port will also be deleted.

5. Optionally, define extensible attributes. For information, see *Using Extensible Attributes*.
6. Do one of the following:

   - Click **Save & Edit** to add the HA member to the Grid and launch the editor. You can configure additional properties, such as the MTU size, or add the member to a NAT group.
   - Click **Save & New** to add the HA member to the Grid and launch the wizard again to add another member.
   - Click **Save & Close** to add the HA member to the Grid and close the wizard.

The communication protocol for all the services in a dual mode (IPv4 and IPv6) HA member is the same protocol as the one that is used for VRRP advertisements. For example, if you select **IPv4** in the **Send HA and Grid Communication over** field in step 2 of the *Add Grid Member* wizard, then IPv4 is set as the communication protocol for all the services. However, you can override the communication protocol for all the services in a dual mode HA member. For information, see Communication Protocol for a Dual Mode Appliance below.

Changing the Member Type

When you change the **Member Type** from *Infoblox* to *Virtual NIOS*, Infoblox displays an error indicating that the network port of a vNIOS member must be set to Automatic. If you encounter this error, follow the steps mentioned below to change the **Member Type** to **Virtual NIOS**:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
2. Expand the **Toolbar** and click **Add** -> **Add Grid Member**.
3. In the *Add Grid Member* wizard, leave the **Member Type** as **Infoblox,** fill other details and click **Next**.
4. In the **Network** tab select **High Availability Pair**.
5. Change the port settings to **Automatic** for **Node1 HA**.
6. Select **Standalone Member**.
7. Click **Previous** and change the **Member Type** to **vNIOS**.

Changing the Communication Protocol for a Dual Mode Appliance

You can change the default communication protocol for a dual mode appliance. You can force the appliance to use a specific protocol to join the Grid Master and for the reporting services. But for services with two types of resolution (A and AAAA records), you can set the preferred communication protocol.
To change the communication protocol for a dual mode appliance:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Grid Member Properties* editor, select the **Network** tab -> **Basic** tab, and then complete the following:
    - **Communication Protocol Settings and Preferences**: This setting is not applicable for an HA pair. Select either **IPv4** or **IPv6** from the drop-down list. This setting will force the appliance to use the specified protocol for Grid and reporting services and this is the preferred protocol for services with two types of resolution (A and AAAA records).
    - **Customized Settings**: Select this and do the following:
        - **Always use this Communications Protocol for**: For a Grid Master, you can select either **IPv4** or **IPv6** from the **Reporting** drop-down list. This setting will force the Grid Master to use the specified communication protocol for reporting service. For a Grid member, you can select either **IPv4** or **IPv6** from the **Grid** and **Reporting** drop-down list. This setting will force the Grid member to use the specified communication protocol for Grid and reporting service.
        - **Always Prefer this Communications Protocol for**: This field lists the services which has two types of resolution (A and AAAA records). Select either **IPv4** or **IPv6** from the drop-down list for the service which you want the appliance to use this as the preferred communication protocol. The appliance uses the preferred protocol first for the service.

Joining Appliances to the Grid

Grid members can join the Grid using IPv4 protocol in an IPv4-only Grid and using IPv6 protocol in an IPv6-only Grid. In a dual mode Grid, the Grid members may join the Grid using IPv4 or IPv6. Similarly, a Grid Master candidate can join the Grid using IPv4 in an IPv4-only Grid and using IPv6 in an IPv6-only Grid. But for a Grid Master candidate to join a dual mode Grid, it should be configured in dual mode. If you have configured the MGMT port for the Grid member, then the Grid member can join the Grid using the MGMT port. You can use the Grid Setup Wizard or access the *Join Grid* dialog box to join appliances to a Grid. The Grid Setup Wizard launches when you first log in to an appliance. You can also launch it from the Toolbar as described in *Grid Setup Wizard*.
To join a single appliance and HA pair to a Grid using the Grid Manager GUI:

1. Log in to the appliance or HA pair that you want to add to the Grid. The appliance or HA pair must be online and able to reach the Grid Master.
2. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
3. Expand the Toolbar and click **Join Grid**.
4. In the *Join Grid* dialog box, enter the following:
    - **Virtual IP of Grid Master**: Type the VIP address of the HA Grid Master or the LAN1 address of the single Grid Master for the Grid to which you want to add the appliance. Entries may be an IPv4 or IPv6 address.
    - **Grid Name**: Type the name of the Grid.
    - **Grid Shared Secret**: Type the shared secret of the Grid.

- **Use MGMT port to join Grid**: If you have already enabled the MGMT port (see *Grid Communications*), this option becomes available. Select it to connect to the Grid through the MGMT port.

5. Click **OK** to begin the join operation.
   To confirm that the appliance has successfully joined the Grid, log in to the Grid Master and navigate to the **Grid** tab, select the **Grid Manager** -> **Members** tab. This panel lists the Grid members. Check the icon in the Status column of the newly added member. (green = the appliance has joined the Grid and is functioning properly; yellow = the appliance is in the process of joining the Grid; red = the appliance has not joined the Grid). You can also use the CLI command set network to join an appliance to a Grid.

To join a single appliance and HA pair to a Grid using the Grid Setup Wizard:

1. Log in to the appliance or HA pair that you want to add to the Grid. The appliance or HA pair must be online and able to reach the Grid Master.
2. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
3. Expand the Toolbar and click **Grid Properties** -> **Setup (Grid Setup Wizard)**.
4. On the next screen, specify the Grid properties and click **Next**
   - **Grid Name:** Enter a text string that the two appliances use to authenticate each other when establishing a VPN tunnel between them. This must match the Grid name you entered for node 1.
   - **Grid Master's IP Address**: Enter the same VIP you entered for node 1.
   - **Shared Secret**: Enter a text string that both appliances use as a shared secret to authenticate each other when establishing a VPN tunnel between them. This must match your entry in node 1.
5. On the next screen verify the IP address settings of the member and click **Next**.
6. The last screen displays the settings you specified in the previous panels of the wizard. Verify that the information is correct and click **Finish**.
   To confirm that the appliance has successfully joined the Grid, log in to the Grid Master and navigate to the **Grid** tab, select the **Grid Manager** -> **Members** tab. This panel lists the Grid members. Check the icon in the Status column of the newly added member. (Green = The appliance has joined the Grid and is functioning properly; Yellow = The appliance is in the process of joining the Grid; Red = The appliance has not joined the Grid). You can also use the CLI command set network to join an appliance to a Grid.

Grouping Members by Extensible Attributes

When you have a few members in your Grid, you can organize and group them by extensible attributes that contain the same values. Using the **Group Results** function, you can organize your members in a meaningful way and quickly identify them based on common data. When you group members by multiple extensible attributes, the appliance groups the members hierarchically based on the order of the filters. For example, when you filter members first by extensible attribute "Site equals London" and then by extensible attribute "Organization equals Engineering," the appliance groups corresponding members first by Site and then by Organization based on the values you enter. In the **Grid** tab -> **Grid Manager** tab ->**Members** tab, Grid Manager displays the grouped members in a hierarchical view that displays the member group name (**London**). You can click the London link and drill down to the next level of grouping. In this case, Grid Manager displays the organization group (**Engineering**) in the **Members** tab. When you click the **Engineering** link to drill down to the next level, all associated members that belong to this member group (**London** -> **Engineering**) are displayed.
To go back to a previous hierarchical view, click the link of the corresponding level in the breadcrumb.
To group members by extensible attributes:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
   or
   From the **Grid** tab, select the **Grid Manager** tab -> **Services** tab.
   Note that you can use the "Group Results" function for the following services: DNS, DHCP, TFTP, FTP, HTTP, NTP, bloxTools, Captive Portal, and Reporting services.
   or
   From the **Data Management** tab, select the **DHCP**, **File Distribution**, or **DNS** tab -> **Members/Servers** tab.
2. Complete the following to group members with the same extensible attribute value:
   - **Group Results**: Select this checkbox to enable the appliance to group members by extensible attributes.
   - **Group By**: From the drop-down list, select the first extensible attribute that you want the appliance to use for filtering members.

Grid Manager displays data per group of members configured with the same extensible attribute value.
To add additional **Group By** filter, click the + icon, and then select a value from the drop-down list. You can apply up to 10

Group By filters. You can also delete a filter by clicking the - icon.
When you enable reporting service on the Grid and configure multi-site cluster, you can group reporting members by reporting site extensible attributes. For information about reporting clusters, see *Configuring Reporting Clusters*.
Grid Manager displays the following information for the specified extensible attribute:

- <*Selected extensible attribute*>: Displays the selected extensible attribute value.
- **Status**: This is the overall status for all members in the group. Depending on the status of each member, the overall status can be one of the following: **Working**, **Warning**, **Failed**, **Offline**, **Inactive**, or **Unknown**. For information about the status, *Status Dashboard*.
  Note that in an HA pair, when one of the appliances is in the **Working** status and the other appliance has a status other than **Working**, **Inactive**, and **Unknown**, then the overall status of HA members is **Warning**. When you use filters and the group by extensible attribute feature, filters take precedence over the group by function.

When you drill-down to the member level, Grid Manager displays the members in the group.

Configuring an IPv6-only Grid

An IPv6-only Grid uses IPv6 as the communication protocol and it includes an IPv6 Grid Master and the Grid members, which can be either IPv6 or dual mode (IPv4 and IPv6). In order to configure an IPv6-only Grid, you have to first create an IPv6 Grid Master and then join the Grid members using their IPv6 addresses.
The process of configuring an IPv6-only Grid involves the following steps:

1. Make a console connection to the Grid Master and configure an IPv6 address for the Grid Master using the CLI command set network. For information, see *Method 2 – Using the CLI*.
2. Open a web browser and make an HTTPS connection to the IPv6 address of LAN1 port of the Grid Master.
3. Log in using the default username and password **admin** and **infoblox**. For detailed information about logging in to the GUI, see *Logging on to the NIOS UI*.
4. The Grid Setup Wizard appears when you first log in to the appliance. You can use it to create an IPv6 HA Master or IPv6 single Grid Master. For information about creating an HA Master, see *Creating a Grid Master#CreatinganHAGridMasterCreating an HA Grid Master* and for information about creating a single Grid Master, see *Creating a Single Grid Master*.
   The type of network connectivity for the Grid Master should be set to IPv6. To verify, navigate to the **Grid** tab -> **Grid Manager** tab -> **Members** tab -> *member* checkbox -> Edit icon. In the *Grid Member Properties* editor, select the **Network** tab -> **Basic** tab, check that the **Type of Network Connectivity** is set to **IPv6**. The Grid members can join the Grid Master using IPv6 only.
   Note:
   You can add additional IPv4 and IPv6 addresses for LAN2 and MGMT ports for the Grid services, in the **Additional Ports and Addresses** table. But for an IPv6-only Grid, you can configure IPv6 address for the VLAN port.
5. Legacy Data Connector virtual machines are not supported on IPv6-only Grids.
6. Add IPv6 single members and HA members to the Grid. For information, see *Adding Grid Members*.
   Note that to add a discovery member to an IPv6-only grid, add the member first and then install its discovery license. If the system displays the "Cannot configure IPv6-only settings on member because it has a discovery license installed." in the **Grid Member Properties Editor** dialog box of the discovery member, disregard the error message.
7. You can use the Grid Setup Wizard or access the *Join Grid* dialog box to join appliances to a Grid. See *Joining Appliances to the Grid*.

You can also configure IPv6 address for the MGMT interface of the appliance and join the Grid through the MGMT interface.

Transforming to an IPv6-only Grid

After an upgrade from a previous NIOS release to NIOS 7.0 or later, each node in the Grid is set to either IPv4 or dual mode (IPv4 and IPv6). Transforming an IPv4-only Grid to an IPv6-only Grid may take a longer duration. Hence, before removing the IPv4 addresses from each Grid member, you have to configure additional IPv6 Grid communication protocol for each Grid member so that all the services function properly using IPv6.
Note the following before converting an IPv4-only or a dual mode Grid to an IPv6-only Grid:

- If a Grid member is designated as a Master Candidate, the Grid manager does not allow you to change the type of network connectivity of the Grid Master or the Grid Master Candidate. Therefore, you must disable the Grid member from being a Grid Master Candidate before changing the type of network connectivity of the Grid Master or the Grid Master Candidate. You can deselect the **Master Candidate** option in the **General** tab of the *Grid Member Properties* editor to disable a member from being a Master Candidate. Note that at this point, the Grid will not have a Grid Master Candidate and this may result in an unrecoverable condition, if the Grid Master goes down.
- You must stop all services on the Grid Master and Grid members that uses IPv4.
- If external servers like authentication servers, forwarders, root name servers, backup servers, etc. is configured with IPv4 addresses, then it will not work after converting the Grid to an IPv6-only Grid. Hence, make sure that you change the IPv4 address of the external server to IPv6 address before converting the Grid to an IPv6-only Grid.
  Note that Infoblox recommends that you back up the configuration after you convert a Grid to IPv6-only mode. Restoring the old backup by performing a forced restore, may prevent the Grid members from rejoining the Grid Master after the restore.

The process of transforming an IPv4-only or dual mode Grid to an IPv6-only Grid involves the following steps:

1. Convert the Grid Master into dual mode (IPv4 and IPv6) if it is in IPv4 mode, as follows:
   - Login to the Grid Master, from the **Grid** tab -> **Grid Manager** tab -> **Members** tab -> select the Grid Master and click the Edit icon.
   - In the *Grid Member Properties* editor, select the **Network** tab -> **Basic** tab.
   - In the **Type of Network Connectivity** field, select **IPv4 and IPv6** from the drop-down list and enter the network information for LAN1 (IPv6) address in the **Ports and Addresses** table.
     For HA Master, select **IPv4** in the **Send HA and Grid Communication Over** field, and enter the network information for VIP (IPv6), Node1 LAN1 (IPv6), Node2 LAN1 (IPv6) in the **Ports and Addresses** table.
   - Save the configuration and click **Restart** if it appears at the top of the screen.
2. Similarly, convert all the Grid members into dual mode (IPv4 and IPv6) if it is in IPv4 mode. All the members will rejoin the Grid using IPv4.
3. Force each Grid member to rejoin the Grid using IPv6, as follows:
   - From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox -> Edit icon.
   - In the *Grid Member Properties* editor, select the **Network** tab -> **Basic** tab.
   - In the **Always Force or Prefer this Communications Protocol** field, select **IPv6** from the drop-down list, and also select **IPv6** in the **Send HA and Grid Communication over** field if the member is an HA pair.
     This setting will force the Grid member to rejoin the Grid using IPv6 and it uses IPv6 for all the services.
   - Save the configuration and click **Restart** if it appears at the top of the screen.
4. Configure each Grid member to provide DNS service using IPv6, as follows:
   - From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon.
   - In the *Member DNS Properties* editor, select the **General** tab -> **Basic** tab.
   - Enable the IPv6 checkbox for the desired interface (LAN1, LAN2, or MGMT) under **DNS Interfaces**.
   - Ensure that the primary and secondary servers are configured with an IPv6 address for each zone, before disabling the IPv4 checkbox for LAN1, LAN2, or MGMT interface.
   - Save the configuration and click **Restart** if it appears at the top of the screen.
     Note:
     When you transform an IPv4-only or dual mode Grid to an IPv6-only Grid, the LAN1 port for IPv4 is always enabled. The LAN1 port is disabled only when the Grid is configured using IPv6 from the beginning.
   - For vNIOS appliances, some of the options in the *DNS Interfaces* section may vary depending on your vNIOS configuration. For example, if you are using a single network interface instance of vNIOS for GCP, you will see choices specific to the LAN1 interface only. For more information, see the vNIOS documentation specific to your product at *Appliances*.
5. Configure each Grid member to provide DHCP service using IPv6, as follows:
   - From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox -> Edit icon.
   - In the *Member DHCP Properties* editor, select the **General** tab -> **Basic** tab.
   - Disable the IPv4 checkbox for LAN1 and LAN2 interface under **DHCP Interfaces**.
   - Enable the IPv6 checkbox for the desired interface (LAN1 or LAN2) under **DHCP Interfaces**.
     If IPv6 network is not configured, you can create an IPv6 network. For information, see *Managing IPv6 Networks*.
   - Save the configuration and click **Restart** if it appears at the top of the screen.

6. Enable each Grid member and the Grid Master to use IPv6 for all the services, as follows:
    - From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox -> Edit icon.
    - In the *Grid Member Properties* editor, select the **Network** tab -> **Basic** tab, and select **Customized Settings** and specify the following:
        - **Always Force this Communication Protocol for**: Select **IPv6** from the drop-down list for the Grid and reporting service.
        - **Always Prefer this Communication Protocol for**: Select **IPv6** from the drop-down list as the preferred communication protocol for the listed services which has two types of resolution (A and AAAA records). The appliance uses the preferred protocol first for the service.
        - Save the configuration and click **Restart** if it appears at the top of the screen.
7. When all the services are functioning using IPv6, you can remove the IPv4 addresses from all the Grid members by converting the Grid member from dual mode (IPv4 and IPv6) to IPv6 mode, as follows.
    - From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox -> Edit icon.
    - In the *Grid Member Properties* editor, select the **Network** tab -> **Basic** tab.
    - In the **Type of Network Connectivity** field, select **IPv6** from the drop-down list.
    - Save the configuration and click **Restart** if it appears at the top of the screen.
8. Similarly, you can convert the Grid Master from dual mode (IPv4 and IPv6) to IPv6 mode after converting all the Grid members to IPv6 mode.
   Ensure to remove the IPv4 addresses from the Grid Master only after you remove the IPv4 addresses from all the Grid members.

Auto-Provisioning NIOS Appliances

In addition to using the Grid Setup Wizard or access the *Join Grid* dialog box to join appliances to a Grid, you can set up an appliance using the auto-provisioning feature, which allows a DHCP server to automatically assign an IP address to the appliance. You can then join the auto-provisioned appliance to the Grid.
Auto-provisioning is enabled by default for new installations of physical appliances, but it is not supported for vNIOS appliances. When you connect the appliance to the network, a lease request is automatically sent to the DHCP server. The DHCP server fingerprints the client as "Infoblox Appliance," as the DHCP client provides the unique option sequence (1,28,2,2,3,3,15,6,12) and vendor ID (INFOBLOX). The DHCP server assigns a DHCP lease and a dynamic IP address to the appliance. If the DHCP lease request fails, the default IP address (192.168.1.2) is assigned to the appliance. The DHCP client tries to send the lease request for a duration of one minute when the appliance is either in the factory default state or in the auto-configured default IP address state after a reboot. If you do not use auto-provisioning to set up the appliance, then you can wait one minute before connecting the appliance to the network. Otherwise, the DHCP server will assign a dynamic IP address to the appliance. Note that if you have already set the IP address for the appliance through the Infoblox CLI, GUI, or API, then auto-provisioning is disabled for the appliance and the lease address is not requested. When auto-provisioning is enabled for an appliance, the DNS, DHCP, FTP, TFTP, HTTP, NTP, bloxTools, Captive Portal, Reporting services, as well as backup and restore are disabled for the member until a static IP address is set for the appliance. You can join a single appliance or HA pair to the Grid. After the appliance joins the Grid, the static IP address is set for the appliance.

Note

- Auto-provisioning supports only IPv4 addressing and not IPv6 addressing.
- Auto-provisioning supports only physical appliances. You cannot auto-provision a hybrid HA setup of a physical and virtual appliance.

When you upgrade or downgrade the appliance to a release that includes this feature, auto-provisioning is disabled for the appliance.

Setting Up Physical Appliances Using Auto-Provisioning

Complete the following to set up an appliance using auto-provisioning and to join the auto-provisioned appliance to the Grid Master:

1. Connect the appliance to a network using an Ethernet cable, connect it to a power source, and then turn on the power. For information about cabling the appliance to a network and powering the appliance, refer to the user guide or installation guide that ships with the product.
   A lease request is automatically sent to the DHCP server that assigns a DHCP lease and a dynamic IP address to the appliance. The DHCP client tries to send the lease request for a duration of one minute and if the request fails, the default IP address (192.168.1.2) is assigned to the appliance.
2. Join the appliance to the Grid Master. You can join the auto-provisioned appliance to the Grid Master using the *Connect* dialog box. You can also join an appliance to the Grid using the *JoinGrid* dialog box. For more information, see *Adding Grid MembersJoining Appliances to the Grid.*
   A static IP address is set and auto-provisioning is automatically disabled for the appliance after it joins the Grid.

Only the following physical platforms supports Auto-Provisioning:

IB-4015, IB-4025, TE-815, TE-825, TE-1415, TE-1425, TE-2215, TE-2225, TR-1405, TR-2205, TR-4005.

> ⚠ Note
>
> When auto-provisioning is disabled for an appliance and the network address is not preserved, auto-provisioning will be re-enabled and a DHCP lease request is sent to the DHCP server if you reset the appliance using the CLI command `reset all auto_provision` or reset the database using the CLI command `reset database auto_provision`. However, if the static IP address for an appliance is set and network settings are preserved, auto-provisioning will be re-enabled for the appliance but the lease address will not be requested if you reset the database using the CLI command `reset database auto_provision`.

Joining Auto-Provisioned Appliances to the Grid

You can join a predefined appliance with a DHCP lease to the Grid Master using the *Connect* dialog box. You can join a single appliance or an HA pair to the Grid Master. For an HA pair, the member which is offline will join the Grid Master and it will become the active node. When both the members of an HA pair are offline, Node 1 of an HA pair is joined to the Grid Master.
Only superusers can join a Grid member to the Grid Master. If the Grid member fails to join the Grid, then the remote console is enabled for the appliance and you can join the appliance to a Grid through the remote console. You can log in to the remote console using the user name, **admin** and the Grid shared secret as the password.
To join a single appliance or an HA pair to a Grid Master, complete the following:

1. Log in to the Grid Master. Note that the single appliance or the HA pair must be online and the Grid Master must be able to reach the appliance.
2. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
3. Add the appliance as a Grid member. For information about adding Grid members to the Grid, see *Adding Grid Members*.
4. Select the Grid member that you want to join to the Grid Master, expand the Toolbar and click **Connect**.
5. The following fields are displayed in the *Connect* dialog box:
   - **Host Name**: The name of the member.
   - **Configured IPv4 Address**: The IPv4 address of the member.
   - **Site**: The site to which the IP address belongs. This is one of the predefined extensible attributes.
   - **Temporary IPv4 Address**: Enter the IPv4 address of the DHCP lease or click **Select** to select the DHCP lease.
     Grid Manager displays the *Lease Selector* dialog box from which you can select the DHCP lease. Note that the *Lease Selector* displays the active DHCP leases which are fingerprinted as "Infoblox Appliance".
6. Click **Next** to retrieve the appliance information.
   The Grid Master uses SSL to connect to the appliance and it gets the appliance information. Grid Manager displays the following information for the appliance:
   - **Remote Appliance Type**: The appliance type.
   - **Remote Appliance Serial Number**: The serial number of the appliance.

- **Licenses**: Grid Manager displays the Grid license and the licenses that are pre-provisioned on the member.
  It displays the following information:
  - **Type**: The license type.
  - **String**: The license string. If the license string is not displayed, you can enter or paste it here.

7. Click **Connect** to join the appliance to the Grid Master.
   To confirm that the appliance has successfully joined the Grid, check the status in the **Status** column of the newly added member. (Green = The appliance has joined the Grid Master and is functioning properly; Yellow = The appliance is in the process of joining the Grid Master; Red = The appliance has not joined the Grid Master).

Pre-Provisioning NIOS and vNIOS Appliances

Before joining a member to the Grid, you can first enable provisional licenses and make necessary configurations on the offline member, which allows DNS and DHCP data to be associated with the member prior to its deployment. Note that pre-provisioned members are treated as offline members. There are a few guidelines to consider before you pre-provision a member. For more information about the guidelines, see Guidelines for Pre-provisioning Offline Grid.
When you add a new member to the Grid, the **Pre-Provisioning** tab is displayed in the *Grid Member Properties* editor. You can pre-provision the member by defining its hardware model and enable certain provisional licenses through the **Pre-Provisioning** tab. This tab is not displayed after the member successfully joins the Grid. NIOS supports the following provisional licenses: Cloud Platform, DHCP, DNS, DNS Traffic Control, Enterprise (formerly Grid), FireEye, Microsoft Management, RPZ (Response Policy Zone), and vNIOS. You must enable provisional licenses before you can make supported configurations on the pre-provisioned member. For more information about these licenses, see *About Provisional Licenses*.

> ⚠ Note
>
> You must have the Enterprise and vNIOS licenses pre-provisioned in order for a vNIOS appliance to join the Grid. For a cloud virtual appliance, include the Cloud Platform license.

To pre-provision an offline Grid member and join it to the Grid at a later time, complete the following:

1. Add a new single member or HA member to the Grid, as described in *Adding a Single Member* or *Adding an HA Member.*
2. Pre-provision the offline member, as described in Configuring Pre-Provisioned Members below.
3. Configure services to use the pre-provisioned member.
4. Obtain permanent licenses you have specified for pre-provisioning and use the **set license** CLI command to install the licenses on the member. For more information about CLI commands, refer to the *Infoblox CLI Guide*.
5. Join the pre-provisioned member to the Grid, as described in *Joining Appliances to the Grid.* For guidelines about joining pre-provisioned members, see Guidelines for joining Pre-Provisioned Members.

Guidelines for Pre-provisioning Offline Grid Members

Before you pre-provision a Grid member, consider the following:

- A pre-provisioned Grid member is an offline member. When you upgrade a Grid that has a pre-provisioned member, the upgrade behaves the same way as it does when you upgrade the Grid that has an offline member. Note that you cannot pre-provision a member or update its settings during a scheduled upgrade. For more information about upgrades, see *Upgrading NIOS*.
- You cannot change the pre-provisioned member configuration after you save it. To change the configuration, you must first delete the member and pre-provision it again. If you want to delete certain provisional licenses or change the hardware model for the pre-provisioned member, you must also first delete the existing member and define a new one. For information about deleting a member, see *Removing a Grid Member.*
- When you assign a network, zone, or IPv4 DHCP failover association to a pre-provisioned member, the **Restart Service** button is not displayed. If you restart any service on a pre-provisioned member, no action is actually taken even though you may receive a message indicating that the operation may take a few minutes. When you

join the member to the Grid, NIOS will run respective member services on the joined member. For more information about service restarts, see *Restarting Services*.

- NIOS allows you to backup information about the pre-provisioned member. When you perform a forced restore however, NIOS does not restore the pre-provisioned licenses if you have already installed permanent NIOS licenses on the corresponding member. For more information about backup and restore, see *Backing up and Restoring Configuration Files*.
- You can use **Manage Member Services** to manage the pre-provisioned member services. For more information, see *Monitoring Member Services.*

Configuring Pre-Provisioned Members

The pre-provisioning feature is disabled by default. You must select a supported hardware model for the member to enable this feature.
To pre-provision an offline member, login to the Grid Master and complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, and then click the Add icon.
2. In the *Add Grid Member* wizard, add a new member as described in *Adding a Single Member.*
3. After you add the member to the Grid, select the member in the **Members** tab and click the Edit icon.
4. In the *Grid Member Properties* editor, select the **Pre-Provisioning** tab, and complete the following:
    - **Member Type**: Displays the member type that you have selected in the **General** tab. The pre-provisioning feature is supported only for **Infoblox** and **Virtual NIOS** member types. Note that you must select a hardware model for the member in order to enable the pre-provisioning feature.
    - **Hardware Model**: Select the hardware model from the drop-down list. Grid Manager displays only the supported hardware models for the specified member type. Once you select the hardware model, the pre-provisioning feature is enabled for the member. NIOS allows you to pre-provision HA members that have the same or different hardware models for Node 1 and Node 2. A few hardware specific features, such as DSCP, VLAN, LAN2, and LOM (Light Out Management), are enabled based on the pre-provisioned hardware model you specify here.
    - **Provisional Licenses**: Select the licenses that you want to enable for the pre-provisioned member. You can select the licenses only after you have specified the hardware model for the member. Once you select and enable a license, you can no longer modify the hardware model for the member. Note that the permanent licenses that you later add to the member must include the ones that are specified for pre-provisioning.
5. Save the configuration.
   Note that after you save the configuration, you can no longer modify the hardware model for the member. You also cannot disable any provisional licenses, though you can add new ones. To disable provisional licenses, you must first remove the pre-provisioned member and then configure a new one.

About Provisional Licenses

If a member has never joined a Grid, you can pre-provision this member provided that you define the hardware model for the member and assign provisional licenses to it. Provisional licenses are not permanent NIOS licenses. Though they do not have expiration dates or validity periods, you must replace these licenses with corresponding permanent licenses before you join the member to the Grid.

> ⚠ Note
>
> Before you join the member to the Grid, use the CLI command `set license` to add corresponding permanent licenses that you have specified for pre-provisioning. For information about CLI commands, refer to the Infoblox CLI Guide{_}. You can also allocate pre-purchased licenses from the pool. For information, see You can use the following OpenStack cloud-init template to configure an IB-V815 as a Grid Master

NIOS supports the following provisional licenses: Cloud Platform, DHCP, DNS, DNS Traffic Control, Enterprise (formerly Grid), FireEye, Microsoft Management, RPZ (Response Policy Zone), and vNIOS.

After you configure the offline member, you can select the pre-provisioned member from the corresponding wizards and editors based on the required license(s). The following table lists the wizards and editors from which you can select a pre-provisioned member when required pre-provisioned licenses are enabled:

Wizards and editors from which you can select a pre-provisioned member	Required license(s)
DNS Zones and Name Server Groups	dns
DHCP IPv4 and IPv6 networks	dhcp
IPv4 DHCP Failover Association	dhcp
Microsoft servers Note that the initial synchronization with Microsoft servers is read-only. When you join the appliance to the Grid, the appliance removes all Microsoft management objects that you have configured on the Microsoft servers after the synchronization. The configuration on the Microsoft servers will replace the configuration on the NIOS appliance.	ms_management
Grid Members	vnios
Grid license	enterprise
Response Policy Zones	RPZ
Response Policy Zones	FireEye
DNS Traffic Control	DTC
Cloud tabs and related wizards and editors	cloud_api

Note

⚠ If you configure a DHCP Failover using an online member and a pre-provisioned member, assign it to a range, and start DHCP service, no addresses will be served because the initial synchronization does not happen due to the pre-provisioned offline member. NIOS logs the following message in the syslog:

```
2013-12-24T08:37:23+00:00 daemon (none) dhcpd[8790]: info DHCPDISCOVER
from cb:86:a8:45:6c:5c via 10.120.21.236: not responding (recovering)
```

Guidelines for Joining Pre-Provisioned Members to the Grid

Before you join a pre-provisioned member to the Grid, ensure that you verify the appliance model and provisional licenses for the member. For information about how to join a member to the Grid, see *Joining Appliances to the Grid*. Note the following about joining a pre-provisioned member to the Grid:

- If you install fewer permanent licenses than the specified provisional licenses, you cannot join the member to the Grid.
- If the pre-provisioned member does not have any provisional licenses enabled, you can join the member to the Grid provided that you install a permanent Grid license on the member.
- You must install at least the set of permanent licenses that were specified for pre-provisioning along with any other needed licenses, except for the following:

        - You can join the member to the Grid if the pre-provisioned member is a vNIOS virtual appliance and has only the DNS license enabled, and you install both the vNIOS and DNS licenses on the member.
        - Similarly, you can join the member to the Grid if the pre-provisioned member is a vNIOS virtual appliance and has both DNS and DHCP licenses enabled, and you install the vNIOS, DNS, and DHCP licenses on the member.
    - After you successfully join the pre-provisioned member to the Grid, provisional licenses are removed and permanent licenses take effect.
    - After the member joins the Grid successfully, the **Pre-Provisioning** tab is not displayed in the *Grid Member Properties* editor.

Configuring a Grid

You can configure an IPv4-only, IPv6-only, or a dual mode (IPv4 and IPv6) Grid, but the configuration example uses IPv4 addresses. In this example, you configure seven NIOS appliances in a Grid serving internal DHCP and DNS for an enterprise with the domain name corpxyz.com. There are four sites: HQ and three branch offices. A hub-and-spoke VPN tunnel system connects the sites, with HQ at the hub. The distribution and roles of the NIOS appliances at the four sites are as follows:

- HQ site (four appliances in two HA pairs):
    - HA Grid Master: Hidden primary DNS server
    - HA member: Secondary DNS server and DHCP server for HQ
- Site 1 (two appliances in an HA pair): HA member, secondary DNS server and DHCP server for Site 1
- Site 2 (one appliance): Single member, secondary DNS server and DHCP server for Site 2

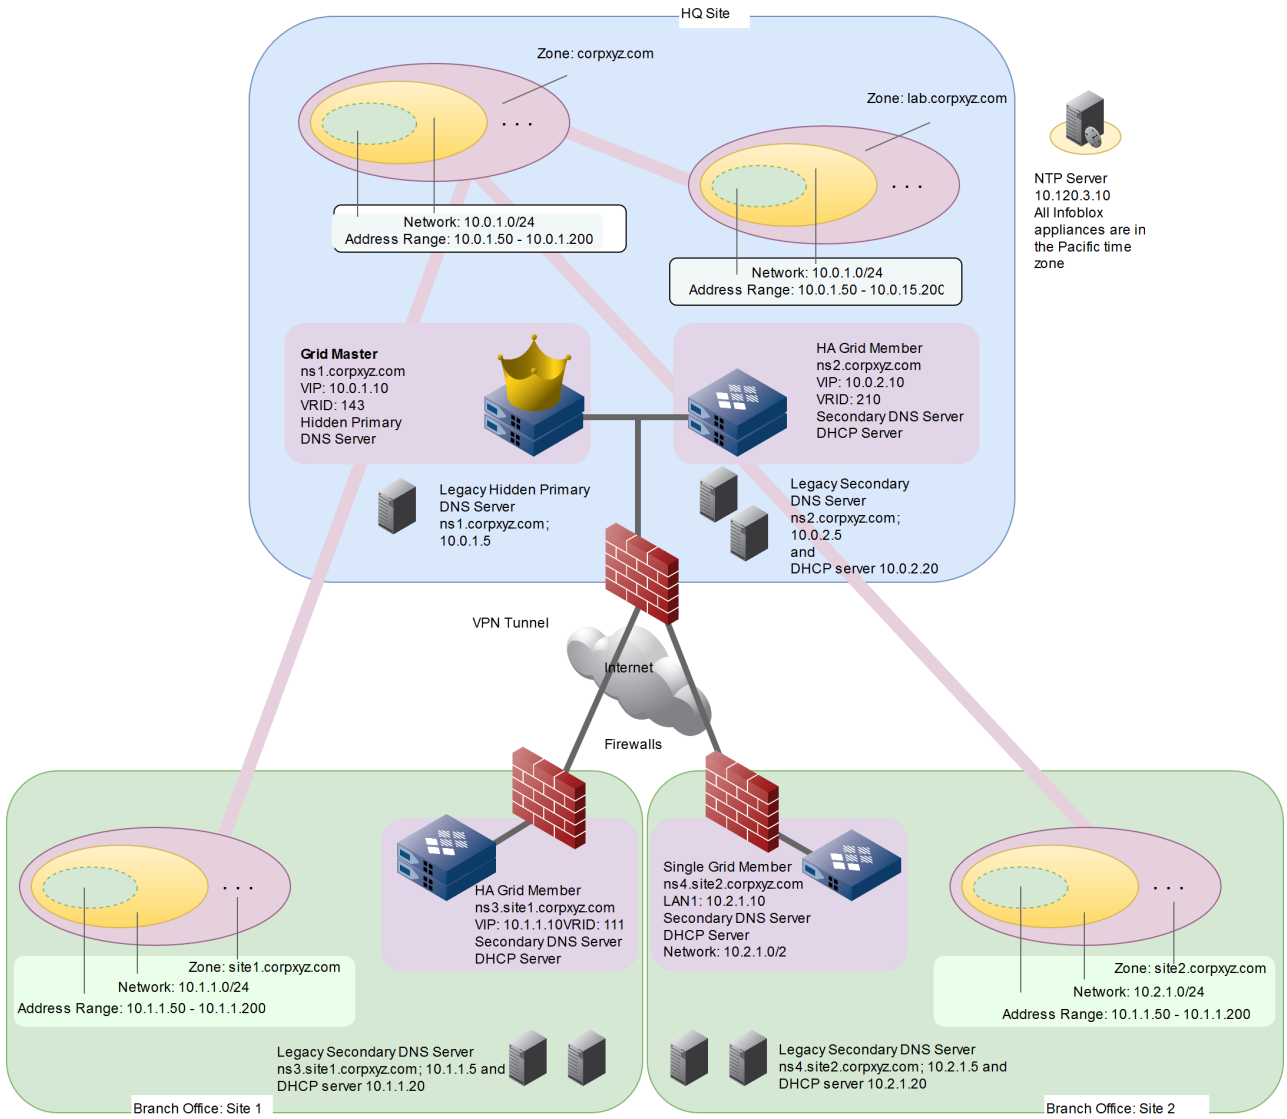
> ⚠ Note
>
> When adding an Infoblox appliance to an existing Grid, you must first check whether the Grid is running the minimum required software release of the appliance. For information, refer to the document, *Minimum Required Release Software for Hardware Platforms*, that was shipped with your product.

To create a Grid, you first create a Grid Master and then add members. The process involves these three steps:

1. Configuring two appliances at HQ as the Grid Master. For more details, see Create the Grid Master below.
2. Logging in to the Grid Master and defining the members that you want to add to the Grid; that is, you configure Grid member settings on the Grid Master in anticipation of later joining those appliances to the Grid. For more details, see Define Members on the Grid Master below.
3. Logging in to the individual appliances and configuring them so that they can reach the Grid Master over the network and join the Grid. For more details, see Join Appliances to the Grid below.

After creating the Grid and adding members, you use the Data Import Wizard to import DHCP and DNS data from legacy servers. For more details, see Import DHCP Data and Import DNS Data below.
Finally, you transition DHCP and DNS service from the legacy servers to the Infoblox Grid members. For more details, see Enable DHCP and Switch Service to the Grid below.

Network Diagram



Cable All Appliances to the Network and Turn On Power

Cable the NIOS appliances to network switches. After cabling each appliance to a switch and connecting it to a power source, turn on the power. For information about installing and cabling the appliance, refer to the user guide or installation guide that ships with the product.

1. At HQ and Site 1, connect Ethernet cables from the LAN1 and HA ports on the appliances in each HA pair to a switch, connect the appliances to power sources, and turn on the power for each appliance.
   Note that when connecting the nodes of an HA pair to a power source, connect each node to a different power source if possible. If one power source fails, the other might still be operative.
2. At Site 2, connect an Ethernet cable from the LAN1 port on the single appliance to a switch, connect the appliance to a power source, and turn on the power for that appliance.

Creating the Grid Master

> **Note**
>
> IPv6 addressing is fully supported on Infoblox Grid Masters, HA pairs and standalone HA pairs, and appliances. Examples in the sections of this chapter use IPv4.

Configure two appliances at HQ to be the two nodes that make up the HA pair forming the Grid Master.

Grid Master – Node 1

1. By using the LCD or by making a console connection to the appliance that you want to make Node 1 of the HA pair for the Grid Master, change the default network settings of its LAN1 port to the following:
   - **IP Address**: **10.0.1.6**
   - **Netmask**: **255.255.255.0**
   - **Gateway**: **10.0.1.1**
2. Connect your management system to the HQ network, open a browser window, and connect to *https://10.0.1.6*.
3. Log in using the default username and password **admin** and **infoblox**.
4. Review the End-User License Agreement and click **I Accept**.
5. Read about the *Infoblox Customer Experience Improvement Program* and choose whether to participate (opt in) or not participate (opt out) in the program. By default, participation is enabled. If you want to opt out of the program, select **To Opt-Out of the alert program, please click here**. For more information about the program, see *Configuring the Customer Experience Improvement Program.*
6. Click **OK**. The *Grid Setup* wizard appears.
7. On the first screen, select **Configure a Grid Master** and click **Next**.
8. Specify the Grid properties:
   - **Grid Name:** Enter **corpxyz**.
   - **Shared Secret:** Enter **Mg1kW17d**.
   - **Confirm Shared Secret:** Enter **Mg1kW17d**.
   - **Hostname:** Enter **ns1.corpxyz.com**.
   - **Type of Network Connectivity:** Select **IPv4** from the drop-down list.
   - **Is the Grid Master an HA pair?**: Select **Yes**.
9. Specify the network properties and click **Next**:
   - **Virtual Router ID:** Enter **143**.
   - **Required Ports and Addresses:** Enter the details in the table to set up the HA pair, see at the end of the procedure.
10. **Enter a new password**: **1n85w2IF**. Retype it and click **Next**.
11. Then, complete the following:
    - **Time zone:** Select **(UTC – 8:00 Pacific Time (US and Canada), Tijuana**
    - Enable **NTP**, click the Add icon and enter the IP address of the NTP server: **10.120.3.10**
12. Click **Finish**. When you click **Finish**, the Infoblox GUI application restarts.

Interface	Address	Subnet Mask (IPv4) or Prefix Length (IPv6)	Gateway	Port Setting
VIP (IPv4)	10.0.1.10	255.255.255.0	10.0.1.1	Automatic
Node2 HA (IPv4)	10.0.1.9	255.255.255.0	10.0.1.1	Automatic
Node2 LAN1 (IPv4)	10.0.1.8	255.255.255.0	10.0.1.1	Automatic
Node1 HA (IPv4)	10.0.1.7	255.255.255.0	10.0.1.1	Automatic

Interface	Address	Subnet Mask (IPv4) or Prefix Length (IPv6)	Gateway	Port Setting
Node1 HA (IPv4)	10.0.1.7	255.255.255.0	10.0.1.1	Automatic

Grid Master – Node 2

1. By using the LCD or by making a console connection to the appliance that you want to make Node 2 of the HA pair for the Grid Master, change the default network settings of its LAN1 port to the following:
   - **IP Address**: **10.0.1.8**
   - **Netmask**: **255.255.255.0**
   - **Gateway**: **10.0.1.1**
2. In the login window, type **10.0.1.8** in the **Hostname** field.
3. Log in using the default username and password, **admin** and **infoblox**.
4. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox.
5. Expand the Toolbar and click **Join Grid** and specify the following:
   - **Virtual IP of Grid Master**: **10.0.1.10**
   - **Grid Name:** Enter **corpxyz**
   - **Grid Shared Secret:** Enter **Mg1kW17d**
6. Confirm the configuration, and then on the last screen of the wizard, click **Finish**. The HTTPS session terminates, but the login window remains open.
7. In the login window, type **10.0.1.10** (the VIP address for the Grid Master) in the **Hostname** field.
8. Log in using the default username **admin** and the password **1n85w2IF**.
9. To check the status of the two nodes of the HA Grid Master, navigate to the **Grid** tab, select the **Grid Manager** -> **Members** tab. This panel lists the Grid members. Check the icon in the **Status** column of the Grid Master. The colors indicate the following:
   a. **Green**: The appliance has joined the Grid and is functioning properly.
   b. **Yellow**: The appliance is in the process of joining the Grid
   c. **Red**: The appliance has not joined the Grid.
   You can also use the CLI command set network to join an appliance to a Grid. Check that the status indicators are all green in the *Detailed Status* panel.

During the joining process, an appliance passes through the following four phases:

1. **Offline**: The state when a Grid member—in this case, the second node of the HA pair composing the Grid Master—is not in contact with the active node of the master.
2. **Connecting**: The state when an appliance matching a member configuration contacts the master to join the Grid and negotiates secure communications and Grid membership.
3. **Synchronizing**: The master transmits its entire database to the member.
4. **Running**: The state when a member is in contact with the master and is functioning properly.

> ⚠ Note
> Depending on the network connection speed and the amount of data that the master needs to synchronize with the member, the process can take from several seconds to several minutes to complete.

Defining Members on the Grid Master

Before logging in to and configuring the individual appliances that you want to add to the Grid, define them first on the Grid Master. You can configure a Grid member in IPv4, IPv6, or a dual mode (IPv4 and IPv6), but the configuration example uses IPv4 addresses.

HQ Site – HA Member

1. From the **Grid** tab, select the **Grid Manager** -> **Members** tab.
2. Expand the Toolbar and click **Add** -> **Add Grid Member**.
3. In the *Add Grid Member* wizard, complete the following and click **Next**:

- **Member Type**: Select **Infoblox**.
- **Host Name**: Enter **ns2.corpxyz.com**.
- **Comment**: Enter **HQ Site - ns2.corpxyz.com**.

4. Enter the following information about the member that you are adding to the Grid and click **Save & Close**:
   - **Type of Network Connectivity**: Select **IPv4** from the drop-down list.
   - **High Availability Pair**: Select this option.
   - **Virtual Router ID**: **210**
   - **Required Ports and Addresses**:

Interface	Address	Subnet Mask (IPv4) or Prefix Length (IPv6)	Gateway	Port Settings
VIP (IPv4)	10.0.2.10	255.255.255.0	10.0.2.1	Automatic
Node1 HA (IPv4)	10.0.2.7	255.255.255.0	10.0.2.1	Automatic
Node2 HA (IPv4)	10.0.2.9	255.255.255.0	10.0.2.1	Automatic
Node1 LAN1 (IPv4)	10.0.2.6	255.255.255.0	10.0.2.1	Automatic
Node2 LAN1 (IPv4)	10.0.2.8	255.255.255.0	10.0.2.1	Automatic

Site 1 – HA Member

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
2. Expand the Toolbar and click **Add** -> **Add Grid Member**.
3. In the *Add Grid Member* wizard, enter the following and click **Next**:
   - **Member Type**: Select **Infoblox**.
   - **Host Name**: Enter **ns3.site1.corpxyz.com**
   - **Comment**: Enter **Site 1 - ns3.site1.corpxyz.com**
4. Specify the following information about the member that you are adding to the Grid and click **Save & Close**:
   - **Type of Network Connectivity:** Select **IPv4** from the drop-down list.
   - **High Availability Pair**: Select this option.
   - **Virtual Router ID**: Enter **111**.
   - **Required Ports and Addresses**:

Interface	Address	Subnet Mask (IPv4) or Prefix Length (IPv6)	Gateway	Port Settings
VIP (IPv4)	10.1.1.10	255.255.255.0	10.1.1.1	Automatic
Node1 HA (IPv4)	10.1.1.7	255.255.255.0	10.1.1.1	Automatic
Node2 HA (IPv4)	10.1.1.9	255.255.255.0	10.1.1.1	Automatic
Node1 LAN1 (IPv4)	10.1.1.6	255.255.255.0	10.1.1.1	Automatic
Node2 LAN1 (IPv4)	10.1.1.8	255.255.255.0	10.1.1.1	Automatic

Site 2 – Single Member

1. From the **Grid** tab, select the **Grid Manager** -> **Members** tab.
2. Expand the Toolbar and click **Add** -> **Add Grid Member**.
3. In the *Add Grid Member* wizard, enter the following and click **Next**:

- **Member Type**: Select **Infoblox**
- **Host Name: ns4.site2.corpxyz.com**
- **Comment: Site 2- ns4.site2.corpxyz.com**

4. Specify the following information about the member that you are adding to the Grid and click **Next**:
   - **Type of Network Connectivity:** Select **IPv4** from the drop-down list.
   - **Standalone Member:** Select this option.
   - **Required Ports and Addresses:** Click the empty fields and enter the following information:
     - **Address:** Enter **10.2.1.10**.
     - **Subnet Mask (IPv4) or Prefix Length (IPv6)**: Enter **255.255.255.0**
     - **Gateway**: Enter **10.2.1.1**
     - **Port Settings**: Select **AUTOMATIC**.
5. Save the configuration and click **Restart** if it appears at the top of the screen.
6. Log out from the Grid Master.

Join Appliances to the Grid

To complete the process of adding appliances to the Grid, log in to and configure each individual appliance so that it can contact the Grid Master.

HQ Site – HA Grid Member (Node 1)

Make a console connection to the appliance that you want to make Node 1 in the HA pair, and then enter the following:

```
Infoblox > set network
 NOTICE: All HA configuration is performed from the GUI. This interface is used only to configure a standalone node or to join a Grid.
 Enter IP address: 10.0.2.6
 Enter netmask : 255.255.255.0
 Enter gateway address : 10.0.2.1
 Configure IPv6 network settings? (y or n):n Become Grid member? (y or n): y
 Enter Grid Master VIP: 10.0.1.10
 Enter Grid Name: corpxyz
 Enter Grid Shared Secret: Mg1kW17d
 New Network Settings: IP address: 10.0.2.6
 Netmask: 255.255.255.0
 Gateway address: 10.0.2.1
 Join Grid as member with attributes: Grid Master VIP: 10.0.1.10
 Grid Name: corpxyz
 Grid Shared Secret: Mg1kW17d
 WARNING: Joining a Grid will replace all the data on this node!
 Is this correct? (y or n): y
 Are you sure? (y or n): y
```

The Infoblox application restarts. After restarting, the appliance contacts the Grid Master and joins the Grid as Node 1.

HQ Site – HA Member (Node 2)

Make a console connection to the appliance that you want to make Node 2 in the HA pair, and then enter exactly the same data you entered for Node 1 except that the IP address is 10.0.2.8.

After the application restarts, the appliance contacts the Grid Master and joins the Grid as Node 2, completing the HA member configuration for the HQ site.

Site 1 – HA Grid Member (Node 1)

Make a console connection to the appliance that you want to make Node 1 in the HA pair at Site 1 and use the `set network` command to configure its basic network and Grid settings. Use the following data:

- **IP Address**: **10.1.1.6**
- **Netmask**: **255.255.255.0**
- **Gateway**: **10.1.1.1**
- **Grid Master VIP**: **10.0.1.10**
- **Grid Name**: **corpxyz**
- **Grid shared secret**: **Mg1kW17d**

The Infoblox application restarts. After restarting, the appliance contacts the Grid Master and joins the Grid as Node 1.

Site 1 – HA Grid Member (Node 2)

Make a console connection to the appliance that you want to make Node 2 in the HA pair at Site 1 and enter exactly the same data that you entered for Node 1 except that the IP address is 10.1.1.8.

After the application restarts, the appliance contacts the Grid Master and joins the Grid as Node 2, completing the HA member configuration for Site 1.

Site 2– Single Grid Member

Make a console connection to the appliance that you want to make Node 1 in the HA pair at Site 1 and use the set network command to configure its basic network and Grid settings. Use the following data:

- **IP Address**: **10.2.1.10**
- **Netmask**: **255.255.255.0**
- **Gateway**: **10.2.1.1**
- **Grid Master VIP**: **10.0.1.10**
- **Grid name**: **corpxyz**
- **Grid shared secret**: **Mg1kW17d**

The Infoblox application restarts. After restarting, the appliance contacts the Grid Master and joins the Grid.
To check the status of all the Grid members, log in to the Grid Master at 10.0.1.10, and from the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, select **10.0.1.10** and click the Detailed Status icon. Check that the status indicators are all green in the Detailed Status panel. As an appliance joins a Grid, it passes through the following phases: Offline, Connecting (Downloading Release from Master), Synchronizing, and Running.

> ⚠ Note
> Depending on the network connection speed and the amount of data that the master needs to synchronize with the member, the process of joining a Grid can take from several seconds to several minutes to complete.

The Grid setup is complete.

Import DHCP Data

The Data Import Wizard is a software tool that you can download from the Infoblox Support site to your management system. With it, you can import data from legacy DHCP and DNS servers to NIOS appliances. In this example, you use it to import both DHCP and DNS data to the Grid Master at 10.0.1.10, which then uses the database replication mechanism to send the imported data to other Grid members. In the wizard, you also specify which Grid members serve the imported data. The wizard supports various types of DHCP formats, such as the following:

- ISC DHCP
- Lucent VitalQIP
- Microsoft
- Nortel NetID
- CSV (comma-separated values); you can also import IPAM data in CSV format. In this example, all the DHCP data is in standard ISC DHCP format.

Importing DHCP Data for HQ and Site 2

1. Save the DHCP configuration file from your legacy DHCP server at 10.0.2.20 to a local directory.
2. Visit *https://support.infoblox.com*, log in with your support account, and download the *Data Import Wizard*. The *Data Import Wizard* application downloads to a container within a Java sandbox on your management system and immediately launches, displaying the *Welcome* page.
3. After reading the information in the left panel, click **Next**.
4. Select Import to Infoblox Appliance, enter the following, and then click **Next**:
    - **Hostname or IP address**: **10.0.1.10**
    - **Username**: **admin**
    - **Password**: **1n85w2IF**
5. Select the following, and then click **Next**:
    - What kind of data would you like to import? **DHCP/IPAM**
    - Which legacy system are you importing from? **ISC DHCP**
    - Which appliance will be serving this data? **10.0.2.10**
6. Type the path and file name of the DHCP configuration file saved from the legacy server, and then click **Next**.
   Or
   Click **Browse**, navigate to the file, select it, click **Open**, and then click **Next**.
7. In the *Global DHCP Configuration* table, double-click the *Value* cell for the *domain-name-servers* row, and change the IP addresses to **10.0.2.10**.
8. When satisfied with the data, click **Import**.
   You can view the status of the importation process and a summary report in the *Data Import Wizard* Log.
9. To enable DDNS updates, log in to the Grid Master, from the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **Grid DHCP Properties**.
10. In the **DDNS** -> **Basic** tab of the *Grid DHCP Properties* editor, select **Enable DDNS Updates**.
11. Save the configuration and click **Restart** if it appears at the top of the screen.
12. To check the imported DHCP configuration file, from the **Data Management** tab, select the **DHCP** tab, -> **Members** tab -> **10.0.2.10** checkbox. Expand the Toolbar and click **View DHCP Configuration**.
13. In the DHCP configuration file, check that all the imported subnets are present, and navigate to the beginning of the file and check that you see the `ddns-updates on` statement. (If you see `ddns-updates` **off**, enable DDNS updates for the Grid as explained in steps 9-12.)

Importing DHCP Data for Site 1

1. Repeat the steps as described in Configuring a Grid-Importing DHCP Data for HQ and Site 2, saving the DHCP configuration file from your legacy DHCP server at 10.1.1.20, and importing it to the Grid Master at 10.0.1.10 for the member with IP address 10.1.1.10 to serve.
2. Check the imported DHCP configuration file by logging in to the Grid Master and from the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **10.1.1.10** checkbox. Expand the Toolbar and click **View DHCP Configuration**.

Importing DHCP Data for Site 3

1. Repeat the steps as described in Configuring a Grid-Importing DHCP Data for HQ and Site 2, saving the DHCP configuration file from your legacy DHCP server at 10.1.1.20, and importing it to the Grid Master at 10.0.1.10 for the member with IP address 10.3.1.10 to serve.
2. After the importation process completes, check the imported DHCP configuration file by logging in to the Grid Master and from the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **10.3.1.10** checkbox. Expand the Toolbar and click **View DHCP Configuration**.

Import DNS Data

Using the *Infoblox Data Import Wizard*, import DNS data from the legacy hidden primary server at 10.0.1.5 to the new hidden primary server at 10.0.1.10 (the Grid Master). The following are three phases to this task:

1. Before Using the Wizard:
    - Save the named.conf file from the legacy server to a file in a local directory on your management system.
    - Enable the legacy server to perform zone transfers to the NIOS appliance.
    - Configure three name server groups for the Grid and allow the Grid Master/hidden primary DNS server at 10.0.1.10 to receive DDNS updates from the Grid members at 10.0.2.10, 10.1.1.10, and 10.3.1.10. These members act as secondary DNS servers and DHCP servers.
2. Using the Wizard: Define the source, destination, and type of DNS data in the DNS configuration file (named.conf) that you want to import.
3. After Using the Wizard: Check the imported DNS configuration file.

In this example, all the DNS data is in BIND 9 format. The *Data Import Wizard* supports various types of DNS formats, such as the following:

- BIND 4, 8, and 9
- Microsoft
- Lucent VitalQIP
- Nortel NetID

Before Using the Wizard

You must set up the legacy server and Grid Master before using the *Data Import Wizard*.

Legacy Server

1. Log in to the legacy name server at 10.0.1.5 and save the named.conf file, which contains all the DNS settings that you want to import into the Infoblox name server, to a local directory on your management system.
2. On the legacy server, enable zone transfers to the NIOS appliance.

Infoblox Grid Master – DDNS Updates

1. Log in to the Grid Master at 10.0.1.10, and from the **Data Management** tab, select the **DNS** tab -> **Members** tab -> **10.0.1.10** checkbox and select the Edit icon.
2. In the *Member DNS Configuration* editor, select the **Updates** tab -> **Basic** tab and enter the following:
    - Select **Override**.

- Allow updates from: Click the Add icon and select **IPv4 Address**. Enter **10.0.2.10** in the **Name** field of the new row.

3. Click the Add icon again and add **10.1.1.10** and **10.2.1.10** as IP addresses from which you allow DDNS updates.
4. Save the configuration and click **Restart** if it appears at the top of the screen.
   Note when all DNS servers are members in the same Grid, the members use database replication to synchronize all their data—including DNS zone data. You can change the default behavior so that Grid members use zone transfers instead. In this example, Grid members use database replication.

Infoblox Grid Master – Name Server Groups

1. From the **Data Management** tab, select the **DNS** tab -> **Name Server Groups** tab.
2. Click the Add icon to open the *Add Name Server Group* wizard.
3. Enter the following:
   - **Name Server Group Name:** HQ-Group
4. Click the Add icon and add the following:
   - **Grid Primary**: **ns1.corpxyz.com**; **Stealth**: Select this checkbox.
   - **Grid Secondary**: **ns2.corpxyz.com**; **Grid replication (recommended)**: Select this checkbox.
5. Click **Save & New**.
6. Repeat steps 2 to 4 to create another group. Name it **Site1-Group**, and use **ns1.corpxyz.com** as the hidden primary server, **ns3.site1.corpxyz.com** as a secondary server, and Grid replication for zone updates.
7. Repeat steps 2 to 4 to create another group. Name it **Site2-Group**, and use **ns1.corpxyz.com** as the hidden primary server, **ns4.site2.corpxyz.com** as a secondary server, and Grid replication for zone updates.

Using the Wizard

While progressing through the *Data Import Wizard*, you must define the source, destination, and type of DNS data that you want to import. You then make some simple modifications to the data and import it.

Defining the Source, Destination, and Type of DNS Data

1. Launch the *Data Import Wizard*.
2. After reading the information in the left panel of the welcome page, click **Next**.
3. Select **Import to Infoblox Appliance**, enter the following, and then click **Next**:
   - **Hostname or IP address**: **10.0.1.10**
   - **Username**: **admin**
   - **Password**: **1n85w2IF**
     The *Data Import Wizard* Log opens in a separate window behind the wizard. Leave it open while you continue.
4. Select the following, and then click **Next**:
   - **What kind of data would you like to import?**: **DNS**
   - **Which legacy system are you importing from?**: **BIND 9**
   - **Which appliance will be serving this data?**: **10.0.1.10**
5. Select the following, and then click **Next**:
   - **What BIND 9 DNS configuration file would you like to use?**: Click **Browse**, navigate to the named.conf file you saved from the legacy server, select it, and then click **Open**.
   - **What type of BIND 9 DNS data do you want to import?**: **DNS zone information** and **DNS record data**
   - **Where is the BIND 9 DNS record data?**: **Zone transfer(s) from a DNS server**; **10.0.1.5**

The wizard displays two tables of data. The upper table contains global DNS server configuration parameters. The lower table contains zone configurations.
The *Data Import Wizard* Log presents a summary listing the number of views, zones, and DNS records in the configuration file.

> ⚠ Note
> Only superusers can import A, AAAA, shared A, and shared AAAA records with a blank name. Limited-access users must have read/write permission to **Adding a blank A/AAAA record** to import A, AAAA, shared A, and shared AAAA records with a blank name, otherwise, the import operation might fail. You can assign global

permission for specific admin groups and roles to allow to import A, AAAA, shared A, and shared AAAA records with a blank name. For more information,
see *Administrative Permissions for Adding Blank A or AAAA Records*.

Modifying DNS Data

While importing data from the legacy DNS server, you cancel the importation of global configuration settings, and apply the name server groups you created in *Before Using the Wizard* to the zones you want to import.

1. In the *Global DNS Configuration* table, select all rows by clicking the top row and then **SHIFT**+click the bottom row.
2. Right-click the selected rows to display the *Set Import Options* dialog box, select **Do not import**, and then click **Apply**.
3. In the *DNS Zones* table, clear the **Import** checkbox for the default view.
4. Select **corpxyz.com**, **lab.corpxyz.com** and all the corresponding reverse-mapping zones.
   Tip: You can use **SHIFT**+click to select multiple contiguous rows and **CTRL**+click to select multiple noncontiguous rows.
5. Right-click the selected rows, and then select **Set Import Options**.
6. In the *Set Import Options* dialog box, enter the following, and then click **Apply**:
   - **Set Zone Type**: No change
   - **Set Import Option**: No change
   - **Set View**: default
   - **Set Member**: HQ-Group master
7. Select **site1.corpxyz.com** and all the reverse-mapping zones with 1 in the second octet in the zone name (1.1.10.in-addr.arpa, 2.1.10.in-addr.arpa, 3.1.10.in-addr.arpa, and so on).
8. Right-click the selected rows, and then select **Set Import Options**.
9. In the *Set Import Options* dialog box, make the same selections as in *6*, but choose **Site1-Group** master from the **Set Member** drop-down list.
10. Similarly, select **site2.corpxyz.com** and all the reverse-mapping zones with 2 in the second octet in the zone name.
11. Right-click the selected rows, and then select **Set Import Options**.
12. In the *Set Import Options* dialog box, make the same selections as in *6*, but choose **Site2-Group** master from the **Set Member** drop-down list.

Importing DNS Data

1. Click **Import**.
   The wizard imports the global DNS parameters and zone-specific configuration settings from the named.conf file and performs a zone transfer of the data from the legacy server.
2. Use the *Data Import Wizard* Log to monitor progress and review results afterward.
   The log lists all the zones that the wizard imports and concludes with a total of all the successfully and unsuccessfully imported zones.
   Note if the wizard is unable to import a zone, an error message with an explanation appears in the log.
3. To close the *Data Import Wizard*, click **Exit**. This closes the *Data Import Wizard* Log as well.

After Using the Wizard

After you import data, you must restart services on the Grid Master and delete the A records for the legacy servers from the corpxyz.com zone. You can also confirm that the imported data is correct and complete by checking the DNS configuration and the forward- and reverse-mapping zones.

1. Log in to the Grid Master (10.0.1.10), select the **Grid** tab, expand the Toolbar, and then click the Restart Services icon.
   Note when importing data through the wizard rather than entering it through the GUI, the Restart Services icon does not change to indicate you must restart service for the appliance to apply the new data. Still, restarting service on the Grid Master is necessary for the imported configuration and data to take effect.

2. To remove A records for the legacy servers, from the **Data Management** tab, select **DNS** tab -> **Zones** tab -> **corpxyz.com**.
3. Expand the **Records** section, select the following A records in the *corpxyz.com* zone, and then click the Delete icon:
    a. ns1 (for 10.0.1.5)
    b. ns2 (for 10.0.2.5)
    c. ns3.site1.corpxyz (for 10.1.1.5)
    d. ns4.site3.corpxyz (for 10.2.1.5)
4. Remove the respective A records for legacy servers from the *site1.corpxyz* and *site3.corpxyz* subzones.
5. To check the imported DNS configuration file, from the **Data Management** tab, select the **DNS** tab -> **Members** tab -> **10.0.1.10** checkbox. Expand the Toolbar and click **View** -> **View DNS Configuration**.
Note that if you do not see the imported DNS configuration file, ensure that you enabled DNS and restarted the services.
6. Scroll through the DNS configuration log to check that each imported zone has an allow-update statement like the following one for the `10.1.10.in-addr.arpa` reverse-mapping zone:

```
zone "10.1.10.in-addr.arpa" in {
  …
 allow-update { key DHCP_UPDATER; 10.0.2.10; 10.1.1.10; 10.2.1.10; };
  …
 };
```

Enable DHCP and Switch Service to the Grid

Finally, you must enable DHCP service on the three Grid members at 10.0.2.10, 10.1.1.10, and 10.2.1.10, and switch DNS and DHCP service from the legacy DNS and DHCP servers to them.

1. Log in to the Grid Master (10.0.1.10) and from the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **10.0.2.10** checkbox. Expand the Toolbar and click **Start**.
2. Repeat step 1 to enable DHCP on 10.1.1.10 and 10.3.1.10.
Note to start the DNS service, as described in *Starting and Stopping the DNS Service.* The Grid members are ready to serve DHCP and DNS, and send DDNS updates.
3. Take the legacy DHCP and DNS servers offline.

Managing a Grid

After you configure a Grid Master and add members, you might need to perform the following tasks:

- *Changing Grid Properties*
- *Configuring Security Level Banner*
- *Configuring Notice and Consent Banner*
- *Configuring Informational Level Banner*
- *Configuring Recursive Deletions of Networks and Zones*
- *Setting the MTU for VPN Tunnels*
- *Removing a Grid Member*
- *Promoting a Grid Master Candidate*
    - *Testing the Connection of the Master Candidate with the Grid Members*
    - *Promoting the Master Candidate*
    - *Reconnecting Groups After Grid Master Candidate Promotion*
- *Enabling Read-only API Access on the Grid Master Candidate*

Changing Grid Properties

You can change a Grid name, its shared secret, and the port number of the VPN tunnels that the Grid uses for communications. Note that changing the VPN port number, time zone, date or time requires a product restart.
To modify the properties of a Grid, do the following:

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Expand the Toolbar and select **Grid Properties** -> **Edit**.
3. In the *Grid Properties* editor, select the **General** tab -> click the **Basic** tab, and then modify any of the following:
    - **Grid Name:** Type the name of a Grid. The default name is *Infoblox*.
    - **Shared Secret:** Type a shared secret that all Grid members use to authenticate themselves when joining the Grid. The default shared secret is *test*.
    - **Shared Secret Retype:** Type the shared secret again to confirm its accuracy.
    - **Time Zone:** Choose the applicable time zone from the drop-down list.
    - **Date:** Click the calendar icon to select a date or enter the date in YYYY-MM-DD format.
    - **Time:** Click the clock icon to select a time or enter the time in HH:MM:SS format.
    - **VPN Port:** Type the port number that the Grid members use when communicating with the Grid Master through encrypted VPN tunnels. The default port number is 1194. For more information about port numbers for grid communication, see *Creating a Grid Master.*
    - **Enable Recycle Bin:** Select the checkbox to enable the Recycle Bin. The Recycle Bin stores deleted items when the user deletes Grid, DNS, or DHCP configuration items. Enabling the Recycle Bin allows you to undo deletions and to restore the items on the appliance at a later time. If you do not enable this feature, deleted items from the GUI are permanently removed from the database.
    - **Audit Logging:** Select one of the following:
        - **Detailed**: This is the default type. It is automatically selected. It provides detailed information on all administrative changes such as the date and time stamp of the change, administrator name, changed object name, and the new values of all properties.
        - **Brief**: Provides information on administrative changes such as the date and time stamp of the change, administrator name, and the changed object name. It does not show the new value of the object.
        - **WAPI Detailed**: Select this option to view detailed WAPI (RESTful API) session information logs for successful WAPI calls such as PUT, POST, and DELETE. You can view the URI, InData and response time for each WAPI call. For more information, see *Monitoring Tools*.
        - In the *Grid Properties* editor, select the **General** tab -> click the **Advanced** tab (or click Toggle Advanced Mode) and modify any of the following:
            - **Enable GUI Redirect from Member**: Select this checkbox to allow the appliance to redirect the Infoblox GUI from a Grid member to the Grid Master.
              Note that if read-only API access is enabled for a Grid Master Candidate, then selecting the **Enable GUI Redirect from Member** checkbox for the Grid Master Candidate does not redirect the Infoblox GUI from the Grid Master Candidate to the Grid Master. For more information about enabling read-only API access on a Grid Master Candidate, see Enabling Read-only API Access on the Grid Master Candidate below.
            - **Enable GUI/API Access via both MGMT and LAN1/VIP**: Select this checkbox to allow access to the Infoblox GUI and API using both the MGMT and LAN1 ports for standalone appliances and MGMT and VIP ports for an HA pair. This feature is valid only if you have enabled the MGMT port. For information about enabling the MGMT port, see *Appliance Management*.
              Note that the appliance uses the MGMT port only to redirect the Infoblox GUI from a Grid member to the Grid Master even after you enable the **Enable GUI/ API Access via both MGMT and LAN1/VIP** feature.
    - **Show Restart Banner**: Select this checkbox to enable the appliance to display the **Restart Banner** at the top of Grid Manager whenever the appliance notifies you that a service restart is required.
    - **Require Name**: Select this checkbox to prompt the administrator to input the username before performing the service restart. When you select this checkbox, the appliance displays the *Confirm Restart Services* dialog box. Enter the username in the **Name** field and click **Restart Services**. For information about restarting service, see *Restarting Services.*
4. Save the configuration.

If you changed the VPN port number, time zone, date or time, Grid Manager displays a warning indicating that a product restart is required. Click **Yes** to continue, and then log back in to Grid Manager after the application restarts.

Configuring Security Level Banner

You can publish a security banner that indicates the security level of the Infoblox Grid. It appears on the header and footer of all pages of Grid Manager. The security level can be Top Secret, Secret, Confidential, Restricted, and Unclassified. Each message type is associated with a predefined security level color. You can modify this color at any point of time. Grid Manager automatically uses an appropriate contrasting text font color that goes with the banner color. Only superusers can configure and enable this feature.
To configure the advanced security level banner for a Grid:

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Expand the Toolbar and select **Grid Properties** -> **Edit**.
3. In the *Grid Properties* editor, select the **Security** tab -> **Advanced** tab.
4. Complete the following:
    - **Enable Security Banner:** Select this to enable the display of the security banner.
    - **Security Level:** From the drop-down list, select the security level for the banner.
    - **Security Level Color:** The default color is displayed in the drop-down. If necessary, using the drop-down list, select the required color for the security level banner. When you change the security level, Grid Manager resets default color for that level.
    - **Classification Message:** Enter the message you want to display in the security banner. You can enter up to 190 characters.
5. Save the configuration.

Security banner that you have configured will appear on the header and footer of the Grid Manager screen including the Login screen.

Configuring Notice and Consent Banner

You can configure and publish a notice and consent banner as the first login screen that includes specific terms and conditions you want end users to accept before they log in to the Infoblox Grid. When an end user tries to access Grid Manager, this banner is displayed as the first screen. Before accessing the login screen of the Grid Manager, the user must accept the terms and conditions displayed on the consent screen. Only superusers can configure and enable this feature.
To configure the notice and consent banner, do the following:

1. From the **Grid** tab, open the **Grid Manager** tab.
2. Expand the **Toolbar** and select **Grid Properties** -> **Edit**.
3. In the *Grid Properties* editor, select the **Security** tab -> **Advanced** tab, and then specify the following:
    - **Enable Notice and Consent Banner**: Select this checkbox to enable the display of the notice and consent banner. In the text field, enter the message that you want the banner to show. The message cannot exceed 10,000 characters.
4. Save the configuration.

This banner appears as the first screen when users access Grid Manager. Users must read the terms and conditions and then click **Accept** on the consent screen before they can access the login screen of Grid Manager.

Configuring Informational Level Banner

You can publish the informational banner for multiple uses, such as to indicate whether the Infoblox Grid is in production or a lab system. The banner can also be used for issuing messages of the day. The informational level banner appears on the header of the Grid Manager screen. You can publish the banner information you want and set the banner color. Grid Manager automatically uses an appropriate contrasting text font color that goes with the banner color. Only superusers can configure and enable this feature.
To configure the advanced informational banner for a Grid`, do the following:

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Expand the Toolbar and select **Grid Properties** -> **Edit**.
3. In the *Grid Properties* editor, select the **General** tab -> **Advanced** tab

4. Specify the following:
    - **Enable informational GUI Banner:** Select this checkbox to enable the display of the informational banner message.
    - **Banner Color:** The default color is displayed in the drop-down. If necessary, using the drop-down list, select the required color for the informational level banner.
    - **Message:** Enter the message you want to display in the informational banner. You can enter up to 190 characters.
5. Save the configuration.
   Informational banner appears on the header of the Grid Manager screen.

Configuring Recursive Deletions of Networks and Zones

Use Grid Manager, to configure a group of users that are allowed to delete or schedule the deletion of a network container, its child objects, a zone and the zone's child objects. For instructions on deleting a network container or a zone, see *Deleting Network Containers* and *Removing Zones*.
When you select **All Users** or **Superusers**, these users can choose to delete a parent object and reparent its child objects, or they can choose to delete a parent object and all its child objects. These options appear only if a network container or a zone has child objects. For instructions on scheduling recursive deletion of network containers and zones, see *Scheduling Recursive Deletions of Network Containers and Zones*.
When you select **Nobody**, all the users can delete the parent object only. All the child objects, if any, are re-parented. For more information about scheduling deletions, see as described in *Scheduling Deletions* .Note that you can restrict specific users to perform recursive deletions of network containers and zones only through Grid Manager. These settings do not prevent other users from performing recursive deletions through the API.

> ⚠ Note
> You must have Read/Write permission to all the child objects in order to delete a parent object. Recursive deletion is applicable to all zone types except stub and forward-mapping zones.

The appliance puts all deleted objects in the Recycle Bin, if enabled. You can restore the objects if necessary. When you restore a parent object from the Recycle Bin, all its contents, if any, are re-parented to the restored parent object. For information about Recycle Bin, see *Finding and Restoring Data*.
To configure the group of users to perform recursive deletions:

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Expand the Toolbar and select **Grid Properties** -> **Edit**.
3. In the *Grid Properties* editor, select the **General** tab -> **Advanced** tab.
4. Under **Present the option of recursive deletion of networks or zones to**, select one of the following:
    - **All Users**: Select this to allow all users, including superusers and limited-access users, to choose whether they want to delete the parent object and its contents or the parent object only when they delete a network container/network or a zone. This option is selected by default.
    - **Superuser**: Select this to allow only superusers to choose whether they want to delete the parent object and its contents or the parent object only when they delete a network container/network or a zone.
    - **Nobody**: When you select this, users can only delete the parent object (network container or zone). All child objects, if any, are re-parented.
5. Save the configuration.

Setting the MTU for VPN Tunnels

You can configure the VPN MTU (maximum transmission unit) for any appliance with a network link that does not support the default MTU size (1500 bytes) and that cannot join a Grid because of this limitation. If an appliance on such a link attempts to establish a VPN tunnel with a Grid Master to join a Grid, the appliance will receive a PATH-MTU error, that indicates that the path MTU discovery process has failed. For information about the MTU discovery process, see *RFC 1191, Path MTU Discovery*.
To avoid this problem, set a VPN MTU value on the Grid Master for any appliance that cannot link to it using a 1500-byte MTU. When the appliance contacts the master during the key exchange handshake that occurs during the Grid-joining operation, the master sends the appliance the MTU setting to use.
To set the VPN MTU for a Grid member, do the following:

1. In the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox -> Edit icon.
2. Select the **Network** -> **Advanced** tab of the *Grid Member Properties* editor.
3. In the **VPN MTU** field, enter a value between 600 and 1500.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Removing a Grid Member

You might want or need to remove a member from a Grid, perhaps to disable it or to make it an independent appliance or an independent HA pair. Before you remove a member, make sure that it is not assigned to serve any zones or networks. To remove a Grid member do the following:

1. In the **Grid** tab, open the **Grid Manager** tab -> **Members** tab
2. Select the *Grid_member* checkbox
3. Click the Delete icon.

Promoting a Grid Master Candidate

To promote a Grid Master candidate to a Grid Master, you must have already designated a member as a Grid Master Candidate, by selecting the **Master Candidate** option in the **General** tab of the *Grid Member Properties* editor. You can designate any member as a Grid Master Candidate. The Grid Master Candidate gets a complete copy of the Grid database. Therefore, Infoblox recommends that you configure the same appliance models for the Grid Master and Grid Master Candidates. By default, the Grid Master promotion uses UDP port 1194. Make sure that the UDP 2114 and UDP 1194 ports are open between the Grid members and a newly designated Grid Master. During a Grid Master promotion, the newly promoted Grid Master continuously contacts all Grid members, including the original Grid Master on the UDP port 2114, until it reaches them. Upon reaching them, the newly promoted Grid Master notifies all Grid members that it is the new Grid Master. Next, the Grid Members restart and attempt to establish normal Grid communications (via BloxSync) with the newly promoted Grid Master. Before promoting a Grid Master Candidate, check your firewall rules to ensure that the Master Candidate can communicate with all the Grid members. For information about grid communications, see *About Grids*.

> ⚠ Note
> Before promoting a Grid Master Candidate, ensure that valid client SSL certificates are installed. For more information about installing certificates, see *Managing Certificates*.

Testing the Connection of the Master Candidate with the Grid Members

Before promoting a Grid Master Candidate, check whether the Grid Master Candidate is connected to the rest of the Grid members, by scheduling a test promotion. You can do this either by using Grid Manager or by using the NIOS CLI. For information about scheduling a test promotion by using the NIOS CLI, see *show test_promote_master* and *set test_promote_master*.

The connection of the Grid Master Candidate to the rest of the Grid members is checked by sending specifically crafted test packets from the Grid Master Candidate and checking whether the Grid members are able to receive these packets.

To test the connection of the Grid Master Candidate with the Grid members, complete the following:

1. In the **Grid** tab -> **Grid Manager** tab, expand the Toolbar, and then click **GMC Promote Test**.
2. In the *GMC Promote Test* editor, do the following:
    a. Click the Schedule icon at the top of the wizard. In the *Schedule Change* panel, do one of the following:
        - To run a test promotion immediately, select **Now**.
        - To schedule a test promotion to run later, select **Later**, and enter a date, time, and time zone.
    b. From the **Select GMC** drop-down list, select the Grid Master Candidate that you want to promote to Grid Master.
    c. In the **Timeout (secs)** field, set the timeout for the packet to be received in seconds. That is, if the packet is not received by the Grid members within this timeout, the connection is deemed to have failed.
    d. Select the **Continuous Testing** checkbox if you want the Grid Master Candidate to send packets to the selected Grid members on a continual basis. The maximum period of time for which packets can be sent is 120 seconds.

e. In the **Members** table, select the Grid members to which the Grid Master Candidate must establish a connection.

3. Click **Start** to start the test promotion. You can click **Stop** at any time to stop the test promotion.
4. Click **GMC Promotion Test Results** to view the status of the test promotion.

⚠ Notes

- You cannot upgrade the Grid during a test promotion.
- You can test promote of only one Grid Master Candidate at a time.
- If new members are added when a test promotion is in progress, connection between the new members and the Grid Master Candidate will not be tested.
- If Threat Protection is enabled in the Grid and the member running the Threat Protection service is in the list of tested members, you must set the value in the **Timeout** field to at least 30 seconds. This is because Threat Protection needs to publish a new rule that allows traffic to pass from tested members. If you set a lower timeout value, the packets may be dropped, and the test will report that the member cannot connect to the tested Grid Master Candidate.
- Communication between DUT and Grid Master is not tested because of firewall complications and running the OpenVPN connection. Communication is supposed to be already checked and DUT is already connected to Grid Master.
- You cannot run continuous testing when a regular test is in progress and you cannot run a regular test when continuous testing is in progress.
- If multiple public cloud instances such as AWS, Azure, GCP and so on are configured as the Grid Master Candidate, ensure that these instances are able to communicate with other public cloud instances. Otherwise, the Grid Master Candidate promote test does not work.
- When you configure a Grid Master Candidate which includes an External NTP server and when you promote a Grid Master Candidate to Grid Master, the External NTP is enabled in the Grid Master Candidate. In case you try to edit the member properties an error message is displayed. Therefore, Infoblox recommends that you remove the External NTP configuration before you promote the Grid Master Candidate.

Promoting the Master Candidate

To promote a Master Candidate, you can make a direct serial connection to the console port on the active node of an HA Candidate or to the console port on a single Candidate. You can also make a remote serial connection (using SSH v2) to the candidate. Enter the following Infoblox CLI command to promote a Master Candidate:

```
set promote_master.
```

You can do one of the following to promote a Master Candidate:

- Immediately notify all Grid members about the promotion.
- Set a sequential notification to provide wait time for Grid members to join the new Grid Master. Staggering the restarts of Grid members can minimize DNS outages. The sequential order for Grid members to join the new Grid Master begins with the old Grid Master and then the Grid members in FQDN order. The default delay time is 120 seconds. You can configure the delay time from a minimum of 30 seconds up to 600 seconds.

⚠ Notes

- During a Grid Master promotion, ensure that you do not designate a Grid member as a Grid Master Candidate or promote a Master Candidate. In addition, wait up to two hours since the last promotion to perform another Grid Master promotion. Otherwise, you might experience unnecessary member reboots. Whenever possible, separate any operations that require product restarts by at least an hour.
- When a Grid Master Candidate is selected as a subscribing member, then after Grid Master Candidate promotion, the subscription still takes place through the previous Grid Master Candidate member which is new a Grid member.

To promote a Grid Master Candidate, do the following:

1. Establish a serial connection (through a serial console or remote access using SSH) to the Master Candidate. For information about making a serial connection, as described in Method 2-Using the CLI, see *Deploying a Single Independent Appliance*.
2. At the CLI prompt, use the command `set promote_master` to promote the Master Candidate and send notifications to all Grid members immediately, or promote the Master Candidate to the Grid Master immediately and specify the delay time for the Grid members to join the new Grid Master. For more information about the command, refer to the *Infoblox CLI Guide*.
3. To verify the new master is operating properly, log in to the Infoblox Grid Manager on the new master using the VIP address for an HA master or the IP address of the LAN1 port for a single master.
4. Check the icons in the **Status** column. Also, select the master, and then click the Detailed Status icon in the table toolbar. You can also check the status icons of the Grid members to verify that all Grid members have connected to the new master. If you have configured delay time for Grid member notification, it will take some time for some members to connect to the new master. You can also check your firewall rules and log in to the CLI to investigate those members.

⚠ Note that when you promote the Master Candidate to a Grid Master, the IP address will change accordingly. If you have configured a FireEye appliance, then any changes in the Grid Master IP address, FireEye zone name, associated network view or the DNS view will affect the **Server URL** that is generated for a FireEye appliance. The FireEye appliance will not be able to send alerts to the updated URL when there is a change in the IP address. You must update the URL in the FireEye appliance to send alerts to the NIOS appliance. For more information, see *Configuring FireEye RPZs*.

Reconnecting Groups After Grid Master Candidate Promotion

This feature gives you more control over the Grid Master Candidate promotion, minimizes service outages by allowing you to group the members and schedule a time for the groups to reconnect to the newly promoted Grid Master. As soon as the scheduled time arrives, members of Grid Master Candidate groups will re-connect to the newly promoted master.

To schedule a group reconnection to the newly promoted Grid Master Candidate, do the following:

1. From the Grid tab -> **Grid Manager** tab, expand the Toolbar, and then click **GMC Group Promotion**.
2. In the **GMC Group Promotion Schedule** editor, specify the following:
   - **Activate GMC Group Promotion Schedule**: Select this option to enable the scheduled reconnection of the group after the Grid Master Candidate is promoted.
   - Click the **+** icon and specify the following in **Add GMC Group Wizard**:
     - **Name**: Provide the group's name.
     - **Promotion Policy**: Select either **Simultaneously** or **Sequentially**, as required.
       Simultaneously: Select this option to simultaneously reconnect the group members after the Grid Master Candidate promotion at the same time.
       Sequentially: Select this option to sequentially reconnect the group members after Grid Master Candidate promotion in a sequence. Note that when you select sequentially, each group member joins the Grid master in a sequence with an interval of 30 seconds.
     - **Time Zone**: Select a time zone that applies to the start time you enter. If this time zone is different from the Grid time zone, the appliance converts the time you enter here based on the Grid time zone, after you save this schedule. When you display this schedule again, it displays the converted time. Selecting the time zone here does not affect any time zone settings in the Grid. (For information about setting the Grid and member time zones, see *Managing Time Settings*). After the Grid Master Candidate promotion, members will reconnect based on the selected time zone.
     - **Date**: Enter a start date of the group members reconnecting after Grid Master Candidate promotion in YYYY-MM-DD (year-month-day) format. You can click the calendar icon to select a date from the calendar widget.
     - **Time**: Enter a start time of the group members reconnecting after Grid Master Candidate promotion in hh:mm:ss AM/PM (hour:minute:second in AM or PM) format. You can select a time from the drop-down list.

- **Comment**: Enter your comments.
- Click **Next**.
- In the **Members Assignment** wizard, select the Grid member(s) to add to the newly created group.

3. **Save** and **close** the wizard.

To modify an existing group, on the **GMC Group Promotion Schedule** editor:

1. Click Edit icon, and modify the changes in **Add GMC Group Wizard**.
2. **Save** and **close** the wizard.

To delete an existing Grid Master Candidate group, do the following in the **GMC Group Promotion Schedule** editor:

1. Click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes**.

After enabling the Grid Master Candidate group promotion, use the `set promote_master` CLI command to start the Grid Master Candidate promotion.
Use the `set gmc_promotion disable` CLI command to disable the **Activate GMC Group Promotion Schedule** option. Note that, this command can be executed on Grid Master and Grid Master Candidate. For more information see, *set gmc_promotion*.

⚠ Notes

- If the **Activate GMC Group Promotion Schedule** option is not enabled on Grid Master, and if you choose to continue with Grid Master Candidate promotion using the command, `set promote_master`, then the Grid Master Candidate promotion works as described in *Promoting the Master Candidate*.
- By default, all the members are part of the **Default** group. The Grid Master Candidate group members can be customized according to your requirement; however Grid Master Candidate cannot be customized as Grid Master Candidate is part of the **Default** group only.
- If you want to reconnect members of any group to the newly promoted Grid Master, irrespective of the scheduled time, you can click **Join Group Now** option, by selecting the following **Join Group Now** icon, 

  in **GMC Group Promotion Schedule** editor. This works only during the promotion of a Grid Master Candidate. That is, **Join Group Now** is activated (enabled) only during the promotion of Grid Master Candidate group; it is disabled after the scheduled time of all the groups expires after the Grid Master Candidate is promoted. For any offline member, the **Join Group Now** will be disabled 8 hours after the Grid Master Candidate promotion.
- The **Add GMC Group Wizard** in the **GMC Group Promotion Schedule** editor is available only for future schedules. The maximum scheduled time for the promotion of any Grid Master Candidate group is 8 hours.
- We do not recommend enabling a schedule Grid upgrade and **GMC Group Promotion Schedule** at the same time.
- The **Time Zone** for any group, displays the Grid Manager's time zone, and if there are any member(s) in the group, the **Time Zone** automatically reflects the first group member(s) time zone.
- The scheduled **Time** displays the new time zone, if the **Time Zone** is modified or if a member is moved across different groups.
- During the Grid Master Candidate promotion, if a Grid member is offline, Grid Manager continuously attempts to connect to the offline Grid member for every 60 seconds.
- If the **GMC Group Promotion Schedule** editor is disabled after Grid upgrade, then you can unset the previously triggered Grid Master Candidate promotion, by using the CLI command `set gmc_promotion forced_end`. It is recommended to run this command when the Grid is completely upgraded. For more information see, *set gmc_promotion*.

Enabling Read-only API Access on the Grid Master Candidate

You can enable read-only API access on the Grid Master Candidate to provide additional scalability of read/write API requests on the Grid Master, which in turn improves the performance of the Grid Master. The read-only API access is disabled by default for new installations.

When you enable read-only API access on an HA Grid Master Candidate, you can access the API service only on an active node. If the API service is disabled for an admin group, the users in the admin group cannot access read-only API service on the Grid Master Candidate, even though read-only API access is enabled for the Grid Master Candidate. Also, the users in the admin group should have at least read-only permission to access the API service.

> ⚠ Note
> When you upgrade the Grid Master Candidate to NIOS 7.1 and later, read-only API access is disabled. But when you upgrade the Grid Master Candidate from NIOS 7.1 to a later release with read-only API access enabled, then this setting is retained after the upgrade is completed.

The appliance logs all API logins in the audit log and syslog. You can view the audit log and syslog of the Grid Master Candidate under the **Administration** -> **Logs** tab.

To enable read-only API access on the Grid Master Candidate:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_Master_Candidate* checkbox, and then click the Edit icon.
    - In the *Grid Member Properties* editor, select the **General** tab -> **Basic** tab, and then do the following: **Read Only API access**: This field is displayed only when the Grid member is designated as a Master Candidate. Select this checkbox to enable read-only API access on the Grid Master Candidate. Enabling this checkbox will only allow read-only API access and not write API access. Note that if you enable this checkbox, you cannot access the GUI using the IP address of the Grid Master Candidate.
2. Save the configuration.

Grid Bandwidth Considerations

Infoblox Grid technology relies upon database replication for its core functionality. When designing a Grid, it is important to consider the amount of traffic generated by this replication and the overall number of Grid members. Other communication between Grid members (such as log retrieval and monitoring functions) occurs as well. All of this traffic is securely communicated between the Grid Master and Grid members through encrypted VPN tunnels.
One component of the traffic through the tunnels is database replication traffic. There are three types to consider:

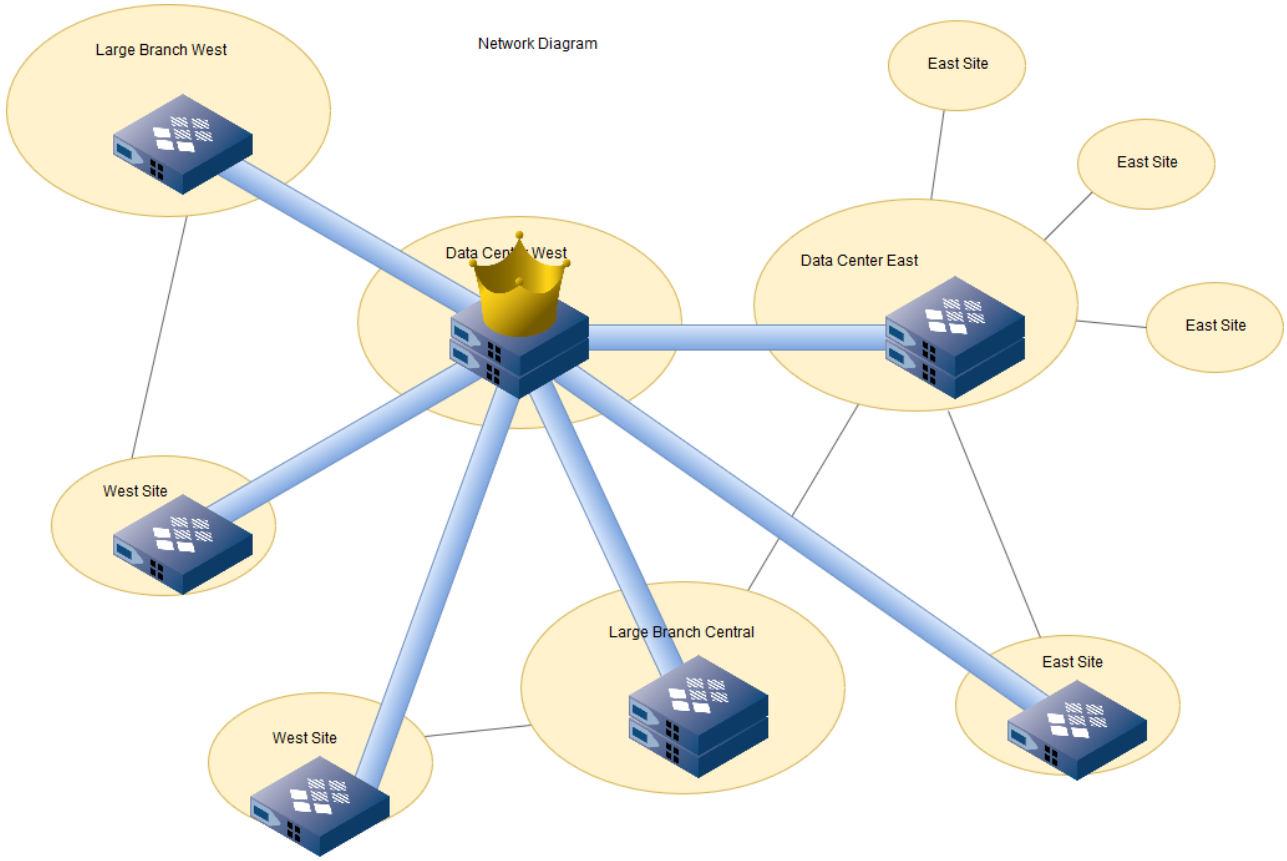
- **Complete database replication to a Master Candidate** — Occurs when a Master Candidate joins or rejoins a Grid. The Grid Master sends the complete database to a Master Candidate so that it has all the data it needs if it ever becomes promoted from member to master.
- **Partial database replication** — Occurs when an appliance or HA pair joins or rejoins the Grid as a regular member (which is not configured as a Master Candidate). The Grid Master sends it the section of the database that mainly applies just to the member.
- **Ongoing database updates** — Occurs as changes are made to the Grid configuration and data. The Grid Master sends all ongoing database updates to Master Candidates and individual member-specific updates to regular members.

If there are no or very few DNS dynamic updates, and no or very few DHCP lease offers and renewals issued, then this type of replication traffic is minimal.
If there are many DDNS (dynamic DNS) updates (many per second) and/or many DHCP lease offers and renewals (many per second), then the replication traffic is the largest component of the VPN traffic among Grid members.

> **Note**
>
> A Grid Master replicates data to single members and to the active node of HA members. The active node then replicates the data to the passive node in the HA pair.

At a minimum, there must be 256 Kbps (kilobits per second) bandwidth between the Grid Master and each member, with a maximum round-trip delay of 500 milliseconds. For ongoing database updates, the amount of data sent or received is 15 Kb for every DDNS update, and 10 Kb for every DHCP lease -offer/renew. The baseline amount for heartbeat and other maintenance traffic for each member is 2 Kbps. Measure the peak DNS and DHCP traffic you see in your network to determine the bandwidth needed between the Grid Master and its members for this activity.
For example, you might decide to place your Grid members in the locations shown in the below figure.

Grid Deployment



In this example, the Grid Master is optimally placed in the Data Center West. There are a total of seven members: the HA Grid Master, three HA members, and three single members. If all the members are Master Candidates, the Grid Master replicates all changes to the other six members. Assuming that the master receives 20 dynamic updates per minute and 40 DHCP lease renews per minute, the calculation for Grid bandwidth is:

20 DDNS updates/minute/60 secs = 0.333 DDNS updates/sec * 15 Kb = 5 Kbps *6 members= 30 Kbps
40 DHCP leases/minute/60 secs = 0.666 DHCP leases/sec * 10 Kb = 6.7 Kbps * 6 members = 40.2 Kbps
2 Kbps of Grid maintenance traffic * 6 members = 12 Kbps

Total 82.2 Kbps

Another component is the upgrade process. See *Upgrading NIOS Software* for more information.
Bandwidth requirements, database size, and update rate determine the maximum size of the Grid you can deploy. Based on the various factors discussed above, you can determine the amount of bandwidth your Grid needs. If your calculations exceed the available bandwidth, then you might need to modify your deployment strategy, perhaps by splitting one large Grid into two or more smaller ones.

> **Note**
>
> This calculation does not take into account existing traffic other than DNS and DHCP services, so factor and adjust accordingly.

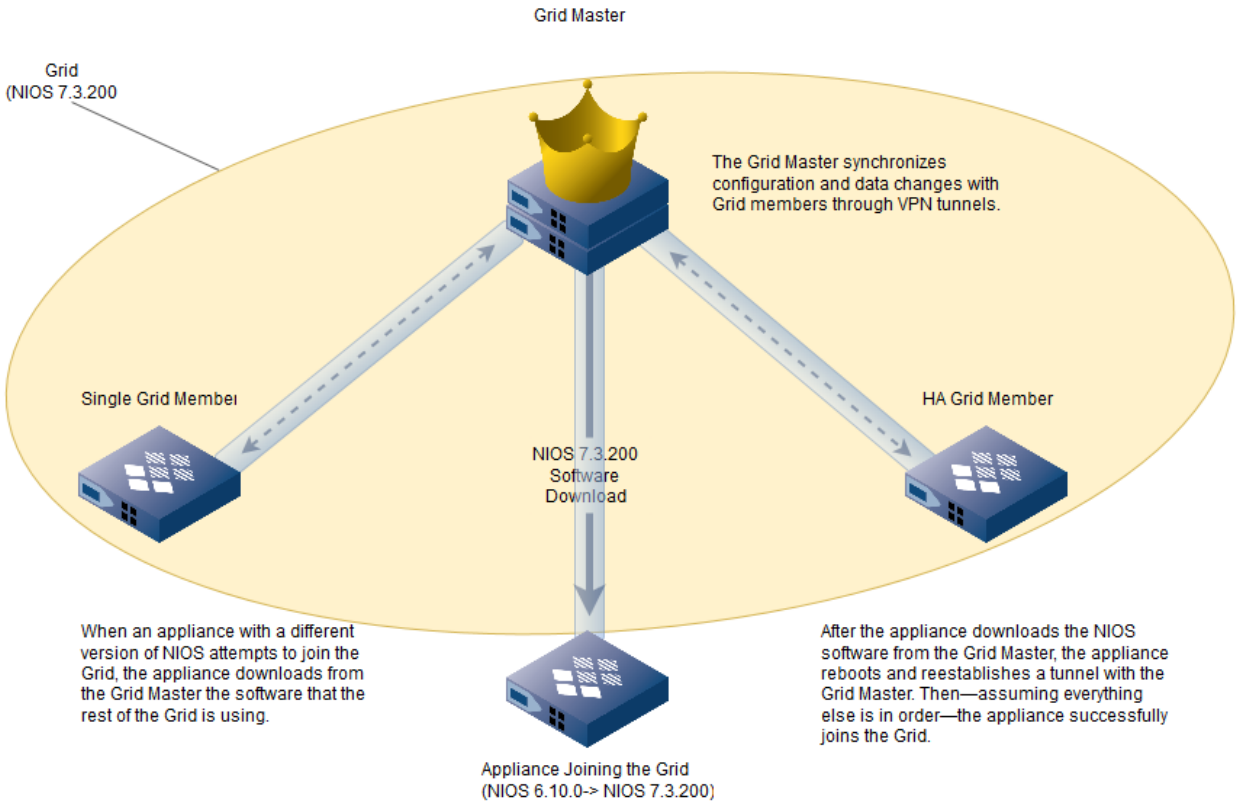
For international networks, because of bandwidth and delay requirements, a geographical grouping of Grid members might be the best approach. For example, if you have a global presence, it may make the most sense to have a North American Grid, a South American Grid, a European Grid, and an Asia/Pacific Grid.

Automatic Software Version Coordination

When you add an appliance or HA pair to a Grid as a new member, it is important that it is running the same version of software as the other members in the Grid. Infoblox provides two methods for coordinating the software version:

- Manual Upgrade and Downgrade: Before adding an appliance or HA pair to a Grid, you can manually upgrade or downgrade the software on the appliance or HA pair to the version used by the rest of the Grid.
- Automatic Upgrade and Downgrade: The Grid Master automatically compares the software version of each appliance attempting to enter a Grid with that in use by the rest of Grid. If the versions do not match, the Grid Master downloads the correct version to the new appliance or HA pair.
  Note that the Grid Master checks the software version every time an appliance or HA pair joins the Grid. The software version check occurs during the initial join operation and when a member goes offline and then rejoins the Grid.

Automatic Upgrade of An Appliance Joining a Grid



When a single appliance attempts to join the Grid for the first time, the following series of events takes place:

1. The appliance establishes an encrypted VPN tunnel with the Grid Master.
2. The master detects that the software version on the appliance is different from that in the rest of the Grid. For example, the appliance is running NIOS 6.10.0 software but the rest of the Grid is running NIOS 7.3.200 software.
3. The appliance downloads the NIOS 7.3.200 software from the Grid Master.
4. After the upgrade is complete, the NIOS application automatically restarts.
5. After the appliance reboots, it again contacts the Grid Master and step 1 is repeated. Because the software versions now match, the appliance can complete its attempt to join the Grid.

When an HA pair attempts to join the Grid for the first time, the following series of events takes place:

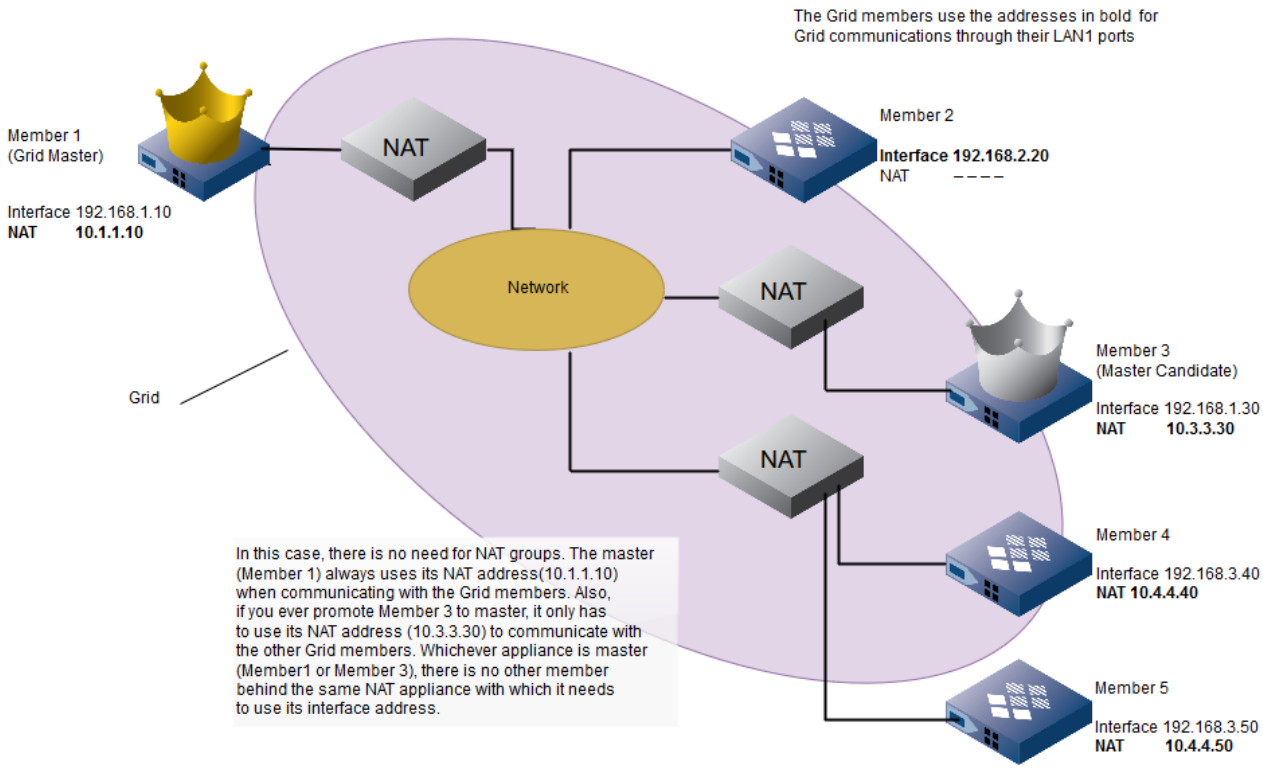
1. The active node of the HA pair establishes an encrypted VPN tunnel with the Grid Master.
2. The master detects that the software version on the node is different from that in the rest of the Grid. For example, the active node is running NIOS 6.10.0 software but the rest of the Grid is running NIOS 7.3.200 software.
3. The appliance downloads the NIOS 7.3.200 software from the Grid Master.
4. After the upgrade is complete, the NIOS application on the active node automatically restarts. This causes an HA failover.
5. The new active node (which was previously the passive node) attempts to join the Grid, repeating steps 1 – 4.
6. When the NIOS application on the currently active node restarts, there is another failover, and the currently passive node becomes active again.
7. The active node again contacts the Grid Master and step 1 is repeated. Because the software versions now match, it can complete its attempt to join the Grid.

NAT Groups

> **Note**
>
> Infoblox NAT and NAT groups do not support NAT IPv6 operation.

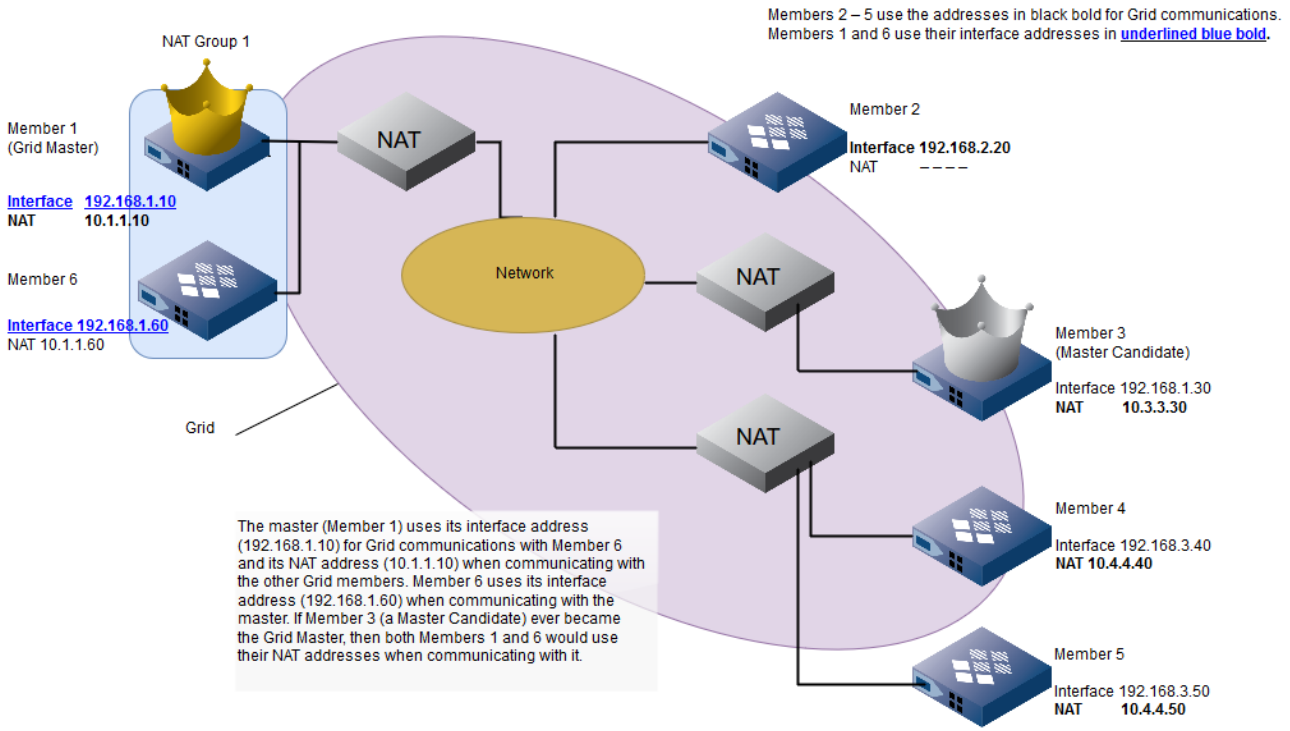
NAT groups are necessary if the Grid Master is behind a NAT appliance and there are members on both sides of that NAT appliance. Any members on the same side as the master go into the same NAT group as the master and use their interface addresses for Grid communications with each other. Grid members on the other side of that NAT appliance do not go in the same NAT group as the master and use the master's NAT address for Grid communications. These other members outside the NAT appliance can—but do not always need to be—in a different NAT group. To see when NAT groups become necessary for Grid communications, compare the figure NAT without NAT Groups below with the figures Grid Master in NAT Group and Grid Master and Master Candidate in NAT Groups.

NAT without NAT Groups



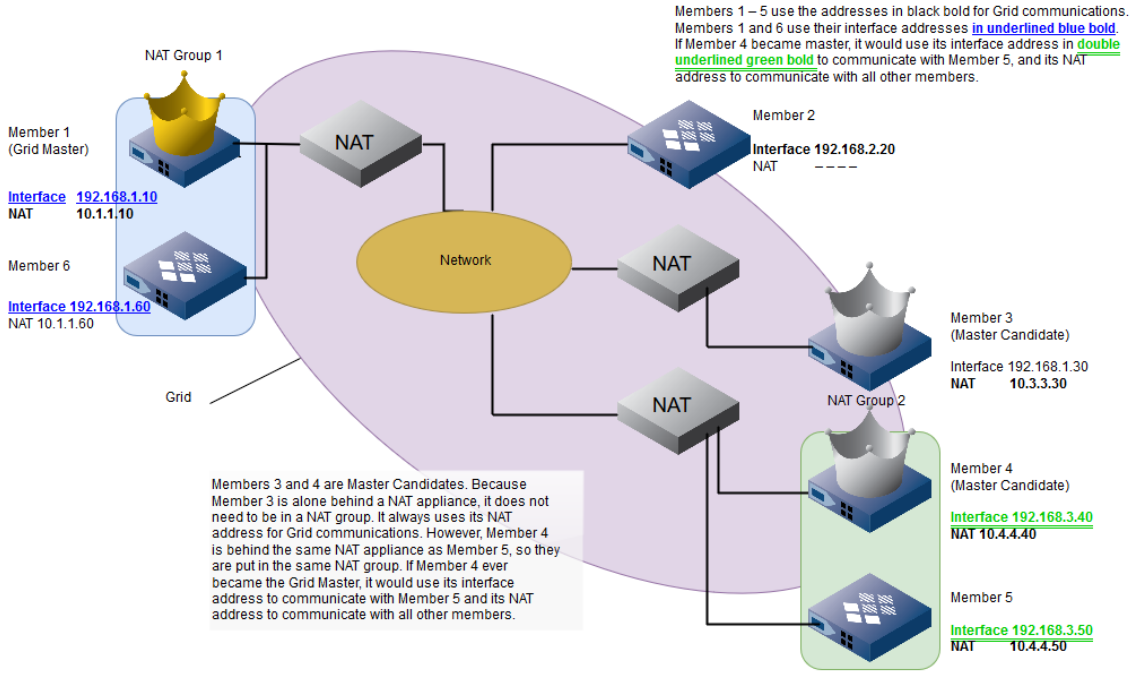
> **Note**
>
> A single or HA member using its MGMT port for Grid communications cannot be separated from the Grid Master behind a NAT appliance. For more information, see *Using the MGMT Port.*

Grid Master in NAT Group



The same use of NAT groups that applies to a Grid Master also applies to Master Candidates. If there are no other members behind the same NAT appliance as a Master Candidate, then the Master Candidate does not need to be in a NAT group. It always uses its NAT address for Grid communications. If another member is behind the same NAT appliance as the Master Candidate, then both the candidate and that member need to be in the same NAT group so that —if the candidate becomes master—they can use their interface addresses to communicate with each other (see the figure below).

Grid Master and Master Candidate in NAT Groups



Although some members might not need to be in a NAT group, it is good practice to put all members in NAT groups in anticipation of adding or rearranging Grid members within the network. For example, in NAT without NAT Groups – Grid Master and Master Candidate in NAT Groups, Member 4 did not need to be in a NAT group until it became configured as a Master Candidate. At that point, because Member 5 is also behind the same NAT appliance, it became necessary to create NAT Group 2 and add Members 4 and 5 to it. Similarly, if you add another member behind the NAT appliance in front of Member 3, then you must create a new NAT group and add Member 3 and the new member to it. Always using NAT groups can simplify such changes to the Grid and ensure that NAT appliances never interrupt Grid communications. To create a NAT group:

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Expand the Toolbar and select **Grid Properties** -> **Edit**.
3. In the *Grid Properties* editor, select the **NAT Groups** tab.
4. Click the Add icon, and enter a name in the **Name** field and optionally, a comment in the Comment field.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

To add members to the NAT group:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
2. Select a Grid member and click the Edit icon.
3. In the *Grid Member Properties* editor, select the **Network** -> **Advanced** tab and complete the following:
    - **Enable NAT Compatibility (IPv4 only):** Select this checkbox. NAT group is not supported by IPv6 appliances.
    - **NAT Group:** From the drop-down list, select the NAT group you previously created.
    - **NAT Addresses:** For a single Grid Master or member, enter the address configured on the NAT appliance that maps to the interface address of the LAN1 port. A single master or member that serves DNS uses this NAT address for Grid communications and—if it serves DNS—DNS messages.

For an HA Grid Master or member, enter the address configured on the NAT appliance that maps to its VIP address. An HA master uses its VIP NAT address when communicating with Grid members. An HA member that serves DNS uses its VIP NAT address for its DNS messages. It uses its LAN1 port NAT address for Grid communications.

- **Node 1 (if HA)**

    - **NAT IP Address:** Enter the address configured on the NAT appliance that maps to the interface address of the LAN1 port on Node 1. When Node 1 of an HA member is active, it uses its NAT address for Grid communications.
- **Node 2 (if HA)**
    - **NAT IP Address:** Enter the address configured on the NAT appliance that maps to the interface address of the LAN1 port on Node 2. When Node 2 of an HA member is active, it uses its NAT address for Grid communications.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Deploying Independent Appliances

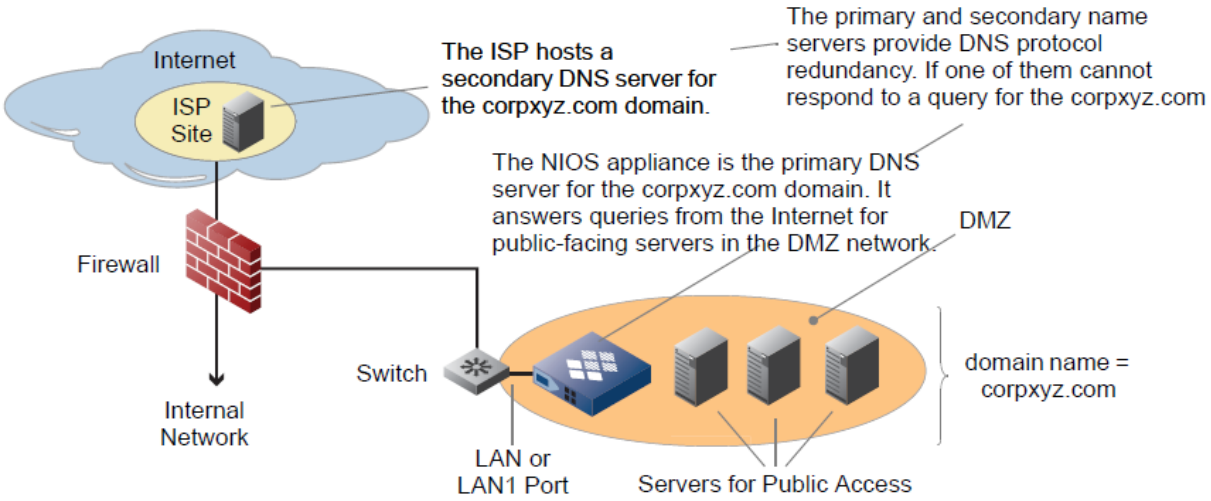
This section explains how to deploy single independent appliances and independent HA pairs. Independent appliances run NIOS without the Grid upgrade and are deployed independently from a Grid. This chapter includes the following topics:

Independent Deployment Overview

> **Note**
>
> Infoblox appliances support IPv4 and IPv6 networking configurations in most deployments cited in this chapter. You can set the LAN1 port to an IPv6 address and use that address to access the NIOS UI and the NIOS Setup Wizard. All HA operations can be applied across IPv6. You can also set a dual mode appliance by configuring both IPv4 and IPv6 address for the LAN1 port. Topics in this and following chapters generally use IPv4 examples. Also note that LAN2 and the MGMT port also support IPv6. DNS services are fully supported in IPv6 for the LAN1, LAN2, MGMT and VLAN ports. DHCP services are fully supported in IPv6 for the LAN1 and LAN2 ports. Example networks throughout this chapter use IPv4 addressing.

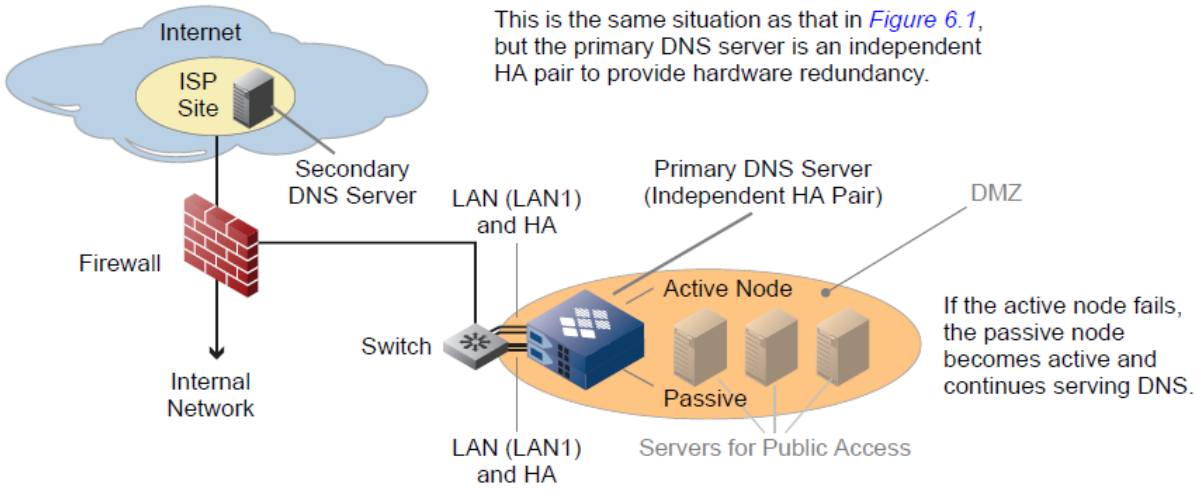
You can deploy the NIOS appliance as a Grid member in an Infoblox Grid or independently as a standalone deployment. NIOS appliances support both IPv4 and IPv6 networks and you can deploy them in either IPv4, IPv6, or dual mode (IPv4 and IPv6). Grids offer many advantages for large organizations while independent deployments can be sufficient for smaller sites. For example, if your ISP hosts one name server to respond to external DNS queries, you can deploy a single independent NIOS appliance as the other name server, as shown in the below figure.

Single Independent Appliance as a DNS Server



Using primary and secondary name servers provides DNS protocol redundancy, and configuring two DHCP servers as DHCP failover peers provides DHCP protocol redundancy. However, you can only have hardware redundancy if you deploy appliances in an HA (high availability) pair. Should the active node in an HA pair fail, the passive node becomes active and begins serving data, as shown in the below figure. For more information about HA pairs, see *About HA Pairs*.

Independent HA Pair



System Manager GUI

When you deploy an independent appliance, you use System Manager to manage the appliance. Though other chapters in this guide contain information that assumes a Grid deployment and describes the Grid Manager GUI, most of the configuration procedures are applicable to an independent appliance, with the following differences:

- In the Dashboard, there is no *Grid Status* widget, and the *Members Status* widget in Grid Manager is the *System Status* widget in System Manager.
- Functions related to a Grid, such as joining a Grid and managing Grid licenses, do not exist in System Manager.
- The Grid related tabs and functions in Grid Manager are the system related tabs and functions in System Manager.

- Functions related to the **Members** tab in Grid Manager appear in the **Nodes** tab or the Toolbar of another subtab in System Manager.

For example, the following navigation path for a Grid:

- From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox, and then click **HTTPS Cert** -> **Download Certificate** from the Toolbar.

is the following for an independent appliance:

- From the **System** tab, select the **System Manager** tab -> **Nodes** tab, and then click **HTTPS Cert** -> **Download Certificate** from the Toolbar.

Deploying a Single Independent Appliance

To deploy a single independent NIOS appliance, connect its LAN1 port to the network and change its default IP settings so that it can connect to its surrounding IP address space. The default LAN settings are as follows:

- IP address: 192.168.1.2
- Netmask: 255.255.255.0
- Gateway: 192.168.1.1

When deploying a single independent appliance, you can use one of the following methods to set up the initial configuration:

- *Method 1 - Using the LCD*
  - Requirements: Physical access to a powered up NIOS appliance.
  - Advantage: You do not need any other equipment.
- *Method 2 - Using the CLI*
  - Requirements: A serial connection from your management system to the console port on the NIOS appliance. You can also enable remote console access so that you can use the CLI over a network connection. For more information, see *Restricting GUI/API Access.*
  - Advantage: You do not need to change the IP address of the management system to connect to the NIOS appliance.
- *Method 3 - Using the Infoblox NIOS Startup Wizard*
  - Requirements: An HTTPS connection from your management system to the LAN1 port on the NIOS appliance.
  - Advantage: The wizard provides step-by-step guidance for changing not only the IP settings for the LAN1 port, but also changing the appliance host name and admin password, setting the system clock, and—if using NTP (Network Time Protocol)—enabling the NIOS appliance to be an NTP client.

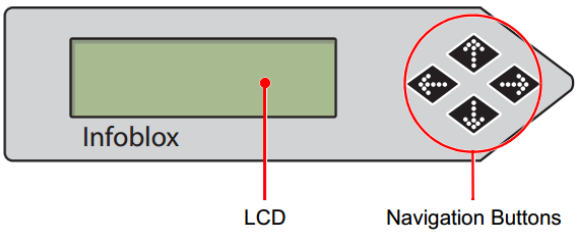
Note that you can configure network settings using the Startup wizard any time after you have configured the appliance. To start the wizard, from System Manager, select the **System** tab, and then click **System Properties** -> **Startup Wizard** from the Toolbar.

After you configure the network settings on a single independent appliance, you can migrate data from legacy DNS and DHCP servers to the NIOS appliance. Several tools and methods are available for migrating data and configuration settings. For a list of the available options, see *Infoblox Tools for Migrating Bulk Data.*

Method 1 – Using the LCD

Some of the NIOS appliances have an LCD and navigation buttons on the front panel that allow you to view system status and license information, as well as configure network settings for the LAN1 port.

Infoblox LCD and Navigation Buttons



The LCD panel is on the front of some of the NIOS appliances.

You can deploy a single independent NIOS appliance by setting its LAN1 port IP address, netmask, and gateway through the LCD. This is the simplest method because you do not need anything other than a physical access to the appliance to complete the initial configuration.

> ⚠ Note
>
> LCD does not support IPv6 addressing.

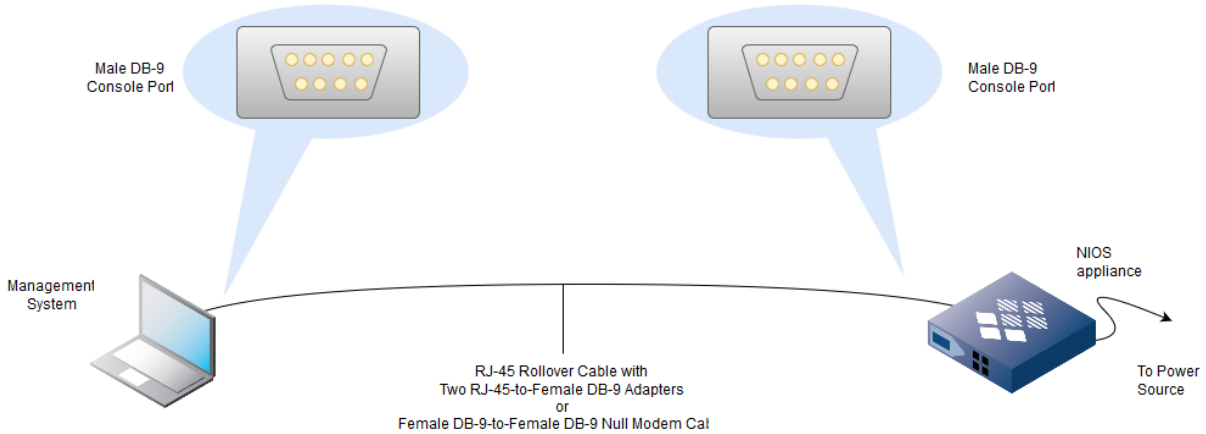
1. Connect the power cable from the NIOS appliance to a power source and turn on the power.
   At startup, the Infoblox logo appears in the LCD on the front panel of the appliance. Then the LCD scrolls repeatedly through a series of display screens.
2. To change the network settings for the LAN1 port, press one of the navigation buttons.
   The LCD immediately goes into the input mode, in which you can enter the IP address, netmask, and gateway for the LAN1 port.
3. Use the navigation buttons to enter an IP address, netmask, and gateway address for the LAN1 port.
4. Cable the LAN1 port of the NIOS appliance to a network as described in the installation guide that shipped with your product.

Method 2 – Using the CLI

You can use the Infoblox CLI to make an initial network configuration through the set network command. To access the CLI, make a direct serial connection from your management system.

1. Connect a console cable from the console port on your workstation to the male DB-9 console port on the NIOS appliance. The DB-9 pin assignments follow the EIA232 standard. You can use one RJ-45 rollover cable and two female RJ-45-to-female DB-9 adapters, or a female DB-9-to-female DB-9 null modem cable.

   Console Connection



2. Use a serial terminal emulation program, such as Hilgraeve Hyperterminal® (provided with Windows® operating systems), to launch a session. The connection settings are as follows:
   - **Bits per second**: 9600
   - **Data bits**: 8

- **Parity**: None
- **Stop bits**: 1
- **Flow control**: Xon/Xoff

3. Log in to the appliance using the default username and password (**admin** and **infoblox**).
4. At the Infoblox command prompt, enter **set network** to change the network settings, such as the IP address, netmask, and gateway for the LAN1 port. You can configure either IPv4 or IPv6 address for the LAN1 port.
   Note that In the following example, the variable ip_addr1 is the IP address of the LAN1 port and ip_addr2 is the IP address of the gateway for the subnet on which you set the ip_addr1 address. Infoblox appliances support IPv4 and IPv6 networking configurations in all deployments cited in this chapter. You can set the LAN1 port to an IPv6 address and use that address to access the NIOS UI.

   You can configure an IPv4 address for the LAN1 port as follows:

```
Infoblox > set network

NOTICE: All HA configuration is performed from the GUI. This interface is
used only to configure a standalone node or to join a Grid.

Enter IP address: ip_addr1

Enter netmask: netmask

Enter gateway address: ip_addr2

Configure IPv6 network settings? (y or n): y

Enter IPv6 address [Default: none]: 2001:db8:a22:a00::29
Enter IPv6 Prefix Length [Default: none]: 64

Enter IPv6 gateway [Default: none] 2001:db8:a22:a00::1
 Become Grid member? (y or n): n
```

   To avoid configuring IPv6 network settings, you can press **N** at the command line.
   You can configure an IPv6 address for the LAN1 port as follows:

```
Infoblox > set network
NOTICE: All HA configuration is performed from the GUI. This interface is
used only to configure a standalone node or to join a grid.
Enter IP address : 2620:010A:6000:2400:0000:0000:0000:6508
Enter IPv6 Prefix Length: 64

Enter IPv6 gateway [Default: none]: 2620:010A:6000:2400:0000:0000:0000:0001
```

```
Configure IPv4 network settings? (y or n):n

Become grid member? (y or n): n
```

To configure IPv4 network settings, you can press **Y** at the command line and configure IPv4 address, netmask, and the gateway address. After you confirm your network settings, the Infoblox application automatically restarts. You can press **N** to avoid configuring IPv6 on the command line. After you confirm your network settings, the Infoblox application automatically restarts.

5. Cable the LAN1 port to a network. For information about installing and cabling the appliance, refer to the user guide or installation guide that was shipped with the product.

Method 3 – Using the Infoblox NIOS Startup Wizard

When you first make an HTTPS connection to a NIOS appliance, the *Infoblox NIOS Startup Wizard* guides you through the deployment options and basic network settings. You can also change the password of the superuser (admin) and set up the system clock.

Note that you can configure network settings using the Startup wizard any time after you have configured the appliance. To start the wizard, from Grid Manager, select the **System** tab, and then click **System Properties** -> **Startup Wizard** from the Toolbar.

To make an HTTPS session to the appliance, you must be able to reach its IP address from the management system.

> ⚠ Note
>
> If you have already set the IP address of the LAN1 port through the LCD or CLI so that you can reach it over the network—and you have already cabled the appliance to the network—you can skip the first step.

1. If you have not changed the default IP address (192.168.1.2/24) of the LAN1 port through the LCD or CLI—and the subnet to which you connect the appliance is not 192.168.1.0/24—put your management system in the 192.168.1.0/24 subnet and connect an Ethernet cable between the management system and the appliance.
2. Open an Internet browser window and enter **https://*<IP_address_of_the_appliance>*** to make an HTTPS connection. For information about supported browsers, see *Supported Browsers*.
   Several certificate warnings may appear during the login process, because the preloaded certificate is self-signed and has the host name *www.infoblox.com,* which may not match the destination IP address you entered in step 1. To stop the warning messages from occurring each time you log in to Grid Manager, you can generate a new self-signed certificate or import a third-party certificate with a common name that matches the FQDN (fully qualified domain name) of the appliance. For information, see *Managing Certificates.*
3. Enter the default username and password (**admin** and **infoblox**) on the Grid Manager login page, and then click **Login** or press **ENTER**. For information, see *Logging on to the NIOS UI.*
4. Read the Infoblox End-User License Agreement (EULA), and then click **I Accept**.
   Note that if you want to view the privacy policy of Infoblox, then on the EULA screen, click **Infoblox Privacy Policy**. Grid Manager displays the policy on a new browser tab.
5. Read about the *Infoblox Customer Experience Improvement Program* and choose whether to participate (opt in) or not participate (opt out) in the program. By default, participation is enabled. If you want to opt out of the program, select **To Opt-Out of the alert program, please click here**. For more information about the program, see *Configuring the Customer Experience Improvement Program.*
6. Click **OK**. The *Grid Setup* wizard appears.
7. In the first screen of the *NIOS Setup* wizard, complete the following:
8. **Type of Network Connectivity:** Select the type of network connectivity for the appliance from the drop-down list:
   - **IPv4 and IPv6**: Select this to configure a dual mode appliance.
   - **IPv4**: Select this to configure an IPv4 appliance.
   - **IPv6**: Select this to configure an IPv6 appliance.
9. **Are you configuring an HA pair or a standalone appliance?**: Select **Configuring a standalone appliance**. To configure an independent HA pair, see *Deploying an Independent HA Pair.*

10. Click **Next** and complete the following to configure network settings:
    - **Host Name**: Enter a valid domain name for the appliance.
    - **Ports and Addresses**: This table lists the network interfaces based on the type of network connectivity of the appliance. For an IPv4 appliance, specify the network information for LAN1 (IPv4) interface and for an IPv6 appliance, specify the network information for LAN1 (IPv6) interface. For a dual mode appliance, specify the network information for both LAN1 (IPv4) and LAN1 (IPv6) interfaces.
      Enter correct information for the following by clicking the field:
        - **Interface**: Displays the name of the interface. You cannot modify this.
        - **IP Address**: Type the IPv4 or IPv6 address depending on the type of interface. An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight 16-bit groups of hexadecimal digits separated by colons (example: 2001:db8:0000:0123:4567:89ab:0000:cdef or 2001:db8::123:4567:89ab:0:cdef).
        - **Subnet Mask (IPv4) or Prefix Length (IPv6)**: Specify an appropriate subnet mask for IPv4 address or prefix length for IPv6 address. The prefix length ranges from 2 to 127.
        - **Gateway**: Type the IPv4 or IPv6 address of the default gateway depending on the type of interface. For the IPv6 interface, you can also type **Automatic** to enable the appliance to acquire the IPv6 address of the default gateway and the link MTU from router advertisements.
        - **Port Settings**: Select the port settings from the drop-down list. The list contains all the settings supported by the hardware model. The default is **Automatic**. The appliance automatically detects the port settings.
11. Click **Next** and complete the following to set admin password:
    - **Yes**: To change the default password.
    - **No**: To keep the default password. Infoblox recommends that you change the default password.
      When you select **Yes**, complete the following:
    - **Password**: Enter a password for the superuser admin account. The password must be a single alphanumeric string without spaces and at least four characters long. The password is case-sensitive.
    - **Retype Password**: Enter the same password.
12. Click **Next** and complete the following to configure time settings:
    - **Time Zone**: Select the applicable time zone from the drop-down list. The default is **(UTC) Coordinated Universal Time**.
    - **Would you like to enable NTP?**:
    - Select **Yes** to synchronize the time with external NTP servers, and then click the Add icon. Grid Manager adds a row to the NTP Server table. Click the row and enter either the IP address (IPv4 or IPv6) or the resolvable host name of an NTP server. You can view a list of public NTP servers at ntp.isc.org.
    - Select **No** to specify the time settings for the appliance.
    - **Date**: Enter the date in YYYY-MM-DD format. You can also click the calendar icon to select a date from the calendar widget.
    - **Time**: Enter the time in HH:MM:SS AM/PM format. You can also click the clock icon to select a time from the drop-down list.
13. Click **Next** to view the summary of the configuration. Review the information and verify that it is correct. You can change the information that you entered by clicking **Previous** to go back to a previous step.
14. Click **Finish**. The appliance restarts and disconnects Grid Manager.

In a dual mode independent appliance, the communication protocol for all the services is set to IPv4 by default. You can change the default communication protocol for the services.

Changing the Communication Protocol for a Dual Mode Independent Appliance

You can change the default communication protocol for a dual mode appliance. You can force the appliance to use a specific protocol for the reporting services and for services with two types of resolution (A and AAAA records), you can set the preferred communication protocol.

To change the communication protocol for a dual mode independent appliance, complete the following:

1. From the **System** tab, select the **System Manager** tab -> click **System Properties** from the Toolbar, and select **Edit** from the drop-down list.
2. In the *System Properties* editor, select the **Network** tab -> **Basic** tab, and then complete the following:

- **Communication Protocol Settings and Preferences**: Select either **IPv4** or **IPv6** from the drop-down list. This setting will force the appliance to use the specified protocol for the reporting services and this is the preferred protocol for services with two types of resolution (A and AAAA records).
- **Customized Settings**: Select this and perform the following:
  - **Always use this Communications Protocol for**: Select either **IPv4** or **IPv6** from the drop-down list. This setting will force the appliance to use the specified communication protocol for reporting services.
  - **Always prefer this Communications Protocol for**: Select either **IPv4** or **IPv6** from the drop-down list to specify the preferred communication protocol for the listed services, which has two types of resolution (A and AAAA records). The appliance uses the preferred protocol first for the service.

Configuration Example: Deploying a NIOS Appliance as a Primary DNS Server

In this example, you will configure the NIOS appliance as a primary DNS server for corpxyz.com. Its FQDN (fully-qualified domain name) is ns1.corpxyz.com. The interface IP address of the LAN1 port is 10.1.5.2/24. Because this is a private IP address, you must also configure the firewall to perform NAT (network address translation), mapping the public IP address 1.1.1.2 to 10.1.5.2. Using its public IP address, ns1 can communicate with appliances on the public network.

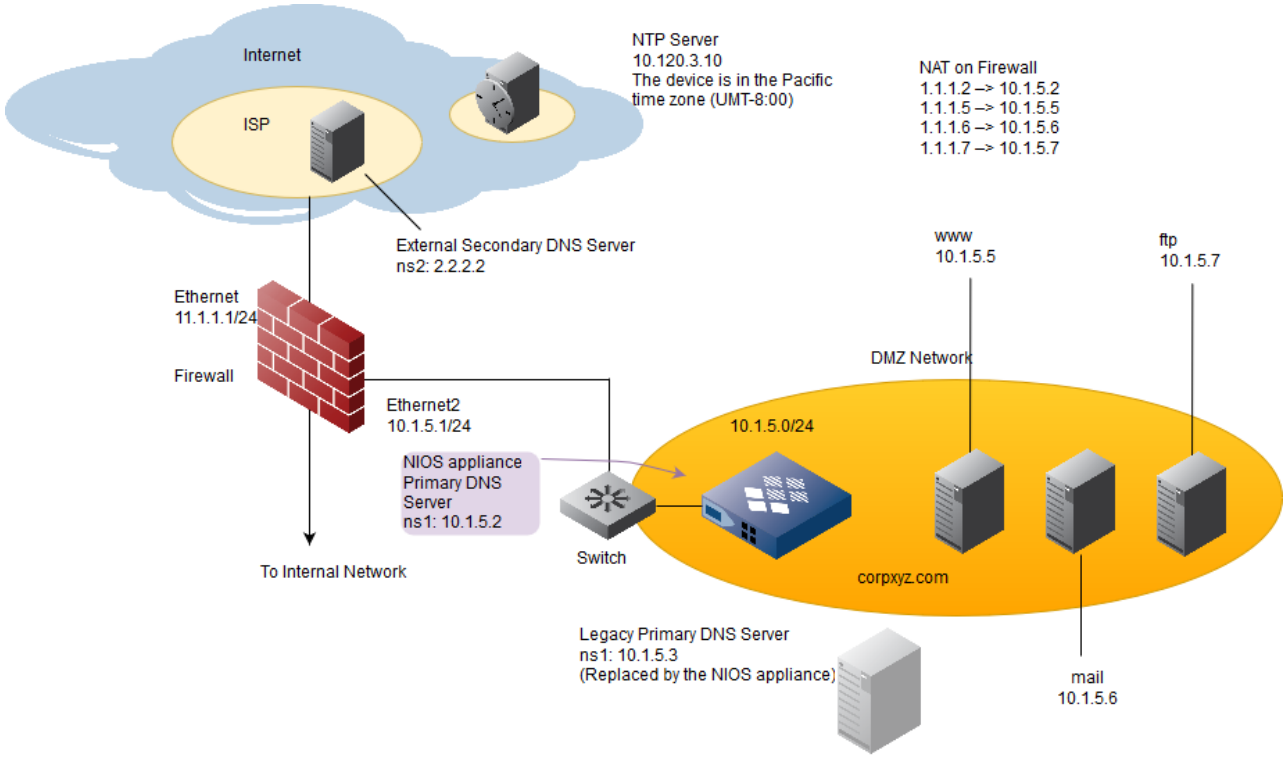
The FQDN and IP address of the external secondary DNS server are ns2.corpxyz.com and 2.2.2.2. The ISP hosts this server. You can deploy NIOS appliance in IPv4, IPv6, or dual mode (IPv4 and IPv6), but the configuration example uses IPv4 addresses.

The primary and secondary servers answer queries for the following public-facing servers in the DMZ:

- www.corpxyz.com
- mail.corpxyz.com
- ftp.corpxyz.com

When you create the corpxyz.com zone on the NIOS appliance, you import zone data from the legacy DNS server at 10.1.5.3.

Example 1 Network Diagram



Cabling the Appliance to the Network and Turning On Power

Connect an Ethernet cable from the LAN1 port of the NIOS appliance to a switch in the DMZ network and turn on the power. For information about installing and cabling the appliance, refer to the user guide or installation guide that ships with the product.

Specifying Initial Network Settings

Before you can configure the NIOS appliance through Grid Manager, you must be able to make a network connection to it. The default network settings of the LAN1 port are 192.168.1.2/24 with a gateway at 192.168.1.1 (the HA and MGMT ports do not have default network settings). To change these settings to suit your network, use either the LCD or the console port.

In this example, you change the IP address/netmask of the LAN1 port to 10.1.5.2/24, and the gateway to 10.1.5.1.

LCD

The NIOS appliance has an LCD and navigation buttons on its front panel.

At startup, the Infoblox logo appears in the LCD on the front panel of the appliance. Then the LCD scrolls repeatedly through a series of display screens.

1. To change the network settings from the default, press one of the navigation buttons.
   The LCD immediately goes into input mode, in which you can enter the IP address, netmask, and gateway for the LAN1 port.
2. Use the navigation buttons to enter the following information:
   - IP Address: 10.1.5.2
   - Netmask: 255.255.255.0
   - Gateway: 10.1.5.1

Specifying Appliance Settings

When you make the initial HTTPS connection to the NIOS appliance, the NIOS Startup Wizard guides you through the basic deployment of the appliance on your network. Use the wizard to enter the following information:

- Deployment: single independent appliance
- Host name: ns1.corpxyz.com
- Password: SnD34n534
- NTP (Network Time Protocol) server: 10.120.3.10; time zone: (UMT – 8:00 Pacific Time (US and Canada), Tijuana

1. Open an Internet browser window and enter *https://10.1.5.2*.
2. Accept the certificate when prompted.
   Several certificate warnings may appear during the login process. This is normal because the preloaded certificate is self-signed and has the hostname *www.infoblox.com,* which does not match the destination IP address you entered in step 1. To stop the warning messages from occurring each time you log in to Grid Manager, you can generate a new self-signed certificate or import a third-party certificate with a common name that matches the FQDN (fully-qualified domain name) of the appliance. This is a very simple process. For information about certificates, see *Creating a Login Banner*.
3. Enter the default username and password (**admin** and **infoblox**) on the Grid Manager login page, and then click **Login** or press **ENTER**. For information, see *Logging on to the NIOS UI*.
4. Read the Infoblox End-User License Agreement, and then click **I Accept** to proceed.
5. Read about the *Infoblox Customer Experience Improvement Program* and choose whether to participate (opt in) or not participate (opt out) in the program. By default, participation is enabled. If you want to opt out of the program, select **To Opt-Out of the alert program, please click here**. For more information about the program, see *Configuring the Customer Experience Improvement Program*.

6. Click **OK**. Grid Manager may take a few seconds to load your user profile.
7. In the first screen of the *NIOS Startup* wizard, complete the following:
    - **Type of Network Connectivity**: Select **IPv4** from the drop-down list.
    - **Are you configuring an HA pair or a standalone appliance?**: Select **Configuring a standalone appliance**. To configure an independent HA pair, see *Deploying an Independent HA Pair*.
8. Click **Next** and complete the following to configure network settings:
    - **Host Name**: Enter **ns1.corpxyz.com**.
    - **Ports and Addresses**: Specify the network settings for LAN1 (IPv4) port.
      Enter correct information for the following by clicking the field:
        - **IP Address**: Enter **10.1.5.2** as the IPv4 address for the LAN1 port.
        - **Subnet Mask (IPv4) or Prefix Length (IPv6)**: Enter **255.255.255.0** as the subnet mask for the LAN1(IPv4) port.
        - **Gateway**: Enter **10.1.5.1** as the gateway of the subnet on which the LAN1 port is set.
        - **Port Settings**: Use the default value **Automatic**.
9. Click **Next** and complete the following to set admin password:
    - **Would you like to set admin password?**: Click **Yes**.
    - **Password**: Enter **SnD34n534**.
    - **Retype Password**: Enter **SnD34n534** again.
10. Click **Next** and complete the following to configure the time settings:
    - **Time Zone**: Select UMT – 8:00 Pacific Time (US and Canada), Tijuana from the drop-down list.
    - **Would you like to enable NTP?**: Select **Yes** to synchronize the time with external NTP servers, and then click the Add icon. Grid Manager adds a row to the NTP Server table. Click the row and enter **10.120.3.10** in the **NTP Server** field.
11. Click **Next** to view the summary of the configuration. Review the information and verify that it is correct. You can change the information you entered by clicking **Previous** to go back to a previous step.
12. Click **Finish**.

Enabling Zone Transfers on the Legacy Name Server

To allow the appliance to import zone data from the legacy server 10.1.5.3, you must configure the legacy server to allow zone transfers to the appliance at 10.1.5.2.

Legacy BIND Server

1. Open the named.conf file using a text editor and change the allow-transfer statement as shown below:
    - **For All Zones** — To set the allow-transfer statement as a global statement in the named.conf file for all zones:

      ```
      options {
      zone-statistics yes;
      directory "/var/named/named_conf"; version "";
      recursion yes;
      listen-on { 127.0.0.1; 10.1.5.3; };
      …
      allow-transfer {10.1.5.2; }; transfer-format many-answers;
      };
      ```
    - **For a Single Zone** — To set the allow-transfer statement in the named.conf file for the corpxyz.com zone:

      ```
      zone "corpxyz.com" in { type master;
      allow-transfer {10.1.5.2;};
      notify yes;
      };
      ```
2. After editing the named.conf file, restart DNS service on the appliance for the change to take effect.

Legacy Windows 2000/2003 Server

1. Click **Start** -> **All Programs** -> **Administrative Tools** -> **DNS**.
2. Click **+** (for ns1) -> **+** (for Forward Lookup Zones) -> **corpxyz.com**.
3. Right-click **corpxyz.com**, and then select **Properties** -> **Zone Transfers**.
4. On the *Zone Transfers* page in the *corpxyz.com Properties* dialog box, enter the following:
   - **Allow zone transfers**: Select this.
   - **Only to the following servers**: Select this.
   - **IP address**: Enter **10.1.5.2**, and then click **Add**.
5. To save the configuration and close the *corpxyz.com Properties* dialog box, click **OK**.

Importing Zone Data on an Independent Appliance

You can import zone data from a legacy server or manually enter it. When you import both forward-mapping and reverse-mapping zone data, the NIOS appliance automatically creates Infoblox host records if corresponding A and PTR records are present. You can then modify the host records to add MAC addresses. However, if you only import forward-mapping zone data, the NIOS appliance cannot create host records from just the A records. In that case, because you cannot later convert A records to host records, it is more efficient to create the corpxyz.com zone, and define host records manually.

Infoblox host records are data models that represent IP devices within the Infoblox semantic database. The NIOS appliance uses a host object to define A, PTR, and CNAME resource records in a single object, as well as a DHCP fixed address if you include a MAC address in the host object definition. The host object prevents costly errors because you only maintain a single object for multiple DNS records and a DHCP fixed address. Therefore, it is advantageous to use host records instead of separate A, PTR, and CNAME records.

> ⚠ Note
>
> If you only have forward-mapping zones on your legacy servers and you want to add reverse-mapping zones, automatically convert A records to host records in the imported forward-mapping zones, and create reverse host records in corresponding reverse-mapping zones, create the reverse-mapping zones on the NIOS appliance and then import the forward-mapping zones data. The NIOS appliance automatically converts the imported A records to host records in the forward-mapping zones and creates reverse host records in the reverse-mapping zones.

You also have the option of using the *Data Import Wizard* for loading DNS and DHCP data. For large data sets, this option is an efficient approach. To download the *Data Import Wizard*, visit *www.infoblox.com/import/*.

In this example, when you create the corpxyz.com forward-mapping zone, you import zone data for the existing corpxyz.com zone from the legacy server at 10.1.5.3. When you create the 1.1.1.0/24 reverse-mapping zone, you also import the reverse-mapping zone records from the legacy server. After the appliance has both the forward- and reverse-mapping zone data, it converts the A and PTR records to Infoblox host records.

Creating a Name Server Group

1. Open an Internet browser window, enter *https://10.1.5.2*, and then log in to Grid Manager using the username **admin** and password **SnD34n534**.
2. From the **Data Management** tab, select the **DNS** tab -> **Name Server Groups** tab, and then click the Add icon -> **Name Server Group**.
3. In the *Name Server Group* wizard, complete the following:
   - **Name**: Enter **corpxyz** as the group name.
   - **Name Servers**: Click the Add icon -> **Primary**.
   - In the *Add Primary* section, Grid Manager displays the host name of the independent appliance. Click Add.
     Grid Manager adds the independent system as the primary server.
   - Click the Add icon -> **External Secondary**.

- In the *Add External Secondary* section, complete the following:
    - **Name:** Enter **ns2.corpxyz.com**.
    - **Address:** Enter **2.2.2.2**.
    - **Stealth:** Clear this checkbox.
    - Click **Add**. Grid Manager adds the external secondary to the name server group.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Creating a Forward-Mapping Zone

> **Note**
> To import zone data, you must first create a zone and save it.

1. To create an authoritative zone, from the **Data Management** tab, select the **DNS** tab -> **Zones** tab, and then click the Add icon -> **Authoritative Zone**.
2. In the *Add Authoritative Zone* wizard, select **Add an authoritative forward-mapping zone.**
3. Click **Next** and complete the following:
    - **Name:** Enter **corpxyz.com**.
    - **Comment:** Enter **DNS zone**.
4. Click **Next** to assign a name server group to the zone.
5. Click the **Zones** tab, select the **corpxyz.com** checkbox, and then click the Edit icon.
6. In the *Authoritative Zone* editor, select the **Name Servers** tab, and then complete the following:
    - **Use this name server group**: Select this, and then select **corpxyz** from the drop-down list.
7. Save the configuration and click **Restart** if it appears at the top of the screen.

Importing Zone Data

1. To import zone data to the corpxyz.com zone that you created earlier, click the **Zones** tab, select the **corpxyz.com** checkbox, and then click **Import Zone** from the Toolbar.
2. In the *Import Zone* editor, complete the following:
    - **Address**: Enter the IP address **10.1.5.3** of the DNS server from which you want to import zone data.
    - **Create Hosts and Bulk Hosts during import**: Select this option to allow the appliance to merge imported records into hosts and bulk hosts. If you do not select this option, then resource records are imported one-to-one with each DNS record from the imported zone producing a corresponding DNS record on the NIOS appliance.
        - **Create PTR records for Hosts if necessary**: Select this to create host records from the imported address records, even if the corresponding PTR records or the authoritative reverse zones that would contain them, do not exist. If you do not select this option, then host records will be created for imported address records only if a corresponding PTR record exists.
        - **Create PTR records for Bulk Hosts if necessary**: Select this to create bulk host records from the imported address records, even if the corresponding PTR records or the authoritative reverse zones that would contain them, do not exist. If you do not select this option, then bulk host records will be created for the imported address records only if the corresponding PTR records exist.
3. Click **Import**.
4. After successfully importing the zone data, click **corpxyz.com** in the **Zones** tab.
   You can see all the imported forward-mapping zone data in the *Records* panel. Because you have not yet imported the reverse-mapping zone data, most of the records appear as A records.
5. To import the reverse-mapping zone data, from the **Zones** tab, click the Add icon -> **Authoritative Zone**.
6. In the *Add Authoritative Zone* wizard, select **Add an authoritative IPv4 reverse-mapping zone.**
7. Click **Next** and complete the following:
    - **IPv4 Network:** Enter **1.1.1.0**.
    - **Netmask**: Select **24** from the drop-down list.
    - **Comment:** Enter **Reverse-mapping zone**.
8. Click **Save & Close**.
9. To assign a name server group to the reverse-mapping zone, click the **Zones** tab, select the 1.1.1.in-addr.arpa checkbox, and then click the Edit icon.
10. In the *Authoritative Zone* editor, select the **Name Servers** tab, and then complete the following:
    - **Use this name server group**: Select this, and then select **corpxyz** from the drop-down list.

11. Click **Save & Close**.
12. To import reverse-mapping zone data, click the **Zones** tab, select the corpxyz.com checkbox, and then click **Import Zone** from the Toolbar.
13. In the *Import Zone* editor, complete the following:
    - **Address:** Enter the IP address **10.1.5.3** of the DNS server from which you want to import zone data.
14. Click **Import**.
15. After successfully importing the zone data, click **1.1.1.in-addr.arpa** on the **Zones** tab. You can see all the imported reverse-mapping zone data in the *Records* panel.
16. Click **corpxyz.com** in the Forward Mapping Zones list.
    Because you have now imported both the forward- and reverse-mapping zone data, most of the records appear as host records.
17. Finally, you must remove the ns1 host record for the legacy server (value 1.1.1.3). To remove it, select the ns1 checkbox (the host record for 1.1.1.3), and then click the Delete icon.

Designating the New Primary on the Secondary Name Server (at the ISP Site)

In this example, the external secondary name server is maintained by an ISP, so you must contact your ISP administrator to change the IP address of the primary (or *master*) name server. (If you have administrative access to the secondary name server, you can make this change yourself.)

Because a firewall performing NAT exists between the secondary and primary name servers, specify the NAT address 1.1.1.2 for the primary name server instead of 10.1.5.2.

Secondary BIND Server

1. Open the named.conf file using a text editor and set ns1 (with NAT address 1.1.1.2) as the primary from which ns2 receives zone transfers in the named.conf file for the corpxyz.com zone.
2. After editing the named.conf file, restart DNS service for the change to take effect.

Secondary Windows 2000/2003 Server

1. Click **Start** -> **All Programs** -> **Administrative Tools** -> **DNS.**
2. Click **+** (for ns2) -> **+** (for Forward Lookup Zones) -> **corpxyz.com**.
3. Right-click **corpxyz.com**, and then select **Properties** -> **General**.
4. On the *General* page in the *corpxyz.com Properties* dialog box, enter the following:
    - **Zone file name**: corpxyz.com.dns
    - **IP address**: Enter **1.1.1.2** and then click **Add**.
    - In the IP Address field, select **1.1.1.3** (the NAT IP address of the legacy DNS server), and then click **Remove**.
5. To save the configuration and close the *corpxyz.com Properties* dialog box, click **OK**.

Configuring NAT and Policies on the Firewall

Change the NAT and policy settings on the firewall to allow bidirectional DNS traffic to and from ns1.corpxyz.com and NTP traffic from ns1.corpxyz.com to the NTP server at 10.120.3.10.

For example, enter the following commands on a Juniper firewall running ScreenOS 4.x or later:

```
set address dmz ns1 10.1.5.2/32
 set address untrust ntp_server 10.120.3.10/32 set interface ethernet1 mip
1.1.1.2 host 10.1.5.2 set policy from dmz to untrust ns1 any dns permit
 set policy from untrust to dmz any mip(1.1.1.2) dns permit set policy from dmz
to untrust ns1 ntp_server ntp permit
```

At this point, the new DNS server can take over DNS service from the legacy server. You can remove the legacy server and unset any firewall policies permitting traffic to and from 10.1.5.3.

Deploying an Independent HA Pair

To deploy an independent HA pair, you cable the HA and LAN1, LAN1 (VLAN), or LAN2, LAN2 (VLAN) ports to the network and configure the IP settings for these ports and the VIP address within the same subnet. For more information about HA pairs, see *About HA Pairs.*

The default LAN1 or LAN2 settings are as follows:

- IP address: 192.168.1.2
- Netmask: 255.255.255.0
- Gateway: 192.168.1.1

You can configure an HA pair using the *Infoblox NIOS Startup Wizard*. IPv4 and IPv6 network values are supported for the *NIOS Startup Wizard* and for HA Pair configuration. The NIOS appliance MGMT port also can be configured to support an IPv6 address.

- Requirements: HTTPS connections from your management system to the Ethernet ports on the two appliances.
- Advantage: The startup wizard provides step-by-step guidance for configuring the network settings of the VIP address and HA and LAN1 or LAN1 (VLAN) ports on both nodes, for setting the host name, admin password, and system clock, and—if using NTP (Network Time Protocol)—for enabling the HA pair as an NTP client.

Using the Infoblox NIOS Startup Wizard to Configure an HA Pair

When you first make an HTTPS connection to the NIOS appliance, the Infoblox NIOS Startup Wizard guides you through various deployment options, basic network settings, and opportunities for changing the password of the superuser *admin* and for setting the system clock.

Configuring the Connecting Switch

To ensure that VRRP (Virtual Router Redundancy Protocol) works properly, configure the following settings at the port level for all the connecting switch ports (HA, LAN1, LAN1 (VLAN), LAN2, and LAN2 (VLAN)):

- Spanning Tree Protocol: Disable. For vendor specific information, search for "HA" in the Infoblox Knowledge Base system at *https://support.infoblox.com*.
- Trunking: Disable
- EtherChannel: Disable
- IGMP Snooping: Disable
- Port Channeling: Disable
- Speed and Duplex settings: Match these settings on both the Infoblox appliance and switch
- Disable other dynamic and proprietary protocols that might interrupt the forwarding of packets

> ⚠ Note
>
> By default, a NIOS appliance automatically negotiates the optimal connection speed and transmission type (full or half duplex) on the physical links between its LAN1, HA, and MGMT ports and the Ethernet ports on the connecting switch. If the two appliances fail to auto-negotiate the optimal settings, see *Modifying Ethernet Port Settings* for steps you can take to resolve the problem.

Putting Both Nodes on the Network

1. Use one of the methods described in *Deploying a Single Independent Appliance* to configure the network settings of the LAN1 port of each node so that they are on the same subnet and you can reach them across the network.

2. Cable the LAN1 port and the HA port on each node to the network switch.
3. Cable your management system to the network switch.

Configuring Node 1

1. Open an Internet browser window and enter **https://* *<the IP address of the appliance>** to make an HTTPS connection to the first node. For information about supported browsers, see *Supported Browsers.*
   Several certificate warnings may appear during the login process because the preloaded certificate is self-signed and has the hostname *www.infoblox.com,* which may not match the destination IP address that you entered in step 1. To stop the warning messages from occurring each time you log in to Grid Manager, you can generate a new self-signed certificate or import a third-party certificate with a common name that matches the FQDN (fully qualified domain name) of the appliance. For information, see *Creating a Login Banner*.
2. Enter the default username and password (**admin** and **infoblox**) on the Grid Manager login page, and then click **Login** or press **ENTER**. For information, see *Logging on to the NIOS UI.*
3. Read the Infoblox End-User License Agreement, and then click **I Accept** to proceed.
4. Read about the *Infoblox Customer Experience Improvement Program* and choose whether to participate (opt in) or not participate (opt out) in the program. By default, participation is enabled. If you want to opt out of the program, select **To Opt-Out of the alert program, please click here**. For more information about the program, see *Configuring the Customer Experience Improvement Program*.
5. Click **OK**. Grid Manager may take a few seconds to load your user profile.
6. In the first screen of the *Grid Setup* wizard, select **Configure a Grid Master** and click **Next**.
7. Specify the following:
   - **Grid Name**: Type the name of the Grid. The default name is *Infoblox*.
   - **Shared Secret:** Enter the shared secret that both nodes use to authenticate each other when establishing a VPN tunnel for ensuing bloxSYNC traffic. The default shared secret is **test**.
   - **Confirm Shared Secret:** Enter the shared secret again.
   - **Host Name**: Enter a valid domain name for the node.
   - **Type of Network Connectivity:** Select the type of network connectivity from the drop-down list:
     - **IPv4 and IPv6:** Select this to configure a dual mode HA pair.
     - **IPv4:** Select this to configure an IPv4 HA pair.
     - **IPv6**: Select this to configure an IPv6 HA pair.
   - Select **Yes** in the **Is the Grid Master an HA pair** field for the first appliance of the HA pair.
     - **Send HA and Grid Communication over:** Select either **IPv4** or **IPv6**. This field is displayed only when you configure a dual mode (IPv4 and IPv6) HA pair.
8. Click **Next** and complete the following to set properties for the first node:
   - **Virtual Router ID**: Enter the VRID (virtual router ID). This must be a unique VRID number—from 1 to 255—for this subnet.
   - **Ports and Addresses**: This table lists the network interfaces depending on the type of network connectivity. For IPv4 HA pair, specify the network information for VIP (IPv4), Node1 HA (IPv4), Node2 HA (IPv4), Node1 LAN1 (IPv4), and Node2 LAN1 (IPv4) interfaces. For IPv6 HA pair, specify the network information for VIP (IPv6), Node1 LAN1 (IPv6), and Node2 LAN1 (IPv6) interfaces.
     For a dual mode HA pair, if you select **IPv4** in the **Send HA and Grid Communication over** field in step 2 of the *NIOS Startup* wizard, specify the network information for the following interfaces: VIP (IPv4), Node1 HA (IPv4), Node1 LAN1 (IPv4), Node2 HA (IPv4), Node2 LAN1 (IPv4), VIP (IPv6), Node1 LAN1 (IPv6), and Node2 LAN1 (IPv6) ports. If you select **IPv6** in the **Send HA and Grid Communication over** field in step 2 of the *NIOS Startup* wizard, specify the network information for the following interfaces: VIP (IPv4), Node1 LAN1 (IPv4), Node2 LAN1 (IPv4), VIP (IPv6), Node1 LAN1 (IPv6), and Node2 LAN1 (IPv6).
     Click the empty fields and complete the following information:
     - **Interface**: Displays the name of the interface. You cannot modify this.
     - **Address**: Type the IPv4 or IPv6 address depending on the type of interface.
     - **Subnet Mask (IPv4) or Prefix Length (IPv6)**: Specify an appropriate subnet mask for IPv4 address or prefix length for IPv6 address. The prefix length ranges from 2 to 127.
     - **Gateway**: Type the IPv4 or IPv6 address of the default gateway depending on the type of interface. For IPv6 interface, you can also type Automatic to enable the appliance to acquire the IPv6 address of the default gateway and the link MTU from router advertisements.
     - **Port Settings**: Select the port settings from the drop-down list. The list contains all settings supported by the hardware model. The default is **Automatic**. The appliance automatically detects the port settings.

9. Click **Next** and complete the following to set admin password:
    - **Yes**: To change the default password.
    - **No**: To keep the default password.
      If you select **Yes**, complete the following:
    - **Password**: Enter a password for the superuser admin account. The password cannot contain spaces and it must be at least four characters long. The password is case-sensitive.
    - **Retype Password**: Enter the same password.
10. Click **Next** and complete the following to configure time settings:
    - **Time Zone**: Select the applicable time zone from the drop-down list. The default is **(UTC) Coordinated Universal Time**.
    - **Would you like to enable NTP?**:
    - Select **Yes** to synchronize the time with external NTP servers. Click the Add icon. Grid Manager adds a row to the NTP Server table. Click the row and enter either the IPv4 or IPv6 address or the resolvable host name of an NTP server. You can view a list of public NTP servers at ntp.isc.org.
    - Select **No** to specify a date and time.
        - **Date**: Enter the data in YYYY-MM-DD format. You can also click the calendar icon to select a date from the calendar widget.
        - **Time**: Enter the time in HH:MM:SS AM/PM format. You can also click the clock icon to select a time from the drop-down list.
11. Click **Next** to view the summary of the configuration. Review the information and verify that it is correct. You can change the information you entered by clicking **Previous** to go back to a previous step.
12. Click **Finish**.

Configuring Node 2

1. Open an Internet browser window and enter **https://* *<the IP address of the appliance>** to make an HTTPS connection to the second node. For information about supported browsers, see *Supported Browsers*. Several certificate warnings may appear during the login process because the preloaded certificate is self-signed and has the host name *www.infoblox.com,* which may not match the destination IP address you entered in step 1. To stop the warning messages from occurring each time you log in to Grid Manager, you can generate a new self-signed certificate or import a third-party certificate with a common name that matches the FQDN (fully qualified domain name) of the appliance. For more information, see *Creating a Login Banner*.
2. Enter the default username and password (**admin** and **infoblox**) on the Grid Manager login screen, and then click **Login** or press **ENTER**. For more information, see *Logging on to the NIOS UI*.
3. Read the Infoblox End-User License Agreement, and then click **I Accept** to proceed.
4. Read about the *Infoblox Customer Experience Improvement Program* and choose whether to participate (opt in) or not participate (opt out) in the program. By default, participation is enabled. If you want to opt out of the program, select **To Opt-Out of the alert program, please click here**. For more information about the program, see *Configuring the Customer Experience Improvement Program*.
5. Click **OK**. Grid Manager may take a few seconds to load your user profile.
6. In the first screen of the *NIOS Setup* wizard, complete the following:
    - **Type of Network Connectivity:** Select the type of network connectivity from the drop-down list:
        - **IPv4 and IPv6:** Select this to configure a dual mode HA pair.
        - **IPv4:** Select this to configure an IPv4 HA pair.
        - **IPv6:** Select this to configure an IPv6 HA pair.
    - Select **Configuring an HA pair** to configure an independent HA pair and click **No** to configure the first node of an HA pair
7. Click **Next** and complete the following to configure network settings:
    - **HA Virtual IP address**: Enter the VIP (virtual IP) address and its netmask.
    - **HA Pair Name**: Enter a name for the HA pair. The default name is **Infoblox**. Ensure that you use the same name as the first node.
    - **Shared Secret**: Enter a text string that both nodes use as a shared secret to authenticate each other when establishing a VPN tunnel. The default shared secret is a test. This must be the same shared secret that you entered on the first appliance.
    - **Show Password**: Click this to display the shared secret. Clear it to conceal the shared secret.
8. Click **Next**, and then complete the following to set properties for the second appliance:
    - **IP Address**: Enter the IPv4 or IPv6 address of the appliance.

- **Subnet Mask**: Enter the subnet mask of the appliance.
  Or
  Prefix Length: Enter the prefix length if you have entered the IPv6 address in the **IP Address** field. The prefix length ranges from 2 to 127.
- **Gateway**: Enter the IP address of the gateway of the subnet of the interface.

9. Click **Next** to view the summary of the configuration. Review the information and verify that it is correct. You can change the information you entered by clicking **Previous** to go back to a previous step.
10. Click **Finish**.

The setup of the HA pair is complete. When you next make an HTTPS connection to the HA pair, use the VIP address.

The communication protocol for all the services in a dual mode (IPv4 and IPv6) HA appliance is the same protocol as the one used for VRRP advertisements. For example, if you select **IPv4** in the **Send HA and Grid Communication Over** field on the first screen of the *NIOS Setup* wizard, then IPv4 is set as the communication protocol for all the services. However, you can override the communication protocol for all the services in a dual mode HA pair. For information, see *Changing the Communication Protocol for a Dual Mode Independent Appliance*.

Configuration Example: Configuring an HA Pair for Internal DNS and DHCP Services

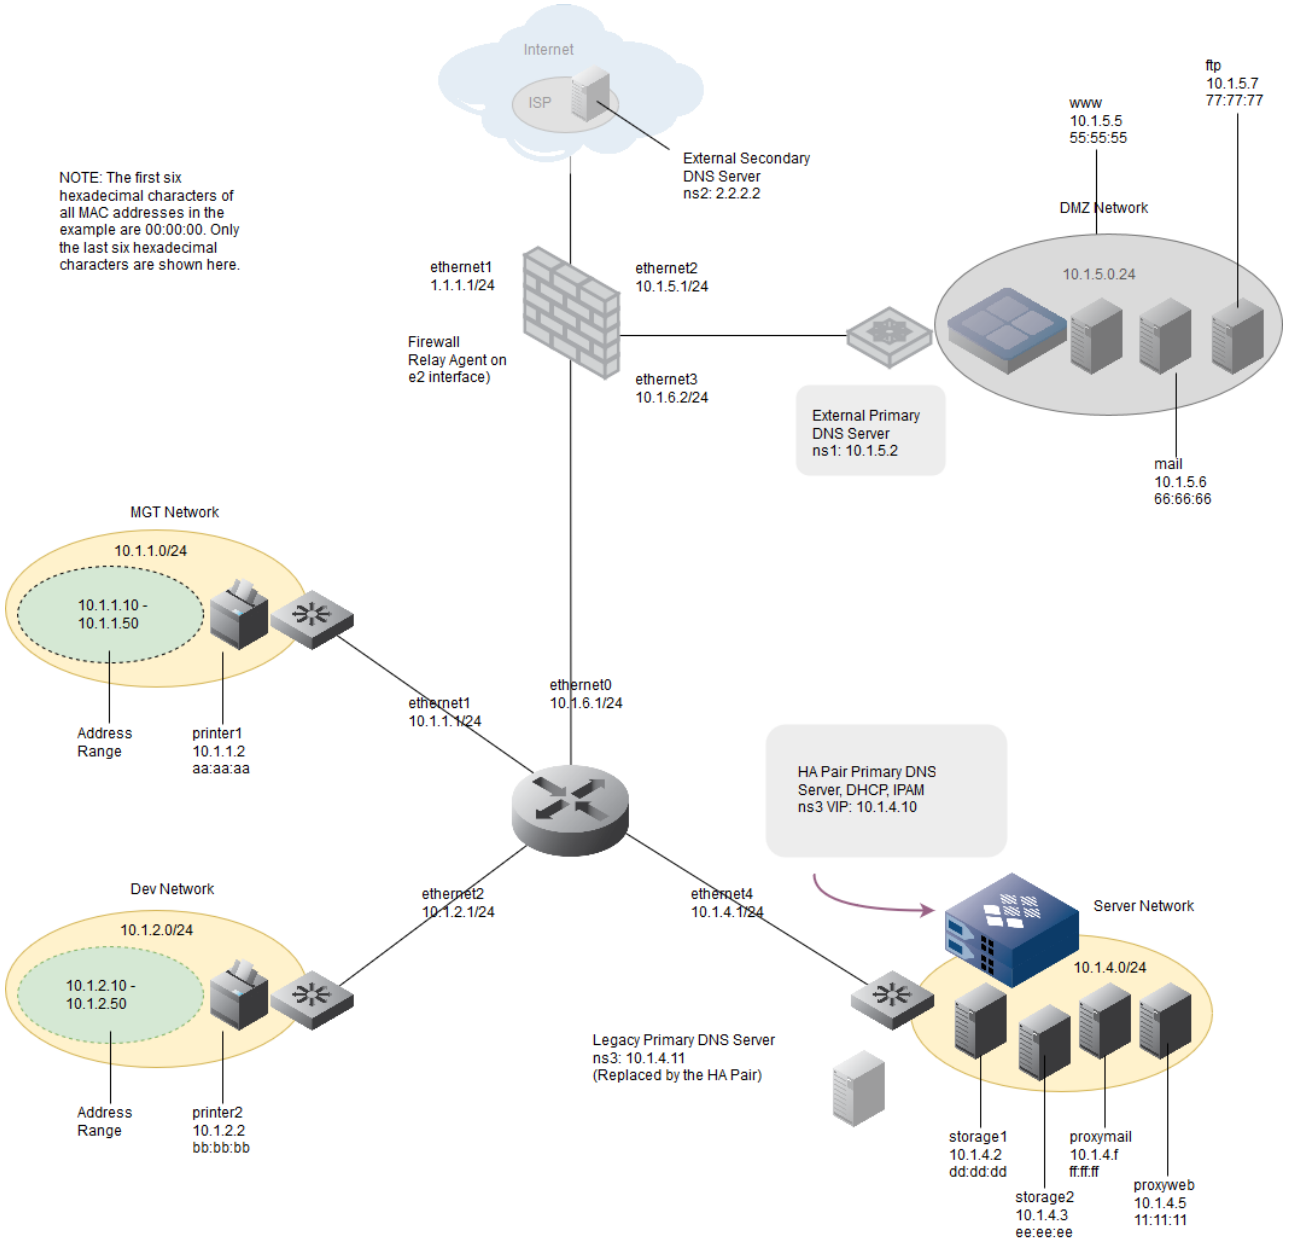
In this example, you set up an HA pair of NIOS appliances to provide internal DNS and DHCP services. The HA pair answers internal queries for all hosts in its domain (corpxyz.com). It forwards internal queries for external sites to ns1.corpxyz.com at 10.1.5.2 and ns2.corpxyz.com at 2.2.2.2. It also uses DHCP to provide dynamic and fixed addresses. You can deploy the HA appliance in IPv4, IPv6 or dual mode(IPv4 and IPv6), but the configuration example uses IPv4 addresses.

The HA pair consists of two appliances (nodes). The IP addresses of the VIP (virtual IP) address of the HA pair and the HA and LAN1 ports on each node are as follows:

HA Pair IP Addresses	
VIP 10.1.4.10 (the address that the active node of the HA pair uses)	
Node 1	Node 2
• LAN1 10.1.4.6 • HA 10.1.4.7	• LAN1 10.1.4.8 • HA 10.1.4.9

The virtual router ID number for the HA pair is 150. The ID number must be unique for this network segment. When you create the corpxyz.com zone on the HA pair, you import DNS data from the legacy server at 10.1.4.11.

Example 2 Network Diagram



An HA pair of NIOS appliances provide internal DNS services. It answers internal queries for all hosts in its domain. It forwards internal queries for external sites to ns1 and ns2. It also serves DHCP, providing both dynamic and fixed addresses.

Cabling Appliances to the Network and Turning On Power

Connect Ethernet cables from the LAN1 and HA ports on both NIOS appliances to a switch in the server network and turn on the power for both appliances. For information about installing and cabling the appliance, refer to the user guide or installation guide that ships with the product.

Specifying Initial Network Settings

Before you can configure the appliances through Grid Manager, you must be able to make a network connection to them. The default network settings of the LAN1 port are 192.168.1.2/24 with a gateway at 192.168.1.1 (the HA and MGMT

ports do not have default network settings). To change these settings, you can use the LCD or make a console connection to each appliance.

Node 1

Using the LCD or console port on one of the appliances, enter the following information:

- IP Address: **10.1.4.6** (for the LAN1 port)
- Netmask: **255.255.255.0**
- Gateway: **10.1.4.1**

Node 2

Using the LCD or console port on the other appliance, enter the following information:

- IP Address: **10.1.4.8** (for the LAN1 port)
- Netmask: **255.255.255.0**
- Gateway: **10.1.4.1**

After you confirm your network settings, the Infoblox GUI application automatically restarts.

Specifying Appliance Settings

When you make the initial HTTPS connection to a NIOS appliance, the Infoblox NIOS Startup Wizard guides you through the basic deployment of the appliance on your network. To set up an HA pair, you must connect to and configure each appliance individually.

Node 1

1. Open an Internet browser window and enter ***https://10.1.4.6***.
2. Accept the certificate when prompted. Several certificate warnings may appear during the login process. This is normal because the preloaded certificate is self-signed and has the hostname *www.infoblox.com,* which does not match the destination IP address you entered in step 1. To stop the warning messages from occurring each time you log in to Grid Manager, you can generate a new self-signed certificate or import a third-party certificate with a common name that matches the FQDN (fully-qualified domain name) of the appliance. This is a very simple process. For information about certificates, see *Setting Login Options*.
3. Enter the default username and password (**admin** and **infoblox**) on the Grid Manager login page, and then click **Login** or press Enter. For information, see *Logging on to the NIOS UI*.
4. Read the Infoblox End-User License Agreement, and then click **I Accept** to proceed.
5. Read about the *Infoblox Customer Experience Improvement Program* and choose whether to participate (opt in) or not participate (opt out) in the program. By default, participation is enabled. If you want to opt out of the program, select **To Opt-Out of the alert program, please click here**. For more information about the program, see *Configuring the Customer Experience Improvement Program*.
6. Click **OK**. Grid Manager may take a few seconds to load your user profile.
7. In the first screen of the *NIOS Setup* wizard, complete the following:
    - **Type of Network Connectivity:** Select **IPv4** as the communication protocol from the drop-down list.
    - Select **Configuring an HA pair** and click **Yes** to configure the first appliance.
    - **Send HA and Grid Communication over:** Select **IPv4** from the drop-down list for VRRP advertisements.
8. In the *NIOS Startup* wizard, select **Configuring an HA pair**. Click **Yes** to configure the first appliance.
9. Click **Next** and complete the following to configure network settings:
    - **Host Name**: Enter **ns3.corpxyz.com.**
    - **HA Pair Name:** Use the default name **Infoblox**.
    - **Shared Secret:** Enter **37eeT1d**.
10. Click **Next** and complete the following to set properties for the first node:
    - **Virtual Router ID**: Enter **150**.
    - **Required Ports and Addresses**: In the table, click the empty fields and enter the following information for each corresponding interface in the table:
        - VIP (IPv4): **10.1.4.10**

- Node 1 HA (IPv4): **10.1.4.7**
- Node 2 HA (IPv4): **10.1.4.9**
- Node 1 LAN1 (IPv4): **10.1.4.6**
- Node 2 LAN1 (IPv4): **10.1.4.8**
- Subnet Mask: **255.255.255.0**
- Gateway: **10.1.4.1**
  Note that Some fields are prepopulated by Grid Manager based on the existing configuration of the appliance. All fields are required.

11. Click **Next** and complete the following to set admin password:
    - **Would you like to set admin password?**: Click **No**.
12. Click **Next** and complete the following to configure time settings:
    - **Time Zone**: Select UMT – 8:00 Pacific Time (US and Canada), Tijuana from the drop-down list.
    - **Would you like to enable NTP?**: Select **Yes** to synchronize the time with external NTP servers, and then click the Add icon. Grid Manager adds a row to the NTP Server table. Click the row and enter **10.120.3.10** in the **NTP Server** field.
13. Click **Next** to view the summary of the configuration. Review the information and verify that it is correct. You can change the information you entered by clicking **Previous** to go back to a previous step.
14. Click **Finish**.

Node 2

1. From the **System** tab, select the **System Manager** tab, and then click **System Properties** -> **Setup Wizard** from the Toolbar.
2. In the first screen of the *NIOS Setup* wizard, complete the following:
    - **Type of Network Connectivity**: Select **IPv4** as the communication protocol from the drop-down list.
    - Select **Configuring an HA pair** and click **Yes** for configuring node 2 of the HA pair.
3. In the *NIOS Startup* wizard, select **Configuring an HA pair** to configure an independent HA pair. Click **No** for configuring node 2 of the HA pair.
4. Click **Next**, and then complete the following to configure network settings:
    - **HA Virtual IP address**: Enter **10.1.4.10**.
    - **HA Pair Name**: Use the default name **Infoblox**.
    - **Shared Secret**: Enter **37eeT1d**.
    - **Show Password**: Click this to display the shared secret.
5. Click **Next**, and then complete the following to set properties for the second appliance:
    - **IP Address**: Enter **10.1.4.8**.
    - **Subnet Mask**: Enter **255.255.255.0**.
    - **Gateway**: Enter **10.1.4.1**.
6. Click **Next** to view the summary of the configuration. Review the information and verify that it is correct. You can change the information you entered by clicking **Previous** to go back to a previous step.
7. Click **Finish**.

The setup of the HA pair is complete. From now on, when you make an HTTPS connection to the HA pair, use the VIP address 10.1.4.10.

Enabling Zone Transfers

To allow the NIOS appliance to import zone data from the legacy server at 10.1.4.11, you must configure the legacy server to allow zone transfers to the appliance at 10.1.4.10.

Legacy BIND Server

1. Open the named.conf file using a text editor and change the allow-transfer statement to allow zone transfers to the appliance at 10.1.4.10. For a sample of the required changes to the named.conf file.
2. After editing the named.conf file, restart DNS service for the change to take effect.

Legacy Windows 2000/2003 Server

Navigate to the *corpxyz.com Properties* dialog box, and then add 10.1.4.10 to the list of IP addresses to which you want to allow zone transfers.

Importing Zone Data

You can import zone data from a legacy server to an independent HA pair. Use the following information:

- Forward-mapping zone: **corpxyz.com**
- Import zone from: **10.1.4.11**
- Reverse-mapping zone: **1.1.1.0**

Defining Networks, Reverse-Mapping Zones, DHCP Ranges, and Infoblox Hosts

In this task, you enter data manually. For large data sets, you have the option of using the *Data Import Wizard* for loading DNS and DHCP configurations and data to make the process more efficient. To download the *Data Import Wizard*, visit *www.infoblox.com/import/*.

Networks

You can create all the subnetworks individually (which in this example are 10.1.1.0/24, 10.1.2.0/24, 10.1.4.0/24, and 10.1.5.0/24), or you can create a parent network (10.1.0.0/16) that encompasses all the subnetworks and then use the Infoblox split network feature to create the individual subnetworks automatically. The split network feature accomplishes this by using the IP addresses that exist in the forward-mapping zones to determine which subnets it needs to create. This example uses the split network feature. For information about creating networks, see *Configuring IPv4 Networks*.

1. From the **Data Management** tab, select the **IPAM** tab, and then click **Add** -> **Add IPv4 Network** from the Toolbar.
2. In the *Add Network* wizard, complete the following:
    - **Address:** 10.1.0.0
    - **Netmask:** Use the netmask slider to select the /16 (255.255.0.0) netmask.
3. Click Next to select a server. Click the Add icon. Grid Manager displays ns3.corpxyz.com in the table.
4. Click **Save & Close**.
5. On the **IPAM** tab, select the **10.1.0.0/16** checkbox, and then select **Split** from the Toolbar.
6. In the *Split Network* dialog box, complete the following:
    - **Subnetworks:** Move the slider to 24.
    - **Immediately Add:** Select **Only networks with ranges and fixed addresses**.
    - **Automatically create reverse-mapping zones**: Select this checkbox.
7. Click **OK**.
   The appliance creates the following 24-bit subnets for the imported Infoblox hosts:
    - 10.1.1.0/24
    - 10.1.2.0/24
    - 10.1.4.0/24
    - 10.1.5.0/24
8. From the **IPAM** tab, select the 10.1.1.0/24 checkbox, and then click the Edit icon.
9. In the *DHCP Network* editor, enter information on the following tabs:
    - *General*: **Comment: MGT**
    - *Server Assignment*: Add **ns3.corpxyz.com** as a server
10. Click **Save & Close**.
11. To modify the other networks, repeat steps #8 – 10 for each network and use the following information:
    - 10.1.2.0/24 Network:
        - **Comment:** Dev
        - **Server Assignment:** ns3.corpxyz.com
    - 10.1.4.0/24 Network:
        - **Comment:** Server
        - **Server Assignment:** ns3.corpxyz.com
    - 10.1.5.0/24 Network:

- **Comment:** DMZ
- **Server Assignment:** ns3.corpxyz.com

DHCP Ranges

1. On the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> ***10.1.1.0/24***, and then click **Add** -> **DHCP Range** from the Toolbar.
2. In the *Add Range* wizard, complete the following:
   Start: 10.1.1.10
   End: 10.1.1.50
3. Click **Next**, and then select **Server**. Grid Manager displays ns3.corpxyz.com as the assigned member.
4. Click **Save & Close**.
5. In the **Networks** tab, click ***10.1.2.0/24***, and then click **Add** -> **DHCP Range** from the Toolbar.
6. In the *Add Range* wizard, complete the following:
   Start: 10.1.2.10
   End: 10.1.2.50
7. Click **Next**, and then select **Server**. Grid Manager displays ns3.corpxyz.com as the assigned member.
8. Click **Save & Close**.

Infoblox Hosts

Defining both a MAC and IP address for an Infoblox host definition creates a DHCP host entry—like a fixed address—that you can manage through the host object. To add a MAC address to each host record that the appliance created when you imported forward—and reverse—mapping zone records:

1. On the **Data Management** tab, select the **IPAM** tab -> ***10.1.1.0/24*** -> ***10.1.1.2***.
2. In the **Related Objects** tab, select the checkbox of the host record, and then click the Edit icon.
3. In the *Host Record* editor, click the MAC Address field, and then enter the following:
   - **MAC Address: 00:00:00:aa:aa:aa**
4. Click **Save & Close**.
5. Follow steps 1 – 4 to modify hosts with the following information:
   - printer2
     - IP Address: 10.1.2.2
     - MAC Address: 00:00:00:bb:bb:bb
   - storage1
     - IP Address: 10.1.4.2
     - MAC Address: 00:00:00:dd:dd:dd
   - storage2
     - IP Address: 10.1.4.3
     - MAC Address: 00:00:00:ee:ee:ee
   - proxymail
     - IP Address: 10.1.4.4
     - AC Address: 00:00:00:ff:ff:ff
   - proxyweb
     - IP Address: 10.1.4.5
     - MAC Address: 00:00:00:11:11:11
   - www
     - IP Address: 10.1.5.5
     - MAC Address: 00:00:00:55:55:55
   - mail
     - IP Address: 10.1.5.6
     - MAC Address: 00:00:00:66:66:66
   - ftp
     - IP Address: 10.1.5.7
     - MAC Address: 00:00:00:77:77:77

Defining Multiple Forwarders

Since ns3.corpxyz.com is an internal DNS server, you configure it to forward DNS queries for external DNS name resolution to the primary and secondary DNS servers—ns1.corpxyz.com at 10.1.5.2 and ns2.corpxyz.com at 2.2.2.2.

1. From the **Data Management** tab, select the **DNS** tab, and then select **System DNS Properties** from the Toolbar.
2. In the *System DNS Properties* editor, click the Add icon on the **Forwarders** tab. Grid Manager adds a row to the table. Complete the following:
    - **Address:** Type **2.2.2.2**. Click **Add** again to add another forwarder.
    - **Address:** Type **10.1.5.2**.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Each of the forwarders is assigned a random response time. The appliance sends the initial outbound query to the forwarder that has the lowest response time. If the first forwarder does not reply, the appliance tries the one with the next lowest random response time. The appliance adjusts and keeps track of the response times of the forwarders and uses the quicker one for future queries. If the quicker forwarder does not respond, the appliance then uses another one.

Enabling Recursion on External DNS Servers

Since the HA pair forwards outbound queries to the two external DNS servers ns1.corpxyz.com (10.1.5.2) and ns2.corpxyz.com (2.2.2.2) for resolution, you must enable recursion on those servers. When a DNS server employs recursion, it queries other DNS servers for a domain name until it either receives the requested data or an error that the requested data cannot be found. It then reports the result back to the server that queried—in this case, the internal DNS server ns3.corpxyz.com (10.1.4.10), which in turn reports back to the DNS client.

Infoblox Server in the DMZ Network (ns1.corpxyz.com, 10.1.5.2)

1. On the **Data Management** tab, select the **DNS** tab, and then click **System DNS Properties** from the Toolbar.
2. In the *System DNS Properties* editor, select the **Allow Recursion** checkbox on the **Queries** tab, and then click the Add icon -> **IPv4 Address**. Grid Manager adds a row to the **Allow recursive queries from** table. Complete the following:
    - **Permission**: Select **Allow** from the drop-down list.
    - **Name**: Enter **10.1.1.52**.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

BIND Server at ISP Site (ns2.corpxyz.com, 2.2.2.2)

1. Open the named.conf file using a text editor and change the recursion and allow-recursion statements to allow recursive queries from 1.1.1.8 (the NAT address of ns3).

```
options {
zone-statistics yes;
directory "/var/named/named_conf"; version"";
recursion yes;
listen-on { 127.0.0.1; 2.2.2.2; };
…
allow-recursion {1.1.1.8;};
transfer-format many-answers;
};
```

2. After editing the named.conf file, restart DNS service for the change to take effect.

Windows 2000/2003 Server at ISP Site (ns2.corpxyz.com, 2.2.2.2)

1. Click **Start** -> **All Programs** -> **Administrative Tools** -> **DNS**.
2. Right-click **ns3**, and then select **Properties** -> **Advanced**.
3. On the *Advanced* page in the *ns3 Properties* dialog box, clear the **Disable recursion** checkbox.
4. To save the configuration change and close the *ns3 Properties* dialog box, click **OK**.

Modifying the Firewall and Router Configurations

Configure the firewall and router in your internal network to allow the following DHCP, DNS, and NTP traffic:

- To allow messages to pass from the DHCP clients in the DMZ—the web, mail, and FTP servers—to ns3 in the Server network, configure policies and DHCP relay agent settings on the firewall.
- To forward DHCP messages from DHCP clients in the MGT and Dev networks to ns3 in the Server network, configure relay agent settings on the router.
- To translate the private IP address of ns3 (10.1.4.10) to the public IP address (1.1.1.8) when forwarding DNS queries from ns3 to ns2, set a MIP (mapped IP) address on the firewall.
- To allow DNS queries from ns3 to ns1 and ns2 and NTP traffic from ns3 to the NTP server, configure firewall policies.

Firewall

For example, enter the following commands on a Juniper firewall running ScreenOS 4.x or later:

DHCP Relay Configuration

```
set address trust ns3 10.1.4.10/32
```

```
set interface ethernet2 dhcp relay server-name 10.1.4.10
```

```
set policy from dmz to trust ns1 ns3 DHCP-Relay permit
```

DNS Forwarding

```
set interface ethernet1 mip 1.1.1.8 host 10.1.4.10
```

```
set policy from trust to untrust ns3 ns2 dns permit
```

```
set policy from trust to dmz ns3 ns1 dns permit
```

NTP

```
set policy from dmz to untrust ns1 ntp_server ntp permit
```

Router

For example, enter the following commands on a Cisco router running IOS for release 12.x or later:

DHCP Relay Configuration

```
interface ethernet1
```

```
ip helper-address 10.1.4.10 interface ethernet2
```

```
ip helper-address 10.1.4.10
```

Enabling DHCP and Switching Service to the NIOS Appliance

With the Infoblox in place and the firewall and router configured for relaying DHCP messages, you can switch DHCP service from the legacy DHCP server at 10.1.4.11 to the HA pair at 10.1.4.10 (VIP address).

> ⚠ Note
>
> To minimize the chance of duplicate IP address assignments during the transition from the legacy DHCP server to the appliance, shorten all lease times to a one-hour length in advance of the DHCP server switch. Then, when you take the legacy DHCP server offline, the DHCP clients quickly move to the new server when their lease renewal efforts fail, and they broadcast DHCPDISCOVER messages. To determine how far in advance you need to shorten the lease length, find the longest lease time (for example, it might be two days). Then change the lease length to one hour at a slightly greater interval of time before you plan to switch DNS service to the appliance (for example, three days before the switch over).
>
> By changing the lease length this far in advance, you can be sure that all DHCP leases will be one-hour leases at the time of the switch-over. If the longest lease length is longer—such as five days—and you want to avoid the increased amount of traffic caused by more frequent lease renewals over a six-day period, you can also employ a stepped approach: Six days before the switch-over, change the lease lengths to one-day leases. Then two days before the switch-over, change them to one-hour leases.

1. Open an Internet browser window, enter *https://10.1.4.10*, and then log in to the appliance using the username **admin** and password **SnD34n534**.
2. From the **Data Management** tab, select the **DHCP** tab, and then click **Start** from the Toolbar.
3. In the *Start Member DHCP Service* dialog box, click **Yes**. The HA pair is ready to provide DHCP service to the network.
4. Take the legacy DHCP server at 10.1.4.11 offline.
   When the DHCP clients are unable to renew their leases from the legacy DHCP server, they broadcast DHCPDISCOVER messages to which the new DHCP server responds.

Managing and Monitoring

Infoblox provides tools for managing IP address usage and several types of logs to view events of interest and DHCP and DNS data. After configuring the appliance, you can use the following resources to manage and monitor IP address usage, DNS and DHCP data, and administrator and appliance activity.

IPAM (IP Address Management)

IPAM offers the following services:

- **Simple IP address modification**: Within a single IP address-centric data set, you can modify the Infoblox host, DHCP, and DNS settings associated with that IP address.
- **Address type conversion**: Through IPAM functionality, you can make the following conversions:
  - Currently active dynamic addresses to fixed addresses, reserved addresses, or Infoblox hosts.
  - Fixed addresses to reservations or hosts.
  - Reservations to hosts.
- **Device classification**: You can make detailed descriptions of appliances in DHCP ranges and appliances defined as Infoblox hosts and as fixed addresses.
- **Three distinct views of IP address usage**: To monitor the usage of IP addresses on your network, you can see the following different views:
  - High-level overall network view: On the **Data Management** tab, select the **IPAM** tab -> *member*. You can view the network usage in the Net Map or List view. You can also drill down to specific IP address to get detailed information.

- DHCP lease history records: From the **Data Management** tab, select the **DHCP** tab -> **Leases** tab -> **Lease History**.

Logs

The following list has some useful information:

- Logs, as described in *Monitoring the Appliance*.
  - Audit Log – Contains administrator-initiated events.
  - System Log – Contains events related to hardware and software operations.
- DNS statistics, as described in *Configuring DNS Services.*
  - DNS Configuration – Contains DNS server settings for the Infoblox DNS server.
  - Zone Statistics – Contains the results of all DNS queries per zone.
- DHCP information, as described in Configuring DHCP Properties.
  - DHCP Configuration – Contains DHCP server settings and network, DHCP range, and host settings for the Infoblox DHCP server.
  - DHCP Leases – Contains a real-time record of DHCP leases.
  - DHCP Lease History – Contains a historical record of DHCP leases.
  - DHCP Statistics – Contains the number of currently assigned static and dynamic addresses, and the high and low watermarks per network.
  - Network Statistics – Contains the number of static hosts, dynamic hosts, and available hosts per network.

Verifying the Deployment

After you deploy a single independent appliance or HA pair, you can make an HTTPS connection to it, log in, and check its status.

Single Independent Appliance

From the Dashboard, check the appliance status in the *System Status* widget. For information, see *Member Status (System Status).*

- If the Status icon is green, the appliance has a network connection and is operating properly.
- If the Status icon is red, there is a problem. To determine what it is, look at the system log file for this appliance by selecting the **Administration** tab -> **Logs** tab -> **Syslog**.

Independent HA Pair

1. Make an HTTPS connection to the VIP address of the HA pair, log in, and check the status of both nodes.
2. From the Dashboard, check the appliance status in the *SystemStatus* widget. For information, see *Member Status (System Status).*

- If the Status icon is green, both nodes have connectivity with each other and are operating properly.
- If the Status icon is yellow, the two nodes are in the process of forming an HA pair.
- If the Status icon is red, the passive node is offline or there is a problem. To determine what it is, look at the system log file by selecting the **Administration** tab -> **Logs** tab -> **Syslog**. You can also gather information from the **System** tab -> **SystemManager** tab.

Infoblox Tools for Migrating Bulk Data

Typically, the next step after cabling a single independent appliance to a network and configuring its network settings—or cabling two independent appliances to a network and configuring them as an HA pair—is to import data from legacy DNS, DHCP, and TFTP servers. Infoblox provides several tools to accomplish this:

- The CSV import feature allows you to import DNS, DHCP, and IPAM data through Grid Manager. You can add, overwrite, or merge data using this feature. The appliance updates the database based on import settings and the data you specify in the data files. From the **Data Management** tab of Grid Manager, you can access the *Import*

Manager editor from which you start a data import. You can also export existing data to a CSV file. You can use this file to modify data, and then re-import the data into the database using the CSV import feature. For information, see *About CSV Import .*

- The Infoblox Data Import Wizard is a useful tool that simplifies the importation of DNS, DHCP and IPAM, and TFTP settings and data into a NIOS appliance. For large data sets, this option is an efficient approach. To download the Data Import Wizard, visit *www.infoblox.com/import/*.
- For smaller DNS data sets, you can use the zone import feature, which allows you to import data on a per-zone basis (see *Importing Zone Data*).

Deploying Cloud Network Automation

The Infoblox Cloud Network Automation solution automates IPAM (IP address management) for physical and virtual network devices on your CMP (whether it is private, public, or hybrid). Instead of manually provisioning IP addresses and DNS name spaces for network devices and interfaces, you can use Cloud Network Automation to leverage DNS and DHCP features of the Grid to manage your cloud networks. When your cloud consists of a large number of servers and VMs (virtual machines) that have multiple associated network interfaces, manually provisioning and de-provisioning IP addresses and managing DNS and DHCP data can become error-prone. Utilizing Cloud Network Automation can minimize human errors by streamlining IPAM, improve visibility of your cloud networks, and maximize the flexibility and efficiency that virtualization offers in your cloud environment.
To maximize the capability of Cloud Network Automation, ensure that you understand the operations of Cloud Network Automation and how to deploy necessary components to suit your network topology and CMP. For detailed information about the Cloud Network Automation operations, see *Cloud Network Automation*.

With valid licenses installed, you can configure Cloud Platform Appliances in your Grid to provide DNS and DHCP services for virtual machines and network devices deployed through a CMP (Cloud Management Platform). To deploy a Grid that contains cloud members, it is important to understand the required components, how to configure the members to enable Cloud Network Automation, and which cloud API objects are supported.

Cloud Network Automation

Cloud Network Automation

The Cloud Network Automation figure shows the basic concept and operations of Cloud Network Automation, which includes two major components: the Grid Master that has a Cloud Network Automation license installed and one or more Cloud Platform Appliances that provide the ability to process API requests. Instead of sending all API requests to the Grid Master, you can send requests directly to the Cloud Platform Appliances. The Cloud Network Automation license installed on the Grid Master enables visibility and reporting on cloud tenants, VM IP addresses, and DNS record allocation. This license can be used in conjunction with Cloud Platform Appliances to provide local survivability and additional scalability of cloud API requests within individual data centers, or it can be used with an existing Grid Master servicing all cloud API

requests.
A Cloud Platform Appliance is a Grid member designed and dedicated to accept and process WAPI (RESTful API) requests related to cloud objects, in addition to serving DNS and DHCP protocols. You can deploy multiple Cloud Platform Appliances within your Grid to scale the processing of API requests or to provide redundancy. Cloud Platform Appliances include built-in HTTPS proxy capability that redirects cloud API requests to the appropriate Cloud Platform Appliance or to the Grid Master for processing. In other words, cloud API requests can be sent to any of the Cloud Platform Appliances within the Grid and the call is either processed locally or transparently forwarded to the appliance that is authoritative for the object referenced in the cloud API request. For information about supported Cloud Platform Appliances and their specifications, see *Supported Cloud Platform Appliance Models*. Once you have installed the Cloud Platform license on the appliance, fixed address configuration takes effect immediately by default and no DHCP service restart is required on the Cloud Platform Appliance. For information about this feature, see *Configuring Fixed Addresses without Restarting DHCP Service*. You can also add and delete IPv4 and IPv6 fixed addresses, reservations, and host records within any delegated IP address ranges through Grid Manager (the Infoblox GUI), in addition to using cloud API calls. For more information, see *Managing IPv4 DHCP Data* and *Managing IPv6 DHCP Data*.
On the CMP, you can either deploy a cloud adapter and use it as the cloud API client for sending cloud API requests to the Cloud Platform Appliances, or you can customize your CMP to make cloud API requests directly to Cloud Platform Appliances or to the Grid Master. The cloud adapter can be configured to send API requests always to a single Cloud Platform Appliance or to different Cloud Platform Appliances to handle situations where the primary Cloud Platform Appliance may not be available or to distribute API load among multiple Cloud Platform Appliances. Infoblox Cloud Network Automation supports the following cloud adapters: Infoblox IPAM Plug-In for VMware, OpenStack Adapter, and AWS (Amazon Web Services) API Proxy. For information about the IPAM Plug-In for VMware and OpenStack Adapter, refer to their respective Quick Start Guides. For information about the AWS API Proxy and how to set up AWS configurations, refer to the *InfobloxInstallationGuideforvNIOSforAWS*.
In order to distribute API processing and provide additional scalability both for updating APIs and serving DNS and DHCP protocols, Cloud Network Automation enables you to delegate specific sets of IPAM, DNS, and DHCP data to one or more Cloud Platform Appliances. Once authority for an object or set of objects has been delegated to a Cloud Platform Appliance, cloud API requests to create, modify, or delete objects under the scope of delegation for that appliance are processed locally and available immediately for serving DNS and DHCP to VMs within the cloud. This eliminates the need to send requests to the Grid Master to create, modify, or delete objects within the Grid. Changes made to objects on individual Cloud Platform Appliances are synchronized with the Grid Master in near real time using Grid replication to provide centralized visibility while retaining distributed processing capability. If a Cloud Platform Appliance is not authoritative for the object referenced in the cloud API requests, it automatically proxies that request to the Cloud Platform Appliance that is authoritative for the object or to the Grid Master (if it is authoritative for the object). Similarly, cloud API requests made to the Grid Master are proxied to the authoritative Cloud Platform Appliance or processed locally on the Grid Master if it is authoritative for the object. For information about authority delegation for supported objects, see *About Authority Delegation*. For information about proxying cloud API requests, see *About Cloud API Requests*.
Cloud API requests are processed through the cloud API service that operates on the Cloud Platform Appliance. This service can also be enabled on the Grid Master as well as other Cloud Platform Appliances. The cloud API service is HTTPS-based; therefore, to ensure that the cloud API service functions properly, port 443 for HTTPS connectivity must be open between the CMP and each Cloud Platform Appliance and/or the Grid Master receiving the cloud API requests. To ensure that the proxying function works properly, port 443 for HTTPS must be open bi-directionally between each of the Cloud Platform Appliances as well as between each Cloud Platform Appliance and the Grid Master. You must also configure your firewalls and ACLs accordingly. Note that this service uses the VIP address on each Infoblox appliance as the destination address.
All objects created, modified, or deleted by the cloud adapter are reflected in the NIOS database. You can view cloud objects and their associated data in the **Cloud** tab of Grid Manager if the Cloud Network Automation license is installed on the Grid Master. For more information, see *Viewing Cloud Objects*. Note that it is possible to use Cloud Platform Appliances without deploying the Cloud Network Automation license. However, without the Cloud Network Automation license, VM and tenant information is only displayed as extensible attributes associated with IPAM, DHCP, and DNS objects in Grid Manager rather than in separate tables under the **Cloud** Tab.
Before you can send cloud API requests to a Cloud Platform Appliance or the Grid Master, you must create admin groups that have cloud API access. Only admin users that have cloud API access and applicable permissions may be used for sending cloud API requests. If the Cloud Network Automation license is installed on the Grid Master, it is also possible to assign **Tenant** permissions to admin users to restrict these users to only be able to view objects related to a given tenant or a set of tenants. For information about admin groups and how to manage admin users, see *Managing Administrators*.

Note that there is no current capability to bi-directionally synchronize NIOS data with CMP data. Therefore, cloud information in NIOS is accurate only up to the point when specific cloud API requests are received by the Cloud Platform Appliance from an adapter running on a CMP. Only cloud information obtained through API requests to the Infoblox API service will be available in NIOS.

> **Note**
>
> Unlike standard WAPI requests, all cloud API related events are logged to the NIOS syslog instead of the NIOS audit log.

Deploying Cloud Network Automation

Licensing Requirements

To enable Cloud Network Automation, you must install valid licenses on the Grid Master and Cloud Platform Appliance members. Depending on your deployment scenarios, you can take advantage of Elastic Scaling to automatically deploy virtual cloud appliances, either inside or outside your CMP.
The following valid licenses are part of the Cloud Network Automation solution:

- Cloud Network Automation license on the Grid Master and Grid Master Candidate
- Cloud Platform license on the Cloud Platform AppliancesThe license you install on the Grid Master enables the **Cloud** user interface functions in Grid Manager and **Tenant** permissions.

The license you install on the Cloud Platform Appliance enables the cloud API service on the Cloud Platform Appliance. Note that it is possible to use the Cloud Network Automation solution only with the Cloud Network Automation license or with one or more Cloud Platform Appliances. In the case when only the Cloud Network Automation license is installed on the Grid Master, all cloud API requests are sent to the Grid Master instead of to individual Grid members. Creation of cloud objects through cloud API requests is visible in the **Cloud** tab of Grid Manager on the Grid Master.
When Cloud Platform Appliances are used without the Cloud Network Automation license, cloud API requests are sent either to the Cloud Platform Appliances or to the Grid Master. However, the **Cloud** tab in Grid Manager is not available on the Grid Master for viewing cloud objects created through cloud API requests.
You can also use the CLI command set temp_license to generate and install temporary licenses. This provides licensed features and functionality for the interim, while you wait for your permanent licenses to arrive. For information about how to install a temporary license, see *Adding Temporary Licenses*. Note that the temporary license is only effective on the Grid Master, not the Grid Master Candidate.
For an HA pair, ensure that you use the same appliance models for both nodes and install the Cloud Platform license on both nodes as well. For information about supported models, see *Supported Cloud Platform Appliance Models*. If a failover occurs and the passive node does not have a valid license, the cloud API service will stop and all resource delegations to the Cloud Platform Appliance will also stop.
Note that the Cloud Network Automation license on the Grid Master is incompatible with the following licenses:

- Multi-Grid Manager
- Reporting

Cloud Platform licenses are only supported on Cloud Platform Appliances. They may not be installed on any other Infoblox physical or virtual appliances. The following licenses and functionality are not supported on the Cloud Platform Appliances:

- Microsoft Management
- Multi-Grid Management
- Network Insight
- Reporting
- Tiered DNS Cache Acceleration
- DNS Cache Acceleration
- Load Balancing
- Infoblox
- RIR (Regional Internet Registry)

Before you install or remove the Cloud Platform license, consider the following:

- Installing or removing the Cloud Platform license stops the cloud API service.
- When you remove the Cloud Platform license from the appliance, it still serves DNS and DHCP if those licenses are installed on the appliance. However, the appliance will no longer be able to run the cloud API service. In addition, you cannot delegate authority to this member for objects that have not already been delegated to this appliance. Existing delegations to this member remain in the NIOS database, but API requests proxied from other Cloud Platform Appliances or from the Grid Master will fail.

Licensing Configurations

Depending on your Grid configuration and how you want to deploy Cloud Network Automation, Infoblox supports the following licensing configurations. For information about cloud licenses and how to install them, see *Licensing Requirements*.

- **In an Infoblox Grid, the Grid Master has the Cloud Network Automation license installed and the Cloud Platform Appliance has the Cloud Platform license installed**: The Grid Master can process both regular RESTful API and cloud API requests and the Cloud Platform Appliance can process cloud API requests. With the Cloud Platform license installed, cloud API requests can be proxied among the Grid Master and Cloud Network Appliances based on the delegation authority of the referenced objects. You can also manage the cloud API service and cloud objects through the **Cloud** tab in Grid Manager
- **In an Infoblox Grid, the Grid Master does not have the Cloud Network Automation license installed but the Cloud Platform Appliance has the Cloud Platform license installed**: The Grid Master can process both regular RESTful API and cloud API requests and the Cloud Platform Appliance can process cloud API requests. With the Cloud Platform license installed, cloud API requests can be proxied among the Grid Master and Cloud Network

Appliances based on the authority delegation of the referenced objects. Without the Cloud Network Automation license however, only objects whose authority has been delegated to Cloud Platform Appliances can be managed through Grid Manager. You will not have visibility of cloud objects, such as tenant information, through Grid Manager because the **Cloud** user interface function (the **Cloud** tab) is not available without the Cloud Network Automation license. You may manage cloud objects and their respective data through cloud API requests.

- **In an Infoblox Grid with other Grid members but without Cloud Platform Appliances, the Grid Master has the Cloud Network Automation license installed**: The Grid Master can process both regular RESTful API and cloud API requests. You can also manage cloud objects through the **Cloud** tab in Grid Manager.
- **Standalone Grid Master with the Cloud Network Automation license installed**: The appliance can process both regular RESTful API and cloud API requests. You can also manage the cloud API service and cloud objects through the **Cloud** tab in Grid Manager.
- **Standalone Grid Master without the Cloud Network Automation license installed**: The appliance can process only regular RESTful API requests, but not cloud API requests. You cannot manage the cloud API service nor cloud objects through Grid Manager because the **Cloud** user interface function (the **Cloud** tab) is not available.

The following table summarizes the supported licensing scenarios:

	Cloud Network Automation License on Grid Master	**Cloud Platform License on Cloud Platform Appliance**	**Supports Regular RESTful API Calls on Grid Master**	**Supports Cloud API Calls on Grid Master and/or Cloud Platform Appliance(s)**	**Cloud User Interface Function in Grid Manager**
Infoblox Grid **with** Cloud Platform Appliance (s)	✓	✓	✓	✓	✓
Infoblox Grid **with** Cloud Platform Appliance (s)	✗	✓	✓	✓	✗
Infoblox Grid with other Grid members but **without** Cloud Platform Appliance (s)	✓	N/A	✓	✓	✓
Standalone Grid Master	✓	N/A	✓	✓	✓
Standalone Grid Master	✗	N/A	✓	✗	✗

Administrative Permissions

You must define admin users and their permissions in the admin group and assign specific roles to it before you can use these admin users to send cloud API requests. You can also define object permissions to specific admin groups or admin

users so they can manage specific objects through cloud API requests. For more information, see *About Admin Accounts* and *About Admin Groups*.

> **Note**
>
> When you deploy Cloud Network Automation, the *cloud-api-only* is created automatically. You cannot delete this admin group.

Depending on where a cloud API request is sent and whether the scope of delegation for an object is explicit or implicit, permissions configured for the admin user and object may or may not apply. In addition, depending on the objects referenced in cloud API requests, specific restrictions may apply. For supported objects and their restrictions, see *Supported Cloud API Objects*.

For cloud API requests, admin permissions are applied based on the delegation status of the objects referenced in the requests. If an object is not delegated (owned by the Grid Master) and the cloud API request is sent directly to the Grid Master or proxied to the Grid Master, all applicable admin and object permissions apply. On the other hand, if authority for an object referenced in a cloud API request is explicitly delegated to a Cloud Platform Appliance and the request is sent to this appliance, the admin user has full permission for this object within the scope of delegation. In this case, specific permissions configured for the admin user and the referenced object are ignored. For more information about admin and object permissions, see *About Administrative Permissions*.
It is important to note that once you delegate authority of an object to the Cloud Platform Appliance, specific admin and object permissions are not enforced. Therefore, if you do not want certain objects to be created or modified through a cloud API request, do not delegate the authority of these objects and their parent objects to a Cloud Platform Appliance. For example, if you do not want host records to be created through cloud API requests, do not delegate the authority of the relevant networks, zones, or both to the Cloud Platform Appliance. On the other hand, if you want the ability to restrict permissions for specific objects referenced in cloud API updates, you can create different admin groups or admin users that are authorized to make cloud API updates on respective Cloud Platform Appliances. The following example illustrates this capability.

Configuration Example

If you want to restrict the creation and modification of records for networks 10.10.10.0/24 and 10.10.20.0/24 through cloud API updates, do the following:

1. Create two admin users **APIUser1** and **APIUser2** in an admin group.
2. Delegate the authority of network 10.10.10.0/24 to Cloud Platform Appliance 1 (**CP1**) and 10.10.20.0/24 to Cloud Platform Appliance 2 (**CP2**).
3. On **CPI**, add **APIUser1** and on **CP2**, add **APIUser2** to the list of administrators that can send cloud API requests, as described in *Configuring Grid and Member Cloud API Properties.*

Now when you use **APIUser1** to send cloud API requests, you can add and modify records for network 10.10.10.0/24, but you cannot do so for network 10.10.20.0/24. Conversely, you can add and modify records for network 10.10.20.0/24 only when you use **APIUser2**.

Cloud Network Automation Administrative Permissions

You must define admin users and their permissions in the admin group and assign specific roles to it before you can use these admin users to send cloud API requests. You can also define object permissions to specific admin groups or admin users so they can manage specific objects through cloud API requests. For more information, see *About Admin Accounts* and *About Admin Groups*.

> **Note**
>
> When you deploy Cloud Network Automation, the *cloud-api-only* is created automatically. You cannot delete this admin group.

Depending on where a cloud API request is sent and whether the scope of delegation for an object is explicit or implicit, permissions configured for the admin user and object may or may not apply. In addition, depending on the objects referenced in cloud API requests, specific restrictions may apply. For supported objects and their restrictions, see *Supported Cloud API Objects*.

For cloud API requests, admin permissions are applied based on the delegation status of the objects referenced in the requests. If an object is not delegated (owned by the Grid Master) and the cloud API request is sent directly to the Grid Master or proxied to the Grid Master, all applicable admin and object permissions apply. On the other hand, if authority for an object referenced in a cloud API request is explicitly delegated to a Cloud Platform Appliance and the request is sent to this appliance, the admin user has full permission for this object within the scope of delegation. In this case, specific permissions configured for the admin user and the referenced object are ignored. For more information about admin and object permissions, see *About Administrative Permissions*.
It is important to note that once you delegate authority of an object to the Cloud Platform Appliance, specific admin and object permissions are not enforced. Therefore, if you do not want certain objects to be created or modified through a cloud API request, do not delegate the authority of these objects and their parent objects to a Cloud Platform Appliance. For example, if you do not want host records to be created through cloud API requests, do not delegate the authority of the relevant networks, zones, or both to the Cloud Platform Appliance. On the other hand, if you want the ability to restrict permissions for specific objects referenced in cloud API updates, you can create different admin groups or admin users that are authorized to make cloud API updates on respective Cloud Platform Appliances. The following example illustrates this capability.

Configuration Example

If you want to restrict the creation and modification of records for networks 10.10.10.0/24 and 10.10.20.0/24 through cloud API updates, do the following:

1. Create two admin users **APIUser1** and **APIUser2** in an admin group.
2. Delegate the authority of network 10.10.10.0/24 to Cloud Platform Appliance 1 (**CP1**) and 10.10.20.0/24 to Cloud Platform Appliance 2 (**CP2**).
3. On **CPI**, add **APIUser1** and on **CP2**, add **APIUser2** to the list of administrators that can send cloud API requests, as described in *Configuring Grid and Member Cloud API Properties.*

Now when you use **APIUser1** to send cloud API requests, you can add and modify records for network 10.10.10.0/24, but you cannot do so for network 10.10.20.0/24. Conversely, you can add and modify records for network 10.10.20.0/24 only when you use **APIUser2**.

Supported Cloud Platform Appliance Models

The following table lists the Infoblox vNIOS virtual appliances that you can use as Cloud Platform Appliances. A Cloud Platform Appliance can only be configured as a Grid member, not a standalone appliance. To configure an HA pair, you must use the same vNIOS models for both the active and passive nodes. For information about HA pairs, see *About HA Pairs*.

Note

Cloud Platform Appliances do not support auto-provisioning. Pre-provisioning is supported for DNS and DHCP data. For information about pre-provisioning Cloud Platform Appliances, see *Pre-Provisioning NIOS and vNIOS Appliances*.

Supported Cloud Platform Appliances

vNIOS Appliance	Storage (GB)	# of CPU Cores	Virtual CPU Core Frequency	Memory Allocation
CP-V805	250	2	2000 MHz	16 GB

CP-V1405	250	4	6000 MHz	32 GB
CP-V2205	250	8	12000 MHz	64 GB

Setting Up Cloud Network Automation

To set up Cloud Network Automation, ensure that you understand the required components, licenses, and firewall configuration, as described in *Cloud Network Automation Operations*. You also need to understand what a Grid is and how to set up a Grid and deploy vNIOS appliances. For more information, see *About Grids*.
Following are high-level steps for setting up Cloud Network Automation:

1. Evaluate your network topology and IPAM requirements, and then decide how you want to set up your Grid in the cloud environment. Based on your requirements, install and configure a cloud adapter that supports Cloud Platform Appliances on your CMP. This adapter functions as the cloud API client. For information about how to install and configure the cloud adapter, refer to the *Quick Start Guide* for the cloud adapter you are deploying, available on the Infoblox Support site. If you are implementing Cloud Network Automation in your Amazon VPCs (Virtual Private Clouds), refer to the *Infoblox Installation Guide for vNIOS for AWS*.
2. Obtain valid licenses through your Infoblox representatives. Note that Cloud Platform licenses may only be installed on cloud virtual appliances. They may not be installed on physical or virtual Trinzic Enterprise appliances. Deploy the Cloud Platform Appliances and install the Cloud Platform license along with the Enterprise, vNIOS, DHCP, and DNS licenses included in the license bundle for the Cloud Platform Appliance. If you plan to use the Cloud user interface functionality on the Grid Master, obtain a Cloud Network Automation license for your Grid Master and Grid Master Candidate. For information about how to obtain and install licenses, see *Managing Licenses*.

If you are implementing Cloud Network Automation in AWS, consider Elastic Scaling to see if it better fits your business needs when you purchase your licenses. You can purchase multiple dynamic licenses and automatically pre-provision vNIOS cloud appliances according to your business needs.

1. If the Cloud Platform Appliance is not part of the Grid, join it to the Grid. For more information about how to join a member to the Grid, see *Joining Appliances to the Grid*. If you have implemented Elastic Scaling, ensure that you follow the necessary steps to automatically provision your vNIOS cloud appliances and join them to the Grid. For more information, see *Using Elastic Scaling to Pre-provision and Launch vNIOS Members*.
2. Log in to Grid Manager and complete the following:
    - Start the cloud API service on the Cloud Platform Appliance, as described in *Starting the Cloud API Service*. The cloud API service is disabled by default.

- Define admin groups and admin permissions for Cloud Network Automation, as described in *About Admin Accounts* and *About Admin Groups*.
- Control which users can send API requests, as described in *Configuring Grid and Member Cloud API*.
- Add global and object permissions for admin users who can manage cloud objects, as described in *Managing Permissions*.

You can now start sending API requests through the cloud adapter or AWS API Proxy. To understand the API request process and the supported API objects, see *About Cloud API Requests*.

About Cloud API Service

The cloud API service provides the ability to automate management of IP addresses and DNS records so your cloud environment can take full advantage of IPAM, DNS, and DHCP capabilities in NIOS without the need for manual intervention. This service is supported for the following scenarios:

- Communication between the cloud adapter (acting as an API client) and the Cloud Platform Appliance or between Cloud Platform Appliances. This cloud API service accepts and processes a subset of the WAPI requests that are currently supported on the Grid Master either directly from an adapter or proxied through another Cloud Platform Appliance or from the Grid Master.

- Communication between the cloud adapter and the Grid Master, or between Cloud Platform Appliances and the Grid Master. This cloud API service processes requests received directly from the cloud adapter or processes requests received by other Cloud Platform Grid members.

The admin users that you use to send cloud API requests must have applicable access to the cloud API in order for the API requests to be processed. For information about admin groups, see *Managing Admin Groups and Admin Roles*.

Starting the Cloud API Service

To start the cloud API Service:

1. From the **Grid** tab, select the **Services** tab -> *cloud_member* checkbox.
2. Click **Cloud API** on the top navigation bar, and then click **Start** from the Toolbar.

Monitoring Cloud API Service

To monitor the status of the cloud API service, from the **Cloud** tab, select the **Members** tab -> *cloud_member* link. Grid Manager displays the service status, as described in *Service Status*.
You can also monitor the cloud API service through the following:

- View the cloud API service through the Member service status, as described in *Member Status*.
- Configure the appliance to receive SNMP traps for the cloud API service, as described in *Monitoring with SNMP*.
- View *Cloud Statistics* widget on the Dashboard, as described in *Cloud Statistics*.
- Review event messages in the syslog, as described in *Viewing the Syslog*.

About Cloud API Requests

In your cloud environment, the cloud adapter acts as the cloud API client. Only API requests made by admin users who have the correct permissions on the cloud API ACL (Access Control List) are processed by the cloud API service. When the Cloud Platform Appliance receives a cloud API request, it processes the request based on authority delegation of the objects and respective cloud extensible attributes. For information about cloud extensible attributes, see *Extensible Attributes for Cloud Objects*. If the Cloud Platform Appliance is not authoritative for the referenced objects, it proxies the request to the authoritative appliance that can be another Cloud Platform Appliance or to the Grid Master if no authority delegation is defined. For information about proxying cloud API requests, see Proxying Cloud API Requests below.

Note

For the cloud API service to function properly, configure your networks and firewalls accordingly to allow port 443 HTTPS connectivity between the cloud adapter and Cloud Platform Appliance, between the cloud adapter and the Grid Master (if applicable), between the Grid Master and Cloud Platform members, and between each Cloud Platform member.

If you are using the AWS API Proxy to send API requests, ensure that you understand how to set up and configure the proxy. For detailed information, refer to the *Infoblox Installation Guide for vNIOS for AWS*.
When implementing Cloud Network Automation in AWS, you can use Elastic Scaling to allocate and deallocate dynamic licenses and automatically spin up vNIOS Grid members and join them to the Grid. You can purchase and install NIOS feature licenses in advance and store them in a license pool container on the Grid Master. You can then decide when and how to automatically provision and configure vNIOS for AWS cloud virtual appliances. When you remove a vNIOS cloud appliance, the licenses on this appliance are released and returned to the license pool and are available for the next deployment.

Cloud API Request Process

As described in the below table, all cloud API requests are subject to the following process before responses are returned. The appliance

Cloud API Request Process

Steps	Descriptions	Configuration that affects the outcome of this step
Authentication and categorization	All cloud API requests are authenticated based on the authentication sources. Once authenticated, the requests are categorized as either a cloud API request or not. All requests that specify user identity as users defined in admin groups with cloud API access are *Managing Admin Groups and Admin Roles* categorized as cloud API requests.	Define admin user accounts that can be used to send cloud API requests. For information, see *Managing Admin Groups and Admin Roles.*
Authorization	All cloud API requests are subject to authorization based on the ACLs (Access Control Lists) defined for the Grid or Cloud Platform Appliance. You can control which admin accounts can be used to send API requests. The ACLs can contain admin users in admin groups with cloud API access or remote authenticated users.	Define ACLs on the Grid Master or Cloud Platform Appliance. For information, see *Configuring Grid and Member Cloud API Properties.*
Proxying Requests	If a Cloud Platform Appliance is not authoritative for a cloud API request, it proxies the request either to the authoritative Cloud Platform Appliance or to the Grid Master for processing. Similarly, if an object has been delegated and the API request is made to the Grid Master, the Grid Master proxies that request to the authoritative Cloud Platform Appliance.	Ensure that HTTPS connectivity between each Cloud Platform member and between each Cloud Platform member and the Grid Master is functioning properly for proxying. For information, see Proxying Cloud API Requests below.
Validation	NIOS performs a final validation on the cloud API request based on permissions configured for the admin users and restrictions for the applicable objects. If the request is processed within the scope of an explicit delegation, the admin user is considered to have full permissions within the scope, and any permission defined for admin groups with cloud API access is ignored. Otherwise, the request is subject to validation for all permissions defined for admin groups with cloud API access.	Define admin permissions for admin groups with cloud API access. For information, see *About Admin Groups.*
Auditing	Cloud API related events are logged to the NIOS syslog of the Grid member that processes the API requests instead of to the NIOS audit log.	Configure syslog server for the cloud member. For information, see *Viewing the Syslog.*

Supported Cloud API Objects

The following table lists all the supported cloud API object types, methods, and functions. In your cloud API requests, you cannot include RESTful API object types, methods, and functions that are not listed in the table, even when the Grid Master supports them for other purposes. Note that the supported types and operations for cloud API requests are sub sets of all types and operations supported on the Grid Master.
Before you send any cloud API requests, ensure that you understand the implications and restrictions for each supported

object. NIOS uses extensible attributes to associate specific information with a cloud object. For information about the default cloud extensible attributes and how to use them, see *Extensible Attributes for Cloud Objects*.
In AWS (Amazon Web Services), you can create a VPC (Virtual Private Cloud) and a subnet using the same network address and subnet mask. For example, you can add 172.29.02.0/24 as the VPC and 172.29.2.0/24 as the subnet and create VMs in the subnet. However, you cannot add a network container and a network using the same network address and subnet mask in NIOS. Therefore, when you send an API request to create such VPC and subnet in AWS, NIOS recognizes only the VPC, not the subnet. As a result, you are not able to create VMs under the subnet. For more information about how to create VPCs and subnets in AWS for NIOS, refer to the *Infoblox Installation Guide for vNIOS for AWS*.
In addition, when you delegate authority for supported cloud objects, NIOS may process the requests differently based on the following:

- How the object was first created.
- Whether authority for the object has already been delegated to a Cloud Platform Appliance.

For details about authority delegation and restrictions for each object, see *About Authority Delegation*.

> ⚠ Note
>
> NIOS does not process cloud API requests that contain unsupported object types or any combination of supported object types with unsupported methods and functions. Although you can use all the fields in a supported object type, some restrictions may apply to supported values for some of these fields. For restrictions, see the **Comments** field in the below table for the corresponding object.

Supported Cloud API Objects for Cloud API Service

> ⚠ Note
>
> The cloud API service does not support scheduling and workflow approval requests. Objects deleted through a cloud API request are not stored in the Recycle Bin, except for DNS zones and network views. For information about the Recycle Bin, see *Using the Recycle Bin* .

Supported Object Type	Cloud API Object	Allowed Operations in cloud API Requests	Authority Delegation and Restrictions	Required Extensible Attributes in cloud API Requests (for creations only)
Network View	networkview	Read, Create, Modify, Delete	See *Network Views* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type
IPv4 Network Container	networkcontainer	Read, Create, Modify, Delete Function: next_available_network	Split network, join networks, and RIR related operations are not supported. See *IPv4 andIPv6 Networks and Network Containers* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type

Supported Object Type	Cloud API Object	Allowed Operations in cloud API Requests	Authority Delegation and Restrictions	Required Extensible Attributes in cloud API Requests (for creations only)
IPv6 Network Container	ipv6networkcontainer	Read, Create, Modify, Delete Function: next_available_network	Split network, join networks, and RIR related operations are not supported. See *IPv4 andIPv6 Networks and Network Containers* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type
IPv4 Network	network	Read, Create, Modify, Delete Function: next_available_ip	Split network, join networks, and RIR related operations are not supported. See *IPv4 andIPv6 Networks and Network Containers* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type
IPv6 Network	ipv6network	Read, Create, Modify, Delete Function: next_available_ip	Split network, join networks, and RIR related operations are not supported. See *IPv4 andIPv6 Networks and Network Containers* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type
IPv4 DHCP Range	range	Read, Create, Modify, Delete Function: next_available_ip	See *DHCP Ranges* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type
IPv6 DHCP Range	ipv6range	Read, Create, Modify, Delete Function: next_available_ip	See *DHCP Ranges* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type
IPv4 Fixed Address (Reservation)	fixedaddress	Read, Create, Modify, Delete Function: next_available_ip You can also create and delete through Grid Manager. All required Cloud EAs are automatically populated in the GUI.	See *IPv4 and IPv6 Fixed Addresses* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type

Supported Object Type	Cloud API Object	Allowed Operations in cloud API Requests	Authority Delegation and Restrictions	Required Extensible Attributes in cloud API Requests (for creations only)
IPv6 Fixed Address (Reservation)	ipv6fixedaddress	Read, Create, Modify, Delete Function: next_available_ip You can also create and delete through Grid Manager. All required Cloud EAs are automatically populated in the GUI.	See *IPv4 and IPv6 Fixed Addresses* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type
DNS View	view	Read, Modify	See *DNS Views* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type
DNS Zone	zone_auth	Read, Create, Modify, Delete	See *DNS Zones* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type
Host Record	record:host	Read, Create, Modify, Delete You can also create and delete through Grid Manager. All required Cloud EAs are automatically populated in the GUI.	See *Host Records* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type
	record:host_ipv4addr	Read, Create, Modify, Delete Function: next_available_ip You can also create and delete through Grid Manager. All required Cloud EAs are automatically populated in the GUI.		
	record:host_ipv6addr	Read, Create, Modify, Delete Function: next_available_ip You can also create and delete through Grid Manager. All required Cloud EAs are automatically populated in the GUI.		

Supported Object Type	Cloud API Object	Allowed Operations in cloud API Requests	Authority Delegation and Restrictions	Required Extensible Attributes in cloud API Requests (for creations only)
Resource Record	record:a	Read, Create, Modify, Delete Function: next_available_ip	See *DNS Resource Records* for information about authority delegation.	Tenant ID Cloud API Owned CMP Type
	record:aaaa	Read, Create, Modify, Delete Function: next_available_ip		
	record:cname	Read, Create, Modify, Delete		
	record:ptr	Read, Create, Modify, Delete Function: next_available_ip		
	record:mx	Read, Create, Modify, Delete		
	record:naptr	Read, Create, Modify, Delete		
	record:srv	Read, Create, Modify, Delete		
	record:txt	Read, Create, Modify, Delete		
Grid Member	member	Read only Function: restartservices	API requests calling for service restarts on a Grid member can be processed by the Cloud Platform Appliance only if the member requested is also the Cloud Platform Appliance processing the request.	N/A
Grid	grid	Read only Function: restartservices	All cloud API requests calling for service restarts are proxied to the Grid Master.	N/A
Extensible Attribute	extensibleattributedef	Read only	You can use cloud attributes as source objects to obtain the next available IP address or network. When doing so, you must also include the respective network view for the object.	N/A

Proxying Cloud API Requests

In Cloud Network Automation, the primary Cloud Platform Appliance that receives cloud API requests can act as a proxy for other authoritative Cloud Platform members and for the Grid Master. This proxying mechanism is important when the Cloud Platform Appliance cannot process requests that contain objects for which it is not authoritative, or when objects in the requests do not have authority delegation and must be processed by the Grid Master.
Note that only successfully authenticated and authorized requests that require proxying are sent to the respective appliance for processing. Proxying is limited to one hop within the Grid. Therefore, if the destination appliance cannot process a proxied request, the request will not be forwarded and an error is returned to the client.

> ⚠ Note
>
> Only cloud API requests can be proxied.

To ensure that the proxying mechanism functions properly, configure your systems to allow for the following communication:

- Allow all HTTPS connectivity among the Cloud Platform Appliances as well as to the Grid Master based on your organization's firewall requirements.
- Ensure that you use the VIP or the MGMT address if it is enabled (including that for the Grid Master) as the destination IP for the HTTPS connectivity. Note that this is a per member setting.
- Grant appropriate permissions to admin groups with cloud API access to ensure that tasks for objects outside of the delegation function properly on the Grid Master.

Sample Cloud API Requests

This section includes sample cloud API requests for supported objects:
Adding a network view:

```
curl -H "Content-Type: application/json" -k1 -u cloud:infoblox -X POST
https://10.0.0.2/wapi/v2.0/networkview -d '{"name": "netview1", "extattrs":
{ "Tenant ID":{"value": "1011"} ,"Cloud API Owned":{"value":"True"},"CMP
Type":{"value":"vCO/vCAC"}}}'
```

Adding a network within the delegated network view in the above example:

```
curl -H "Content-Type: application/json" -k1 -u cloud:infoblox -X POST
https://10.0.0.2/wapi/v2.0/network -d '{ "network":
"20.0.0.0/24","network_view":"netwview1","extattrs": { "Tenant ID":{"value":
"1011"} ,"Cloud API Owned":{"value":"True"},"CMP Type":{"value":"vCO/
vCAC"}}}'
```

Adding a DHCP range within the network created in the above example:

```
curl -H "Content-Type: application/json" -k1 -u cloud:infoblox -X POST
https://10.0.0.2/wapi/v2.0/range -d '{ "end_addr": "20.0.0.40", "member":
{"_struct": "dhcpmember1", "ipv4addr": "10.0.0.2", "name":
" corpxyz.com "},"network": "20.0.0.0/24", "network_view": "netview1",
"start_addr": "20.0.0.35", "extattrs": {"Tenant ID":{"value": "1011"} ,"CMP
Type":{"value":"vCO/vCAC"},"Cloud API Owned":{"value":"True"}}}'
```

Adding an A Record:

```
curl -H "Content-Type: application/json" -k1 -u cloud:infoblox -X POST
https://10.0.0.2/wapi/v2.0/record:a -d '{"name": "corp200.com",
"ipv4addr":"20.0.0.2","view": "default.netview1","extattrs": {"Tenant ID":
{"value": "1011"} , "CMP Type":{"value":"vCO/vCAC"},"Cloud API Owned":
{"value":"True"},"VM ID":{"value":"12"}}}'
```

Adding a Fixed address:

```
curl -H "Content-Type: application/json" -k1 -u cloud:infoblox -X POST
https://10.0.0.2/wapi/v2.0/fixedaddress -d '{"ipv4addr": "20.0.0.5",
"network_view": "netview1","mac":"15:06:32:16:00:00","extattrs": { "Tenant
ID":{"value": "1011"} ,"CMP Type":{"value":"vCO/vCAC"} ,"VM ID":
{"value":"352"},"Cloud API Owned":{"value":"True"}}}'
```

Adding a zone:

```
curl -H "Content-Type: application/json" -k1 -u cloud:infoblox -X POST
https://10.0.0.2/wapi/v2.0/zone_auth -d '{ "fqdn":"test.com","grid_primary":
[{"name": "infoblox.localdomain", "stealth": false},{"name": "corpxyz.com",
"stealth": false}],"view": "default.netview1","extattrs": { "Tenant ID":
{"value": "1011"} , "CMP Type":{"value":"vCO/cCAC"} ,"Cloud API Owned":
{"value":"True"}}}'
```

Adding a network container:

```
curl -H "Content-Type: application/json" -k1 -u cloud:infoblox -X POST
https://10.0.0.2/wapi/v2.0/networkcontainer -d '{ "network":
"200.0.0.0/24","network_view": "netview1","extattrs": { "Tenant ID":
{"value": "1011"} ,"Cloud API Owned":{"value":"True"},"CMP Type":
{"value":"vCO/vCAC"}}}'
```

Add a host record:

```
curl -H "Content-Type: application/json" -k1 -u cloud:infoblox -X POST
https://10.0.0.2/wapi/v2.0/record:host -d '{ "ipv4addrs":
[{ "configure_for_dhcp": false,"ipv4addr": "20.0.0.1", "mac":
"11:11:22:22:33:33"}],"ipv6addrs": [{"configure_for_dhcp": false,"duid":
"11:22", "ipv6addr": "13::1"},{"configure_for_dhcp": false,"duid": "21:22",
"ipv6addr": "13::2"}],"name": "host.corpxyz.com", "view": "default.netview1"}'
```

Adding an MX Record:

```
curl -H "Content-Type: application/json" -k1 -u cloud:infoblox -X POST
https://10.0.0.2/wapi/v2.0/record:mx -d '{ "mail_exchanger":
```

```
" abc.com ","name":" def.corpxyz.com ", "preference":
10,"view":"default.netview1","extattrs": { "Tenant ID":{"value": "1011"} ,
"CMP Type":{"value":"vCO/vCAC"}, "Cloud API Owned":{"value":"False"},"VM
ID":{"value":"230"}}}
```

Sample Cloud API Requests for Elastic Scaling

Creating a Member:

```
curl -H "Content-Type: application/json" -k1 -u cloud:cloud -X POST https://
10.40.240.88/wapi/v2.2/member -d '{"platform": "VNIOS", "host_name":
"test1.com", "vip_setting": {"address": "1.1.1.1", "gateway": "1.1.0.2",
"subnet_mask": "255.255.0.0"}}'
```

Getting a Member:

```
curl -H "Content-Type: application/json" -k1 -u cloud:cloud -X GET https://
10.40.240.88/wapi/v2.2/member
```

Adding Pre-Provisioned Information for the Member:

```
curl -H "Content-Type: application/json" -k1 -u cloud:cloud -X PUT https://
10.40.240.101/wapi/v2.2/member/b25lLnZpcnR1YWxfbm9kZSQ3:test1.com -d
'{"pre_provisioning": {"hardware_info": [{"hwmodel": "CP-V1405", "hwtype":
"IB-VNIOS"}], "licenses": ["cloud_api", "dhcp", "dns", "enterprise",
"vnios"]}}'
```

Creating and Delegating a Network View:

```
curl -H "Content-Type: application/json" -k1 -u cloud:cloud -X POST https://
10.40.240.88/wapi/v2.2/networkview -d '{"name":"testnv", "extattrs":{"Tenant
ID":{"value": "1011"} , "CMP Type":{"value":"vm130ctest"}, "Cloud API
Owned":{"value":"True"}} }
```

Creating and Delegating a Network:

```
curl -H "Content-Type: application/json" -k1 -u cloud:cloud -X POST https://
10.40.240.88/wapi/v2.2/network -d '{"network":"21.0.0.0/8",
"network_view":"default", "cloud_info":{"delegated_member": {"ipv4addr":
"1.1.1.1","name":"test1.com"}},"extattrs":{ "Tenant ID":{"value": "1011"} ,
"CMP Type":{"value":"vm130ctest"}, "Cloud API Owned":{"value":"True"}} }'
```

Undelegating a Network:

```
curl -H "Content-Type: application/json" -k1 -u cloud:cloud -X PUT https://
10.40.240.88/wapi/v2.2/network/ZG5zLm5ldHdvcmskMjEuMC4wLjAvOC8w:21.0.0.0/8/
default -d '{"cloud_info": {"delegated_member": null }}'
```

Creating and Delegating an Authoritative Zone

```
curl -H "Content-Type: application/json" -k1 -u cloud:cloud -X POST https://
10.40.240.88/wapi/v2.2/zone_auth -d '{"fqdn": "test.com", "grid_primary":
[{"name": "test1.com", "stealth": false}], "view": "default", "extattrs":
{ "Tenant ID":{"value": "1011"} , "CMP Type":{"value":"vm130ctest"}, "Cloud
API Owned":{"value":"True"}}}'
```

Deleting a Member:

```
curl -H "Content-Type: application/json" -k1 -u cloud:cloud -X DELETE
https://10.40.240.88/wapi/v2.2/member/b25lLnZpcnR1YWxfbm9kZSQ3:test1.com
```

Creating Token for the Pre-Provisioned Member (note that only superuser can create a token; you must configure superusers admin groups with cloud API access):

```
curl -H "Content-Type: application/json" -k1 -u cloud:cloud -X POST
https://10.40.240.88/wapi/v2.2/member/b25lLnZpcnR1YWxfbm9kZSQ3:test1.com?
_function=create_token
```

Reading Token for the Pre-Provisioned Member (note that only superuser can create a token; you must configure superusers admin groups with cloud API access):

```
curl -H "Content-Type: application/json" -k1 -u cloud:cloud -X POST https://
10.40.240.88/wapi/v2.2/member/b25lLnZpcnR1YWxfbm9kZSQ3:test1.com?
_function=read_token
```

About Authority Delegation

Authority delegation in Cloud Network Automation is the ability to assign full and exclusive control of IP addresses and DNS name spaces to a Cloud Platform Appliance. You can perform authority delegation only through the Grid Master. When you delegate the authority of IP addresses and DNS name spaces to a Cloud Platform Appliance, the Grid Master loses its authority over the scope of delegation for these IP addresses and name spaces as well as any objects within them. Note that authority delegation for an object can be explicitly assigned or inherited from parent objects. For information about how to delegate authority for supported object types, see Guidelines for Delegating below .
NIOS admin users who do not belong to admin groups with cloud API access are not allowed to create new cloud objects, nor can they modify or delete existing cloud objects in delegated spaces; but they can modify the permissions and certain extensible attribute values for these objects. Only admin users with cloud API access and the correct global and object permissions can be used to send cloud API requests to create, modify, and delete objects within the delegated scope.

> ⚠ Note
>
> You can delegate authority only to Cloud Platform Appliances, but not to other Grid members.

Objects that are in queue for scheduled executions or approvals are locked and cannot be delegated. Authority delegation and reclaiming of authority are subject to approval and can be scheduled.

Guidelines for Delegating Authority

You can initiate explicit delegation of authority only through Grid Manager on the Grid Master. The cloud API service can only be used for implicit or automatic delegation of an object such as creating a network under a network container that has been delegated, in which network is implicitly delegated to the member to which the network container is delegated. The Grid Master can explicitly delegate authority only for the following object types:

- Network View
- Network Container (both IPv4 and IPv6)
- Network (both IPv4 and IPv6)
- DHCP Range (IPv4 and IPv6)
- DNS Authoritative Zone (Note that zones are implicitly delegated if the assigned name server is a Cloud Platform Appliance.)

Consider the following when you delegate authority for an object:

- You can delegate authority for supported objects to one and only one Cloud Platform Appliance, except for DNS zones.
- When delegating authority for a parent object, all child objects within the scope of delegation inherit the same authority delegation.
- You cannot delegate authority for the following:
    - Objects whose parents already have a delegation configured.
    - Individual IPAM and DNS records including fixed addresses, host records, A/AAAA/PTR records, etc.
- When you use Elastic Scaling to pre-provision an offline Cloud Platform Appliance, any object authority delegated to this offline member does not take effect until the member joins the Grid. Therefore, you can still create child objects through Grid Manager under the delegated objects when the member is offline.
- You can override the inheritance of authority delegation at the object level only if the parent object has not been delegated. The Grid Master assumes authority for objects that do not fall within the scope of delegation.
- If a supported object has already been delegated, you cannot re-delegate it to another appliance. If you want to re-delegate this object, you must first un-delegate it.
- For explicitly delegated objects, you can only modify the permission and extensible attributes from Grid Manager and the Infoblox API other than cloud API requests. For explicitly delegated zones however, you can modify any properties from Grid Manager and the Infoblox API other than cloud API requests.
- When you create or delete a delegated object through a cloud API request, the appliance returns an OK message if the operation is successful. It returns an ERROR message if the operation fails. You can then change the options in the request and try again. The appliance sends a WARNING message when certain operations require attention.
- You can reclaim the authority that you delegated to a Cloud Platform Appliance. Once the authority is reclaimed, it goes back to the Grid Master. Before you reclaim authority for any object, ensure that the Cloud Platform Appliance is online and properly connected to the Grid Master for the reclaiming process to function properly.
- The Cloud Platform Appliance can run discovery on any network containers or networks that are reachable by the appliance. The default discovery settings for network containers and networks are inherited from their parent objects. For information about discovery, see *About Discovery*.

Note

Any Cloud Platform Appliances that are removed from the Grid automatically lose authority over objects that were delegated to them. The Grid Master becomes authoritative for these objects.

Delegating Authority for Cloud Objects

You can delegate authority when you create a new object that has not been delegated or does not inherit authority delegation from one of its parent objects.
See the following sections for detailed information about delegating authority for supported objects.

Network Views

Consider the authority delegation guidelines mentioned in the table below when you create, modify, or delete a network view. See *Sample Cloud API Requests* for a sample cloud API request.
For information about how to create network views from the Grid Master, see *Adding Network Views*.

Authority Delegation for Network Views

Cloud API Requests	Standard API and WAPI Requests	Comments
• You can delegate authority for a network view to only one Cloud Platform Appliance. • When you create a new network view, authority is automatically delegated to the Cloud Platform Appliance that processes the request. • To balance network views among multiple Cloud Platform Appliances in the Grid, ensure that you configure your cloud adapter accordingly. • If you want to share a network view among different Cloud Platform members, you must manually provision it and its child objects and delegate them to the respective Cloud Platform members.	• You can delete a network view from the Grid Master only if it has not been delegated to any Cloud Platform Appliance. • When you create a network view on the Grid Master, it is shared among all Grid members in the Grid. • You can delegate a network view from the Grid Master to a Cloud Platform Appliance only if the child objects within the network view are delegated to the same Cloud Platform Appliance. • When you reclaim authority for a network view, any DNS zones in the network view remain assigned to their name servers, including the Cloud Platform Appliance that has lost authority over the network view. In other words, the DNS zone remains under the authority of that Cloud Platform Appliance.	• When you create a network view through a cloud API request, you must include the following extensible attributes in the cloud API request: Tenant ID, Cloud API Owned, and CMP Type.

IPv4 and IPv6 Networks and Network Containers

Consider the authority delegation guidelines mentioned in the table below when you create, modify, or delete a network or network container. See *Sample Cloud API Requests* for a sample cloud API request. For information about how to create IPv4 and IPv6 networks from the Grid Master, see *Adding IPv4 Networks* and *Adding IPv6Networks*.
For information about how to create IPv4 and IPv6 networks using network templates from the Grid Master, see *Adding IPv4 Network Templates* and *Adding IPv6 Network Templates*.

Authority Delegation for Networks and Network Containers

Cloud API Requests	Standard API and WAPI Requests	Comments

• You can delegate authority for a network or network container to only one Cloud Platform Appliance, but you can delegate authority of multiple networks and network containers to the same Cloud Platform Appliance.
• When you create a new network or network container through a cloud API request, authority is automatically delegated to the primary Cloud Platform Appliance that processes the request.
• When you create a network using a network template, you must provide the name of the template and reference it in the cloud API request.
• Delegation for a network or network container (except for unmanaged networks) can be done through explicit delegation or inheritance from the parent object.
• You cannot delete networks and network containers using cloud API requests if they have already been explicitly delegated. You must first un-delegate them before deleting them.
• Networks and network containers associated with a DNS zone cannot be delegated.
• You can delegate a network or network container if all the following are true:
  • It has not been delegated to a Cloud Platform Appliance.
  • It is not part of a network or network container that has been delegated to a Cloud Platform Appliance.
  • It does not contain any networks or DHCP ranges that are delegated to a different Cloud Platform Appliance.
  • It does not belong to a delegated network view.
• All discovery related attributes for a network or network container return the default values.
• You cannot modify the discovery settings for networks that are in a delegated network container. You cannot create discovered networks in a network container whose authority has been delegated. You also cannot convert unmanaged networks. A discovered unmanaged IP address may co-exist with an IP address created through a cloud API request.
• Although no DHCP service restart is required, you can perform a DHCP service restart on a Cloud Platform Appliance through a cloud API request.
	• You cannot create, modify, or delete a network or network container on the Grid Master if the object has been delegated to a Cloud Platform Appliance.
	• You can create a network or network container and delegate it to a Cloud Platform Appliance using a network template.
	• You can delegate a network or network container to a Cloud Platform Appliance only if the child objects within the network or network container are delegated to the same Cloud Platform Appliance.
	• You cannot perform a recursive deletion of a network container if one of the child objects in the container has been delegated.
	• DHCP utilization usage for a network or network container is only updated on the Grid Master.
	• Discovered IP addresses that are within a delegated network are created on the Grid Master and replicated to the Cloud Platform Appliance that is relevant to the IP addresses.
		• When you create a network or network container through a cloud API request, you must include the following extensible attributes in the request: Tenant ID, Cloud API Owned, and CMP Type.
		• If a network is explicitly delegated (not through inheritance), you can convert a network to a network container only if the size of the network remains the same; the network delegation is transferred to the network container.
		• The Cloud Platform Appliance does not support split network, john networks, and RIR related operations.

DHCP Ranges

Consider the authority delegation guidelines mentioned in the table below when you create, modify, or delete a DHCP range. See *Sample Cloud API Requests* for a sample cloud API request.
For information about how to create IPv4 and IPv6 ranges, see *Adding IPv4 Address Ranges* and *Modifying IPv6 Address Ranges*.
For information about how to create IPv4 and IPv6 ranges using range templates, see *Adding IPv4 Range Templates* and *Adding IPv6 Range Templates*.

Authority Delegation for DHCP Ranges

Cloud API Requests	Standard API and WAPI Requests	Comments

• You can delegate authority for a DHCP range to only one Cloud Platform Appliance, but you can delegate authority for multiple DHCP ranges to the same Cloud Platform Appliance.
• When you create a new DHCP range, authority is automatically delegated to the Cloud Platform Appliance that processes the request or to the Grid Master if the Grid Master processes the request.
• When you create a DHCP range using a range template, you must know the name of the template and reference it in the cloud API request.
• You can delegate authority for reserved ranges in a Microsoft synchronized network if:
  • It is not included in any exclusions.
  • It does not conflict with another reserved range.
  You can manage these range addresses through a cloud adapter, such as the IPAM Plug-In for VMware.
• Delegation for a DHCP range can be done through explicit delegation or inheritance from the parent object. You cannot override inherited delegation.
• Note that you cannot delete DHCP ranges using cloud API requests if they have already been explicitly delegated. You must first un-delegate them before deleting them. However, if the delegation is inherited, you can delete the objects through a cloud API request.
• You can delegate a DHCP range to a Cloud Platform Appliance if all the following are true:
  • It has not been delegated to a Cloud Platform Appliance.
  • It is not part of a delegated network or network container in the same network view.
  • It does not belong to a delegated network view.
  • It is a reserved range or a range that has been assigned to a DHCP member that is the same Cloud Platform Appliance to which you want to delegate the range.
• You cannot delegate a DHCP range that has been assigned to a failover association, nor can you assign a DHCP range that has been delegated to a failover association.
• Authority is delegated from the start address to the end address, including exclusions. Note that the exclusions can be used only to restrict IP addresses generated by the next available IP feature.
• All discovery related attributes for a DHCP range return the default values.
• Although no DHCP service restart is required, you can perform a DHCP service restart on a Cloud Platform Appliance through a cloud API request.
	• You cannot create, modify, or delete a DHCP range on the Grid Master if it has been delegated to a Cloud Platform Appliance.
	• You can create a DHCP range and delegate it to a Cloud Platform Appliance using a range template.
	• You can increase the size of a DHCP range that has been explicitly delegated to a Cloud Platform Appliance. The increased size is available for use by the Cloud Platform Appliance after replication.
		• When you create a DHCP range through a cloud API request, you must include the following extensible attributes in the request: Tenant ID, Cloud API Owned, and CMP Type.

Cloud API Requests	Standard API and WAPI Requests	Comments

IPv4 and IPv6 Fixed Addresses

Consider the following authority delegation guidelines when you create, modify, or delete a fixed address:

- You can delegate authority for a fixed address only through inheritance from one of its parent objects, such as its associated network view, network container, network, or DHCP reserved range.
- When you create or modify an IPv4 or IPv6 fixed address, you must include the following extensible attributes in the cloud API request: Tenant ID, Cloud API Owned, and CMP Type.
- You can create a fixed address from the Grid Master using a fixed address template. Note that when you want to reference a template in the cloud API request, you must know the name of the template beforehand.
- When performing any operations on a Cloud Platform Appliance, all discovery related attributes for a fixed address return the default values.
- No DHCP service restart is required when performing any operations for a fixed address on the Cloud Platform Appliance unless automatic DHCP restart is disabled on the appliance. You can however perform a DHCP service restart on the Cloud Platform Appliance to which authority is delegated for a fixed address through a cloud API request.
- You can create, modify, or delete an IPv4 or IPv6 fixed address and reservation on the Grid Master through Grid Manager if the fixed address or reservation is within the scope of a network view, network container, network, or DHCP reserved range whose authority has been delegated to a Cloud Platform Appliance.

See *Sample Cloud API Requests* for a sample cloud API request.
For information about how to create IPv4 and IPv6 fixed addresses, see *Adding IPv4 Fixed Addresses* and *Adding IPv6 Fixed Addresses*.
For information about how to create IPv4 and IPv6 fixed address templates, see *Adding IPv4 Fixed Address/ Reservation Templates* and *Adding IPv6 Fixed Address Templates*.

DNS Views

Consider the following authority delegation guidelines when you create, modify, or delete a DNS view:

- You cannot explicitly delegate authority for a DNS view. The Cloud Platform Appliance automatically gains authority over any DNS view that exists in the network view whose authority is delegated to that appliance.
- You cannot create or delete a DNS view from the Cloud Platform Appliance.
- Through a cloud API request, you can update DNS views defined in a network view that has been delegated to the Cloud Platform Appliance.
- You cannot create, modify, or delete a DNS view in network views that have been delegated to a Cloud Platform Appliance through a standard API request.
- You cannot delete a DNS view as long as it contains at least one DNS zone that has been delegated to a Cloud Platform Appliance.

DNS Zones

Consider the following authority delegation guidelines mentioned in the table below when you create, modify, or delete a DNS zone. See *Sample Cloud API Requests* for a sample cloud API request.
For information about how to create DNS zones, see *Configuring Authoritative Zones*.

Authority Delegation for DNS Zones

Cloud API Requests	Standard API and WAPI Requests	Comments
• The Grid primary of a DNS zone automatically gains authority for the zone if the primary is a Cloud Platform Appliance. When there are multiple primaries configured for the zone, multiple delegations to these primaries are allowed as long as they are Cloud Platform Appliances. • You cannot assign both a Microsoft server and a Grid member as primaries at the same time, although you can assign a Microsoft server as the Grid primary and a Cloud Platform Appliance as the Grid secondary. This allows the Microsoft server to serve changes sent from the cloud adapter. • All resource records in a DNS zone inherit authority delegation from the zone. However, you cannot modify the NS record through a cloud API request. • You can modify all the fields for a zone whose authority has been explicitly delegated. • The cloud member to which authority for a network view is delegated automatically gains authority for authoritative zones defined in that network view. This Cloud Platform Appliance is the only cloud member that can be the Grid primary for the zones defined in this network view. The Grid Master does not have authority for any zone in this network view unless it is assigned as a Grid primary. • The Cloud Platform Appliance can create, modify, and delete a DNS zone in any DNS view defined in a network view whose authority has been delegated to that cloud member. • The Cloud Platform Appliance that is authoritative for a DNS zone can perform changes to the assigned Grid primaries, Grid secondaries, and external servers assigned to the zone as long as the Cloud Platform Appliance remains a Grid primary. But it cannot create, modify, or delete the NS record. • The Cloud Platform Appliance that is authoritative for a DNS zone can create, modify, and delete DNS delegations that are directly parented to that zone. In particular, it may specify any Grid primary, Grid secondary, or external server for that zone. • DNSSEC operations, network associations, and zone locking are not supported if at least one Cloud Platform Appliance is assigned as the Grid primary for any DNS zones. • Although no DHCP service restart is required, you can perform a DHCP service restart on a Cloud Platform Appliance through a cloud API request.	• You cannot create, modify, or delete a DNS zone in a network view whose authority has been delegated to a Cloud Platform Appliance. • You cannot assign a Cloud Platform Appliance as the Grid primary for a zone that is locked or disabled. • You can modify extensible attributes of any DNS zone whose authority has been delegated from the Grid Master.	• Only authority for authoritative forward-mapping and reverse-mapping zones can be delegated. You cannot delegate authority for forward zones, stub zones, and delegated zones even though they may exist in a delegated network view. • When you create a DNS zone using a cloud API request, you must include the following extensible attributes in the request: Tenant ID, Cloud API Owned, and CMP Type.

DNS Resource Records

Consider the following authority delegation guidelines mentioned in the table below when you create, modify, or delete a resource record, including A, AAAA, CNAME, PTR, MX, SRV, TXT, NAPTR records.
See *Sample Cloud API Requests* for a sample cloud API request.

Authority Delegation for DNS Resource Records

Cloud API Requests	Standard API and WAPI Requests	Comments
• Authority delegation for resource records (A, AAAA, CNAME, PTR, MX, SRV, TXT, and NAPTR) is inherited from their parent zones. You can delegate authority for these records by delegating authority for their respective parent zones. • All resource records in a DNS zone inherit authority delegation from their parent zones. However, you cannot modify the NS record through a cloud API request. • If the Cloud Platform Appliance is a Grid primary for a zone, requests that include a supported record is processed locally by the Cloud Platform Appliance. Otherwise, the request is proxied to the Cloud Platform Appliance that is assigned as the only Grid primary for the zone. • If the DNS resource records belong to a zone that is served only by Cloud Platform Appliances, authority for these records are considered delegated. You must create, modify, or delete these records on one of these Cloud Platform Appliances.	• You cannot create, modify, or delete a resource record if it is in a network view whose authority has been delegated to a Cloud Platform Appliance.	• When you create a resource record through a cloud API request, you must include the following extensible attributes in the request: Tenant ID, Cloud API Owned, and CMP Type.

Host Records

Consider the following authority delegation guidelines mentioned in the table below when you create, modify, or delete a host record. See *Sample Cloud API Requests* for a sample cloud API request.

Authority Delegation for Host Records

Cloud API Requests	Standard API and WAPI Requests	Comments

• Authority delegation for a host record is inherited from both the DNS and DHCP portions of the record. For DNS, you can delegate authority for all DNS zones for which the host record is defined. For DHCP, you can delegate authority for the parent network view, network container, network, or DHCP range defined for the host record.
• You can create, modify, or delete a host record or a host IP address whose authority is delegated to a Cloud Platform Appliance through Grid Manager. Note that when you create a host record, you must enable it for DNS within the delegated network view. Otherwise, you will not be able to save the host record.
• The Cloud Platform Appliance can process a cloud API request that includes a host record only if it has gained authority for both DNS and DHCP portions of the host record, as follows:
  • All IP addresses enabled for DHCP within one or more delegation scopes are delegated to the same Cloud Platform Appliance.
  • All DNS records defined for one or more DNS zones have the same Cloud Platform Appliance assigned as the Grid primary.
	• IP addresses defined in the host record that is enabled DHCP follow the same rules for a fixed address. See *IPv4and IPv6 Fixed Addresses* for more information.
	• Names or aliases defined in the host record follow the same rules set for resource records. See *DNS Resource Records* for more information.
		• When you create a host record through a cloud API request, you must include the following extensible attributes in the request: Tenant ID, Cloud API Owned, and CMP Type.

• IP addresses defined in the host record that is enabled for DHCP follow the same rules set for a fixed address. See *IPv4and IPv6 Fixed Addresses* for more information. • Names or aliases defined in the host record follow the same rules set for resource records. See *DNS Resource Records* for more information. • Although no DHCP service restart is required, you can perform a DHCP service restart on a Cloud Platform Appliance through a cloud API request.		

Configuring Grid and Member Cloud API Properties

Only admin users in admin groups with cloud API access can be used to send cloud API queries by default. For information about how to add users to an admin group, see *Creating Local Admins*. To control which admin users,

either from this group or from remote servers, can perform cloud API tasks, you can further define ACLs at the Grid and member levels.

1. **Grid**: From the **Cloud** tab, click **Grid Cloud API Properties** from the Toolbar. Configuration done for the Grid only applies to the current Grid Master; it is not inherited by other Cloud Platform Appliances.
   Member: From the **Cloud** tab, select the **Members** tab -> *member* checkbox, and then click the Action icon

   and select **Edit** from the menu. Configuration done at the member level applies only to the Grid member.
2. In the *Grid Cloud API Properties* (for the current Grid Master) or the *Member Cloud API Properties* editor, select the **General** tab, and then complete the following:
   Administrator allowed to make WAPI request on the Grid Master
   - **None**: When you select this, none of the admin users in admin groups with cloud API access can send cloud API requests to the Grid Master or Cloud Platform Appliance.
   - All: When you select this, all admin users in admin groups with cloud API access can send cloud API requests to the Grid Master or cloud Platform Appliance. This is the default.
   - Set of administrators: Select this to create a list of admin users, both remote and local, who can send cloud API requests. Local users are users defined in admin groups with cloud API access. Remote users are users who log in from other remote servers. These users will be authenticated before they can access the Grid Master or Cloud Platform Appliance.
     To add local users, click the Add icon and select **Local**. In the *Cloud API Admin Selector*, select an admin user from the list. Grid Manager adds the selected user to the table. If you have only one cloud API user, Grid Manager automatically adds this user to the table.
     To add remote users, click the Add icon and select **Remote**. Grid Manager adds a row to the table. Click the **Admin** column to add the username of the administrator. Note that the username you enter here must match the username used on the remote server. Depending on the remote server type, you must create a server group for these remote users and add the group to the admin authentication policy to ensure these admin users can send cloud API requests. For information about how to configure admin server groups and admin authentication policy, see *About Remote Admins*.
     Click the Add icon again to add additional admin users.
     Recycle cloud objects: This only applies to the Grid Master. Select this checkbox to enable the recycling of cloud objects. This is selected by default.
3. Save the configuration.

Extensible Attributes for Cloud Objects

When you first enable Cloud Network Automation, NIOS installs a set of extensible attributes that are specific for cloud usage. Use these cloud extensible attributes to tag objects that belong to the CMP. Note the following when defining cloud extensible attributes through Grid Manager:

- You cannot assign cloud extensible attributes to other NIOS objects, yet you can create smart folders using these cloud attributes or modify their definitions.
- You can define and update cloud extensible attributes on Grid Master, through cloud API requests or Grid Manager, as long as the authority for the corresponding cloud objects are not delegated.
- Existing extensible attributes are automatically enrolled for cloud usage when cloud licensed are installed.
- All cloud extensible attributes are displayed in the **Administration** tab -> **Extensible Attributes** tab in Grid Manager.

To identify a cloud object, you must reference some of these cloud attributes when you create, modify, or delete a specific object. For more information about which extensible attributes are required for cloud API requests, see *Supported Cloud API Objects*.
The following table lists the default cloud extensible attributes come installed on the appliance. Note that some of the attributes are read-only and you cannot modify their properties. These attributes are applicable for specific object types or for identification purposes. See **Comments** for more information about each attribute.

Extensible Attributes for Cloud Usage

Attribute Name	Attribute Type	Comments
Account	String	The CMP user account for creating networks.

Attribute Name	Attribute Type	Comments
Allocation ID	String	The allocation ID of the Elastic IP. Limited to Elastic IP only. Example: eipalloc-5723d13e.
Application Type	String	Indicates the application type, such as Web, DB, or CRM.
Association ID	String	Association ID specific to Elastic IP only.
Attachment ID	String	The attachment ID of the network interface. This is valid for Elastic IP only and present when Network Interface is attached to an instance. Example: eni-attach-d94b09b0.
Availability Zone	String	
Cloud API Owned	List [True, False]	This is read-only. Defines whether an object was created by the cloud adapter.
Cloud Region	String	A region name for an VPC object. Example: us-west-1.
CMP Type	String	This is read-only. Defines the type of CMP, such as VMware or OpenStack.
Host Aggregates	String	
Interface Name	String	The name of the interface.
Is External	List [True, False]	This is read-only. Limited to the object type Network and Network Container.
Is Primary Interface	List [True, False]	This is read-only.
Is Shared	List [True, False]	This is read-only. Limited to the object type Network and Network Container.
IP Type	List [Private, Public, Fixed, Floating, Elastic]	This is read-only. Type of IP address.
Location	String	
Network Encap	String	
Network ID	String	Network ID in OpenStack
Network Name	String	Network name
Physical Network Name	String	
Port Attached Device - Device ID	String	Device ID for associated device, such as OpenStack or equivalent, in other CMPs.

Attribute Name	Attribute Type	Comments
Port Attached Device - Device Owner	String	Device name for associated device, such as OpenStack or equivalent, in other CMPs (e.g. compute:nova, network:dhcp, or netowrk:router_interface).
Port Group	String	VMware or equivalent in other Hypervisors or CMPs.
Port ID	String	Port ID for associated device, such as OpenStack or equivalent, in other CMPs.
Port Name	String	Port name for associated device, such as OpenStack or equivalent, in other CMPs.
Private IP	String	One or more secondary private IP addresses that are assigned to the given Network Interface.
Segmentation ID	String	
Subnet ID	String	
Subnet Name	String	
Tenant ID	String	This is read-only. The unique ID for the tenant object.
vDC	String	
VLAN ID	Integer	The VLAN ID.
VM ID	String	This is read-only. This is the Instance ID in OpenStack.
VM Name	String	Instance Name in OpenStack.
vCD App	String	The application name defined in vCloud Director; previously vApp
vCD Org	String	The organization name defined in vCloud Director; previously vOrg.
VPC ID	String	This is read-only. This is a naming convention that is used at the time of creation. Example: vpc-1a2b3c4d.
VPC Name	String	An optional name tag for the VPC.
VPCs List	String	List of all the VPCs.

You can modify some of the properties for the cloud extensible attributes, except for the read-only attributes. By default, all cloud extensible attributes are configured to allow Read/Write access for the Cloud Platform Appliances. You can change this configuration to read-only so the Cloud Platform Appliances can only access the attribute values, but not modify them. Note that when you reference modification for a read-only attribute in a cloud API request, the Cloud Platform Appliance returns an error because it cannot modify the attribute value. For information about how to configure extensible attributes, see *About Extensible Attributes*.

> **Note**
>
> An upgrade could fail if the name of an existing extensible attribute matches the name of any of the cloud extensible attribute for a different object type. You must define values for all required cloud extensible attributes in a cloud API request.

Extensible Attributes for Tags in AWS and Azure

You can define metadata in the form of tags for AWS and Azure which are captured through a vDiscovery process and you can save the tags as extensible attributes in NIOS. You can use predefined attributes or create your own tags that consists of an user-defined key and an optional value. The tag values defined in AWS and Azure are translated into corresponding extensible attribute values in NIOS.

Note the following about saving tags defined in AWS and Azure as extensible attributes in NIOS:

- You must add extensible attributes in NIOS with the same name as the tags added in AWS or Azure.
- You can add or delete tags in Azure, but cannot update the tags.
- The tags are translated only when the corresponding extensible attributes are created in NIOS.
- The tags are discovered only during the next vDiscovery process after creating the corresponding extensible attributes in NIOS.
- It is not recommended to delete the extensible attributes which you have created for the tags defined in AWS and Azure.

The following table shows the translation of tags defined in AWS and Azure, as extensible attributes in NIOS:

Tag Translation

AWS Object	Azure Object	NIOS Object
EC-2 Instance	Virtual Machine	VM
Interface	Virtual Interface	Managed private IP address: Any DNS record, fixed address, or reservation associated with that IP address.
Interface (tags are the same for private IP address and public IP address of the same interface)	Public IP address (Public IP address has specific tags in Azure)	Managed public IP address: Any DNS record, fixed address, or reservation associated with the IP address.
VPC	Virtual Network	VPC
Subnet	Subnet (no tags for subnet in Azure)	Network

> **Note**
>
> NIOS generates alert messages about tags that are translated and tags that are skipped due to missed extensible attributes or incorrect extensible attributes types will be displayed in the syslog and infoblox.log file.

Viewing Cloud Objects

When you enable the Cloud Network Automation license on the Grid Master, NIOS adds the ability to view new cloud objects such as Tenants and VM IP addresses. You can view cloud objects and their related information in the **Cloud** tab of Grid Manager. The **Cloud** tab provides the following sub tabs for viewing different information related to cloud objects: **Tenants**, **VPCs**, **Networks**, **VMs (by IP Address)**, and **Cloud Platform Members**.
In addition to viewing data in these tabs, you can do the following:

1. Click the Action icon

   and select an action from the menu.
   - Select **Show Active Users** to view all the users who are currently active on the Active Directory domain. For information, see *Viewing Active Network Users*.
2. Modify some of the data in the table. Double click a row, and either modify the data in the field or select an item from a drop-down list. Click **Save** to save the changes. Note that some fields are read-only.
3. Edit the properties of an object.
   - Select the object, and then click the Edit icon.
4. Export the list of objects to a .csv file.
   - Click the Export icon.
5. Print the list of objects.
   - Click the Print icon.
6. Use filters and the **Goto** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Goto** field and select the object from the possible matches.
7. Create a quick filter to save frequently used filter criteria:
   - In the filter section, click Show Filter and define filter criteria for the quick filter.
   - Click **Save** and complete the configuration In the *SaveQuickFilter* dialog box.

The appliance adds the quick filter to the quick filter drop-down list in the panel. Note that global filters are prefixed with [G], local filters with [L], and system filters with [S].

Viewing All Tenants

The **Tenants** tab lists all tenants from the CMP. Tenant is an abstract administrative concept. Similar to a tenant in the CMP, a tenant object in NIOS encompasses all network elements such as networks, zones, VMs, and IP addresses (fixed and floating), network views, default DNS view, and all related extensible attributes associated with that tenant. Multiple tenants can be mapped to the same network view. A tenant can also have VMs (with IP addresses) in its shared or external networks that are in different network views.
In Grid Manager, you can click a tenant name in the **Cloud** tab -> **Tenants** tab and drill down to the **Networks** and **VMs (by IP Address)** sub tabs to view networks and VMs associated with the selected tenant. In the **Tenants** tab -> **VMs** tab, you can click a VM name and drill down more to view the **Networks** and **IP Addresses** sub tabs for the selected VM. You can always click the bread crumb at the top of the viewer to go back to the **Tenants** home tab.
Each tenant has a name and a unique tenant ID. The tenant ID is provided through cloud API requests. You cannot create or delete tenant objects through Grid Manager. All tenants are created and deleted through cloud API requests. However, you can modify the name, extensible attributes, and permissions for a specified tenant through the *Tenant* editor in Grid Manager if you have valid tenant permissions: **All Tenants** or per tenant object. Note that you cannot delegate the authority of any given tenants.
To view all tenant objects:

1. From the **Cloud** tab, click the **Tenants** tab.
2. Grid Manager displays the following information for each tenant:

- **Actions**: Click the action icon

  (shown as a gear in each row) next to a selected tenant and choose from the following:
  - **Edit**: Modify certain general properties.
  - **Extensible Attributes**: Add or modify extensible attributes.
  - **Permissions**: Modify the administrative permissions.
- **Mgmt Platform**: Displays the CMP that manages this tenant. When it displays **Amazon**, it indicates a successful validation of the Amazon account from NIOS to AWS.

- **Name**: The tenant name.
- **ID**: The unique tenant ID.
- **VMs**: The total number of VM objects associated with this tenant. This can include the following object types: Host Record, Fixed Address, and any resource record type such as A, AAAA, PTR, and CNAME records. It also includes unmanaged IP addresses that are associated with the tenant.
- **Networks**: The total number of IPv4 and IPv6 networks and network containers associated with this tenant. Note that this number includes only networks and network containers created by the cloud adapter.
- **Created**: The timestamp when the tenant was first created. You cannot modify this field. This timestamp reflects the time when the tenant object was first seen by the Grid Master, so it may not match the timestamp when the original cloud API request was sent.
- **Last Updated**: The timestamp when the last event associated with this tenant happened. You cannot modify this field. This timestamp reflects the time when the last event associated with this tenant was processed by the Cloud Platform Appliance, so it may not match the timestamp when the original cloud API request was sent.
- **Comment**: Information about this tenant.
- **Network Views**: The network view to which this tenant belongs.
- **Managed**: Indicated whether this tenant is a managed or an unmanaged object in NIOS.
- **Site**: The value entered for this predefined extensible attribute.

You can also select other cloud extensible attributes for display by clicking the down arrow next to any column header and selecting **Columns** -> **Edit Columns**.

> ⚠ Note
>
> The vDiscovery for the OpenStack management platform discovers all tenants if the OpenStack user has the admin role in at least one tenant.

Viewing All VPCs (Virtual Private Clouds)

The **VPCs** tab displays all AWS VPCs . You can also manage selected VPCs, primarily for changing permissions, defining or changing extensible attributes, and changing the delegation settings for a VPC to a different NIOS Cloud member. An Amazon VPC is analogous to a network container in NIOS, and is hence represented as a network container with a special icon.
To view all VPCs:

1. From the **Cloud** tab, click the **VPCs** tab.
2. Grid Manager displays the following information for each VPC:
    - **Actions**: Click the action icon

      (shown as a gear in each row) next to a selected tenant and choose from the following:
        - **Edit**: Modify certain general properties.
        - **Extensible Attributes**: Add or modify extensible attributes.
        - **Permissions**: Modify the administrative permissions.
    - **Mgmt Platform**: Displays the CMP that manages the VPC. When it displays **Amazon**, it indicates a successful validation of the Amazon account from NIOS to AWS.
    - **VPC Name**: The AWS virtual private cloud name. The name is automatically defined by AWS. Each VPC name is a link that opens the Networks tab for the selected VPC. This page lists the individual private networks that exist within the VPC.
    - **Networks**: The number of individual private networks contained in the VPC.
    - **VMs**: The number of Amazon EC2 virtual machine instances currently discovered in the VPC. (You can run a vDiscovery in any VPC.) For information about how to start a vDiscovery, see *Configuring vDiscovery Jobs.*
    - **Tenants**: The number of cloud tenants associated with each VPC.
    - **Cloud Usage**: indicates whether the VPC is associated with any specific cloud extensible attributes or within a scope of delegation. It can be one of the following:
        - **Cloud from adapter**: Indicates that this object has been created by a cloud adapter and it may or may not be within a scope of delegation at the moment.

        - **Cloud from delegation**: Indicates that this object is within the scope of delegation or the object itself defines a scope of authority delegation, and it is not created by a cloud adapter.
        - **Used by cloud**: Indicates that this network or network container is associated with the extensible attribute Is External or Is Shared and the value is set to True, which implies the network is a private or shared network managed by the CMP, and it is not **Cloud from adapter** or **Cloud from delegation**.
        - **Non-cloud**: The object is a regular NIOS object and is not within the scope of any authority delegation nor is it associated with any of these extensible attributes: **Cloud API Owned**, **Is External** or **Is Shared**. NIOS admin users can modify this object based on their permissions.
    - **Owned By**: A cloud object can be owned by the Grid Master or the cloud adapter. When the object is created by the Grid Master, this shows Grid. If the object is created by the cloud adapter, this shows Cloud Adapter.
    - **Delegated to**: The NIOS Cloud appliance to which management of the AWS VPC is delegated. This field tells you whether or not a cloud object (in this case, a virtual private cloud) has been delegated to a Cloud Platform Appliance.
    - **Network**: The network IP. The network listed in this column for the VPC is also viewable from the main **Data Management** –> **IPAM** tab.
    - **Site**: Extensible Attribute listing the site information for the VPC.
    - **Availability Zone**: the Amazon availability zone in which the VPC resides.

You can also select other cloud extensible attributes for display by clicking the down arrow next to any column header and selecting **Columns** -> **Edit Columns**.

Viewing All Cloud Networks

The **Networks** tab displays all IPv4 and IPv6 networks and network containers from the CMP as well as all delegated networks. You can select a specific network or network container and modify its properties in the *Cloud IPv4 Network* or *Cloud IPv6 Network* editor.
To view all cloud networks and network containers:

1. From the **Cloud** tab, click the **Networks** tab.
2. Grid Manager displays the following information for each network and network container:
    - **Actions**: Click the action icon

      (shown as a gear in each row) next to a selected tenant and choose from the following:
        - **Go to Tenant**: Go to the **Tenant** tab to view associated tenant.
        - **Go To DHCP Network Details**: Go to the **DHCP** -> **Networks** tab to view associated details.
        - **Go To IPAM Network Details**: Go to the **IPAM** -> **Networks** tab to view associated details.
        - **Go To Network View Details**: Go to the **IPAM** -> **Network View** tab to view associated details.
        - **Edit**: Modify certain general properties.
        - **Extensible Attributes**: Add or modify extensible attributes.
        - **Permissions**: Modify the administrative permissions.
    - **Mgmt Platform**: Displays the CMP that manages the network. When it displays Amazon, it indicates a successful validation of the Amazon account from NIOS to AWS.
    - **Network**: The IP address and netmask of the network.
    - **Tenant**: The associated tenant for the network.
    - **VPC Name**: The name of the associated VPC in AWS.
    - **Cloud Usage**: This field indicates whether this object is associated with any specific cloud extensible attributes or within a scope of delegation. It can be one of the following:
        - **Cloud from adapter**: Indicates that this object has been created by a cloud adapter and it may or may not be within a scope of delegation at the moment.
        - **Cloud from delegation**: Indicates that this object is within the scope of delegation or the object itself defines a scope of authority delegation, and it is not created by a cloud adapter.
        - **Used by cloud**: Indicates that this network or network container is associated with the extensible attribute **Is External** or **Is Shared** and the value is set to True, which implies the network is a private or shared network managed by the CMP, and it is not **Cloud from adapter** or **Cloud from delegation**.

        - **Non-cloud**: The object is a regular NIOS object and is not within the scope of any authority delegation nor is it associated with any of these extensible attributes: **Cloud API Owned, Is External** or **Is Shared**. NIOS admin users can modify this object based on their permissions.
    - **Owned By**: A cloud object can be owned by the Grid Master or the cloud adapter. When the object is created by the Grid Master, this shows **Grid**. If the object is created by the cloud adapter, this shows **Adapter**.
    - **Delegated To**: This tells you whether a cloud object has been delegated to a Cloud Platform Appliance or not. If the cloud object has a parent object and the parent has been delegated, this field shows the parent delegation and you cannot modify the field.
- **Network View**: The network view to which this network belongs.
- **Active Users**: Displays the number of active users on the selected network.
- **Site**: The value entered for this predefined extensible attribute.

You can also select other cloud extensible attributes for display by clicking the down arrow next to any column header and selecting **Columns** -> **Edit Columns**.

Viewing All Cloud VMs

The **VMs** tab lists all cloud VMs by IP addresses. A VM object is an abstract object representing a virtual machine that is running on the CMP. A VM belongs to one and only one tenant. However, the same VM may have more than one IP addresses (including unmanaged IP addresses) associated with it. Each VM may have an IP address that is part of an overlapping private IP address space and one or more IP addresses in the shared or external networks.
A VM object in NIOS can be a collection of supported object types that have the same value for the extensible attribute **VM ID**. Only the following NIOS object types are considered as existing VMs when they are tagged with the **VM ID** attribute: Host Record, A Record, AAAA Record, and PTR Record, and Fixed Address. A VM object may be defined by objects from different network views, and it can have more than one IP addresses associated with it.

Note: Since a VM can be defined by objects from different network views, the same IP address may appear multiple times if it has been defined in more than one network view. A VM object is a read-only abstract object, therefore you cannot create, modify, or delete it.

After a vDiscovery job is completed, the appliance displays discovered data for each VM in this tab. Available data is displayed based on the vDiscovery configuration and your CMP. For example, if your CMP is AWS, discovered data can include the VPC to which the VM belongs. You can click a VM name and drill down to the **Networks** and **IP Addresses** sub tabs to view networks and IP addresses associated with the selected VM. For more information about vDiscovery, see *Configuring vDiscovery Jobs*.
Note that in addition to managing discovered data through Grid Manager, you can clear any managed or unmanaged discovered data, or clear all discovery data related to a vDiscovery job through a cloud API request. You can use this feature to properly identify VMs that you spin up or de-provision through a cloud adapter. For example, when you use Infoblox IPAM Plug-In for VMware as the cloud adapter to de-provision a VM, you can send a cloud API call to remove the discovered data for this VM so you can avoid IP address conflict with IP addresses manually allocated by the VMware vCenter. For information about cloud API requests, see *About Cloud API Requests*.
In the **VMs** tab, discovered VMs are highlighted in different background colors, as follows:

- **Yellow**: Unmanaged VMs that do not have associated NIOS objects.
- **White**: Discovered VMs that have at least one associated NIOS object and there is no conflicting information between the discovered data and the NIOS data.
- **Red**: Discovered VMs that have at least one associated NIOS object and there is conflicting information between the discovered data and the NIOS data. Depending on the nature of the conflict, you can resolve them as described in *Resolving Conflicting Addresses*. You may also be able to convert or clear unmanaged data, as described in *Managing Unmanaged Data*.

To view all VM objects in NIOS:

1. From the **Cloud** tab, click the **VMs** tab.
2. Grid Manager displays the following information for all cloud VM by IP address:
    - **Actions**: Click the action icon

      (shown as a gear in each row) next to a selected tenant and select the action you want to perform.

- **Mgmt Platform**: Displays the CMP to which this tenant belongs. This can be Amazon, OpenStack, or VMware.
- **VM Name**: The name of the VM.
- **VM ID**: The unique tenant ID to which this VM belongs.
- **Networks**: The number of networks that belong to this VM.
- **IP Address**: The IP address of the VM.
- **VM VPC**: The VPC to which this VM belongs.
- **VM Tenant**: The tenant to which this VM belongs.
- **Port ID**: The port ID for the VM.
- **Network View**: The network view to which this VM belongs.
- **Active Users**: The number of active users on the selected network.
- **FQDN**: The FQDN of the VM.
- **VM Last Updated**: The timestamp when the VM data was last updated.
- **First Discovered**: The timestamp when the VM was first discovered.
- **Last Discovered**: The timestamp when the VM was last discovered.
- **Task Name**: The name of the task that collected the discovered data. It is usually the ID or task name that collected the discovered data.
- **Comment**: Information about the VM.

Depending on you CMP, you can also select additional discovered fields to be displayed in the **VMs** tab by clicking the down arrow next to any column header and selecting **Columns** -> **Edit Columns**. Note that some of these fields contain discovered data that is only relevant to your CMP.

Viewing All Cloud Platform Members

The **Members** tab displays all members that are currently running the cloud API service. To view all cloud members in NIOS:

1. From the **Cloud** tab, click the **Members** tab.
2. Grid Manager displays the following information for each member:
    - **Actions**: Click the action icon

      (shown as a gear in each row) next to a selected tenant and select the action you want to perform.
    - **Name**: The member name.
    - **Status**: The current status of this member.
    - **Comment**: Information about this cloud member.
    - **Site**: The value entered for this predefined extensible attribute.

Select other cloud extensible attributes for display by clicking the down arrow next to any column header and selecting **Columns** -> **Edit Columns**.

Managing Appliance Operations

Managing the operations of a NIOS appliance involves defining system parameters such as time, security, and port settings. It also includes configuring operations such as scheduling tasks, defining approval workflows, managing licenses, managing extensible attributes, and configuring access control for supported operations.

The tasks covered in this section include:

- *Managing Security Operations*
- *Configuring Proxy Servers*
- *Configuring Ethernet Ports*
- *Using the LAN2 Port*
- *Using the MGMT Port*
- *About Lights Out Management*
- *Setting Static Routes*
- *Enabling DNS Resolution*
- *Managing Licenses*
- *About IB-FLEX*
- *Configuring DNS Cache Acceleration*
- *About Elastic Scaling*
- *Managing the Order of Match Lists*
- *Managing NIOS Appliances*
- *Managing the Disk Subsystem on the Infoblox-4010*
- *Restarting Services*
- *Configuring the Orphan Mode*

Configuring Access Control

To effectively manage your core network services, you can grant legitimate hosts access to specific tasks and operations using an access control list (ACL) or anonymous access control entries (ACEs). Depending on your admin permissions, you can configure a named ACL, and then apply it to multiple operations, such as file distribution and DNS zone transfers. For information about admin permissions, see *About Administrative Permissions*.

When you define a named ACL, you add access control types such as IPv4 and IPv6 addresses, IPv4 and IPv6 networks, nested named ACLs, and TSIG key based ACEs to a list, and then grant each entry in the list the Allow or Deny permission. For information about named ACLs and how to configure them, see *Defining Named ACLs*. Note that each operation supports specific access control types. You cannot apply a named ACL to an operation that does not support the access control types contained in the named ACL. For more information about which NIOS operations support access control and which access control types each operation supports, see *Operations that Support Access Control*.

When you add or modify a named ACL, or when you import named ACLs and ACEs to an existing named ACL through CSV import, the appliance does not automatically validate the ACEs in the list. For more information about how to import named ACLs and ACEs, refer to the *Infoblox CSV Import Reference*. To avoid conflicts and unexpected results, you must perform validations for all named ACLs before you use them for access control. When the appliance detects a conflict or an optimized issue about a specific ACE during the validation process, it displays detailed information in a CSV file. For more information about ACL validation, see *Validating Named ACLs*.

Administrative Permissions

You can configure a named ACL at the Grid level and override it at the member and object level. Superusers and limited-access users with Read/Write permission to **All Named ACLs** can create, modify, and delete named ACLs. Users with Read-only permission to **All Named ACLs** can apply a named ACL to a supported object if they have Read/Write permission to the respective object. Other users can only view named ACLs and their entries. For information about admin permissions, see *About Administrative Permissions.*

Operations that Support Access Control

On the appliance, only certain operations support access control. You can apply one named ACL or multiple anonymous ACEs to each operation. However, you cannot apply multiple named ACLs or use a combination of named ACLs and

ACEs. Note that each operation supports different access control types. For example, DNS zone transfers support IPv4 and IPv6 addresses and networks as well as TSIG key based ACEs, while AAAA filtering supports only IPv4 addresses and networks.
When you apply a named ACL to an operation, the appliance validates to ensure that the named ACL contains ACEs that are supported by the operation. The appliance also validates any new ACEs that you add to an existing named ACL. If a named ACL contains access control types that an operation does not support, the appliance displays an error message and you cannot apply that named ACL to the operation. Thus when defining a named ACL for a specific operation or applying an existing named ACL, ensure that it contains access control types that the operation supports. The below table lists access control types for NIOS operations that support access control.

Operations that Support Access Control

Operation Type	**Supported Access Control Types**				
	IPv4 Addresses and Networks	**IPv6 Addresses and Networks**	**TSIG Key Based ACEs**	**DNSone 2.x TSIG Key**	**Any Address and Network**
GUI and API Access	Yes	Yes	No	No	No
NTP Service and NTP Queries	Yes	Yes	No	No	Yes
File Distribution Services	Yes	No	No	No	No
Syslog Proxy Access Control	Yes	Yes	No	No	No
DNS Zone Transfers (excludes zone transfers for Microsoft servers)*	Yes	Yes	Yes	Yes	Yes
Dynamic DNS Updates	Yes	Yes	Yes	No	Yes
DNS Queries	Yes	Yes	Yes	No	Yes
Recursive Queries	Yes	Yes	Yes	No	Yes
Blackhole Lists	Yes	Yes	No	No	Yes
AAAA Filtering	Yes	No	No	No	Yes
Forward DNS Updates	Yes	Yes	Yes	No	Yes
Match Clients for DNS Views	Yes	Yes	Yes	Yes	Yes
Match Destinations for DNS Views	Yes	Yes	Yes	Yes	Yes
DNS64 Clients	Yes	Yes	No	No	Yes

Operation Type	Supported Access Control Types				
	IPv4 Addresses and Networks	IPv6 Addresses and Networks	TSIG Key Based ACEs	DNSone 2.x TSIG Key	Any Address and Network
DNS64 Mapped	Yes	No	No	No	Yes
DNS64 Exclude IPv6	No	Yes	No	No	Yes

Note

* Zone transfers for Microsoft servers do not support named ACLs. However, you can still use individual ACEs to configure access control. For more information about how to configure zone transfer settings for Microsoft servers, see *Setting Zone Properties.* In addition, the DNSone 2.x TSIG key supports only the "Allow" permission. You cannot change "Allow" to "Deny."

Complete the following tasks to use a named ACL:

1. Define a named ACL, as described in *Defining Named ACLs.*
2. Validate the named ACL, as described in *Validating Named ACLs.*
3. Apply the named ACL to specific operations, as described in *Applying Access Control to Operations*.

Applying Access Control to Operations

When you apply access control to NIOS operations, you can use anonymous ACEs or a named ACL. You cannot combine ACEs and named ACLs for access control. Depending on the access control types each operation supports, you may or may not be able to apply a named ACL to a specific operation. For information about which access control types each operation supports in *Operations that Support Access Control* table, see *Operations that Support Access Control*.

Note

If you disable access control or select **None** or **Any** for an operation, the appliance removes the previously applied named ACL or the configured anonymous ACEs. To avoid losing your ACE configuration, Infoblox recommends that you convert the ACEs to a named ACL.

For information about how to apply access control to each supported operation, see the following:

- DNS zone transfers, as described in *Enabling Zone Transfers*.
- DNS queries, as described in *Controlling DNS Queries.*
- Recursive queries, as described in *Enabling Recursive Queries.*
- Dynamic DNS updates, as described in *Configuring DNS Servers for DDNS.*
- AAAA filtering, as described in *Controlling AAAA Records for IPv4 Clients.*
- Blackhole list, as described in *Configuring a DNS Blackhole List.*
- Match clients list for DNS views, as described in *Defining Match Clients Lists.*
- Match destinations for DNS views, as described in *Defining a Match Destinations List.*
- DNS64 clients, DNS64 mapped IPv4 addresses, and DNS64 excluded IPv6 addresses, as described in *Setting DNS64 Group Properties.*
- File distribution services, as described in *Configuring Access Control for File Distribution.*

- Grid Manager and API access, as described in *Configuring Security Features.*
- NTP access control, as described in *Defining NTP Access Control.*
- Syslog proxy access, as described in *Configuring Syslog for Grid Members.*

Defining Named ACLs

Depending on how you plan to use a named ACL and which access control types an operation supports, you can add one or all of the following when you define a named ACL: IPv4 and IPv6 addresses, IPv4 and IPv6 networks, TSIG key based ACEs, DNSone 2.x TSIG keys. You can also add an existing named ACL as a nested ACL to a new or existing named ACL.

When configuring a named ACL, ensure that you define it correctly for the intended operations using the supported access control types. For example, if you want to apply a named ACL to AAAA filtering, do not include IPv6 addresses or networks in the named ACL because AAAA filtering does not support IPv6 addresses and networks. For information about which access control types in *Operations that Support Access Control* table, see *Operations that Support Access Control.*

To define a named ACL:

1. From the **Administration** tab, select the **Named ACLs** tab, and then click the Add icon.
2. In the *Add Named ACL* wizard, complete the following:
    - **Name**: Enter a name for the named ACL. You can enter up to 64 characters.
    - **Comment**: Enter additional information about the named ACL.
3. Click **Next**. Complete the following to add ACEs to the named ACL:
    - Click the Add icon and select one of the following access control types from the drop-down list. Depending on your selection, Grid Manager adds a row to the table directly or expands the panel before adding a row.
        - **IPv4 Address**: Select this to add an IPv4 address. Click the **Entry** field and enter the IPv4 address. The **Operation** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
        - **IPv4 Network**: When you select this, enter the network address in the **Address** field, select the netmask using the slider, and then select **Allow** or **Deny** from the **Permission** drop-down list. Click **Add** and Grid Manager adds the entry to the table.
        - **IPv6 Address**: Select this to add an IPv6 address. Click the **Entry** field and enter the IPv6 address. The **Operation** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
        - **IPv6 Network**: When you select this, enter the network address and its netmask in the **Address** field, and then select **Allow** or **Deny** from the **Permission** drop-down list. Click **Add** and Grid Manager adds the entry to the table.
        - **TSIGKey**: In the **AddTSIGKey** panel, complete the following, and then click **Add** to add the TSIG key to the list:
            - **Key name**: Enter a meaningful name for the key, such as a zone name or the name of the remote name server. This name must match the name of the same TSIG key on other name servers.
              Note that the **Key name** must be a valid domain name without any space and it cannot begin with DHCP_UPDATER.
            - **Key Algorithm**: Select either **HMAC-MD5** or **HMAC-SHA256**.
            - **Key Data**: To use an existing TSIG key, type or paste the key in the **Key Data** field. Alternatively, you can select the key algorithm, select the key length from the **Generate Key Data** drop down list, and then click **Generate Key Data** to create a new key.
        - **DNSone 2.x TSIG Key**: Select this when the client is a NIOS appliance running DNS One 2.x code. The appliance automatically populates the value of the key in the **Entry** field. The **Operation** column displays **Allow** by default. You cannot change the default permission.
        - **Any Address/Network**: Select this to allow or deny permission for any addresses and networks.
        - **Named ACL**: When you select this, Grid Manager displays the *Named ACLs* Selector. Select the named ACLs you want to add to the new ACL. If you have only one existing named ACL, Grid Manager automatically adds the named ACL to the list. The selected named ACL becomes a nested ACL in the newly created named ACL.

Note: The **Order** field in the table displays the position of each entry based on the order it is placed in the list. You can modify this number to change the order of an ACE. You can also select the ACE checkbox and use the up and down arrows next to the table to place the entry in the desired position.

4. Click **Next** to enter extensible attributes for the named ACL. For information, see *About Extensible Attributes.*
5. Save the configuration.

Managing Named ACLs

You can do the following after you have configured named ACLs for access control:

- Preview the list of ACEs in a named ACL, as described in Previewing ACEs in Named ACLs below.
- Validate ACEs in a named ACL, as described in Validating Named ACLs below.
- View a complete list of configured named ACLs, as described in Viewing Named ACLs below.
- Modify information in a named ACL, as described in Modifying Named ACLs below.
- Apply a named ACL to supported operations, as described in *Applying Access Control to Operations*.
- Delete a named ACL, as described in Deleting Named ACLs below.
- Export and print the list of named ACLs.

Previewing ACEs in Named ACLs

You can preview the list of ACEs in a named ACL when you add or modify it. When you click the Preview icon in the *Add Named ACL* wizard or *Named ACL* editor, the appliance lists all the entries in the named ACL, even if you have selected only one or a few entries in the wizard or editor.
To preview a named ACL:

1. From the **Administration** tab, select the **Named ACLs** tab -> *named_acl* checkbox, and then click the Preview icon.
2. In a separate browser window, Grid Manager displays the following information for each ACE in the named ACL:
   - **Entry**: Displays one of the following: IPv4 or IPv6 address, IPv4 or IPv6 network, or TSIG key. Note that if the named ACL contains nested ACLs, all entries in the nested ACLs are displayed in a flat view. Grid Manager does not display the name of the nested ACL.
   - **Type**: The access control type of the entry. This can be **IPv4 Address**, **IPv6 Address**, **IPv4 Network**, **IPv6 Network**, **TSIG Key**, or **DNSone 2.x TSIG Key**.
   - **Operation**: Displays the access permission for the entry. This can be **Allow** or **Deny**.

Validating Named ACLs

When you add or modify a named ACL, the appliance does not automatically validate the ACEs in the list. In addition, when you import named ACLs or ACEs to a named ACL, no automatic validation is performed. To avoid unintended consequences, ensure that you validate your named ACLs before you save them or use them for access control.

> ⚠ Note
>
> When you click the Validate icon in the *Add Named ACL* wizard or *Named ACL* editor, the appliance validates all the entries in the named ACL, even if you have selected only one or a few entries in the wizard or editor.

The following examples demonstrate the importance of validating named ACLs:
Example 1
You configure a named ACL "foo" that includes a Deny permission to 10.0.0.0/16. You then assign "foo" to DNS zone transfers. You later import an "Allow/10.0.0.0/24" entry to "foo" through CSV import. The appliance appends the entry to the end of "foo." When you perform an ACL validation on "foo" after a DNS service restart, the appliance displays a warning message indicating that the new "Allow/10.0.0.0/24" entry is now included in the previously configured "Deny/10.0.0.0/16" entry. Since DNS service works on a first-match access control basis, zone transfers will not be allowed for the 10.0.0.0/24 network, which is probably not your original intent. You can then modify the named ACL to correct this error. On the other hand, if you do not perform the ACL validation, the appliance is not notified about the new network entry in "foo." As a result, you are not notified about the denial of zone transfers to 10.0.0.0/24.

Example 2
You add a nested named ACL "bar" as the first entry to the named ACL "foo." You then add a "Deny All" entry right after "bar" (as the second entry). You later import a new "Allow All" entry to "bar" through CSV import. The "Allow All" entry will be appended to the end of "bar." When you perform an ACL validation on "foo" after the CSV import, the appliance detects a conflict between the "Allow All" (in "bar") and "Deny All" (right after "bar") permissions and displays a warning. Imagine if you do not perform the ACL validation on "foo," the appliance is not notified about the new "Allow All" entry in "bar" and therefore cannot detect the conflict between the "Allow All" and "Deny All" entries. As a result, almost all hosts will get zone transfers, which may not be the outcome you have intended.

Note

It is important that you manually validate each named ACL after a CSV import to ensure data and performance integrity. The appliance does not automatically perform ACL validation.

To validate a named ACL:

1. From the **Administration** tab, select the **Named ACLs** tab -> *named_acl* checkbox, and then click the Validate icon.
   or
   In the *Add Named ACL* wizard or *Named ACL* editor, click the Validate icon.
2. Grid Manager validates all the ACEs in the named ACL and displays a system message at the top of the screen indicating whether all ACEs in the named ACL are valid or not, depending on the validation results. When the appliance detects conflicts or issues related to specific ACEs, it displays the results in a CSV file. You can save the file or open it. Grid Manager displays the following information in the file:
   - **Defined ACL**: The name of the named ACL.
   - **Type of Issue**: The type of issue found. This can be one of the following:
     - **Optimize**: An ACE is a duplicate of a previous entry or an ACE configuration can be a subset of another entry. See optimized suggestions in the **Issue** field.
     - **Conflict**: The same IP address or network has a conflicting permission. Re-configure the ACE based on your requirements.
     - **Warning**: An ACE is a subset of a previously configured entry, but it has a conflicting permission.
   - **ACE A**: The ACE that has a conflict or an optimized issue with ACE B.
   - **ACE B**: The ACE that has a conflict or an optimized issue with ACE A.
   - **Issue**: Detailed information and optimized suggestions about the conflict or issue.

Note

It may take a long time to validate a named ACL that contains a large number of ACEs.

Viewing Named ACLs

To view a list of named ACLs:

- From the **Administration** tab, select the **Named ACLs** tab. Grid Manager displays the following information for each named ACL:
  - **Name**: The name of the named ACL.
  - **Comment**: Information about the named ACL.
  - **Site**: The site to which the named ACL belongs. This is one of the predefined extensible attributes.

You can also do the following in the **Named ACLs** tab:

- Modify data in the table. Double click a row, and either modify the data in the field or select an item from a drop-down list. Click **Save** to save the changes or **Cancel** to exit.
- Sort the named ACLs in ascending or descending order by column.
- Select a named ACL and click the Edit icon to modify data, or click the Delete icon to delete it.

- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the Go to field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters.*
- Print and export data in this tab.

Modifying Named ACLs

You can modify ACEs in an existing named ACL. When you update a named ACL, the appliance validates the updates to ensure that ACEs in the named ACL are valid for the operations to which the name ACL has been applied. For example, if a named ACL is used for file distribution access, you are not allowed to add IPv6 address access control to it because the file transfer operation does not support IPv6 addresses.
To modify a named ACL:

1. From the **Administration** tab, select the **Named ACLs** tab -> *named_acl* checkbox, and then click the Edit icon.
2. The *Named ACL* editor provides the following tabs from which you can modify data:
    - **Genera Basic**: You can modify data in this tab as described in *Defining Named ACLs.*
    - **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific named ACL. You can also modify the values of the extensible attributes. For information, see *About Extensible Attributes.*
    - **Permissions**: This tab appears only if you belong to a superuser admin group. For information about managing permissions, see *About Administrative Permissions*.

Deleting Named ACLs

When you delete a named ACL, the appliance puts it in the Recycle Bin, if enabled. You can restore the named ACL later if needed.

> ⚠ Note
>
> You cannot delete a named ACL that has been applied to an operation or is currently in use by another operation.

To delete a named ACL:

1. From the **Administration** tab, select the **Named ACLs** tab -> *named_acl* checkbox, and then click the Delete icon. You can select multiple named ACLs for deletion.
2. In the *Delete Confirmation* dialog box, click **Yes**.

Managing Time Settings

You can define the date and time settings for your NIOS appliance using the Infoblox Appliance Startup Wizard. Alternatively, you can set the date and time of the appliance anytime after you first configure it if you did not do so using the startup wizard or if you need to change it if, for example, you move an appliance from a location in one time zone to a location in a different time zone. To set the date and time of the appliance, you can either manually enter the values or configure the appliance to synchronize its time with a public NTP server.

Changing Time and Date Settings

If you do not use the NTP service, you can set the date and time for a Grid.

> ⚠ Note
>
> You cannot manually set the date and time if the NTP service is enabled.

To set the time and date for a Grid using the *Grid Properties* editor:

1. From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
2. In the **General** tab of the *Grid Properties* editor, complete the following:
    - **Date:** Click the calendar icon to select a date or enter the date in YYYY-MM-DD format.
    - **Time:** Click the clock icon to select a time or enter the time in HH:MM:SS format. For afternoon and evening hours, use the integers 13-24.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

> ⚠ Note
>
> Changing the date and time resets the application and terminates the management session.

Changing Time Zone Settings

Whether you enable NTP (Network Time Protocol) or manually configure the date and time, you must always set the time zone manually. You can set the time zone for a Grid, which then applies to all members. If different members are in different time zones, you can choose the time zone that applies to most members at the Grid level, and then override the setting for the remaining members.

> ⚠ Note
>
> Changing the time zone does not reset the application nor does it terminate the management session.

To set the time zone for a Grid or member:

1. **Grid:** From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the **General** tab of the editor, select the appropriate time zone.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Monitoring Time Services

In a Grid, the Grid Master and its members use an internal NTP daemon to synchronize their time. It is not user-configurable and functions regardless of how you set the time on the Grid Master. The *Detailed Status* panel contains an NTP Synchronization icon so you can monitor the internal NTP daemon that runs within a Grid to ensure the time among its members is synchronized.
To display the *Detailed Status* panel, from the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Detailed Status icon in the table toolbar of the *Members* panel. The following are descriptions of the NTP status icons in the *Detailed Status* panel:

Icon	Color	Meaning
■	Green	The NTP service is running properly.
■	Yellow	The appliance is synchronizing its time.
■	Red	The NTP service is not running properly. View the corresponding description for additional information.

Using NTP for Time Settings

NTP (Network Time Protocol) is a standard protocol that system clocks use to ensure their time is always accurate. Appliances that use NTP try to get their time as close as possible to UTC (Coordinated Universal Time), the standard timescale used worldwide. NTP uses UDP (User Datagram Protocol) on port 123 for communications between clients and servers.

NTP is based on a hierarchy where reference clocks are at the top. Reference clocks use different methods such as special receivers or satellite systems to synchronize their time to UTC. NTP servers on the first level of the hierarchy synchronize their time with the reference clocks, and serve time to clients as well. Each level in the hierarchy is a stratum; stratum-0 is a reference clock. Stratum-1 servers synchronize their clocks with reference clocks. Stratum-2 servers synchronize their clocks with stratum-1 servers, and so forth. The stratum number indicates the number of levels between the NTP server and the reference clock. A higher stratum number could indicate more variance between the NTP server and the reference clock.

You can configure a NIOS appliance to function as an NTP client that synchronizes its clock with an NTP server. For more information, see NIOS Appliances as NTP Clients below. NTP clients typically use time information from at least three different sources to ensure reliability and a high degree of accuracy. There are a number of public NTP servers on the Internet with which the NIOS appliance can synchronize its clock. For a list of these servers, you can access *http://www.ntp.org* . When NTP is configured, it listens on all interfaces, including the loopback interface on the NIOS appliance.

In a Grid, the Grid Master and Grid members can function as NTP clients that synchronize their clocks with external NTP servers. They can in turn function as NTP servers to other appliances in the network. For more information, see NIOS Appliances as NTP Servers. Note that when the Grid Master functions as an NTP server, it synchronizes its local clock with its NTP clients and does not synchronize time with any other external NTP server. This allows you to deploy multiple NTP servers to ensure accurate and reliable time across the network. To configure the Grid Master and Grid members as NTP clients, you must first enable the NTP service and configure external NTP servers at the Grid level. You can then configure the Grid Master and Grid members to override the Grid-level NTP servers and use their own external NTP servers. Note that a Grid member will not function as an NTP client if you do not enable the NTP service at the Grid level. A Grid member synchronizes its clock with the Grid Master if you do not configure it to use external NTP servers. When an NTP service-enabled member goes offline from the grid, that member sets the Grid Master's NTP configurations. If the Grid Master goes offline (because of a shutdown or a disconnecting network, and so on), the Grid Master Candidate and Grid members synchronize with the external NTP servers.

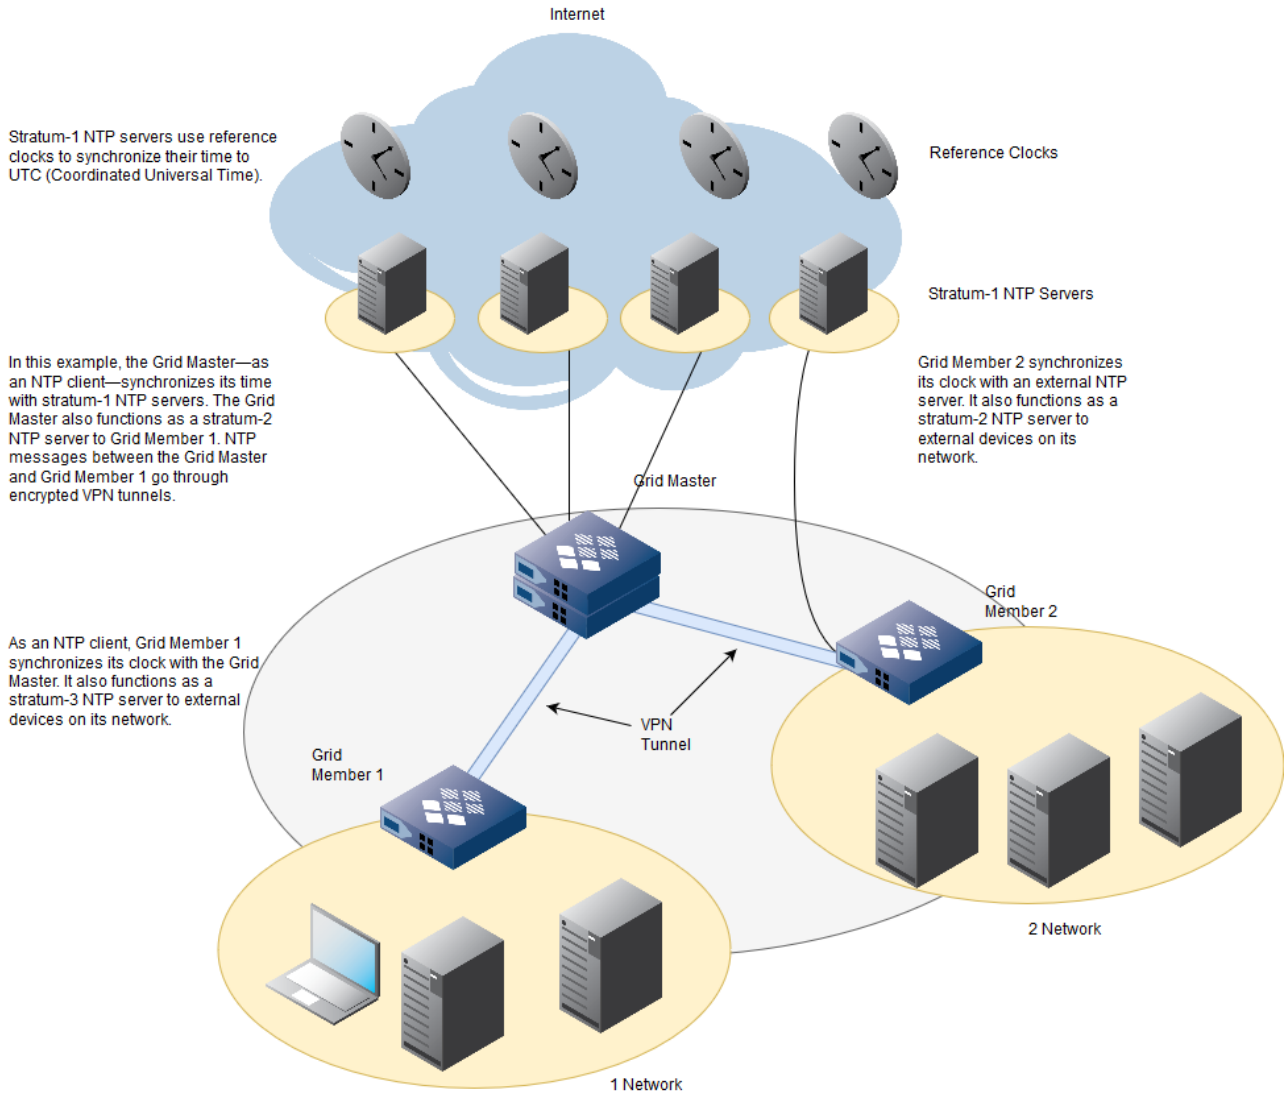
In case of leap second insertion, the Infoblox Grid handles the leap second over a period of time instead of performing a one-time adjustment. In other words, when using the Grid as the NTP server, it follows the standard NTP recovery process by slewing over a certain period of time when handling the leap second. The slewing process could therefore cause synchronization issues among NTP clients. The out-of-sync state is usually resolved when all NTP clients catch up with the server.

The following figure illustrates how NIOS appliances (the Grid Master and Grid members) in a Grid function as the NTP server or the NTP client, depending on your NTP configuration.

Note

The NTP service supports both IPv4 and IPv6 networks.

Infoblox Appliances as NTP Servers



Authenticating NTP

To prevent intruders from interfering with the time services on your network, you can authenticate communications between a NIOS appliance and a public NTP server, and between a NIOS appliance and external NTP clients. NTP communications within the Grid go through an encrypted VPN tunnel, so you do not have to enable authentication between members in a Grid.

NTP uses symmetric key cryptography, where the server and the client use the same algorithm and key to calculate and verify a MAC (message authentication code). The MAC is a digital thumbprint of the message that the receiver uses to verify the authenticity of a message.

As shown in the figure below, the NTP client administrator must first obtain the secret key information from the administrator of the NTP server. The server and the client must have the same key ID and data. Therefore, when you configure the NIOS appliance as an NTP client and want to use authentication, you must obtain the key information from the administrator of the external NTP server and enter the information on the NIOS appliance. When you configure a NIOS appliance as an NTP server, you must create a key and send the key information to clients in a secure manner. A key consists of the following:

- Key Number: A positive integer that identifies the key.
- Key Type: Specifies the key format and the algorithm used to calculate the MAC (message authentication code) of a message.
    - M: The key is a 1-31 character ASCII string using MD5 (Message Digest).

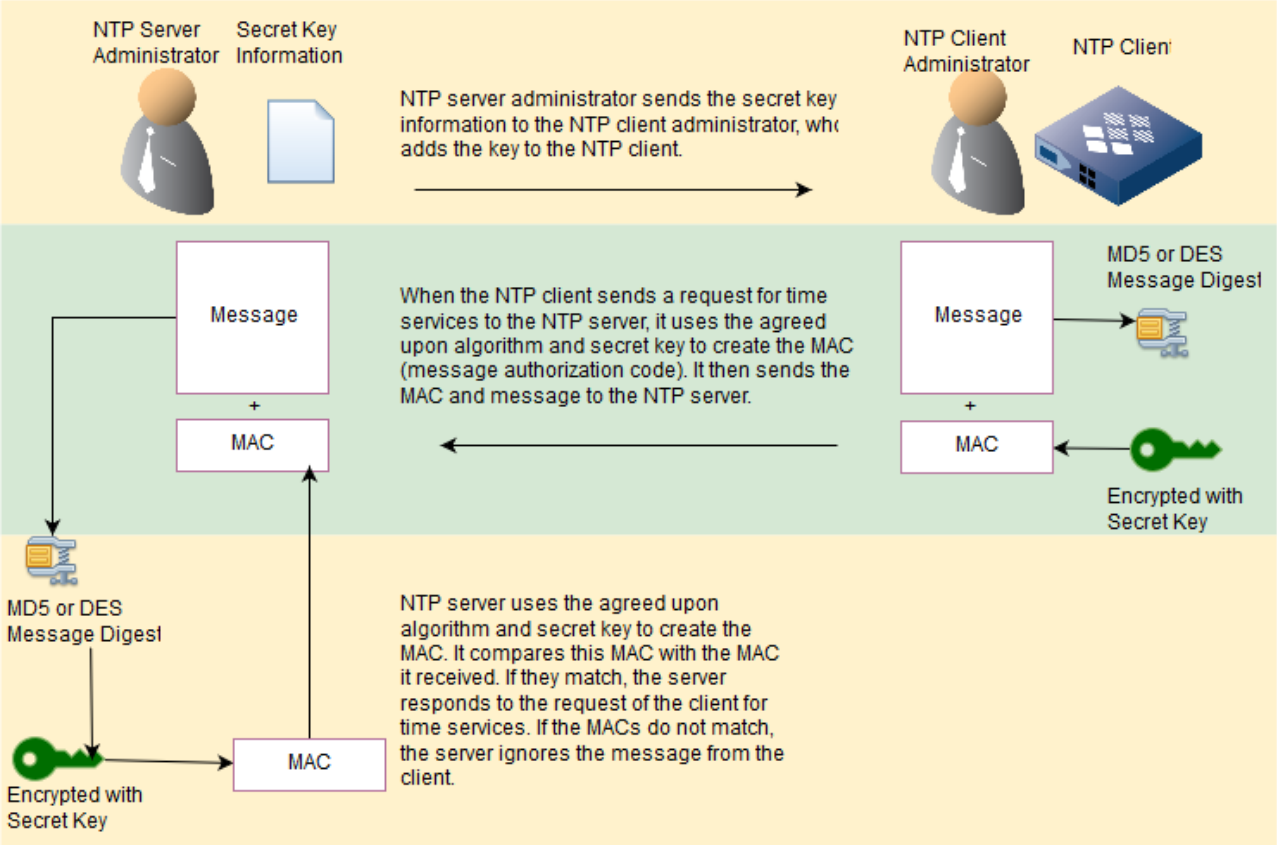
    - S: The key is a 64-bit hexadecimal number in DES (Data Encryption Standard) format. The high order 7 bits of each octet form the 56-bit key, and the low order bit of each octet is given a value so that the octet maintains odd parity. You must specify leading zeros so the key is exactly 16 hexadecimal digits long and maintains odd parity.
    - A: The key is a DES key written as a 1-8 character ASCII string.
    - N: The key is a 64-bit hexadecimal number in NTP format. It is the same as the S format, but the bits in each octet have been rotated one bit right so the parity bit is in the high order bit of the octet. You must specify leading zeros and odd parity must be maintained.
- Key String: The key data used to calculate the MAC. The format depends on the Key Type you select.

When the NTP client initiates a request for time services to the NTP server, it creates the MAC by using the agreed upon algorithm to compress the message and then encrypts the compressed message (which is also called a message digest) with the secret key. The client appends the MAC to the message it sends to the NTP server. When the NTP server receives the message from the client, it performs the same procedure on the message — it compresses the message it received, encrypts it with the secret key and generates the MAC. It then compares the MAC it created with the MAC it received. If they match, the server continues to process and respond to the message. If the MACs do not match, the receiver drops the message.

The following table lists the NTP client server behaviour in different scenarios:

Scenario	Behavior
No authentication on both the NTP client and server	The NTP client will synchronize with the server
Authentication on the NTP server, no authentication on the NTP client	The NTP client will synchronize with the server
Authentication on both the NTP server and client	The NTP client will synchronize with the server
No authentication on the NTP server, authentication on the client	The NTP client will be out-of-synchronization with the server

NTP Client Administrator Obtaining Secret Key from NTP Server Administrator



NIOS Appliances as NTP Clients

You can configure an independent NIOS appliance, a Grid Master, or any Grid member in a Grid as an NTP client that synchronizes its system clock with an external NTP server.

> ⚠ Note
>
> You can configure NIOS appliance as NTP client in either IPv4, IPv6, or dual mode (IPv4 and IPv6) network environment.

When you enable a NIOS appliance to function as an NTP client, you must specify at least one NTP server with which the appliance can synchronize its clock. Infoblox recommends that you specify multiple NTP servers that synchronize their time with different reference clocks and that have different network paths. This increases stability and reduces risk in case a server fails. For a list of public NTP servers, you can access *www.ntp.org.*

When you specify multiple NTP servers, the NTP daemon on the appliance determines the best source of time by calculating round-trip time, network delay, and other factors that affect the accuracy of the time. NTP periodically polls the servers and adjusts the time on the appliance until it matches the best source of time. If the difference between the appliance and the server is less than five minutes, the appliance adjusts the time gradually until the clock time matches the NTP server. If the difference in time is more than five minutes, the appliance immediately synchronizes its time to match that of the NTP server.

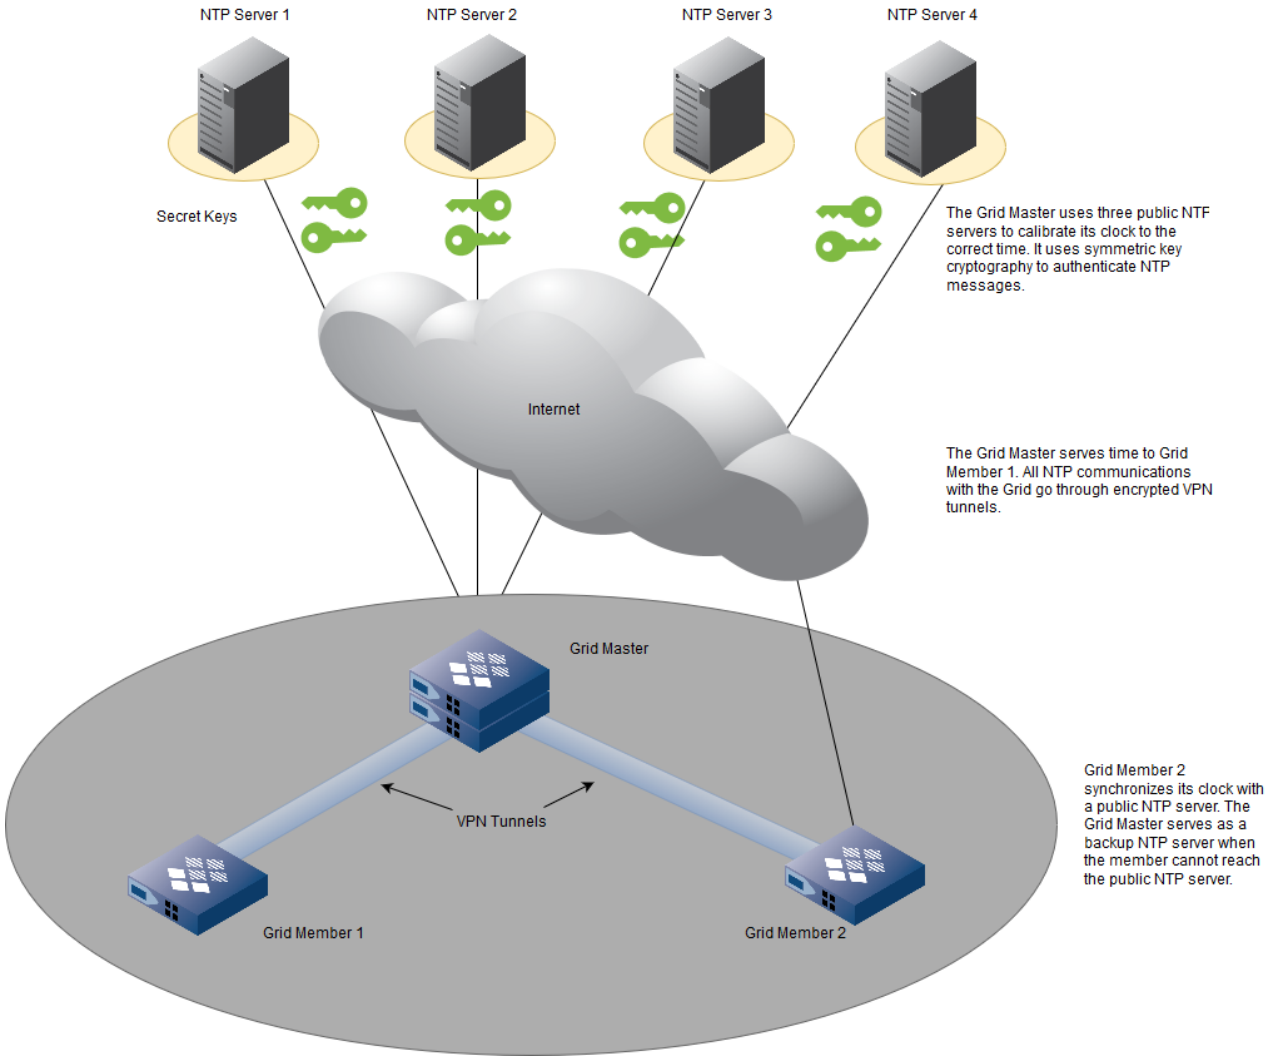
To secure communications between a NIOS appliance and an NTP server, you can authenticate communications between the appliance and the NTP server. When you configure authentication, you must obtain the key information from the administrator of the NTP server and enter the key on the appliance. For information, see Authenticating NTP above.

In a Grid, you can configure the Grid Master and Grid members to synchronize their clocks with external NTP servers. When you enable the NTP service on the Grid, the Grid Master automatically functions as an NTP server to the Grid members. A Grid member can synchronize its time with the Grid Master, an external NTP server, or another Grid member. When Grid members synchronize their times with the Grid Master, the Grid Master and its members send NTP

messages through an encrypted VPN tunnel, as shown in the following figure. When a Grid member synchronizes its time with another Grid member, the NTP messages are not sent through a VPN tunnel.

> **Note**
>
> Grid member cannot act as an NTP server to the Grid Master.

Grid Master as NTP Client



Configuring the Grid to Use NTP

In a Grid, the Grid Master and Grid members can synchronize their clocks with external NTP servers. They then forward the clock time to other appliances in the network. Likewise, in an independent HA pair, the active node communicates directly with an external NTP server. The passive node then synchronizes its clock with the active node.
In a Grid, you must first enable the NTP service and configure external NTP servers at the Grid level before you configure the Grid Master and Grid members as NTP clients.
To configure a Grid Master as an NTP client, perform the following tasks:

- If you want to enable authentication between the Grid members and NTP servers, you must specify the authentication keys before enabling the NTP service. You can specify authentication keys at the Grid and member levels.
- Enable the NTP service on the Grid and specify one or more external NTP servers. For information, see Synchronizing the Grid with External NTP Servers below.

Adding NTP Authentication Keys

To enable authentication between the appliance and the NTP servers, add the authentication keys before enabling the NTP service on the Grid. You can specify authentication keys at the Grid and member levels.

To add NTP authentication keys:

1. **Grid:** From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **NTP** -> **NTP Grid Config**.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox. Expand the Toolbar and click **NTP** -> **NTP Member Config**.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. Click the Add icon in the NTP Keys section and enter the following information.
   - **Key Number:** A positive integer that identifies a key.
   - **Type:** Specifies the key format and the algorithm used to calculate the MAC (message authentication code) of a message.
     - **MD5 in ASCII format (M):** The key is a 1-31 character ASCII string using MD5 (Message Digest).
     - **DES in hex format (S):** The key is a 64-bit hexadecimal number in DES (Data Encryption Standard) format. The high order 7 bits of each octet form the 56-bit key, and the low order bit of each octet is given a value so that the octet maintains odd parity. You must specify leading zeros so the key is exactly 16 hexadecimal digits long and maintains odd parity.
     - **DES in ASCII format (A):** The key is a DES key written as a 1-8 character ASCII string.
     - **DES in NTP format (N):** The key is a 64-bit hexadecimal number in NTP format. It is the same as the S format, but the bits in each octet have been rotated one bit right so the parity bit is in the high order bit of the octet. You must specify leading zeros and odd parity must be maintained.
     - **SHA1 in ASCII format (SHA1):** The key is a 40-character hexadecimal string, and it uses hash based symmetric encryption algorithm.
       Note that FIPS compliance is not supported in SHA-1.
   - **String:** The key data used to calculate the MAC. The format depends on the Key Type you select.
3. Click **Save** to save the entry and keep the editor open so you can enable the Grid to synchronize its time with external NTP servers.

Note that if you enter a new key, the appliance checks if the key already exists in the key list. If the key exists, but either the key type or key string does not match, the NIOS appliance sends an error message.

After you enter an authentication key, you can modify or delete it. Note that you cannot delete a key that an NTP server references. You must first delete all NTP servers that reference that key and then delete the key.

Synchronizing the Grid with External NTP Servers

To enable the Grid to synchronize its time with external NTP servers:

1. From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **NTP** -> **NTP Grid Config**.
2. In the **General** tab of the *Grid NTP Properties* editor, select **Synchronize the Grid with these External NTP Servers**.
3. Click the Add icon to add external NTP servers and enter the following information in the *Add NTP Server* dialog box:
   - **NTP Server (FQDN or IP Address):** Enter either the IP address or the resolvable host name of an NTP server. Entries may be an IPv4 or IPv6 address. You can view a list of public NTP servers at ntp.isc.org. To check whether the DNS server can resolve the NTP server host name, click **Resolve Name**. You must have a DNS name resolver configured. For information, see *Enabling DNS Resolution*.
     As a best practice when configuring NTP servers using the FQDN (instead of an IP address), configure an external DNS name resolver that is reachable by NIOS appliance. Otherwise, the NIOS system startup can be delayed.
   - **Enable Authentication:** Select this option to enable authentication of NTP communications between the external NTP server and the NIOS appliance (the Grid Master or Grid member in a Grid, an independent NIOS appliance, or the active node in an independent HA pair).

Note that to prevent intruders from interfering with the time services on your network, you can authenticate communications between a Grid member and an external NTP server, as well as between a Grid member and external NTP clients. NTP communications within the Grid go through an encrypted VPN tunnel, so you do not have to enable authentication between the Grid Master and Grid members.
Authentication Key: Select a key that you previously entered from the drop-down list.

- Click **Add** to add the NTP server to the list or **Cancel** to cancel the operation. In the table, you can configure some of the following settings:
  - **Preferred**: Select this to mark an external NTP server as the preferred NTP server. You can select only one server as the preferred NTP server. NIOS uses the responses from this preferred server over responses from other external NTP servers. A response from a preferred server will be discarded if it differs significantly from the responses of other servers. Infoblox recommends that you select an NTP server that is known to be highly accurate as the preferred server, such as one that has special time monitoring hardware. Note that this option is enabled only when you have selected the checkbox **Synchronize the Grid with these External NTP Servers**.
  - **Server**: Displays the FQDN or IP address of the NTP server that you added.
  - **Authentication**: When you enable authentication, this column displays **Yes**. Otherwise, it displays **No**.
  - **Key Number**: Displays the authentication key that you have selected.
  - **BURST**: Select this checkbox to configure the NTP client to send a burst of eight packets if the external NTP server is reachable and a valid source of synchronization is available. The NTP client transmits each packet at a regular interval of two seconds. After you add an NTP server and save the configuration, the appliance will enable this option by default. When you deselect this checkbox, the client sends a single packet only once to the server.
  - **IBURST**: Select this checkbox to configure the NTP client to send a burst of eight packets if the external NTP server is not reachable when the client sends the first packet to the server. The NTP client transmits each packet at a regular interval of two seconds. After you add an NTP server and save the configuration, the appliance will enable this option by default. When you deselect this checkbox, the client sends a single packet only once to the server.
    For information about adding NTP authentication keys, see Adding NTP Authentication Keys above.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring Grid Members to Use NTP

Once you configure a Grid member to use external NTP server, make sure that the NTP service is enabled at Grid level. Otherwise, the Grid member will not function as an NTP client.
To configure Grid members to synchronize their time with external NTP servers:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox.
2. Expand the Toolbar and click **NTP** -> **NTP Member Config**.
3. In the **General** tab of the *Member NTP Properties* editor, do the following:
   - **Enable the NTP Server on this Member:** Select this checkbox to configure a Grid Master or a Grid member as an NTP server. If you have configured DNS anycast on the appliance, it can answer NTP requests through the anycast IP address.
   - **Synchronize this Member only with the Grid Master**: Select this checkbox to enable this Grid member to synchronize its time with the Grid Master. This is the default.
   - **Synchronize this Member with other NTP Servers**: Select this checkbox to enable this Grid member to use external NTP servers. When you select this checkbox, you must enter at least one external NTP server for the member.
   - **Exclude the Grid Master as an NTP Server**: Select this checkbox if you want to exclude the Grid Master from being one of the time sources. By default, the appliance automatically configures the Grid Master as the backup NTP server for a Grid member. When the member cannot reach any of its configured NTP servers, it uses the Grid Master as the NTP server. The appliance does not display the Grid Master in the NTP external server list. For a Grid Master, this checkbox has no meaning.
   - **External NTP Servers**: Click **Override** and then click the **Add** icon. In the *Add NTP Server* dialog box, enter the following information:
   - **NTP Server (FQDN or IP Address)**: Enter either the IP address or the resolvable host name of an NTP server. You can view a list of public NTP servers at ntp.isc.org. To check whether the DNS server can resolve the NTP server host name, click **Resolve Name**. You must have a DNS name resolver configured.

- **Enable Authentication**: Select this checkbox to enable authentication of NTP communications between the external NTP server and the NIOS appliance (the Grid Master or Grid member in a Grid, an independent NIOS appliance, or the active node in an independent HA pair).
  Note that to prevent intruders from interfering with the time services on your network, you can authenticate communications between a Grid member and an external NTP server, as well as between a Grid member and external NTP clients. NTP communications within the Grid go through an encrypted VPN tunnel, so you do not have to enable authentication between the Grid Master and Grid members.
  Authentication Key: Select a key that you previously entered from the drop-down list. Note that you must enter authentication keys at the Grid level when you configure a Grid Master or Grid member to use external NTP servers.
- Click **Add** to add the NTP server to the list or **Cancel** to cancel the operation. In the table, click **Override** in the table to override configurable settings. To inherit the same properties as the Grid, click **Inherit**.
  - **Preferred**: Select this to mark an external NTP server as the preferred NTP server. You can select only one server as the preferred NTP server. NIOS uses the responses from this preferred server over responses from other external NTP servers. A response from a preferred server will be discarded if it differs significantly from the responses of other servers. Infoblox recommends that you select an NTP server that is known to be highly accurate as the preferred server, such as one that has special time monitoring hardware. Note that this option is enabled only when you have selected the checkbox **Synchronize this Member with other NTP Servers**.
  - **Server**: Displays the FQDN or IP address of the NTP server that you added.
  - **Authentication**: When you enable authentication, this column displays **Yes**. Otherwise, it displays **No**.
  - **Key Number**: Displays the authentication key that you have selected.
  - **BURST**: Select this checkbox to configure the NTP client to send a burst of eight packets if the external NTP server is reachable and a valid source of synchronization is available. The NTP client transmits each packet at a regular interval of two seconds. After you add an NTP server and save the configuration, the appliance will enable this option by default. When you deselect this checkbox, the client sends a single packet only once to the server.
  - **IBURST**: Select this checkbox to configure the NTP client to send a burst of eight packets if the external NTP server is not reachable when the client sends the first packet to the server. The NTP client transmits each packet at a regular interval of two seconds. After you add an NTP server and save the configuration, the appliance will enable this option by default. When you deselect this checkbox, the client sends a single packet only once to the server.
    Note that NTP members inherit NTP properties from the Grid. Click **Override** in the *Member NTP Properties* wizard to override configurable settings. To inherit the same properties as the Grid, click **Inherit**. For information about adding NTP authentication keys, see Adding NTP Authentication Keys above.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

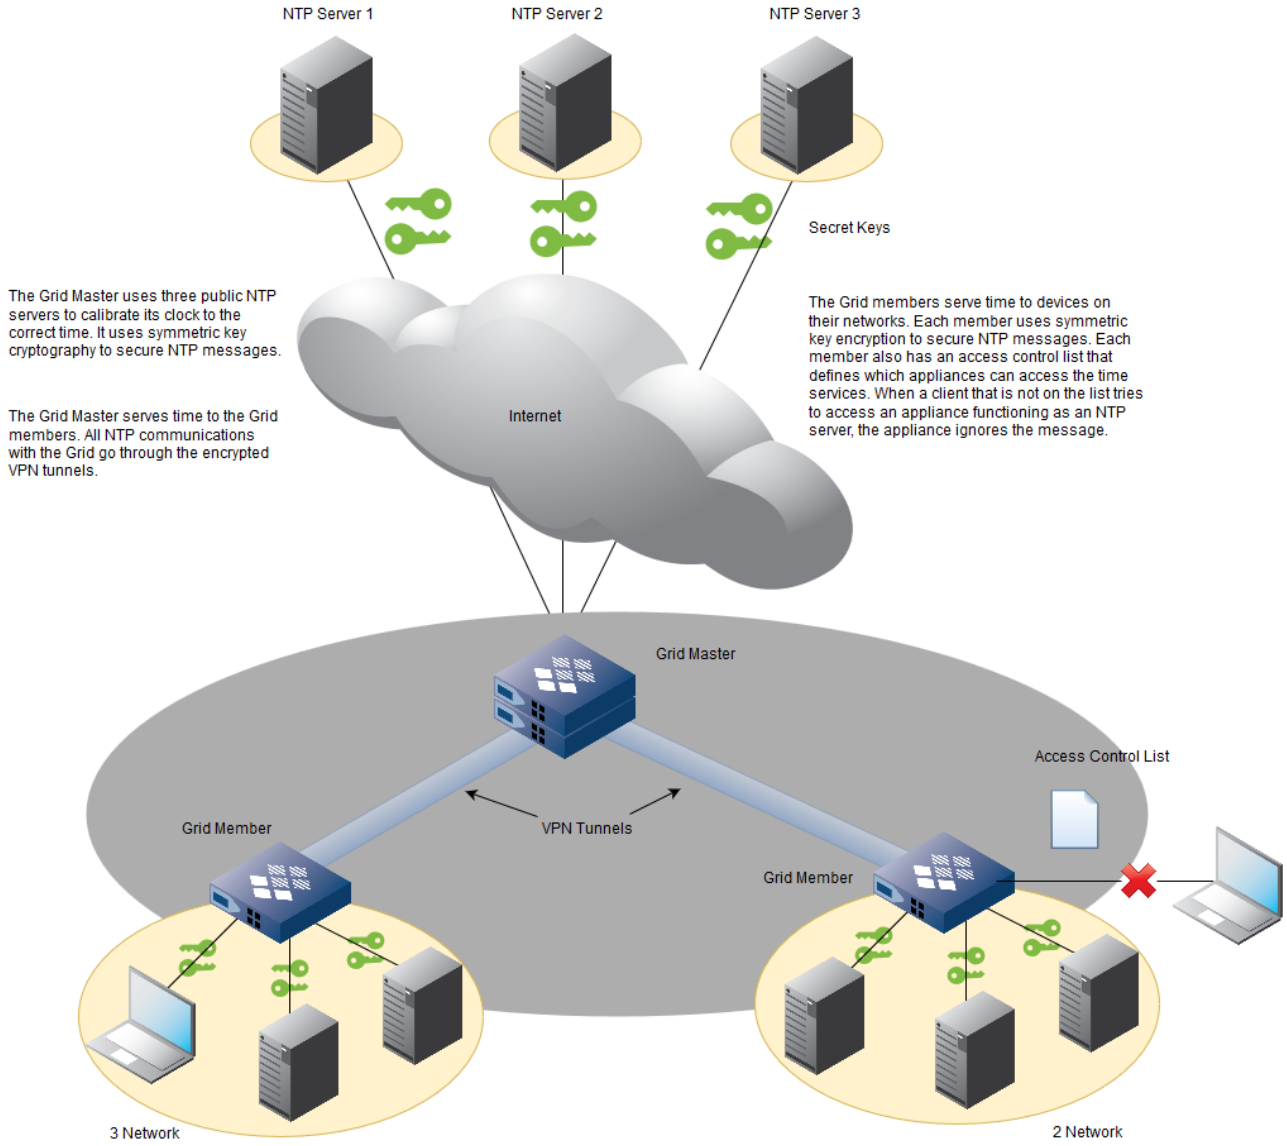
Managing External NTP Servers

You can specify multiple NTP servers for failover purposes. The NIOS appliance attempts to connect to the NTP servers in the order they are listed. A Grid member uses the Grid Master as the NTP server when it cannot reach any of its external NTP servers.
You can change the order of the list by selecting an NTP server and dragging it to its new location or by clicking the up and down arrows. You can add and delete servers and modify their information as well.

NIOS Appliances as NTP Servers

After you enable NTP on a Grid, the Grid members—including the Grid Master—can function as NTP servers to clients in different segments of the network. Similarly, after you enable NTP on an independent appliance or an HA pair, and it synchronizes its time with an NTP server, you can configure it to function as an NTP server as well. When you configure DNS anycast addressing on a Grid member and use it as an NTP server, the member can answer NTP requests from other NTP clients through the anycast IP address.

Grid Members as NTP Servers



To configure a NIOS appliance as an NTP server, perform the following tasks:

- Enable the appliance as an NTP server.
- Enable authentication between the appliance and its NTP clients.
- Optionally, specify which clients can access the NTP service of the appliance.
- Optionally, specify which clients can use ntpq to query the appliance.

Configuring a NIOS Appliance as an NTP Server

You can configure a Grid member—including the Grid Master—or an independent appliance or HA pair to function as an NTP server. When you enable a NIOS appliance to function as an NTP server, you can enable authentication between a NIOS appliance functioning as an NTP server and its NTP clients. When you enable authentication, you must specify the keys that the appliance and its clients must use for authentication. In a Grid, you can enter NTP authentication keys at the Grid level so that all the members can use them to authenticate their clients. You can also
enter keys at the member level, if you want that member to use different keys from those set at the Grid level. After you enter the keys, you can download the key file and distribute the file to the NTP clients.
On an HA member, the NTP service runs on the active node. If there is an HA failover, the NTP service is automatically launched after the passive node becomes active and the NTP traffic uses the HA port on one of the nodes from an HA pair, instead of the LAN1 port. You might receive an error message indicating that the NTP is out of synchronization.

During another HA failover, the currently passive node becomes active again and the NTP traffic uses the LAN1 port, and the NTP is back in synchronization. For information, see *About HA Pairs.*
To enable an appliance as an NTP server and authenticate NTP traffic between a NIOS appliance and an NTP client, perform the following tasks:

- Enable an appliance as an NTP server and define authentication keys. For information, see Enabling an Appliance as an NTP Server below.
- Optionally, define NTP access control, including KoD packet configuration. For information, see Defining NTP Access Control below.
- Optionally, configure anycast addressing for DNS and use the anycast IP address for NTP requests. For information about how to configure DNS anycast, see *Configuring Anycast Addresses*.

Enabling an Appliance as an NTP Server

To enable an appliance as an NTP server and add authentication keys:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox.
2. Expand the Toolbar and click **NTP** -> **NTP Member Config**.
3. In the **General** tab of the *Member NTP Properties* editor, do the following:
    - **Enable the NTP Server on this Member**: Select this option to configure a Grid Master or a Grid member as an NTP server. If you have configured DNS anycast on the appliance, it can answer NTP requests through the anycast IP address.
    - Click **Override** in the NTP Keys section to enter NTP authentication keys at the member level. The member uses these keys when acting as an NTP server and authenticates requests from NTP clients. Clear the checkbox to use the Grid-level authentication keys.
4. Click **Add** in the NTP Keys section. For information, see Adding NTP Authentication Keys above.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

After you enter the authentication keys, you can download the key file (usually called ntp.keys) and distribute it to NTP clients as follows:

1. **Grid:** From the **Grid** tab, select the **Grid Manager** tab.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox.
2. Expand the Toolbar and click **NTP** -> **Download NTP Keys**.
3. In the *Opening ntp.keys* dialog box, save the file, and then click **OK**.
4. Distribute this to the NTP clients using a secure transport.

Defining NTP Access Control

The NTP access control list specifies which clients can use a NIOS appliance as an NTP server. If you do not configure access control, then the NIOS appliance allows access to all clients. You can configure access control at the NTP Grid level and override that at the member level.
In addition, the NIOS appliance can accept queries from clients using ntpq, the standard utility program used to query NTP servers about their status and operational parameters. You can specify from which clients the NIOS appliance is allowed to accept ntpq queries. The appliance does not accept ntpq queries from any client, by default.
You can use an existing named ACL (access control list) or multiple ACEs (access control entries) to control which clients can use the NIOS appliance as an NTP server, as well as those clients from which the appliance can accept queries using ntpq. For information about access control, see *Configuring Access Control*.

To specify which clients can access the NTP service of a NIOS appliance and from which clients a NIOS appliance can accept ntpq queries, and to enable or disable KoD, complete the following:

1. **Grid:** From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **NTP** -> **NTP Grid Config**.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox. Expand the Toolbar and click **NTP** -> **NTP Member Config**.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the **Access Control** tab of the *Grid* or *Member NTP Properties* editor, select one of the following to configure NTP access control:
    - **None**: Select this if you do not want to configure access control for NTP service. When you select **None**, the appliance allows all clients to access the NTP service. This is selected by default.

- **Use Named ACL for Time only:** Select this and click **Select Named ACL** to select a named ACL that contains only IPv4 addresses and networks. NTP queries do not support TSIG key based ACEs. When you select this, the appliance allows clients that have the **Allow** permission in the named ACL to use its NTP service. NTP queries from the named ACL entries specified here are denied. You can click **Clear** to remove the selected named ACL and the appliance accepts ntpq queries from those NTP clients.
- **Use Named ACL for Time + NTP Control (NTPQ):** Select this and click **Select Named ACL** to select a named ACL that contains only IPv4 addresses and networks. NTP queries do not support TSIG key based ACEs. When you select this, the appliance allows clients that have the **Allow** permission in the named ACL to use its NTP service, and for the appliance to accept ntpq queries from those clients as well. You can click **Clear** to remove the selected named ACL.
- **Use this set of ACEs**: Select this to configure individual ACEs. Click the *Add* icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows:
    - **IPv4 Address:** Select this to add an IPv4 address. Click the **Value** field and enter the IPv4 address. The default permission is **Allow**, which means that the appliance allows access to and from this IPv4 client. You cannot change the default permission. In the **Service** field, select **Time only** to allow this client for using the NTP service on the appliance; or select **Time + NTP Control (NTPQ)** to also accept ntpq queries from this client.
    - **IPv4 Network:** Select this to add an IPv4 network. Click the **Value** field and enter the IPv4 network. The default permission is **Allow**, which means that the appliance allows access to and from this IPv4 network. You cannot change the default permission. In the **Service** field, select **Time only** to allow this network for using the NTP service on the appliance; or select **Time + NTP Control (NTPQ)** to also accept ntpq queries from this network.
    - **IPv6 Address:** Select this to add an IPv6 address. Click the **Value** field and enter the IPv6 address. The default permission is **Allow**, which means that the appliance allows access to and from this IPv6 client. You cannot change the default permission. In the **Service** field, select **Time only** to allow this client for using the NTP service on the appliance; or select **Time + NTP Control (NTPQ)** to also accept ntpq queries from this client.
    - **IPv6 Network:** Select this to add an IPv6 network. Click the **Value** field and enter the IPv6 network. The default permission is **Allow**, which means that the appliance allows access to and from this IPv6 network. You cannot change the default permission. In the **Service** field, select **Time only** to allow this network for using the NTP service on the appliance; or select **Time + NTP Control (NTPQ)** to also accept ntpq queries from this network.
    - **Any Address/Network:** Select this to allow access to all IPv4 and IPv6 addresses and networks. The default permission is **Allow**, which means that the appliance allows access to and from all IPv4 and IPv6 clients. You cannot change the default permission. In the **Service** field, select **Time only** to allow clients for using the NTP service on the appliance; or select **Time + NTP Control (NTPQ)** to also accept ntpq queries from all clients.

      After you have added access control entries, you can do the following:
        - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
        - Reorder the list of ACEs using the up and down arrows next to the table.
        - Select an ACE and click the Edit icon to modify the entry.
        - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.
    - **Enable KoD**: When you select this checkbox, the appliance (when acting as an NTP server) sends a KoD (Kiss-o'-Death) packet to the NTP client if the client has exceeded the rate limit. The KoD packet contains the stratum field set to zero and the ASCII string in the Reference Source Identifier field set to RATE, indicating the packets sent by the client have been dropped by the server. When you clear the checkbox, the NTP server drops the packets but does not send any KoD packet to the client. This checkbox is deselected by default. For more information about KoD, see Enabling Kiss-o'-Death for NTP below.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Enabling Kiss-o'-Death for NTP

When an NTP server denies service to an NTP client, which has exceeded the rate limit, it typically drops the packets without notifying the client. In this case, the client, unaware of the situation, continues to transmit packets. To notify the client so it either slows down or stops the packet transmission, you can enable the NIOS appliance (when acting as an NTP server) to transmit a KoD (Kiss-o'-Death) packet. This packet contains the stratum field which is set to zero, implying the sent packet was invalid, and the ASCII string that contains RATE in the reference identifier field, indicating the status of the transmitted packet and access control. When the client receives the KoD packet, it may reduce transmission rate or stop packet transmission to the server. For more information about KoD, refer to *RFC 5905 (Network Time Protocol Version 4: Protocol and Algorithms Specification)*. You can enable KoD at the Grid level and override it at the member level. For more information about enabling KoD, see Defining NTP Access Control above.

Defining NTP Orphan Mode

The NTP orphan mode allows you to configure a stratum value that enables the Grid members to continue serving NTP uninterruptedly using the disconnected NTP service in the absence of external NTP servers of the Grid. When the external NTP servers are reachable again, the Grid connects with the server to serve NTP and derive the NTP stratum values and the Grid automatically switches to the connected mode. For information about orphan mode, see *Configuring the Orphan Mode*.

To configure a user specified stratum for NTP service on a Grid to use the disconnected NTP services, complete the following:

Note

- Unless a special configuration is required, use the default values. In case you configure the values, keep the configuration as simple as possible.
- When you select the **Use Default** option for the stratum value of either the Grid Manager or the Grid member, you will not be able to add or edit the stratum values.
- You can use the `set ntp_stratum` CLI command in maintenance mode to set the local NTP stratum value for both the Grid Manager and member.

1. From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **NTP** -> **NTP Grid Config**.
2. In the **Orphan Mode** tab of the *Grid NTP* editor, specify the following:
   - **Use Default**: Select this if you want to use the default values and do not want to configure the stratum for the Grid Manager and the Grid members. When you select the **Use Default** option, NIOS uses the default stratum value of 12 for the Grid Manager and 14 for the Grid level members.
   - **Grid Manager local NTP stratum**: Specify the NTP stratum value for the Grid Manager, enter a stratum value that is between 2 to 14, both inclusive.
   - **Member local NTP stratum**: Specify the NTP stratum for the Grid members at Grid level, enter a stratum value that is between 3 to 15, both inclusive. However, the minimum NTP stratum value of the member needs to be 1 more than the Grid Manager NTP stratum value.
3. Click **Save & Close** to complete the configuration.

To configure a user specified stratum for NTP service on a member to use the disconnected NTP services, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox. Expand the Toolbar and click **NTP** -> **NTP Member Config**.
   To override a Grid level inherited stratum value, click **Override**. To inherit the same values as the Grid, click **Inherit**.
2. In the **Orphan Mode** tab of the *Member NTP Properties* editor, specify the following:
   - **Use Default**: Select this if you want to use the default values and do not want to configure the stratum value for the Grid Member. When you select the **Use Default** option, NIOS uses the default stratum value of 14 for the Grid member.

- **Member local NTP stratum**: Specify the NTP stratum value for the Grid member, enter a stratum value that is between 2 to 15, both inclusive. By default, if the Grid Manager is set as the NTP server for the Grid member, then the Grid member will generate the stratum value by using the stratum value of the Grid Manager.

3. Click **Save & Close** to complete the configuration.

The NTP service will restart automatically once the configuration has been modified.

Monitoring NTP

When you enable the Grid to synchronize its time with external NTP servers, you can monitor the status of the NTP service by checking the NTP status icons in the *Member Services* panel. To access the panel, from the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then select the Manage Member Services icon in the table toolbar of the Members tab.
The following are descriptions of the NTP status icons in the *Members Services* panel. The type of information that can appear in the **Description** column corresponds to the SNMP trap messages. For information about the Infoblox SNMP traps, see *Configuring SNMP.*

Icon	Color	Meaning
	Green	The NTP service is enabled and running properly.
	Yellow	The NTP service is enabled, and the appliance is synchronizing its time.
	Red	The NTP service is enabled, but it is not running properly or is out of synchronization.
	Gray	The NTP service is disabled.

After you upgrade the Grid to 6.6.x or later, the color of the Grid status icon changes based on the following:

- If you activate an external synchronization, or start the NTP service using the Grid Manager, or do not configure any external NTP servers, except local, then the NTP behavior remains the same and the NIOS appliance displays the Grid status icon in green.
- If you activate an external synchronization and configure one or more external NTP servers, or if the servers are in synchronization with the Grid Master, then the Grid status icon is as follows:
  - Green: NTP is synchronizing with an external server.
  - Red: NTP is synchronizing with the local server and none of the external NTP servers are reachable. This status icon also indicates if there are problems with the NTP service.
  - Yellow: NTP is synchronizing with the local server and at least one external NTP server is reachable; but there could be problems on the external server, such as an exceeded root distance error.

Managing Extensible Attributes

Extensible attributes are identifiers that you use to further define and track a NIOS object. For example, to specify the location of a network, you can add the predefined attribute **Site** and enter a specific location for the network. You can also specify whether an extensible attribute is required for an object or restrict the values that can be entered when you create a new object.
You can also specify if an extensible attribute is inheritable by other objects in an inheritance chain. When you enable the inheritance of an extensible attribute, all descendants in the inheritance chain can inherit the extensible attribute so you do not have to configure it at all object levels. For example, if you define an extensible attribute for a network, the attribute and its value can be automatically added for DHCP ranges and fixed addresses in the network.
An extensible attribute is inheritable by descendants in an inheritance chain if its definition does not restrict it to objects that are not part of an inheritance chain. The appliance supports this inheritance chain: Network View -> Network Container -> Network -> Range -> Host/Fixed Address/Reservation. A parent object can have descendants at one or more levels. For example, a network view, network container, network or DHCP range can be a parent object and have

descendants at one or more levels, while a host, fixed address, and reservation can only be a descendant, not a parent. You can set an extensible attribute to be inheritable by selecting the **Enable Inheritance** option when you define an attribute. For more information, see Configuring Inheritable Extensible Attributes below.

> ⚠ Note
>
> Only superusers can configure extensible attributes.

You can use predefined extensible attributes or specify new ones for different objects. For more information on supported object types and their corresponding fields for the extensible attributes, see *Subscriber Record*. The appliance provides the following predefined extensible attributes that you can customize:

- Region
- Country
- State
- Site
- Building
- VLAN
- ReportingSite (Report Clustering)
- Parental-Control-Policy
- Proxy-All
- User-Name
- White-List
- Black-List
- Subscriber-Secure-Policy
- PC-Category-Policy

> ⚠ Note
>
> Using the **CSV import** option, if you import DHCP network, fixed address or reservation address with Parental control extensible attributes, then the subscriber records are not created.

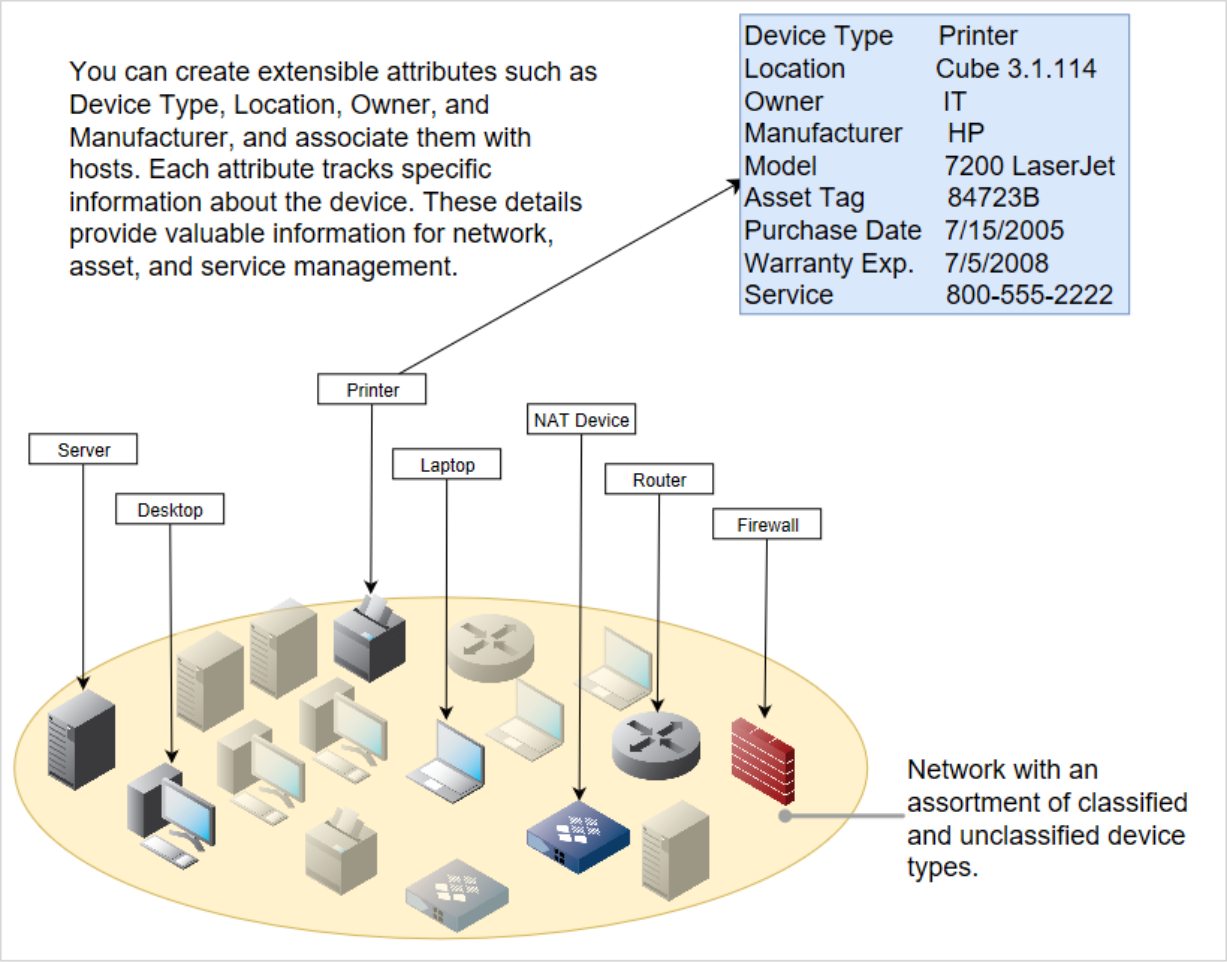
When you use a predefined attribute, you can modify it and change its name, but you cannot change the type of data it accepts. You can also delete predefined attributes that you do not use. All predefined attributes accept text strings. You can define other settings though, as described in Modifying Extensible Attributes below. You can also create your own extensible attributes, as described in Adding Extensible Attributes below.
For example, you can configure the predefined attribute **Site** for fixed addresses and hosts, and define a new attribute **Department** for admin groups. If you enable the option **Allow NATed Subscribers only** in subscriber site, then the extensible attributes used as the default policy for the network, fixed, and reservation address for the DHCP server members, which belong to a Subscriber Site is not supported. For more information on enabling the **Allow NATed Subscribers only** option, see, *Adding Subscriber Sites*.
When you configure an extensible attribute, you can specify the following:

- The type of data that admins enter, such as text strings, integers, or email addresses. You can also restrict admins to a list of values.
- Whether admins can enter multiple values
- A default value
- Whether the attribute is required
  Note that You can specify whether an extensible attribute is required or not only by selecting the **Required** checkbox on the **Administration** > **Extensible Attributes** tab in Grid Manager. You cannot specify whether an extensible attribute is required or not by using CSV or WAPI. For more information about extensible attribute options, see Adding Extensible Attributes below.
- Whether the attribute is inheritable
- The objects associated with the attribute, such as admin groups, DNS views, or DHCP networks.
- Whether the appliance makes an entry in the audit log each time an object with the attribute is added or modified.

Activities such as additions, modifications, and deletions of inheritable extensible attributes, are recorded in the audit log. For more information about how to use the audit log, see *Using the Audit Log*.

Using Extensible Attributes to Define Network Devices figure illustrates a network with different device types. Each device is represented as a host in the NIOS appliance database. You can configure **Device Type**, **Location** and **Owner** as required attributes for hosts. Then when admins add hosts, they will be required to enter values for these attributes in the **Extensible Attributes** tab of the *Add Host* wizard.

Using Extensible Attributes to Define Network Devices



After you configure extensible attributes for an object, the attributes become available in the **Extensible Attributes** tab of the wizard and editor of the corresponding object. Users then add or edit the attribute values, based on your configuration. Users can also specify attributes when searching for data and add attributes as columns in the tables of Grid Manager. For example, you can add the predefined **Site** attribute as a column in the Records panel of the **Zones** tab. For more information about adding columns to tables and customizing Tables, see *About the Grid Manager Interface.*

Users can also group objects in smart folders according to their attributes. For example, a user can create a smart folder that contains all networks in a certain site.

Users can enable the appliance to group members by extensible attributes. For more information, see *Grouping Members by Extensible Attributes*.

When you first enable Cloud Network Automation, NIOS installs a set of extensible attributes that are specific for cloud

usage. You should avoid adding these extensible attributes manually before enabling Cloud Network Automation. For more information, see *Extensible Attributes for Cloud Objects.*

Adding Extensible Attributes

To add a new extensible attribute:

1. From the **Administration** tab, select the **Extensible Attributes** tab.
2. Click the Add icon on any of the toolbars.
3. In the *Add Extensible Attribute* wizard, complete the following:
    - **Name**: Enter the name of the attribute. This is a required field and is case-sensitive. You can enter up to 128 UTF-8 characters.
    - **Type**: Specify the type of data that you want to capture for an object. Select one of the following:
        - **String**: Select this when the attribute is used to define string values, such as names. When you select this type, the wizard displays the **Number of Characters** field where you can enter the minimum and maximum number of characters that users can enter.
        - **List**: Select this when you want to define a list of values for the attribute. Users can then select a value from this list. For example, if you want to restrict an attribute to five specific values, you can define the attribute as a **List** and then list the five values in the *List Values* section. When a user uses the attribute, they are limited to selecting from one of the five values.
          When you select **List**, the wizard displays the List of values table, where you add the allowed values. These values appear in the drop-down list when a user defines the attribute. Click the Add icon to enter values in the table. You can enter up to 64 UTF-8 characters for each value.
          You can also modify list values at a later time. When you modify list values, all object attributes using the modified values are updated to the new values.
          You can also delete values from the list. Note that when you delete a list value, all attributes using the deleted values are removed from the objects. For objects with multiple attribute values, only the deleted values are removed.
          You can also move a value up or down in the list.
        - **Integer**: Select this when the attribute is used to track whole numbers, such as serial numbers. When you select this type, the wizard displays the **Value Limits** fields where you can enter the range of allowed values. Note that you cannot change your entries in the **Value Limits** fields if you modify the attribute at a later date.
        - **Email**: Select this when the attribute is used for email addresses. Email addresses are entered in the format *user@domain.com.*
        - **URL**: Select this when the attribute is used for tracking URLs (Uniform Resource Locators). URLs must be entered in a valid format.
        - **Date**: Select this when the attribute is used for dates. The date value is in YYYY-MM-DD format.
    - **Comment**: Enter additional information about the attribute. You can enter up to 256 UTF-8 characters.
4. Click **Next** and complete the following:
    - **Enable Inheritance:** Select this checkbox if you want to allow the extensible attribute and its values to be inherited by descendants in an inheritance chain. When you select this checkbox, inheritance is enabled for network related objects only. When you select this checkbox and restrict an attribute to certain objects, then the extensible attribute and its value will be inherited by those objects only.
      Note the following:
        - If you create an extensible attribute with inheritance disabled and later enable it, the *Descendant Actions* dialog box may be displayed with the available options for adding an extensible attribute. For more information, see Managing Inheritable Extensible Attributes at the Parent and Descendant Level below.
        - If you create an extensible attribute with inheritance enabled and later disable it, the *Descendant Actions* dialog box may be displayed with the available options for deleting an extensible attribute. For more information, see Deleting Inheritable Extensible Attributes Associated with Parent Objects below.
    - **Allow multiple values:** Select this checkbox if you want to allow multiple values for this attribute to be set on an object. You cannot change this value for predefined attributes. Once you select this checkbox, you cannot deselect it. That is, you cannot allow a single attribute to be set if you selected to allow multiple values to be set on an object.
      Restricting synchronization of extensible attributes

- **Disable sync to MGM**: Select this checkbox to disable synchronization of extensible attributes from the managed Grid to the Multi-Grid Master. This checkbox is available only on the managed Grid when it remains joined with the Multi-Grid Master.
- **Default Value**: Enter the default value that the appliance displays for the attribute. Leave this blank if there is no default value for this attribute. If the attribute type is **String**, you can enter up to 256 UTF-8 characters. If the attribute type is **List**, the value must be one of the list values and can be up to 64 UTF-8 characters.
- **Required**: If you select this option, it is required to enter a value for this attribute when adding or modifying the corresponding object in the GUI.
- **Recommended**: If you select this option, it is recommended to enter a value for this attribute when adding or modifying the corresponding object in the GUI.
- **Optional**: This is selected by default. By selecting this option, you may or may not enter a value for this attribute when adding or modifying the corresponding object in the GUI.
- **Restrict to Specific Object Types**: Click the Add icon to select the object type with which you want to associate the attribute. The appliance adds a row to the table. To delete an object type, select an object type and click the Delete icon. By default, the appliance associates an extensible attribute with all the supported object types.
- **Log Attribute Values When Objects are Updated**: Select this checkbox if you want the appliance to make an entry in the audit log each time an object with this attribute is added or modified. When you select attribute values for audit, they are included in all the audit log entries. For more information about the audit log, see *Using the Audit Log*.
- **Allow cloud members to have the following access to this extensible attribute**: Select this if you are configuring this extensible attribute for Cloud Network Automation. When you select this checkbox, the Cloud Platform Appliance can access this extensible attribute and perform requested tasks based on the cloud API requests. This function is enabled by default for all cloud specific extensible attributes. Note that if you disable this function for any cloud attributes, you will receive an error when you try to perform tasks that involve these attributes through cloud API requests. You can select **Read/Write** or **Read only**. For more information about this feature, see *Deploying Cloud Network Automation*.
    - **Read/Write (and disallow Write access from the GUI and the standard API)**: When you select this, the Cloud Platform Appliance can access and modify the value of this extensible attribute based on the tasks requested only through cloud API requests. You cannot modify this attribute using Grid Manager or the Infoblox API.
    - **Read only**: When you select this, the Cloud Platform Appliance can access this extensible attribute and report the value based on the cloud API requests, but it cannot modify the value. You receive an error if you try to modify this attribute when this option is selected.

5. Save the configuration and click **Restart** if it appears at the top of the screen.

> Warning
> The Cloud Platform member is evicted from the Grid Master if you modify the extensible attribute using Grid Manager.

Grid Manager adds the attribute to the **Extensible Attributes** tab in either the wizard or editor for the specified object types.

> Note
>
> Infoblox recommends that you define values for mandatory extensible attributes using the Grid only and do not use PAPI or RESTful API to define values.

Configuring Inheritable Extensible Attributes

An extensible attribute can be inherited by descendants when it is at the top or in the middle of the inheritance chain. When you add a new extensible attribute to a parent object, the same extensible attribute may or may not already exist at the descendant levels. If the extensible attribute exists on a descendant, you can choose to have the descendant inherit the value from the parent, or retain the original value from the descendant. When the extensible attribute does not exist on the descendant, you can choose to have the descendant either inherit the extensible attribute and its value from the

parent or not inherit anything from the parent.
When you add a range, host, fixed address or IPv4 reservation to a parent object which has inheritable extensible attributes, the newly added object can inherit extensible attributes from the parent object. For example, if you create an IPv4 network with inheritable extensible attributes, and then add a host, the values you specified for the extensible attributes while creating the network can be inherited by the host.
To assist you in identifying whether an extensible attribute value is inherited or overridden, the appliance displays the inheritance state of an attribute in the **Inheritance State** column of an extensible attribute. This column is displayed only for objects that support inheritance. For more information about how to view inheritance states, see Modifying Inheritable Extensible Attributes below.
Following are the supported inheritance states:

Inheritance States

Inheritance	State Description
Inherited	The extensible attribute inherits its value from the parent. You cannot edit the value of an attribute when the inheritance state is set to **Inherited**. You can change the state to **Overridden** and then change the value of the attribute or change the state to **Not Inherited** to remove the inherited value.
Overridden	The extensible attribute overrides the value inherited from the parent. You can change the state to **Inherited** and restore the original inherited value or change the state to **Not Inherited** and remove the inherited value.
Not Inherited	The extensible attribute can inherit its value from the parent, but the attribute does not exist on the descendant. You can change the state to **Inherited** and restore the original inherited value or change the state to **Overridden** and change the value of the attribute. Note that when the state of an inheritable extensible attribute is **Not Inherited**, the corresponding attribute will not be added as a new extensible attribute for objects that are currently not inheriting this extensible attribute.
No Parent	The inheritance state is set to **No Parent** when an object has a parent, but the parent does not have an extensible attribute or the parent's extensible attribute is set to **Not Inherited**.
Disabled	Extensible attribute inheritance is not enabled for the attribute.
No Change	The extensible attributes of the selected objects do not have the same inheritance state for all objects. This state allows you to retain the current state on the selected objects. Note that this state is only seen in the *Multi-object Extensible Attributes* editor.

When you add an inheritable extensible attribute to an object, if there are descendants of this object the *Descendant Actions* dialog box is displayed which will provide options for the descendants. Following is a summary of these options:

- Retain the original value of the attribute for all descendants.
- Inherit the extensible attribute and its value from the parent object.
- Inherit the extensible attribute and its value when it does not exist on descendants.
- If the extensible attribute does not exist on the descendant, do not add it.
- If you are deleting an inherited extensible attribute from a parent object you can retain or remove the extensible attribute from the object's descendants.

To configure default descendant actions for inheritable extensible attributes:

1. From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
2. In the **Extensible Attribute Inheritance** tab, complete the following:
   When adding an extensible attribute that already exists on a descendant:
   - **Keep the descendant's existing value and change the inheritance state to Override:** Select this if you want to retain the existing extensible attribute values for all direct descendants, irrespective of the values you define at the parent level. The inheritance state for all direct descendants will be set to **Overridden**. Note that this is applicable only when you add a new extensible attribute to the parent object that already exists on the descendant. If you modify the value of an existing extensible attribute that is already inherited by the descendant, and select the above option in the Descendant Actions dialog box, then the new value will be inherited by the descendant, but the inheritance state will remain **Inherited**. For example, consider a network 10.0.0.0/16 that has an extensible attribute **Site** with the value **SA** (native). When you add another network 10.0.0.0/24, extensible attribute **Site** inherits its value, **SA**, from the parent object**.** Now, if

you add network 10.0.0.0/8, assign extensible attribute **Site** and set its value to **NY**, then when you choose this option, the value of **Site** will remain as **SA**, but the inheritance state will be changed to **Overridden** for network 10.0.0.0/16; however, network 10.0.0.0/24 will still have its value as **SA** for **Site** with the inheritance state set to **Inherited**.

- **Inherit the parent's value and change the inheritance state to Inherit:** Select this to inherit the extensible attribute values from the parent for all descendants. The inheritance state for all descendants will be set to **Inherited**.
- **Change the inheritance state to Inherit only if the descendant's value is the same as the parent's value. Otherwise, change the state to Override:** Select this to set the inheritance state to **Inherit** if the descendants have the same extensible attribute value as the parent. Otherwise, retain the original extensible attribute value on the descendants and change the inheritance state to **Overridden**.

When adding an extensible attribute that does not exist on a descendant:Do not inherit the value from the parent and change the inheritance state to Not Inherited: Select this if the extensible attributes do not exist on the descendants and you do not want them to inherit the attributes from the parent. The inheritance state is set to **Not inherited**.

- **Inherit the value from the parent and change the inheritance state to Inherited:** Select this if you want all descendants to inherit extensible attributes from the parent, and the inheritance state for all descendants will be set to **Inherited**.

When deleting an extensible attribute:

- **Keep the descendant's value and change the inheritance state to No Parent:** Select this if you want to preserve extensible attributes on all descendants when you delete an inheritable extensible attribute. The inheritance state for direct descendants will be set to **No Parent**.
- **If the current inheritance state is Inherited, remove the extensible attribute. If the current inheritance state is Overridden, keep the value and change the inheritance state to No Parent:** Select this if you want to remove the extensible attributes that are inherited by the descendants. If the inheritance state of the extensible attributes is set to **Inherited** on the descendant, the attributes will be removed; however, if the inheritance state is set to **Overridden**, then the state will be changed to **No Parent**.

3. Save the configuration.

For more information about how to configure inheritable extensible attributes, see *Configuration Examples for Inheritable Extensible Attributes.*

Admin Permissions and Inheritable Extensible Attributes

Permissions for descendant objects can affect the results of the actions that are chosen in the *Descendant Actions* dialog box:

- When you add an extensible attribute to the parent object: The descendants to which you have read-write permission will behave as expected with any of the chosen options in the *Descendant Actions* dialog box.
- When you change the extensible attribute value on the parent object: The descendants that have the same extensible attribute set to **Inherited** will be automatically changed to the new value, even though you may not have write permission for those descendants.
- When you select to preserve descendant values while removing an extensible attribute associated with the parent object, values will be preserved even if you do not have write read-write permission for those descendants.
- When you select to remove an extensible attribute on descendants when removing a parent's extensible attribute, an error message will be displayed if you do not have read-write permission to some of the descendants.

Guidelines for Configuring Inheritable Extensible Attributes

- When you add an inheritable extensible attribute to a parent object, you can choose to have descendants inherit or override the parent's extensible attribute value. You can also choose that the extensible attribute not be added to a descendant.
- When you add a new parent with an inheritable extensible attribute, the options for changes to descendants remain the same as when you add a new inheritable extensible attribute to a parent. For more information, see Configuring Inheritable Extensible Attributes above.
- When you add a new descendant to the existing parent with inheritable attributes, the descendant inherits all the extensible attributes. However, you can select if you want to inherit or override the values. If you set the inheritance state to **Not Inherited**, then the extensible attribute will not exist on the descendant, but you can later change the state to **Inherited** or **Overridden**. For more information, see Managing Inheritable Extensible Attributes at the Parent and Descendant Level below.

- When you delete an inheritable extensible attribute associated with the parent, you can either preserve the extensible attribute values on the descendants or delete the inherited extensible attributes. For more information, see Deleting Inheritable Extensible Attributes Associated with Parent Objects below.
- When you delete a parent object and if there is grandparent, then the extensible attribute will be re-parented when you choose preserve. The current inheritance state of the attribute will be retained. If you delete a parent object and if there is no grandparent, then the inheritance state of the extensible attribute is changed to **No Parent** when you choose preserve.
- When you split a network, the extensible attribute will be copied to the newly created networks. For inheritable extensible attributes, the newly created network inherits the extensible attributes and the state is set to **Inherited.** For more information, see Managing Inheritable Extensible Attributes at the Parent and Descendant Level below.
- When you join two networks to form a larger network, the *Descendant Actions* dialog box is displayed with the following options:
  When joining networks, select the action(s) you want to apply to the merged networks:
  - **Preserve extensible attributes for all descendants of the merged networks and change the inheritance state to No Parent:** Select this if you want to preserve the extensible attributes for all descendants of the merged networks. The inheritance state of the attributes will be changed to **No Parent**.
  - **Remove extensible attributes from descendants of the merged networks**: Select this if you want to remove extensible attributes that are inherited by descendants.
    Note that the options above apply only to extensible attributes which no longer have a parent, due to the merge. If the extensible attributes on descendants are also on the resulting merged network, then they will retain their current state.
    When you add multiple inheritable networks, new networks will automatically inherit all extensible attributes from the parent.

Managing Inheritable Extensible Attributes at the Parent and Descendant Level

You can define if descendants will inherit values from the parent when a new extensible attribute is added to the parent. You can also choose to override the values of the extensible attributes on the descendants.
When you delete an existing attribute, you can choose to either preserve the values at the descendant level or delete the values inherited by the descendants.

> ⚠ Note
> The *Descendant Actions* dialog box is displayed only when an object has descendants and you are modifying extensible attributes that affects those descendants. However, the dialog box is always displayed when a join is performed for a network that has inheritable extensible attributes.

The following section describes configuration changes for inheritable extensible attributes:

1. **Network** Container: From the **Dashboards** tab, select the **Tasks** tab -> click **Add Networks**. Select a network, enter the required details. You can edit the inheritable extensible attributes that are displayed automatically. If this is a parent object, then you can add extensible attributes.
   IPv4 Network: From the **Data Management** tab -> select the **DHCP** tab -> Networks tab. In the Networks section, select **IPv4 Network** from the Add drop-down menu. In the *Add IPv4 Network* wizard, enter the attributes in the **Extensible Attributes** tab after specifying the required details.
   IPv6 Network: From the **Data Management** tab -> select the **DHCP** tab -> **Networks** tab. In the **Networks** section, select **IPv6 Network** from the Add drop-down menu. In the *Add IPv6 Network* wizard, enter the attributes in the **Extensible Attributes** tab after specifying the required details.
   IPv4 Range: From the **Data Management** tab > select the **DHCP** tab -> **Networks** tab -> **Networks** tab -> network > click addr_range, select **Range** from the Add drop-down menu. In the *Add IPv4 Range* wizard, enter the attributes in the **Extensible Attributes** tab after specifying the required details.
   IPv6 Range: From the **Data Management** tab > select the **DHCP** tab -> **Networks** tab -> **Networks** tab -> network > click addr_range, select **Range** from the Add drop-down menu. In the *Add IPv6 Range* wizard, enter the attributes in the **Extensible Attributes** tab after specifying the required details.
   Zones: From the **Data Management** tab > select the **DNS** tab - > **Zones** tab - > click Add. In the *Add Zone* wizard, enter the attributes in the **Extensible Attributes** tab after specifying the required details.
   DNS View: From the **Data Management** tab > select the **DNS** tab - > In the toolbar select Add - > Select **DNS View**. In the *Add DSN View* wizard, enter the attributes in the **Extensible Attributes** tab after specifying the required details.

Host: From the **Data Management** tab > select the **DNS** tab - > **Zones** tab - > click Add. In the Add section, select **Host** or **Bulk Host** from the Add drop-down menu. In the *Add DNS View* wizard, enter the attributes in the **Extensible Attributes** tab after specifying the required details.
Record: From the **Data Management** tab > select the **DNS** tab - > **Zones** tab - > click Add. In the Add section, select **Record** from the Add drop-down menu select the record type. In the *Add DNS View* wizard, enter the attributes in the **Extensible Attributes** tab after specifying the required details.
VLAN Range: From the Data Management tab > select the **VLANs** tab - > click Add, select **VLAN Range** from the Add drop-down menu. In the *Add VLAN Range Wizard,* enter the attributes in the **Extensible Attributes** tab after specifying the required details.
VLANs: From the Data Management tab > select the **VLANs** tab - > click Add, select **VLAN** from the Add drop-down menu. In the *Add VLAN* wizard*,* enter the attributes in the **Extensible Attributes** tab after specifying the required details.

2. You can either add new extensible attributes to the parent object or modify original extensible attribute values. Click on the extensible attribute value displayed in the **Value** column of the respective attribute to modify the original value or click the Add icon to add a new attribute.
3. Select a state from the drop-down list displayed in the **Inheritance State** column. Note that you can only change the inheritance state of a descendant. You must select **Overridden** from the drop-down list to enter a new value. For more information about inheritance states, see Inheritance States table below. When an object has a parent and the parent does not have the object's inheritable extensible attribute, then the inheritance state of the extensible attribute is set to **No Parent** and the state cannot be changed.
4. **Select the inheritable extensible attributes for which you want to modify descendant actions:** Select this checkbox if you would like to apply the actions of the *Descendant Actions* dialog box for existing extensible attributes. Before you select this checkbox, you must select the extensible attributes which will be affected by the actions of the *Descendant Actions* dialog box.
Note this checkbox is not displayed for hosts, fixed addresses, and reservations since they do not have descendants.
5. In the *Descendant Actions* dialog box, select options that will be applied for descendant objects as described in Configuring Inheritable Extensible Attributes.
The *Descendant Actions* dialog box displays all the mentioned options when you perform add and delete operations simultaneously. Consider an example where you add a new inheritable extensible attribute **Site**, and delete an existing inheritable attribute **Region** from the parent object, and then click **Save** to save both changes. In this case, the *Descendant Actions* dialog box displays all the options.
6. Save the configuration.

Viewing Extensible Attributes

To view the configured extensible attributes, from the **Administration** tab, select the **Extensible Attributes** tab. The panel displays the following information:

- **Name**: The name of the extensible attribute.
- Type: The type of data defined by the attribute.
- **Comment**: Comments entered for the extensible attribute.
- Required: Indicates whether users are required to complete this field.
- Restricted to Objects: The object types that are associated with the attribute.
- **Inheritance Enabled:** Indicates whether inheritance is enabled or not. You can do the following in this panel:
- Sort the displayed data in ascending or descending order by column.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*
- Group results by extensible attributes. For more information, see Grouping Results by Extensible Attributes below.
- Add or delete extensible attributes.
- Print or export the data.

Modifying Extensible Attributes

When you modify an extensible attribute, all objects using the modified attributes are updated. You can perform inline editing by double-clicking the row of data that you want to modify. The appliance displays the inline editing editor in the selected row. Click **Save** after modifying the data. Note that you cannot edit extensible attributes that have multiple values.
To modify an extensible attribute:

1. In the **Administration** tab, select the **Extensible Attributes** tab.
2. Select the attribute and click the Edit icon.
3. In the **General** tab of the *Extensible Attributes* editor, you can only change the name of the attribute. You cannot change the data type. The data type for predefined attributes is string.
4. In the **Additional Properties** tab, you can modify any of the fields described in step 4 of Adding Extensible Attributes.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Modifying Inheritable Extensible Attributes

When values are inherited by a descendant, the inheritance state of the inherited extensible attribute is displayed as **Inherited**. You can select **Overridden** and specify a new value or select **Inherited** to retain the same value as the parent. If you select **Not Inherited**, the extensible attribute and its value will not be inherited. The inherited value will have a strike-through and you cannot edit the value when the state is set to **Not Inherited**.
In addition to the attribute values, the **Value** column of an inheritable extensible attribute also displays the name of the source and the object type of the extensible attribute. For example, a *Network Container* has a descendant, *Network,* which inherits an extensible attribute value from *Network Container* and *Network* has a descendant, *Fixed Address* that inherits the same extensible attribute value. In this case, *Fixed Address* shows *Network Container* as the source.

The following table displays various inheritance states and corresponding changes to source and object types that are displayed in the **Value** column of an extensible attribute.

Inheritance State	Source and Object Type in the Value Column
If an extensible attribute is a native attribute (an object which is at the top of the inheritance chain, or does not have ancestors),	**Source** is not displayed in the **Value** column. This column will not display the source details, if none of the selected objects support inheritance.
If the state of an extensible attribute is set to **Inherited,**	then the **Source** and object is displayed. You cannot change the value of the extensible attribute.
If the state of an extensible attribute is set to **Overridden** or **Not Inherited,**	then the **Source** will have a strike-through. You can change the state of such extensible attributes. You cannot change the value of the extensible attribute when the inheritance state is set to **Not Inherited**.

To modify the value and inheritance state of an inheritable extensible attribute:

1. **For IPv4 and IPv6 Network**: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** → *network* -> *addr_range* checkbox, and then click the Edit icon.
   For IPv4 Range, IPv6 Range, Fixed Address, Reservation, and Host: From the **Data Management** tab > select the **DHCP** tab -> **Networks** tab -> **Networks** tab -> *network* > click *addr_range,* click the Edit icon.
   For DNS View: From the **Data Management** tab, select the **DNS** tab - > **Zones** tab - > select the checkbox of the **DNS View** - > click the Edit icon.
   For VLANs: From the **Data Management** tab, select the **VLAN** tab - > select the checkbox of the **VLAN Range / VLAN** - > click the Edit icon.
2. In the editor, click the **Extensible Attributes** tab, select the checkbox of the respective attribute.
3. At the parent level, click on the value you want to change and enter the new value.
   At the descendant level, click on the value you want to change and enter the new value. Note that you can change the value only when the inheritance state is set to **Overridden**.

4. Select a state from the drop-down list displayed in the **Inheritance State** column. Note that you can only change the inheritance state of a descendant. You must select **Overridden** from the drop-down list to enter a new value. For more information, see Inheritance States table above.
5. **Select the inheritable extensible attributes for which you want to modify descendant actions:** Select this checkbox if you would like to apply the actions of the *Descendant Actions* dialog box for existing extensible attributes. Before you select this checkbox, select the extensible attributes which will be affected by the actions of the *Descendant Actions* dialog box. For more information about the *Descendant Actions* dialog box, see Managing Inheritable Extensible Attributes at the Parent and Descendant Level above.
6. Save the configuration.

Deleting Extensible Attributes

When you delete an extensible attribute, the appliance removes the attribute. All the attribute values set on the selected object types are removed from those objects. Once deleted, the attribute no longer exists in the system. Deleted attributes are not moved to the Recycle Bin. This operation might take a long time depending on the amount of data that needs to be deleted.
To delete extensible attributes:

1. In the **Administration** tab, select the **Extensible Attributes** tab.
2. Select the attribute and click the Delete icon.
3. When the confirmation dialog box appears, click **Yes**.

Deleting Inheritable Extensible Attributes Associated with Parent Objects

When you remove an inheritable extensible attribute, which is associated with a parent object, you can choose to retain the descendant extensible attribute or remove it from all the descendants.
Note that you cannot delete extensible attributes that have the inheritance state set to **Overridden**, **Inherited**, and **Not Inherited**. You can delete an extensible attribute that is directly assigned to the object and has its inheritance state set to **No Parent** or if the inheritance state is **Disabled**.
To remove an inheritable extensible attribute associated with a parent object:

1. **IPv4 and IPv6 Network**: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *addr_range* checkbox, and then click the Edit icon.
   For IPv4 Range, IPv6 Range, Fixed Address, Reservation, and Host: From the **Data Management** tab **DHCP** -> tab -> **Networks** tab -> **Networks** tab -> network > click *addr_range,* select the object and click Edit icon.
   For DNS View: From the **Data Management** tab, select the **DNS** tab - > **Zones** tab - > select the checkbox of the **DNS View** - > click the Edit icon.
   For VLANs: From the **Data Management** tab, select the **VLAN** tab - > select the checkbox of the **VLAN Range / VLAN** - > click the Edit icon.
2. In the editor, click the **Extensible Attributes** tab, select the attributes and then click the Delete icon.
3. When you click **Save and Close**, the *Descendant Actions* dialog box is displayed automatically with the following options:
   Select the action(s) you want to apply to descendant objects that have the following extensible attribute(s):
   When deleting an extensible attribute:
   - **Keep the descendant's value and change the inheritance state to No Parent:** Select this if you want to preserve extensible attributes for all descendants. The inheritance state of the extensible attribute changes to **No Parent**.
   - **If the current inheritance state is Inherited, remove the extensible attribute. If the current inheritance state is Overridden, keep the value and change the inheritance state to No Parent:** Select this if you want to remove the extensible attributes that are inherited by the descendants. If the inheritance state of the extensible attributes is set to Inherited on the descendant, the attributes will be removed; however, if the inheritance state is set to Overridden, then the state will be changed to No Parent.
4. Click **Yes** to save the configuration or **No** to exit.

> ⚠ Note
> The deleted extensible attributes will not be moved to the Recycle Bin and you cannot restore extensible attributes that are deleted.

After a superuser admin configures the attributes of an object, they become available in the wizard and editor of the object. This section describes how users can then add and manage the attributes that were configured.
Grid Manager displays the required extensible attributes in the **Extensible Attribute** tab. You must enter values for all required attributes. If an object does not have required attributes, you can add the available optional attributes.
In the **Extensible Attribute** tab of an object, such as a network or host record, you can do the following:

- Enter values for extensible attributes
- Add attributes
- Change the inheritance state of an extensible attribute
- Select if descendants must inherit extensible attribute values from its parent
- Delete optional attributes

To enter values for the extensible attributes of an object:

1. Open the editor of the object. For example, to enter values for the attributes of a network, select it and click its **Extensible Attributes** tab.
2. Click the Value column of the attribute. You must enter values for all required attributes.
3. Depending on the required attribute type, either enter or select a value for the attribute from the Value column.
4. Based on whether the attribute is inheritable, the values are displayed in the **Inheritance State** column. This value can be set to **Inherited**, **Overridden** or **Not inherited**. If the object is at the top of the inheritance chain (Network View), then the inheritance state is not displayed. The inheritance state is set to **No Parent** only if an object has a parent, but the parent does not have the inherited extensible attribute. This column is not displayed if all selected objects do not belong to the supported inheritance chain. Example: Zones, DNS View, DNS records, etc.

To add attributes:

1. Click the Add icon. Grid Manager adds a row to the table with the default attribute displayed.
2. Click the default attribute and expand the list of available attributes.
3. Select an attribute from the drop-down list.
4. Enter or select a value for the attribute from the Value column. To delete an attribute:
5. Click the checkbox beside the attribute you want to delete.
6. Click the Delete icon.

> ⚠ Note
> You cannot delete an extensible attribute which has its inheritance state set to **Inherited**, **Overridden**, and **Not Inherited**. You can delete an extensible attribute that is directly assigned to the object and has its inheritance state set to **No Parent** or if the inheritance state is **Disabled**.

To delete all attributes:

1. Click the **Attribute Name** checkbox.
2. Click the Delete icon.
   Note that you can delete only attributes that are not required. If you have one or more required attributes, you cannot use the delete all function.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Editing Multiple Extensible Attribute Values

You can also manage the extensible attributes of multiple objects at the same time. For example, you can select several zones, and view and modify their extensible attributes all at once in the *Multi-Select Edit Extensible Attributes* editor. Note that Grid Manager may not apply the changes you made to all the selected objects. It applies the change to objects that meet the following criteria:

- You have read/write permission to the object.
- The selected object is not locked by another user or does not have a scheduled pending task.
- If the attribute was restricted to certain object types, the object must be one of those types. To edit multiple extensible attribute values:

1. Select the objects whose extensible attributes you want to modify. You can select specific objects or select all objects in a dataset, as described in *Selecting Objects in Tables*.

2. Expand the Toolbar and click **Extensible Attributes**.
   Grid Manager displays the *Multi-Select Edit Extensible Attributes* dialog box which lists the extensible attributes of the selected objects. It displays the following information for each attribute:
   - **Attribute Name**: This field displays the name of the extensible attribute associated with the selected object.
   - **Value**: If the selected objects have the same value for the attribute, Grid Manager displays that value in this field. If the selected objects have different values for the attribute or if some have values and others do not, this field displays **Multiple Values** and the cell is highlighted in gray.
     An attribute can have multiple rows if it allows multiple values. Grid Manager displays the values that all objects have in common, if any. Otherwise, it displays **Multiple Values**. This column displays the source for inherited extensible attributes only. Note that when you add new extensible attributes, edit values of existing extensible attributes or delete an extensible attribute, then the *Descendant Actions* dialog box is displayed, even if the objects do not have any descendants. For more information about Source values, see Modifying Inheritable Extensible Attributes above.
   - If you select objects that have the same inherited extensible attributes, but objects have different parents, then the **Source** column will display **Multiple Ancestors**.
   - If the inheritance state of an extensible attribute is **Not Inherited**, then the extensible attribute will not be added as a new extensible attribute to objects that are currently not inheriting this extensible attribute.
   - **Inheritance State:** This field displays the inheritance state of an extensible attribute. The column value can be **Inherited**, **Not Inherited**, **No Parent**, **No Change** or **Overridden**. This column is not displayed if all selected objects do not belong to the supported inheritance chain. Example: Zones, DNS View, DNS records, etc.
     If extensible attributes for the selected objects have the same inheritance state, then the respective inheritance state is displayed in this column. When objects have different inheritance states, this column displays **No Change**, so that the current inheritance state is retained on the selected objects. If you then change the inheritance state of an extensible attribute to a specific state, the corresponding attribute will be changed to the selected inheritance state on all selected objects where the extensible attribute is currently inherited. If the object is at the top of the inheritance chain (Network View), then the inheritance state is not displayed. The inheritance state is set to **No Parent** only if an object has a parent, but the parent does not have the inherited extensible attribute. For more information about inheritance states, see Inheritance States table above.
   - **Required**: This field displays **Yes** if the attribute is required in at least one object associated with the attribute. It displays **No** if the attribute is not required in any of the objects.
3. You can do the following:
   - Change the value of an attribute. Depending on the attribute type, select the value and either enter a new value or select one from the drop-down list.
   - Add an attribute to the selected objects. Click the Add icon. In the **Attribute Name** field of the new row, select an attribute from the list of available attributes and specify its value. If the attribute that you added was configured as a required attribute, the **Required** field displays **Yes**. Otherwise, it displays **No**.
   - Delete an attribute. You can delete an attribute if it is not required. Select the attribute and click the Delete icon.
4. Click **OK** when you are finished modifying the extensible attributes.

Grid Manager applies your changes to the applicable objects. This operation might take a long time, depending on the amount of data being modified. You can choose to run this operation in the background, as described in *Tasks Dashboard*.

Grouping Results by Extensible Attributes

You can enable the appliance to group members and services with the same extensible attributes. Grid Manager displayed group data with the same value for the specified extensible attribute.
To group results by extensible attributes:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab or **Services** tab.
   From the **Data Management** tab, select the **DHCP** or **DNS** tab -> **Members/Servers** tab.
2. Complete the following to group members with the same extensible attribute value:
   - **Group Results**: Select this checkbox to enable the appliance to group members by extensible attributes.
   - **Group By**: Select an extensible attribute by which you want to group members from the drop-down list. Grid Manager displays data per group of members configured with the same extensible attribute value.

To add additional Group By filter, click the + icon, and then select a value from the drop-down list. You can apply up to 10 Group By filters. You can also delete a filter by clicking the - icon.

- **Do not inherit the value from the parent and change the inheritance state to Not Inherited:** Select this if the extensible attributes do not exist on the descendants and you do not want them to inherit the attributes from the parent. The inheritance state is set to **Not inherited**.
- **Inherit the value from the parent and change the inheritance state to Inherited:** Select this if you want all descendants to inherit extensible attributes from the parent, and the inheritance state for all descendants will be set to **Inherited**.

Configuration Examples for Inheritable Extensible Attributes

All examples in this section are based on the inheritance chain Network View -> Network Container -> Network -> Range -> Host/Fixed Address/Reservation, in which network view is at the top level and host, fixed address and reservation at the bottom of the inheritance chain.

Example 1

When you add an extensible attribute to the top object, the inheritance state is set to **No Parent**. For example, if you add a new inheritable extensible attribute, **Building**, to a network view, the inheritance state of this extensible attribute is set to **No Parent** for the network view.

Example 2

When you add an extensible attribute **Site** to the parent object **Network** that has a descendant **Range,** you can define **Site** as inheritable and add it to the **Network.** The descendant, **Range**, may or may not have the same extensible attribute. Infoblox displays a list of options that lets you either inherit the value or retain or override the existing value of the extensible attribute at the descendant level. Another option is to inherit the value of **Site**, only if the value for this attribute in **Range** is same as that in **Network**. You can also decide if **Range** should acquire the same value for **Site**, if it is not defined for **Range**. This change can be inherited by the descendants of **Range**.
Depending on your configuration, the inheritance state of the extensible attribute can display **Inherited**, **Overridden or Not Inherited**. If the object is at the top of the inheritance chain (Network View), then the inheritance state is not displayed. The inheritance state is set to **No Parent** only if an object has a parent, but the parent does not have the inherited extensible attribute.

Example 3

Examples in this section show different results when you add a new inheritable extensible attribute to an object located at the top or in the middle of the inheritance chain based on the following:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container			
10.0.0.0/16	Network	Region	ABC	Native
10.1.0.0/16	Network			

Example 3.1: Add an extensible attribute Region with value DEF to 10.0.0.0/8

You select the following options for the existing extensible attribute:

- For descendants that already have this extensible attribute, the existing extensible attribute will always be set to **Inherit**.
- For descendants that do not have this extensible attribute, the descendants will inherit this extensible attribute.

Result:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Region	DEF	Native
10.0.0.0/16	Network	Region	DEF	Inherited from 10.0.0.0/8
10.1.0.0/16	Network	Region	DEF	Inherited from 10.0.0.0/8

Example 3.2: Add an extensible attribute Region with value DEF to 10.0.0.0/8

You select the following options for the existing extensible attribute:

- For descendants that already have this extensible attribute, the existing extensible attribute will always be set to **Override**.
- For descendants that do not have this extensible attribute, the descendants will not inherit this extensible attribute (extensible attribute is set to **Do not Inherit**).

Result:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Region	DEF	Native
10.0.0.0/16	Network	Region	ABC	Overridden
10.1.0.0/16	Network	Region		

Example 3.3: Add an extensible attribute Region with value DEF to 10.0.0.0/8 8

You select the following options for the existing extensible attributes:

- For descendants that already have this extensible attribute, the existing extensible attribute will always be set to **Inherit**.
- For descendants that do not have this extensible attribute, the descendants will not inherit this extensible attribute (extensible attribute is set to **Do not Inherit**).

Result:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Region	DEF	Native
10.0.0.0/16	Network	Region	DEF	Inherited, Source 10.0.0.0/8
10.1.0.0/16	Network	Region		

Example 4

Examples in this section show different results when you remove an existing inheritable extensible attribute from an object located at the top or in the middle of the inheritance chain based on the following:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Region	DEF	Native
10.0.0.0/16	Network	Region	DEF	Inherited from 10.0.0.0/8
10.1.0.0/16	Network	Region	ABC	Overridden

Example 4.1: Remove extensible attribute Region with value DEF from 10.0.0.0/8

You select the following option for the existing extensible attribute:

- Remove extensible attributes with inheritance state set to **Inherited**. Extensible attributes with the state set to **Overridden** are not removed.

Result:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Region		
10.0.0.0/16	Network	Region		
10.1.0.0/16	Network	Region	ABC	Overridden

Example 4.2: Remove extensible attribute Region with value DEF from 10.0.0.0/8 You select the following option for the existing extensible attribute:

- Preserve all descendant extensible attributes, whether the state is set to **Inherited** or **Overridden**. **Result**:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container			
10.0.0.0/16	Network	Region	DEF	Native
10.1.0.0/16	Network	Region	ABC	Native

Example 5

Examples in this section show different results when you remove parent object based on the following:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Region	DEF	Native
10.0.0.0/16	Network Container	Region	DEF	Inherited from 10.0.0.0/8
10.1.0.0/24	Network	Region	DEF	Inherited from 10.0.0.0/8
10.1.0.0/24	Network	Region	ABC	Overriden
10.10.0.0/16	Network Container	Region	GHI	Overriden
10.10.0.0/24	Network	Region	GHI	Inherited from 10.10.0.0/16
10.10.0.0/24	Network	Region	JKL	Overridden

Example 5.1: Removing object 10.0.0.0/8 from the parent level You select the following option for the existing extensible attribute:

- Remove extensible attributes with the inheritance state set to **Inherited**. Extensible attributes with the state set to **Overridden** are not removed.

Result:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/16	Network Container			
10.0.0.0/24	Network			
10.0.1.0/24	Network	Region	ABC	Overridden
10.10.0.0/16	Network Container	Region	GHI	Overridden
10.10.0.0/24	Network	Region	GHI	Inherited from 10.10.0.0/16
10.10.1.0/24	Network	Region	JKL	Overridden

Example 5.2: Removing object 10.0.0.0/8 from the parent level
You select the following option for the existing extensible attribute on descendants:

- Preserve all extensible attributes on the descendant.

Result:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/16	Network Container	Region	DEF	Native

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/24	Network	Region	DEF	Inherited from 10.0.0.0/16
10.0.1.0/24	Network	Region	ABC	Overridden
10.10.0.0/16	Network Container	Region	GHI	Native
10.10.0.0/24	Network	Region	GHI	Inherited from 10.10.0.0/16
10.10.1.0/24	Network	Region	JKL	Overridden

Example 5.3: Remove object 10.10.0.0/16 from the parent level
You select the following option for the existing extensible attribute on descendants:

- Remove extensible attributes with the inheritance state set to **Inherited**. Extensible attributes with the state set to **Overridden** are retained.

Result:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Region	DEF	Native
10.0.0.0/16	Network Container	Region	DEF	Inherited from 10.0.0.0/8
10.0.0.0/24	Network	Region	DEF	Inherited from 10.0.0.0/8
10.0.1.0/24	Network	Region	ABC	Overridden
10.10.0.0/24	Network	Region		
10.10.1.0/24	Network	Region	JKL	Overridden

Example 6
Examples in this section show different results after you add an object in the middle of the inheritance chain based on the following:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Owner	Admin	Native
10.0.0.0/16	Network Container	Owner	Admin	Inherited from 10.0.0.0/8
10.0.0.0/24	Network	Owner	Admin	Inherited from 10.0.0.0/8

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.1.0/24	Network	Owner	Joe	Overridden
10.10.0.0/24	Network	Owner	Admin	Inherited from 10.0.0.0/8
10.10.1.0/24	Network	Owner	Annie	Overridden

Example 6.1: Adding object 10.10.0.0/16 without extensible attributes You select the following option for the existing extensible attribute:

- Retain values if the extensible attribute already exists, and inherit the attribute from the parent object if it does not exist.

Result:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Owner	Admin	Native
10.0.0.0/16	Network Container	Owner	Admin	Inherited from 10.0.0.0/8
10.0.0.0/24	Network	Owner	Admin	Inherited from 10.0.0.0/8
10.0.1.0/24	Network	Owner	Joe	Overridden
10.10.0.0/16	Network Container	Owner	Admin	Inherited from 10.0.0.0/8
10.10.0.0/24	Network	Owner	Admin	Inherited from 10.0.0.0/8
10.10.1.0/24	Network	Owner	Annie	Overridden

Example 7
Examples in this section show different results after you modify inheritable extensible attributes with multiple values based on the following:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container			
10.0.0.0/16	Network Container	Region	MNO	Native
		Region	PQR	Native

Example 7.1: Adding extensible attribute Region with value GHI to 10.0.0.0/8 You select the following option for the existing extensible attributes:

- The descendants that already have this extensible attribute will inherit the value from the parent object.

Result: Multiple values will be replaced with the single inherited value.

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Region	GHI	Native
10.0.0.0/16	Network Container	Region	GHI	Inherited from 10.0.0.0/8

Example 7.2: Adding extensible attribute Region with value GHI to 10.0.0.0/8 You select the following option for the existing extensible attributes:

- The descendants that already have this extensible attribute will override the value.

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Region	GHI	Native
10.0.0.0/16	Network	Region	DEF	Overridden
		Region	ABC	Overridden

Example 8

Examples in this section show different results after you modify existing inheritable extensible attribute of an object, but you do not have required permission to modify some descendants. For information about admin permissions, see *About Administrative Permissions*.

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State	Permission
10.0.0.0/8	Network Container	Owner	Sam	Native	Write
10.0.0.0/16	Network Container	Owner	Sam	Inherited from 10.0.0.0/8	Read
10.0.0.0/24	Network	Owner	Sam	Inherited from 10.0.0.0/8	Read
10.0.1.0/24	Network	Owner	Bob	Overridden	Write

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State	Permission
10.10.0.0/16	Network Container	Owner	John	Inherited from 10.0.0.0/16	Read
10.10.1.0/24	Network	Owner	Max	Overridden	Read
10.20.0.0/16	Network Container	Owner	Sam	Inherited from 10.0.0.0/8	Write
10.20.0.0/24	Network	Owner			Read
10.20.1.0/24	Network	Owner			Read

Example 8.1: Removing object 10.0.0.0/8

You select the following option for the existing inheritable extensible attribute:

- Retain extensible attribute values on descendants that are inherited from this parent object.

Result:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State	Permission
10.0.0.0/16	Network Container	Owner	Sam	Native	Read
10.0.0.0/24	Network	Owner	Sam	Native	Read
10.0.1.0/24	Network	Owner	Bob	Overridden	Write
10.10.0.0/16	Network Container	Owner	John	Overridden	Read
10.10.0.0/24	Network	Owner	John	Inherited from 10.10.0.0/16	Read
10.10.1.0/24	Network	Owner	Max	Overridden	Read
10.20.0.0/16	Network Container	Owner	Sam	Native	Write
10.20.0.0/24	Network				Read
10.20.1.0/24	Network				Read

Example 8.2: Removing object 10.0.0.0/8
You select the following option for the existing inheritable extensible attribute:

- Remove extensible attribute values from descendants that are inherited from this parent object.

The appliance displays an error message when you remove an extensible attribute that is associated with a descendant for which you do not have required permission.
Result:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State	Permission
10.0.0.0/16	Network Container				
10.0.0.0/24	Network				
10.0.1.0/24	Network	Owner	Bob	Overridden	Write
10.10.0.0/16	Network Container	Owner	John	Overridden	Read
10.10.0.0/24	Network	Owner	John	Inherited from 10.10.0.0/16	Read
10.20.0.0/16	Network	Owner	Max	Overridden	Read
10.20.0.0/24	Network Container				Write
10.20.1.0/24	Network				Read

Example 9

Examples in this section show different results after you join multiple networks, based on the following:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.1.0.0/16	Network	Owner	John	Native
10.1.0.1	Fixed Address	Owner	John	Inherited from 10.1.0.0/16
10.2.0.0/16	Network	Owner	Sam	Native
10.2.0.1	Fixed Address	Owner	Jane	Overridden

Example 9.1: Joining networks 10.0.0.0/8 with 10.1.0.0/16
You select the following option for the existing extensible attribute:

- Join networks 10.0.0.0/8 with 10.1.0.0/16.

Result:

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Owner	John	Native
10.1.0.1	Fixed Address	Owner	John	Inherited from 10.0.0.0/8
10.2.0.1	Fixed Address	Owner	Jane	Overridden

Example 9.2: Joining networks 10.0.0.0/8 with 10.2.0.0/16
You select the following option for the existing extensible attribute:

- Join networks 10.0.0.0/8 with 10.2.0.0/16.

Object	Type	Extensible Attribute	Extensible Attribute Value	Inheritance State
10.0.0.0/8	Network Container	Owner	Sam	Native
10.1.0.1	Fixed Address	Owner	Sam	Inherited from 10.0.0.0/8
10.2.0.1	Fixed Address	Owner	Jane	Overridden

Managing Security Operations

The Grid provides certain security-related features. The following sections describe the different security-related features that you can set.

Restricting Remote Console Access

You can restrict admins from accessing the Infoblox CLI from a remote location using an SSH (Secure Shell) v2 client. When you select this only admins who have access rights will be able to access the Infoblox CLI using an SSH (Secure Shell) v2 client. By default, this option is disabled.

Restricting GUI/API Access

You can specify the IP addresses from which administrators are allowed to access the NIOS appliance. When the NIOS appliance receives a connection request, it tries to match the source IP address in the request with IP addresses in the list. If there is at least one item in the HTTP Access Control list and the source IP address in the request does not match it, the NIOS appliance ignores the request.

Caution: If you specify an address or network other than the one from which you are currently accessing the appliance, when you save your configuration, you will lose your administrative session and be unable to reconnect. If you have enabled the **Enable GUI/API Access via both MGMT and LAN1/VIP** feature and configured ACLs to control access to the

GUI and API, then the same set of ACLs are applicable on both the interfaces (LAN1 and MGMT port). For information, see *Enabling GUI and API Access on the MGMT and LAN1/VIP Ports* and Configuring Security Features below.

Enabling HTTP Redirection

You can enable the NIOS appliance to redirect administrative connection requests using HTTP to the secure HTTPS protocol. When you disable redirection, the NIOS appliance ignores any administrative connection requests not using HTTPS. By default, the NIOS appliance does not redirect HTTP connection requests to HTTPS. When you change this setting, the application restarts and your management session terminates.

Modifying the Session Timeout Setting

You can set the length of idle time before an administrative session to the Infoblox GUI times out. The default timeout value is 600 seconds (10 minutes).
If a user does not interact with the application for the specified time, the appliance displays a message that a timeout has occurred. Click **OK** to restart the GUI session. Note that the session timeout is not honored when the Infoblox GUI supports auto-refresh. This means that the Infoblox interface page is automatically refreshed even after you have set the session timeout value.

Warning

If the *Detailed Status Panel* is open, the following actions take place:

- Grid Manager auto refreshes at a rate of 30 seconds.
- Widgets that support user-specified auto refresh, refresh at the rate specified in the **Auto Refresh Period** field.

Therefore, even if you set the session timeout to be greater than the auto refresh rate, auto refresh still takes place. The Grid Manager session does not time out because auto refresh takes precedence over the session timeout. For more information about widgets, see *Status Dashboard*.

Note

If you change the session timeout value, the new setting takes effect only after you log out and log back in.

Disabling the LCD Input Buttons

By default, the LCD input function is enabled, which allows you to use the LCD buttons on the front panel of a NIOS appliance to change the IPv4 address settings of the LAN port. You can disable this function if the appliance is in a location where you cannot restrict access exclusively to NIOS appliance administrators and you do not want anyone to be able to make changes through the LCD.

Configuring Security Features

You can manage only certain features at the member level. To configure security features for the Grid or an individual member:

1. **Grid:** From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then

click the Edit icon.
To override an inherited property, click **Override** next to it and complete the appropriate fields.

2. On the **Security** tab, complete the following:
    - **Session Timeout(s)**: This field is in the *Grid Properties* editor only. Enter a number between 60 and 31536000 seconds (one minute – one year) in the Session Timeout field. The default session timeout is 600 seconds (10 minutes).
    - **Minimum Password Length**: This field is in the *Grid Properties* editor only. Specify the minimum number of characters allowed for an admin password.
    - **Redirect HTTP to HTTPS**: This field is in the *Grid Properties* editor only. Select this option to have the appliance redirect HTTP connection requests to HTTPS.
    - **Restrict GUI/API Access**: To control access to the GUI and API, select one of the following. You can restrict access using a named ACL or define individual ACEs. For information about named ACLs, see *Configuring Access Control.*
        - **Allow Any**: Select this to allow any clients to access the GUI and API. This is selected by default.
        - **Named ACL**: Select this and click **Select Named ACL** to select a named ACL that contains only IPv4 and IPv6 addresses and networks. GUI and API access restriction does not support TSIG key based ACEs. When you select this, the appliance allows GUI and API access for all ACEs in the named ACL. You can click **Clear** to remove the selected named ACL.
        - **Set of ACEs**: Select this to configure individual access control entries (ACEs). Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding.
            - **IPv4 Address** and **IPv6 Address**: Select this to add an IPv4 address or an IPv6 address. Click the **Value** field and enter the IP address. The appliance allows this client to access the GUI and API and restricts others.
            - **IPv4 Network** and **IPv6 Network**: Select this to add an IPv4 network or IPv6 network. Click the **Value** field and enter the network. The appliance allows this network to access the GUI and API and restricts others.
            After you have added access control entries, you can do the following:
            - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
            - Reorder the list of ACEs using the up and down arrows next to the table.
            - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.
        - **Access Restrictions Apply to Remote Console**: Select this to restrict admins from accessing the Infoblox CLI from a remote location using SSH (Secure Shell) v2 client.
        - **Enable Remote Console Access**: Select this option to enable superuser admins to access the Infoblox CLI from a remote location using SSH (Secure Shell) v2 clients. You can set this at the Grid and member levels.
        - **Enable Support Access**: Select this checkbox to enable an SSH (Secure Shell) daemon that only Infoblox Technical Support can access. You can set this at the Grid and member levels.
        - **Restrict Remote Console and Support Access to the MGMT Port**: This field is in the *Grid Member Properties* editor only. Select this checkbox to restrict SSH (Secure Shell) v2 access to the MGMT port only. This restricts Infoblox Technical Support and remote console connections—both of which use SSH v2—to just the MGMT port. For an HA pair, you can make an SSH v2 connection to the MGMT port on both the active and passive node.
        Clear the checkbox to allow SSH v2 access to both the MGMT and LAN ports.
        - **Permanently Disable Remote Console and Support Access**: This field is in the *Grid Properties* editor only.
        Select this option to permanently disable remote console (Secure Shell v2) access for appliance administration and for Infoblox Technical Support.
        - **Enable LCD Input**: Select this checkbox to allow use of the LCD buttons on the front panel of a NIOS appliance to change the IP address settings of the LAN port. Clear this checkbox to disable this function. You can set this at the Grid and member levels.
        - **Disable Concurrent Login**: Select this checkbox to disallow multiple logins per user for the same NIOS session. That is, if you have already logged on to one NIOS session (for example https://

255.255.255.0) you cannot log on to the same IP address from another browser or from another system.
Note that before you disable multiple logins to a NIOS system, ensure that all its existing sessions (if any) are logged out. If not, the existing sessions continue to remain active even after you disable multiple logins.

- **Enable Account Lockout**: Select the checkbox to enable account lockout for the local user. You can enable password security such that if a local user tries to log in to Grid Manager by using an incorrect password, NIOS appliance locks the user account after the configured number of failed login attempts for a configured time period. Only superusers can enable and configure this feature. This feature is applicable only to local users. This option is disabled by default.
  - **Maximum number of attempts**: Enter the maximum number of invalid login attempts to Grid Manager after which NIOS locks the account. You can specify a value from **1** to **99.** The default value is **5**.
  - **Lockout duration**: Enter the time duration in minutes for which the account must be locked. You can specify a value from **1** to **1440**. The default value is **5 mins**.
  - **Never Unlock**: Select the checkbox to permanently lock a local user account which is already locked. Only a superuser can clear the checkbox to unlock the account. NIOS displays a warning message if you enable this option. This option is not applicable to superuser accounts because you cannot permanently lock a superuser account. This option is disabled by default.
    You can also configure account lockout for admin groups. For more information, see *Configuring Account Lockout for Admin Group*.
- **Disable Inactive Users**: Select this checkbox to disable users who have not logged in to NIOS for a specified period of time. You can specify the time period (in days) in the **Disable account if user has not logged in for <time period> days** field. The range of days is from 2 to 9999. You can also specify a reminder to be sent in the **Remind <days> prior to expiration** field. The range of days is from 1 to 30. The number of days you specify in this field is the time from which users start getting daily email reminders that their account will be disabled. NIOS sends the email reminder only if an email address has been configured for the user.
  Select the **Allow user to reactivate account via serial console** and **Allow user to reactivate account via remote console** checkboxes if you want users to activate their account after it has been disabled. To reactivate using the serial console, see *Deploying a Single Independent Appliance*. To reactivate using the remote console, type `ssh <user name>@<ip address>`.
  Note: Reactivating the account using the serial console or the remote console is possible only for superusers.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Enabling and Disabling Remote Console and Infoblox Technical Support Access

Infoblox Technical Support might need access to your NIOS appliance to troubleshoot problems. This function enables an SSH (Secure Shell) daemon that only Infoblox Technical Support can access. By default, this option is disabled. This function also makes it possible for a superuser admin to access the Infoblox CLI from a remote location using an SSH (Secure Shell) v2 client. The management system must have an SSH v2 client to use this function. After opening a remote console connection using an SSH client, log in using a superuser name and password. By default, this option is disabled. Note that only superusers can log in to the appliance through a console connection.
You can permanently disable remote console (Secure Shell v2) access for appliance administration and for Infoblox Technical Support to perform remote troubleshooting. Disabling this type of access might be required in a high-security environment.

> **Warning**
>
> *After permanently disabling remote console and support access, you cannot re-enable them! Not even resetting an appliance to its factory default settings can re-enable them.*

If you have any questions, contact Infoblox Technical Support. To enable or disable remote console and Infoblox technical support access:

1. **Grid**: From the **Grid** tab, select **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> Edit.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
   Independent appliance: From the **System** tab, select the **System Manager** tab, expand the Toolbar and click **System Properties** -> Edit.
2. In the editor, select the **Security** tab -> **Advanced** tab, and then complete the following in the **Remote Console and Infoblox Technical Support Access** section:
   - **Enable Remote Console Access**: Select this checkbox to enable superuser admins to access the Infoblox CLI from a remote location using SSH (Secure Shell) v2 clients. You can set this at the Grid and member levels.
   - **Enable Support Access**: Select this checkbox to enable an SSH (Secure Shell) daemon that only Infoblox Technical Support can access. You can set this at the Grid and member levels.
   - **Support Access Info**: Displays the support access code and the expiration time of the code. Note that the **Enable Support Access** is disabled after the expiration time.
   - **Permanently Disable Remote Console and Support Access**: This field is in the *Grid Properties* editor only. Select this checkbox to permanently disable remote console (Secure Shell v2) access for appliance administration and for Infoblox Technical Support.
3. Save the configuration.

Configuring Proxy Servers

If your network environment does not allow direct HTTP or HTTPS communication with the Internet through a firewall from a secure location in which the Grid Master or standalone appliance resides, you can configure your appliance to use a proxy server so you can receive automatic updates, such as threat protection rulesets and threat analytics bundles, through this connection. You can also configure a proxy server to perform AWS related communication, such as using a proxy server as the AWS API Proxy, performing vDiscovery on AWS endpoints, and pulling DNS data from Amazon Route 53. For information about AWS deployments, refer to the *Installation Guide for vNIOS for AWS*. For information about vDiscovery, see *Configuring vDiscovery Jobs*.

Note

- Configured proxy settings are for the entire Grid. You cannot configure proxy settings for individual members.
- Infoblox supports only basic authentication for vDiscovery jobs performed over a proxy server as not all proxy options used by customers are validated at the Infoblox lab.

Depending on the updates you want to download, you may need to install the respective licenses in your Grid. For example, to download threat protection ruleset updates, the Grid must have the Threat Protection Update license installed. To download threat analytics bundles, you must install the Threat Analytics license. When you configure your appliance to obtain periodic ruleset updates, all updates go through the MGMT port on the Grid Master by default. You can, however, delegate this function to a Grid member using a different interface such as LAN1 or LAN2. For information about how to delegate updates to a Grid member and configure the interface, see Configuring Members and Interfaces for Automatic Updates below.
To configure proxy settings for the Grid, complete the following steps:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Edit** -> **Grid Properties** from the Toolbar.
2. In the *Grid Properties* editor, select the **Proxy Settings** tab -> **Basic** tab, and complete the following:
   - **Use Proxy Server**: When you select this checkbox, the appliance uses the connection that has been established with the proxy server to establish connection with endpoints or download automatic updates, such as threat protection rulesets and threat analytics bundles. The reporting member sends API requests to the proxy server for threat details. For more information, see *Threat Protection Reports*. Similarly, the Grid Master sends API requests to the proxy server for all threat context details. For more information,

see *Viewing the RPZ Threat Details*. This setting applies to the entire Grid. When you clear this checkbox, the appliance does not use the proxy server; however, the configuration will not be affected.

- **Name or IP Address** and **Port**: Enter the name or IP address and port number of the proxy server you plan to use for this connection.
- **HTTPS Proxy Content Inspection**: From the drop-down list, select one of the following methods the proxy server uses to inspect packet content. Note that this section does not apply to AWS deployments.
    - **None**: Select this to use HTTP for the connection. This method does not allow certificate authentication for the proxy server.
    - **Allow Deep Packet Inspection**: This option is not supported for AWS deployments. To eliminate man-in-the-middle attacks, select this to allow deep pack inspection and information extraction for non-compliant protocol, intrusions, or other criteria that determine whether the packets should be routed to an alternate destination. When you select this, you must click **Proxy Server Certificate** and navigate to the proxy server certificate to upload it to the Grid, or you must ensure that a trusted chain has been established before the proxy server can perform deep packet inspection. When you have uploaded a certificate, the appliance displays **Loaded**.
        - **Enable Strict Host Name Checking:** This option is enabled only when you select **Allow Deep Packet Inspection**. As part of the SSL handshake process, the appliance verifies that the CN (Common Name) of the public certificate of the proxy server exactly matches the host name of the proxy server.

Credentials for Proxy Server (if configured at proxy server)

- **Use user name and password to connect to proxy server if configured**: If you have configured user credentials on the proxy server, enter the **Username** and **Password** here. This is optional.

Configuring Members and Interfaces for Automatic Updates

If you want to download specific rulesets or updates from external servers, you can configure members and corresponding interfaces to receive updates automatically. Note that these members must have access to external servers from where the updates are delegated automatically. For a member to access an external server, you must specify the interface that you configure here when you set up an external server.

To delegate automatic updates to a Grid member or change the interface for downloads, complete the following steps:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Edit** -> **Grid Properties** from the Toolbar.
2. In the *Grid Properties* editor, select the **Proxy Settings** tab -> **Basic** tab, and complete the following:
    - In the Members table, click the Add icon and select **Add Member**. In the *Member Selector*, select the member to which you want to delegate the automatic update function. The appliance adds the Grid member to the table. You can add up to five members for automatic updates. When you add multiple members, you can place the selected members in the order you prefer using the arrows next to the table. If for any reasons the first member is unable to receive updates, the appliance goes down the list in the order the members are placed until the next reachable member receives the updates.
    - Click the **Interface** column, and from the drop-down list select the interface (**Any**, **LAN2**, **MGMT** or **VIP)** you want the corresponding member to use for automatic updates. Ensure that the selected interface is configured properly on the member. The default is **Any**, which maps to the LAN1 interface for all appliance models, except for the PT models. For all PT appliances, **Any** maps to the MGMT interface. You can select **MGMT** or **Any** for threat protection members. Note that VLANs are not supported.
      You can click the **Test connectivity to all members** icon to ensure that the connectivity between the ruleset download web site and all Grid members is properly established using the selected interface. The appliance displays a message indicating the connectivity status in the feedback panel.

The table displays the following:

- **Name**: Displays the member name. For the Grid Master, this field displays **Grid Master**.
- **Interface**: Displays the selected interface that is used for automatic updates.

> ⚠ Note
>
> The appliance generates an SNMP trap if any of the configured Grid members failed to receive updates.

Configuring Ethernet Ports

Depending on your deployment and configuration choices, the Ethernet ports on the NIOS appliance perform different functions. The Ethernet ports that handle traffic on the NIOS appliance are as follows:

- LAN1 port – A 10/100/1000-Mbps gigabit Ethernet port that connects the appliance to the network. This is the default port for single independent appliances, single Grid members, and passive nodes in HA pairs. You must use the LAN1 port to set up the appliance initially. It handles traffic for all management services if you do not enable the MGMT and LAN2 ports. The passive node in an HA pair uses this port to synchronize the database with the active node.
- LAN2 port – A 10/100/1000-Mbps gigabit Ethernet port that connects the appliance to the network. The LAN2 port is not enabled by default. You can enable the LAN2 port and define its use through the GUI after the initial setup. By default, the appliance uses the LAN1 port (and HA port when deployed in an HA pair). To enable and configure the LAN2 port, you must have read/write permission to the Grid member on which you want to enable the port. The LAN2 port is available on the TE-815, TE-825, TE-1415, TE-1425, TE-2215, TE-2225, TE-4015 and TE-4025 appliances. For information about how to use the LAN2 port, see *Using the LAN2 Port*.
- HA port – A 10/100/1000-Mbps gigabit Ethernet port through which the active node in an HA (high availability) pair connects to the network using a VIP (virtual IP) address. HA pair nodes also use their HA ports for VRRP (Virtual Router Redundancy Protocol) advertisements.
  MGMT port – A 10/100/1000-Mbps gigabit Ethernet port that you can use for appliance management or DNS service. You can enable the MGMT port and define its use through the GUI after the initial setup. If the MGMT port is enabled, the NIOS appliance uses it for management services (see the Sources and Destinations for Services table below for specific types).

You can do the following on some of the Ethernet ports, depending on your network requirements and configurations:

- Assign VLANs (Virtual LANs) to the LAN1 and LAN2 ports so that NIOS can provide DNS service to different subnetworks on the same interface.
- Implement DiffServ (Differentiated Services) on the appliance by configuring the DSCP (Differentiated Services Code Point) value.

Enabling GUI and API Access on the MGMT and LAN1/VIP Ports

You can access the Infoblox GUI and API through the MGMT and LAN1 or VIP interfaces simultaneously. To do so, you must first configure the MGMT port on the appliance, and then enable the **Enable GUI/API Access via both MGMT and LAN1/VIP** feature. For information about the MGMT port, see *Using the MGMT Port*. When you enable this feature, you can use the MGMT and LAN1ports for standalone appliances and MGMT and VIP ports for an HA pair. This feature is disabled for all new installations and upgrades.

> ⚠ Note
>
> When the Threat Protection service is running on the Advanced Standalone Appliance, then the GUI and API access is allowed only on the MGMT port.

To enable GUI and API access on the MGMT and LAN1/VIP ports:

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Expand the Toolbar and select **Grid Properties** -> **Edit**.
3. In the *Grid Properties* editor, select the **General** tab -> click the **Advanced** tab (or click Toggle Advanced Mode) and complete the following:
   - **Enable GUI/API Access via both MGMT and LAN1/VIP**: Select this checkbox to allow access to the Infoblox GUI and API using both the MGMT and LAN1 ports for standalone appliances and allow both the MGMT and VIP ports for an HA pair. This feature is valid only if you have enabled the MGMT port. For information about enabling the MGMT port, see .
4. Click Save to save the changes.

About Virtual LANs

You can assign VLANs (Virtual Local Area Networks) to the LAN1, LAN2, and VIP (for HA pairs) interfaces so the appliance can provide DNS service to different subnetworks on the same interface. You can also configure VLANs interfaces on supported Network Insight appliances and use them exclusively for discovery purposes. VLANs are independent logical networks that are mutually isolated on the interface so that IP packets can pass between them through one or more switches or routers. You can assign VLANs to provide segmentation services to address issues such as scalability, security, and network management. For example, you can partition your network into segments such as DHCP address allocation, DNS service, guest network, and DMZ (demilitarized zone) to achieve a higher level of security and to increase performance by limiting broadcast domains. You can also add quality of service schemes to optimize your network traffic on the VLAN trunk links by configuring the DSCP (Differentiated Services Code Point) value for the corresponding physical and virtual interfaces.

> **Note**
>
> When you configure VLANs on the following Network Insight appliances: ND-1405, ND-2205, ND-4000, ND-V1405, and ND-V2205, the VLAN interfaces are used exclusively for discovery. You cannot bind other services on these VLAN interfaces of the supported Network Insight appliances. For more information about Network Insight, see *About Network Insight*.

VLAN Tagging

When your VLANs span across multiple networks, VLAN tagging is required. This enables the NIOS appliance to connect to different networks using the same port. VLAN tagging involves adding a VLAN tag or ID to the header of an IP packet so the appliance can identify the VLAN to which the packet belongs. In addition, switches use the VLAN tag to determine the port to which it should send a broadcast packet. The appliance uses the IEEE 802.1Q networking standard to support VLANs and VLAN tagging. On the appliance, you can configure VLANs as tagged networks by adding VLAN tags to them. You can create up to 10 IPv4 and IPv6 addresses per interface and configure a VLAN ID from one to 4094. You can also configure an address, gateway, and a netmask for VLAN. Any IPv4 or IPv6 address with a VLAN ID is considered as a tagged network. For HA pairs, the appliance supports only one VLAN interface for VRRP over an IPv4 or IPv6. It supports one untagged IPv4 and IPv6 address for each interface and considers this as the primary IP address for the network. For an HA pair, if you have multiple VLANs assigned to a VIP interface, then a network failure in any one of the VLAN interface does not trigger a failover of the active member.

Untagged networks are those without VLAN tags assigned to them. When you set up a VLAN as either a tagged or untagged network, ensure that you properly configure the corresponding switch for the VLAN to function properly.

> **Note**
> A tagged VLAN interface receives only those packets that belongs to the tagged network, but an untagged VLAN interface receives all the packets belonging to the tagged and untagged networks of the interface.

VLANs and VLAN tagging are supported on both IPv4 and IPv6 transports. This feature is currently supported on the following Infoblox appliances: Trinzic 1405, 1415, 1425, 2205, 2215, 2225, 4005, Infoblox-4030-10GE, PT-1405, PT-2205, CP-VM-800, CP-VM-1400, and CP-VM-2200. It is also supported on all the Trinzic virtual appliances. VLAN tagging is not supported on TE-100, TE-805, ND-805, TR-805, TE-815, and TE-825. For information about these appliances, refer to the respective installation guides on the Infoblox Support web site at *https://www.infoblox.com/support*.

Currently, only the DNS service can listen on specific VLAN interfaces. The DHCP service listens only on the primary VLAN interface (tagged or untagged). You can also specify VLANs as the source port for sending DNS queries and notify messages. For information about how to configure these, see *Specifying Port Settings for DNS*.

Additional VLAN support is available exclusively for discovery on the following Network Insight appliances: ND-1405,

ND-2205, ND-4000, ND-V1405, and ND-V2205. Binding other services on the VLAN interfaces of the Network Insight appliances is not supported.

> **Note**
> When you join an appliance that supports VLANs to a Grid that does not support VLANs or revert the appliance to a NIOS version that does not support VLANs, the appliance will become unreachable after joining the Grid or being reverted. You must remove VLAN tagging from the corresponding switch in order to reach the downgraded appliance.

Consider the following guidelines when tagging VLANs on the LAN1 and LAN2 ports:

- You can assign VLAN addresses to an interface and add VLAN tags to them. However, you must designate one of the tagged VLANs as a primary address.
- If the primary IPv4 address is tagged with a VLAN ID, all other addresses on the same interface must be tagged with a VLAN ID as well.
- You can use the same VLAN ID to tag only one IPv4 and one IPv6 address on the same interface. You cannot use the same VLAN ID to tag multiple IPv4 and IPv6 addresses on the same interface.
- You can assign one untagged IPv4 and one untagged IPv6 address to the same interface. These addresses are designated as the primary address for the interface.
- For IPv6, you must have a primary IPv6 address (either tagged or untagged) before you can add other tagged IPv6 addresses on the same interface.
- If you have multiple VLANs assigned to the LAN1 interface and the primary VLAN is untagged, DHCP listens on all VLAN interfaces and thus DHCP lease requests will succeed for the additional VLANs assigned to the LAN1 interface, but the request will actually be handled by the primary untagged VLAN interface.
- You can set up the system to define only tagged networks:
  - When the VLAN tag is not set, the appliance considers the network as an untagged network.
  - You can specify a single untagged IPv4 and IPv6 network per interface.
  - The primary network can be tagged or untagged, but you must tag the additional VLANs.
- VMware ESXi does not support tagged and untagged subnets on the same interface simultaneously. As a result, VMware vSwitch cannot perform tag translation on a tagged VLAN ID if there is another untagged VLAN on the same interface.

Configuring VLANs

When you first set up a NIOS appliance, you can assign VLANs through the Grid Setup Wizard. After the initial setup, you can assign VLANs to the LAN1 or LAN2 ports in the Required Ports and Addresses table, as described in Modifying Ethernet Port Settings.
On a Grid member, you can assign up to 10 VLANS for each protocol (IPv4 or IPv6) on the LAN1 and LAN2 ports. You can assign up to 10 IPv4 VLAN addresses and 10 IPv6 VLAN addresses for each interface. You can configure only IPv4 VLAN addresses for an IPv4 Grid member and only IPv6 VLAN addresses for an IPv6 Grid member, but for a dual mode Grid member you can configure both IPv4 and IPv6 VLAN addresses.
To assign additional VLANs to the LAN1 or LAN2 port, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. Select the **Network** -> **Basic** tab in the *Grid Member Properties* editor.
3. In the **Additional Ports and Addresses** table, click the Add icon and select either **MGMT (IPv4), MGMT (IPv6), LAN2 (IPv4)**, **LAN2 (IPv6)**, **Additional Address (loopback) (IPv4), Additional Address (loopback) (IPv6), LAN1 (VLAN)(IPv4), LAN1 (VLAN)(IPv6), LAN2 (VLAN)(IPv4)** or **LAN2 (VLAN)(IPv6)** from the drop-down list. You can add up to 10 IPv4 and 10 IPv6 VLANs for each interface.
   You can configure only IPv4 VLAN addresses for an IPv4 Grid member and only IPv6 VLAN addresses for an IPv6 Grid member, but for a dual mode Grid member you can configure both IPv4 and IPv6 VLAN addresses.
   - For vNIOS appliances, some of the options in the drop-down list may vary depending on your vNIOS configuration. For example, if you are using a single network interface instance of vNIOS for GCP, you will see choices specific to the LAN1 interface and Additional Address only. For more information, see the vNIOS documentation specific to your product at *Appliances*. Note that you can:

    - You can configure only IPv4 VLAN addresses for an IPv4 Grid member and only IPv6 VLAN addresses for an IPv6 Grid member, but for a dual mode Grid member you can configure both IPv4 and IPv6 VLAN addresses.
    - For vNIOS appliances, some of the options in the drop-down list may vary depending on your vNIOS configuration. For example, if you are using a single network interface instance of vNIOS for GCP, you will see choices specific to the LAN1 interface and Additional Address only. For more information, see the vNIOS documentation specific to your product at *Appliances*.
- **MGMT (IPv4)**: Select this to configure IPv4 address for MGMT port.
- **MGMT (IPv6)**: Select this to configure IPv6 address for MGMT port.
- **LAN2 (IPv4)**: Select this to configure IPv4 address for the LAN2 port for DHCP or DNS. This is not applicable to Trinzic 100 appliance.
- **LAN2 (IPv6)**: Select this to configure IPv6 address for the LAN2 port for DHCP or DNS. This is not applicable to Trinzic 100 appliance.
- **Additional Address (loopback) (IPv4):** Select this to add a non-anycast IPv4 address to the loopback interface. Note that you can configure this for IPv4 and dual mode Grid member.
- **Additional Address (loopback) (IPv6)**: Select this to add a non-anycast IPv6 address to the loopback interface. Note that you can configure this for IPv6 and dual mode Grid member.
- **LAN1 (VLAN) (IPv4)**: Select this to add a VLAN to the LAN1 interface. You can add up to 10 IPv4 VLAN addresses. Note that you can configure this for IPv4 and dual mode Grid member. This is supported on the following Infoblox appliances: Trinzic 1405, 1415, 1425, 2205, 2215, 2225, 4005, Infoblox-4030-10GE, PT-1405, PT-2205, CP-VM-800, CP-VM-1400, and CP-VM-2200. It is also supported on all the Trinzic virtual appliances. VLAN tagging is not supported on TE-100, TE-805, ND-805, TR-805, TE-815, and TE-825.
- **LAN1 (VLAN) (IPv6)**: Select this to add a VLAN to the LAN1 interface. You can add up to 10 IPv4 and 10 IPv6 VLAN addresses. Note that you can configure this for IPv6 and dual mode Grid member. This is supported on the following Infoblox appliances: Trinzic 1405, 1415, 1425, 2205, 2215, 2225, 4005, Infoblox-4030-10GE, PT-1405, PT-2205, CP-VM-800, CP-VM-1400, and CP-VM-2200. It is also supported on all the Trinzic virtual appliances. VLAN tagging is not supported on TE-100, TE-805, ND-805, TR-805, TE-815, and TE-825.
- **LAN2 (VLAN) (IPv4)**: Select this to add a VLAN to the LAN2 interface. You can add up to 10 IPv4 VLAN addresses. Note that you can configure this for IPv4 and dual mode Grid member. This is supported on the following Infoblox appliances: Trinzic 1405, 1415, 1425, 2205, 2215, 2225, 4005, Infoblox-4030-10GE, PT-1405, PT-2205, CP-VM-800, CP-VM-1400, and CP-VM-2200. It is also supported on all the Trinzic virtual appliances. VLAN tagging is not supported on TE-100, TE-805, ND-805, TR-805, TE-815, and TE-825.
- **LAN2 (VLAN) (IPv6):** Select this to add a VLAN to the LAN2 interface. You can add up to 10 IPv6 VLAN addresses. Note that you can configure this for IPv6 and dual mode Grid member. This is supported on the following Infoblox appliances: Trinzic 1405, 1415, 1425, 2205, 2215, 2225, 4005, Infoblox-4030-10GE, PT-1405, PT-2205, CP-VM-800, CP-VM-1400, and CP-VM-2200. It is also supported on all the Trinzic virtual appliances. VLAN tagging is not supported on TE-100, TE-805, ND-805, TR-805, TE-815, and TE-825.

4. Enter the following:
    - **Interface**: Displays the name of the VLAN interface. This can be **LAN1 (VLAN)(IPv4)**, **LAN1 (VLAN)(IPv6),** **LAN2 (VLAN)(IPv4),** or **LAN2 (VLAN)(IPv6)** depending on your selection. You cannot modify this.
    - **Address:** Type the IP address for the VLAN port.
    - **Subnet Mask (IPv4) or Prefix Length (IPv6):** For IPv4 address, specify an appropriate subnet mask and for IPv6 address, specify the prefix length. The prefix length ranges from 2 to 127, with common-sense values ranging from /48 to /127 due to the larger number of bits in the IPv6 address.
    - **Gateway:** Type the IPv4 or IPv6 default gateway address for the VLAN port depending on the type of interface. For IPv6 interface, you can also type **Automatic** to enable the appliance to acquire the IPv6 address of the default gateway and the link MTU from router advertisements.
      You can now define a link-local address as the default IPv6 gateway and isolate the LAN segment so the local router can provide global addressing and access to the network and Internet. This is supported for both LAN1 and LAN2 interfaces as well as LAN1 and LAN2 in the failover mode.
    - **VLAN Tag**: Enter the VLAN tag or ID. You can enter a number from 1 to 4094. Ensure that you configure the corresponding switch accordingly.
    - **Port Settings:** For IPv4 only. From the drop-down list, choose the connection speed that you want the port to use. You can also choose the duplex setting. Choose **Full** for concurrent bidirectional data transmission or **Half** for data transmission in one direction at a time. Select **Automatic** to instruct the NIOS appliance to

negotiate the optimum port connection type (full or half duplex) and speed with the connecting switch automatically. This is the default setting. You cannot configure port settings for vNIOS appliances.
    - **DSCP Value**: Displays the Grid DSCP value, if configured. To modify, click **Override** and enter the DSCP value. You can enter a value from 0 to 63.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Implementing Quality of Service Using DSCP

You can implement DiffServ (Differentiated Services) on the appliance by configuring the DSCP (Differentiated Services Code Point) value. DiffServ is a scalable and class-based mechanism that provides relative priorities to the type of services on your network. It can provide low latency for critical network traffic while providing simple best-effort service for non-critical services. The Infoblox DSCP implementation fully conforms to RFC 2475. For more information about DiffServ, refer to RFC 2475, *An Architecture for Differentiated Services*.

In IPv4 and IPv6 headers, DiffServ uses the DS (Differentiated Services) field for packet classification purposes. The DS field defines the layout of the ToS (Type of Services) octet in IPv4 and the Traffic Class octet in IPv6. The first six bits of the DS field are used as the DSCP value, which determines the PHBs (per-hope behaviors) on DiffServ compliant nodes and enables priorities of services to be assigned to network traffic. For more information about the DS field, refer to RFC 2474, *Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers*.

When you configure the DSCP value for DiffServ, the appliance sets priorities for all outgoing IP traffic. It implements QoS (quality of service) rules so you can effectively classify and manage your critical network traffic. To ensure that core network services, such as DNS services, continue to operate in the event of network traffic congestion, you can set the DSCP value for the entire Grid and override it at the member level. Note that on an appliance, all outgoing IP traffic on all interfaces uses the same DSCP value.

DSCP is supported on both IPv4 and IPv6 transports and the DSCP value for both IPv4 and IPv6 transports must be the same. This feature is currently supported on the following Infoblox appliances: Trinzic 2215, 2225, Infoblox-4030-10GE, PT-1405, PT-2205, TE-1415, TE-1425, and TE-4015. For information about these appliances, refer to the respective installation guides on the Infoblox Support web site at *https://www.infoblox.com/support*.

Note

- DSCP is not supported when packets are processed by DNS cache acceleration over software- based DNS cache acceleration appliances: IB-22*x*5, IB-v22*x*5, IB-40*x*5, IB-v40*x*5.
- You can set the DSCP value of the primary LAN using the *set network* CLI command. DSCP values for all other interfaces and VLANs must be set through Grid Manager.

Configuring the DSCP Value

The DSCP value is set to zero (lowest priority) by default. You can change this value for the Grid and override the value at the member level. When you configure the DSCP value at the Grid or member level, all outgoing IP traffic on all interfaces uses the same value. Valid DSCP values are from 0 to 63. You can also set the DSCP value using the Infoblox CLI. For more information, refer to the *Infoblox CLI Guide*.
To configure the DSCP value for the Grid:

1. From the **Grid** tab -> **Grid Manager** tab, click **Grid Properties** -> **Edit** from the toolbar.
2. In the **General** -> **Advanced** tab of the *Grid Properties* editor, complete the following:
    - **DSCP Value**: Enter a value from 0 to 63. The default is 0 and it represents the lowest priority.
3. Save the configuration.

To override the DSCP value for a member:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the **Network** tab -> **Basic** tab of the *Grid Member Properties* editor, complete the following:

- **DSCP Value**: Click **Override**, and then enter a value from 0 to 63. The default is 0 and it represents the lowest priority.

3. Save the configuration.

You can override the Grid and member DSCP value at the interface level. For more information, see the following:

- For the LAN1 port, see Modifying Ethernet Port Settings below.
- For the LAN2 port, see *Using the Lan2 Port*.
- For the MGMT port, see *Using The MGM Port*.

Ethernet Port Usage

This section provides tables that detail the port usage and source and destination ports for different services, depending on your Grid configuration. The below table displays the type of traffic per port for both Grid and independent deployments. For a more detailed list of the different types of traffic, see the Sources and Destinations for Services table below. If necessary, to modify the port numbers, see
Appliance Roles and Configuration, Communication Types, and Port Usage

Appliance Role	HA Pair	HA Status	MGMT Port	Database Synchronization	Core Network Services	Management Services	GUI Access
HA Grid Master	Yes	Active	Disabled	VIP on HA	VIP on HA	LAN1	VIP on HA
HA Grid Master	Yes	Passive	Disabled	LAN1	–	LAN1	–
Single Grid Master	No	–	Disabled	LAN1	LAN1	LAN1	LAN1

To see the service port numbers and the source and destination locations for traffic that can go to and from a NIOS appliance, see the Sources and Destinations for Services table below. This information is particularly useful for firewall administrators so that they can set policies to allow traffic to pass through the firewall as required.

Note

The colors in the tables represent a particular type of traffic and correlate with each other.

Sources and Destinations for Services

DHCP	Client	LAN1, LAN2, VIP, or broadcast on NIOS appliance	17 UDP	68	67	Required for IPv4 DHCP service
DHCP	LAN1, LAN2 or VIP on NIOS appliance	Client	17 UDP	67	68	Required for IPv4 DHCP service
DHCP	Client	LAN1, LAN2, VIP, or broadcast on NIOS appliance	17 UDP	546	547	Required for IPv6 DHCP service
DHCP	LAN1, LAN2 or VIP on NIOS appliance	Client	17 UDP	547	546	Required for IPv6 DHCP service

Service	SRC IP	DST IP	Proto	SRC Port	DST Port	Notes
DHCP Failover	LAN1, LAN2 or VIP on Infoblox DHCP failover peer	LAN1, LAN2 or VIP on Infoblox DHCP failover peer	6 TCP	1024 → 65535	519 or 647	Required for DHCP failover
DHCP Failover	VIP on HA Grid Master or LAN1 or LAN2 on single master	LAN1, LAN2 or VIP on Grid member in a DHCP failover pair	6 TCP	1024 -> 65535	647 or 7911	Required for DHCP failover Port 7911 is used by an API for limited control over ISC DHCP server operations.
DDNS Updates	LAN1, LAN2, or VIP	LAN1, LAN2, or VIP	17 UDP	1024 → 65535	53	Required for DHCP to send DNS dynamic updates
DNS Transfers	LAN1, LAN2, VIP, or MGMT, or client	LAN1, LAN2, VIP, or MGMT	6 TCP	53, or 1024 -> 65535	53	For DNS zone transfers, large client queries, and for Grid members to communicate with external name servers Required for DNS
DNS Queries	Client	LAN1, LAN2, VIP, or broadcast on NIOS appliance	17 UDP	53, or 1024 → 65535	53	For DNS queries Required for DNS
DNS Queries	Client	LAN1, LAN2, VIP, or broadcast on NIOS appliance	6 TCP	53, or 1024 → 65535	53	For DNS queries Required for DNS
NTP	NTP client	LAN1, LAN2, VIP, or MGMT	17 UDP	1024 -> 65535	123	Required if the NIOS appliance is an NTP server

Service	SRC IP	DST IP	Proto	SRC Port	DST Port	Notes
NTP	NTP client	LAN1, LAN2, VIP, or MGMT	17 UDP	1024 -> 65535	123	Required if the NIOS appliance is an NTP server. On an HA member, the NTP service runs on the active node. If there is an HA failover, the NTP service is automatically launched after the passive node becomes active and the NTP traffic uses the LAN2, VIP, or MGMT port on one of the nodes from an HA pair, instead of the LAN1 port. During another HA failover, the currently passive node becomes active again and the NTP traffic uses the LAN1 port, and the NTP is back in synchronization.
RADIUS Authentication	NAS (network access server)	LAN1 or VIP	17 UDP	1024 – 65535	1812	For proxying RADIUS Authentication-Requests. The default destination port number is 1812, and can be changed to 1024 – 63997. When configuring an HA pair, ensure that you provision both LAN IP addresses on the RADIUS server.
RADIUS Accounting	NAS (network access server)	LAN1 or VIP	17 UDP	1024 – 65535	1813	For proxying RADIUS Accounting-Requests. The default destination port number is 1813, and can be changed to 1024 – 63998.
RADIUS Proxy	LAN1 or VIP	RADIUS home server	17 UDP	1814	1024 -> 63997 (auth), or 1024 -> 63998 (acct)	Required to proxy requests from RADIUS clients to servers. The default source port number is 1814, and although it is not configurable, it is always two greater than the port number for RADIUS authentication.

Service	SRC IP	DST IP	Proto	SRC Port	DST Port	Notes
ICMP Dst Port Unreachable	VIP, LAN1, LAN2, or MGMT, or UNIX-based client	LAN1, LAN2, or UNIX-based client	1 ICMP Type 3	–	–	Required to respond to the UNIX-based traceroute tool to determine if a destination has been reached
ICMP Echo Reply	VIP, LAN1, LAN2, or MGMT, or client	VIP, LAN1, LAN2, or MGMT, or client	1 ICMP Type 0	–	–	Required for response from ICMP echo request (ping)
ICMP Echo Request	VIP, LAN1, LAN2, or MGMT, or client	VIP, LAN1, LAN2, or MGMT, or client	1 ICMP Type 8	–	–	Required to send pings and respond to the Windows-based traceroute tool
ICMP TTL Exceeded	Gateway device (router or firewall)	Windows client	1 ICMP Type 11	–	–	Gateway sends an ICMP TTL exceeded message to a Windows client, which then records router hops along a data path
NTP	LAN1 on active node of Grid Master or LAN1 of independent appliance	NTP server	17 UDP	1024 -> 65535	123	Required to synchronize Grid, TSIG authentication, and DHCP failover Optional for synchronizing logs among multiple appliances
SMTP	LAN1, LAN2, or VIP	Mail server	6 TCP	1024 → 65535	25	Required if SMTP alerts are enabled
SNMP	NMS (network management system) server	VIP, LAN1, LAN2, or MGMT	17 UDP	1024 → 65535	161	Required for SNMP management
SNMP Traps	MGMT or LAN1 on Grid Master or HA pair, or LAN1 on independent appliance	NMS server	17 UDP	1024 -> 65535	162	Required for SNMP trap management. Uses MGMT (when enabled) or LAN1 on Grid Master or HA pair, or LAN1 on independent appliance for the source address, depending on the destination IP address.

Service	SRC IP	DST IP	Proto	SRC Port	DST Port	Notes
SSHv2	Client	LAN1, LAN2, VIP, or MGMT on NIOS appliance	6 TCP	1024 -> 65535	22	Administrators can make an SSHv2 connection to the LAN1, LAN2, VIP, or MGMT port Optional for management
Syslog	LAN1, LAN2, or MGMT of NIOS appliance	syslog server	17 UDP	1024 → 65535	514	Required for remote syslog logging
Traceroute	LAN1, LAN2, or UNIX-based appliance	VIP, LAN1, LAN2, or MGMT, or client	17 UDP	1024 → 65535	33000 → 65535	NIOS appliance responds with ICMP type code 3 (port unreachable)
TFTP Data	LAN1 or MGMT	TFTP server	17 UDP	1024 → 65535	69, then 1024 → 63999	For contacting a TFTP server during database and configuration backup and restore operations
VRRP	HA IP on the active node of HA pair	Multicast address 224.0.0.18	112 VRRP	802		For periodic announcements of the availability of the HA node that is linked to the VIP. The nodes in the HA pair must be in the same subnet.
HTTP	Management System	VIP, LAN1, or MGMT	6 TCP	1024 -> 65535	80	Required if the HTTP-redirect option is set on the Grid properties security page
HTTPS/SSL	Management System	VIP, LAN1, or MGMT	6 TCP	1024 → 65535	443	Required for administration through the GUI
Reporting	Reporting Forwarders	LAN1, LAN2, or MGMT on the indexer	6 TCP	1024 - 65535	9997	Required for the reporting service. Communication is single directional from forwarders to the indexer. For example, a forwarder detects events and forwards them to the indexer.
Reporting - Peer Replication	All Reporting Members	LAN1, LAN2, MGMT on each reporting member	TCP	1024 - 65535	7887	Splunk cluster peer replication (traffic among reporting members)

Service	SRC IP	DST IP	Proto	SRC Port	DST Port	Notes
Distributed Search	All Reporting Members	LAN1, LAN2, MGMT on each reporting member	TCP	1024 - 65535	7089	Distributed searches from Search Head to Reporting Members

Modifying Ethernet Port Settings

By default, the NIOS appliance automatically negotiates the optimal connection speed and transmission type (full or half duplex) on the physical links between the 10/100Base-T and 10/100/1000Base-T ports on the NIOS appliance and the Ethernet ports on a connecting switch. It is usually unnecessary to change the default auto-negotiation setting; however, you can manually configure connection settings for a port if necessary.

Occasionally, for example, even though both the NIOS appliance and the connecting switch support 1000-Mbps (megabits per second) full-duplex connections, they might fail to auto-negotiate that speed and type, and instead connect at lower speeds of either 100 or 10 Mbps using potentially mismatched full- and half-duplex transmissions. If this occurs, first determine if there is a firmware upgrade available for the switch. If so, apply the firmware upgrade and test the connection. If that does not resolve the issue, manually set the ports on the NIOS appliance and on the switch to make 1000-Mbps full-duplex connections.

To change Ethernet port settings:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
   Note: You must enable the MGMT port before modifying its port settings. See *Using the MGMT Port* .
2. In the **Network** tab of the *Grid Member Properties* editor, the Required Ports and Addresses table lists the network settings that were configured. This table lists the network settings of LAN1(IPv4) interface for an IPv4 member and LAN1(IPv6) interface for an IPv6 member. For a dual mode Grid member, this table lists the settings for both LAN1(IPv4) and LAN1(IPv6) interfaces. Complete the following to modify port settings:
   - **Interface**: Displays the name of the interface. You cannot modify this.
   - **Address:** Click the field and modify the IP address for the LAN1 port, which must be in a different subnet from that of the LAN2 and HA ports.
   - **Subnet Mask (IPv4) or Prefix Length (IPv6):** For IPv4 address, click the field and specify an appropriate subnet mask and for IPv6 address, specify the prefix length.
   - **Gateway:** Click the field and modify the default gateway for the LAN1 port.
   - **VLAN Tag**: Click the field and enter the VLAN tag ID if the port is configured for VLANs. You can enter a number from 1 to 4095.
   - **Port Settings:** From the drop-down list, choose the connection speed that you want the port to use. You can also choose the duplex setting. Choose **Full** for concurrent bidirectional data transmission or **Half** for data transmission in one direction at a time. Select **Automatic** to instruct the NIOS appliance to negotiate the optimum port connection type (full or half duplex) and speed with the connecting switch automatically. This is the default setting. You cannot configure port settings for vNIOS appliances.
   - **DSCP Value**: Displays the Grid DSCP value. To modify, click **Override** and enter the DSCP value. You can enter a value from 0 to 63.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

The port settings on the connecting switch must be identical to those you set on the NIOS appliance.

Using the LAN2 Port

Note

NIC failover for LAN1 and LAN2 is not supported on AWS members.

The LAN2 port is a 10/100/1000Base-T Ethernet connector on the front panel of the TE-815, TE-825, TE-1415, TE-1425, TE-2215, TE-2225, TE-4015 and TE-4025 appliances. By default, the LAN2 port is disabled and the appliance uses the LAN1 port (and HA port when deployed in an HA pair). Before you can enable and configure the LAN2 port on a Grid member, you must first configure the member and join it to the Grid. You must also have read/write permission to the Grid member on which you want to enable the port. When you enable the LAN2 port and SNMP, the appliance sends traps from this port for LAN2 related events.

You can configure the LAN2 port in different ways. You can enable the port redundancy or port failover feature, which groups the LAN1 and LAN2 ports into one logical interface. The LAN1/LAN2 grouping can be activated for both IPv4 and IPv6. Alternatively, you can configure the LAN2 port on a different IP network than LAN1, and enable the LAN2 port to provide DNS and DHCP services.

Note that you cannot use the LAN2 port to access the GUI and the API, or to connect to the Grid. This can impact the ability of other appliances, such as the NetMRI and PortIQ appliances, to communicate with the Grid Master. Any IPv6 services enabled for the LAN2 port also require provisioning of an IP address on the LAN2 port.

About Port Redundancy

You can configure the LAN2 or LAN2 (VLAN) port to provide redundancy and additional fault tolerance in your network. Port redundancy is transparently supported for both IPv4 and IPv6. When you enable port redundancy, the LAN1 or LAN1 (VLAN) and LAN2 or LAN2 (VLAN) ports are grouped into one logical interface. They share one IP address and appear as one interface to the network. Then, if a link to one of the ports fails or is disabled, the appliance fails over to the other port, avoiding a service disruption.

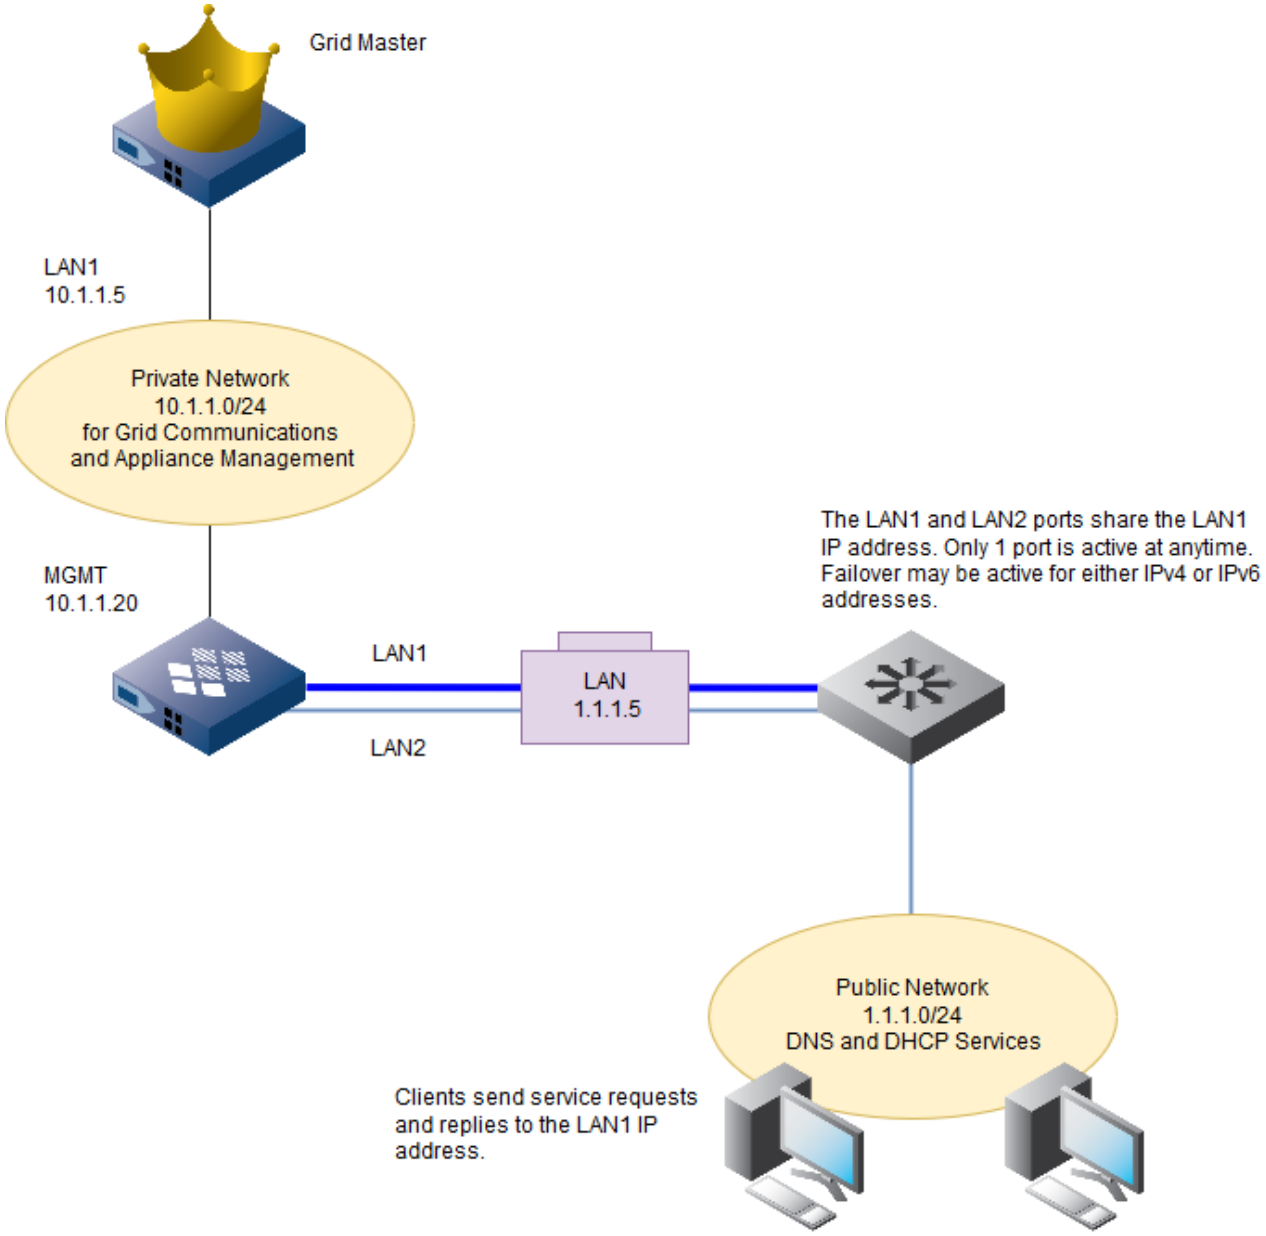
You can connect the LAN1 or LAN1 (VLAN) and LAN2 or LAN2 (VLAN) ports to the same switch or to different switches, but the VLAN configuration between LAN1 and LAN2 must match. One port is active and the other port is idle at all times. In case of failure in the LAN1 or LAN1 (VLAN) port, the LAN2 or LAN2 (VLAN) port becomes active and once the LAN1 or LAN1 (VLAN) port is active again, the LAN2 or LAN2 (VLAN) port becomes passive if the **Use LAN1 when available** option is enabled. For more information, see Enabling Port Redundancy below.

> ⚠ Note
>
> - When configuring port redundancy, the speed of the interfaces is not taken into consideration when selecting the active interface.

The LAN1 or LAN1 (VLAN) and LAN2 or LAN2 (VLAN) ports share the IP address of the LAN1 or LAN1 (VLAN) port; the port that is currently active owns the IP address. When you enable services on the appliance, such as DNS and DHCP, clients send their service requests to the LAN1 or LAN1 (VLAN) port IP address and receive replies from it as well. The port supports the services and features supported on the LAN1 or LAN1 (VLAN) port as listed in Appliance Roles table and Sources and Destinations for Services table, see *Configuring Ethernet Ports*. You cannot enable the port redundancy feature if the LAN2 or LAN2 (VLAN) port is serving DNS or DHCP.
For example, you can use the MGMT port for Grid communications, and the LAN1 and LAN2 ports are connected to the same switch. The LAN1 and LAN2 port share the IP address of the LAN1 port, which is 1.1.1.5. In the illustration, LAN1 is the active port.

You can also have the MGMT port disabled and configure LAN1 and LAN2 for port redundancy. You can enable port redundancy on single or HA independent appliances and Grid members.

Using the LAN2 Failover Feature



Enabling Port Redundancy

Before you enable port redundancy, ensure that both LAN1 and LAN2 are enabled. To enable port redundancy:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the **Network** -> **Basic** tab of the *Grid Member Properties* editor, select the **Enable port redundancy on LAN1/ LAN2** checkbox.
3. Select the **Use LAN1 when available** checkbox to enable the NIOS appliance to automatically revert to the LAN1 port when it is available. In case of a connection failure, if the LAN1 port is not available, the NIOS appliance fails over to the LAN2 port. If you do not enable this option, the NIOS appliance will not automatically revert from the LAN2 port to the LAN1 port when it is available.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

The *Detailed Status* panel displays the status of both the LAN1 and LAN2 ports. In an HA pair, both nodes display the port information when port redundancy is enabled.

Configuring the LAN2 Port

Before you enable the LAN2 port to provide DHCP and DNS services, you must specify its IP address and other properties. You can configure both IPv4 and IPv6 addresses for the LAN2 port of an IPv4, IPv6 and dual mode (IPv4 and IPv6) Grid member.
To configure the LAN2 port:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the **Network** -> **Basic** tab of the *Grid Member Properties* editor, click the Add icon of the **Additional Ports and Addresses** table and select **LAN2 (IPv4)** or **LAN2 (IPv6)** from the drop-down list. Enter the following:
    - **Interface**: Displays the name of the interface. You cannot modify this.
    - **Address:** Type the IP address for the LAN2 port, which must be in a different subnet from that of the LAN1 and HA ports.
    - **Subnet Mask (IPv4) or Prefix Length (IPv6):** Specify an appropriate subnet mask for IPv4 address and prefix length for IPv6 address.
    - **Gateway:** Type the default gateway for the LAN2 port.
    - **VLAN Tag**: Enter the VLAN tag ID if the port is configured for VLANs. You can enter a number from 1 to 4095.For information about VLAN, see *About Virtual LANs.*
    - **Port Settings:** From the drop-down list, choose the connection speed that you want the port to use. You can also choose the duplex setting. Choose **Full** for concurrent bidirectional data transmission or **Half** for data transmission in one direction at a time. Select **Automatic** to instruct the NIOS appliance to negotiate the optimum port connection type (full or half duplex) and speed with the connecting switch automatically. This is the default setting. You cannot configure port settings for vNIOS appliances.
    - **DSCP Value**: Displays the Grid DSCP value. To modify, click Override and then enter the DSCP value. You can enter a value from 0 to 63. For information about DSCP and Implementing Quality of Service Using DSCP, see *Configuring Ethernet Ports.*
    - **LAN2 Virtual Router ID (if HA):** If the appliance is in an HA pair, enter a VRID number.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

The *Detailed Status* panel displays the status of the LAN2 port. In an HA pair, only the active node displays the LAN2 information.

Configuring LAN1/LAN2 for Automated Failover

You can use both LAN1 and LAN2 interfaces for DNS recursion. Both these interfaces have different gateways and you can send the DNS query source using the ANY IP address. If the default route interface goes down, the route redundancy feature configures another working interface so that there is automatic failover of recursion traffic from the failed interface to the working interface. This provides for a seamless flow of recursive traffic movement.

To configure automated failover, ensure that LAN1 and LAN2 have the same network configuration. Automated failover is supported on VLAN, IPv4, and IPv6 configurations.

To enable route redundancy:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the **Network** -> **Basic** tab of the *Grid Member Properties* editor, select the **Enable default route redundancy on LAN1/LAN2** checkbox.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

The *Detailed Status* panel displays the status of both the LAN1 and LAN2 ports.

If you select the **Enable default route redundancy on LAN1/LAN2** checkbox and then run the `show routes` CLI command, the output displays two default routes each having a different metric number. The primary default route that is set using the `set default_route LAN1|LAN2` CLI command has a metric value of 0 and the secondary default route has a metric value of 10 for IPv4 networks. For IPv6 networks, the primary default route has a metric value of 1024 and the secondary default route has a metric value of 1124. For more information, see *show routes*.

In case of a failover, there may be a delay of a few seconds before the switchover to the secondary interface occurs.

If you want to enable port redundancy on LAN2 using WAPI, you have to use the entire `lan2_port_setting` struct even though the LAN2 IP addresses are already configured. The `lan2_port_setting` struct does not support partial updates.

Enabling DHCP on LAN2

You can configure an appliance to provide DHCP service through the LAN1 port, LAN2 port, or both the LAN1 and LAN2 ports. Note that when you enable both ports, they must be connected to different subnets. You can also start and stop DHCP service for IPv4 or IPv6 on the LAN1 or LAN2 port after you have enabled the service.
After you configure the LAN2 port, you can enable DHCP services on the LAN2 port as follows:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. *If you are running DHCP for IPv4*: In the **General** -> **Basic** tab of the *Member DHCP Configuration* editor, select the **IPv4** checkbox for **LAN2** under DHCP Interfaces.
   If you are running DHCP for IPv6: In the **General** -> **Basic** tab of the *Member DHCP Configuration* editor, select the **IPv6** checkbox for **LAN2** under DHCP Interfaces. (An IPv6 address must also be provisioned for the port.)
   You can run either or both protocols for DHCP depending on your network deployment.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Enabling DNS on LAN2

If you enable DNS on an appliance, it always serves DNS on the LAN1 port. Optionally, you can configure the appliance to provide DNS services through the LAN2 port as well. For example, the appliance can provide DNS services through the LAN1 port for internal clients on a private network, and DNS services through the LAN2 port for external clients on a public network.
After you configure the LAN2 port, you can enable DNS services on the LAN2 port as follows:

1. From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the **General** -> **Basic** tab of the *Member DNS Configuration* editor, do the following:
   If you are running DNS for IPv4: In the **General** -> **Basic** tab of the *Member DHCP Configuration* editor, select the **IPv4** checkbox for **LAN2** under DNS Interfaces.
   If you are running DNS for IPv6: In the **General** -> **Basic** tab of the *Member DHCP Configuration* editor, select the **IPv6** checkbox for **LAN2** under DNS Interfaces. (An IPv6 address must also be provisioned for the port.)
   You can run either or both protocols for DNS depending on your network deployment.
   - **Automatically create glue A and PTR records for LAN2's address:** The NIOS appliance can automatically generate A (address) and PTR records for a primary name server whose host name belongs to the name space of the zone. Select this checkbox to enable the appliance to automatically generate an A and PTR record.
   - **Automatically create IPv6 glue AAAA and PTR records for LAN2's address:** automatically generate AAAA and PTR records for the LAN2 IPv6 address. A glue record is the IP address of a name server held at the domain name registry. They are needed to set a domain's name server to a host name within the domain. Example: to set the name servers of ns1.corpxyz.com and ns2.corpxyz.com, provide the glue records, which are in effect the IP addresses, for ns1.corpxyz.com and ns2.corpxyz.com, within specific DNS record types.
     Without the glue records, DNS requests never resolve to the correct IP address because the domain registry does not associate the IP with the correct records.
3. In the **General** -> **Advanced** tab (click **Toggle Advanced Mode** if necessary), select one of the following from the **Send queries from** and the **Send notify messages and zone transfer request from** drop-down lists:
   - **VIP**: The appliance uses the IP address of the HA port as the source for queries, notifies, and zone transfer requests.
   - **MGMT**: The appliance uses the IP address of the MGMT port as the source for queries, notifies, and zone transfer requests.

- **LAN2:** The appliance uses the IP address of the LAN2 port as the source for queries, notifies, and zone transfer requests.
- **Any**: The appliance chooses which port to use as the source for queries, notifies, and zone transfer requests.
  The **Send queries from** drop-down list also includes loopback IP addresses that you configured. You can select a loopback address as the source for queries.

4. Save the configuration and click **Restart** if it appears at the top of the screen.
5. Click **Restart** to restart services.

Using the MGMT Port

The MGMT (Management) port is a 10/100/1000Base-T Ethernet connector on the front panel of the TE-815, TE-825, TE-1415, TE-1425, TE-2215, TE-2225, TE-4015 and TE-4025 appliances. It allows you to isolate the following types of traffic from other types of traffic on the LAN and HA ports:

- Appliance Management
- Grid Communications
- DNS Services

For information about what types of traffic qualify as appliance management, Grid communications, and DNS services, see the Sources and Destinations for Services table in *Configuring Ethernet Ports*.

> **Note**
>
> The MGMT port currently does not support DHCP, NAT, or TFTP. IPv6 addressing may be applied to the MGMT port.

Some NIOS appliance deployment scenarios support more than one concurrent use of the MGMT port. The following table depicts MGMT port uses for various appliance configurations.

Supported MGMT Port Uses for Various appliance Configurations

Appliance Configuration	Appliance Management	Grid Communications	DNS Services
Single Independent Appliance		Not Applicable	
Independent HA Pair		Not Applicable	
Grid Master			
Grid Master Candidate			
HA Grid Member			
Single Grid Member			

* Although you manage all Grid members through the Grid Master, if you enable the MGMT port on common Grid members, they can send syslog events, SNMP traps, and e-mail notifications, and receive SSH connections on that port.

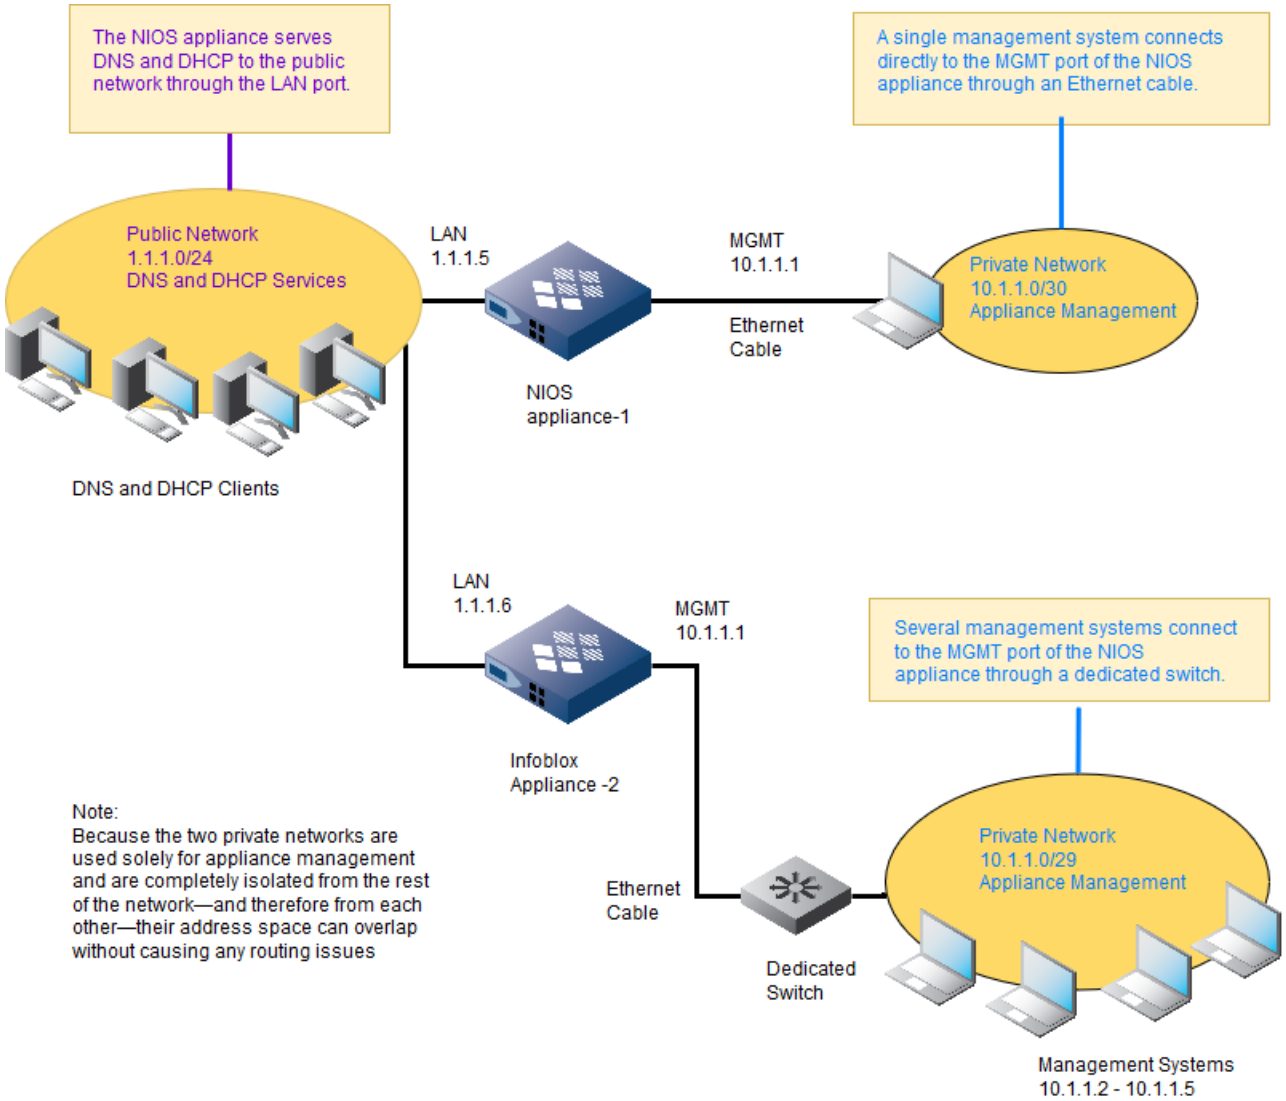
Infoblox does not support MGMT port usage for some appliance configurations (indicated by the symbol ✘ in Supported MGMT Port Uses for Various appliance Configurations table) because it cannot provide redundancy through the use of a VIP. A Grid Master that is an HA pair needs the redundancy that a VIP interface on the HA port provides for Grid communications. Similarly, DNS servers in an HA pair need that redundancy to answer DNS queries. Because the MGMT port does not support a VIP and thus cannot provide redundancy, Grid Masters (and potential Grid Masters) do not support Grid communications on the MGMT port.

In addition, NIOS appliances in an HA pair support DNS services on the active node only (indicated by the symbol in Supported MGMT Port Uses for Various appliance Configurations table). Only the active node can respond to queries that it receives. If a DNS client sends a query to the MGMT port of the node that happens to be the passive node, the query can eventually time out and fail.
The MGMT port is not enabled by default. By default, a NIOS appliance uses the LAN port (and HA port when deployed in an HA pair). You must log in using a superuser account to enable and configure the MGMT port. You can configure both IPv4 address and IPv6 address for the MGMT port of a Grid member. You can enable the MGMT port through the Infoblox GUI, as explained in the following sections.

Appliance Management

You can restrict administrative access to a NIOS appliance by connecting the MGMT port to a subnet containing only management systems. This approach ensures that only appliances on that subnet can access the Infoblox GUI and receive appliance management communications such as syslog events, SNMP traps, and e-mail notifications from the appliance.
If you are the only administrator, you can connect your management system directly to the MGMT port. If there are several administrators, you can define a small subnet—such as 10.1.1.0/29, which provides six host IP addresses (10.1.1.1–10.1.1.6) plus the network address 10.1.1.0 and the broadcast address 10.1.1.7—and connect to the NIOS appliance through a dedicated switch (which is not connected to the rest of the network). The figure below shows how an independent appliance separates appliance management traffic from network protocol services. Note that the LAN port is on a different subnet from the MGMT port.

Appliance Management from One or More Management Systems



Similarly, you can restrict management access to a Grid Master to only those appliances connected to the MGMT ports of the active and passive nodes of the Grid Master.
To enable the MGMT port on an independent appliance or Grid Master for appliance management and then cable the MGMT port directly to your management system or to a network forwarding appliance such as a switch or router:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the **Network** -> **Basic** tab of the *Grid Member Properties* editor, add the MGMT port to the Additional Ports and Addresses table as follows:
3. Click the Add icon and select **MGMT (IPv4)** to configure an IPv4 address or select **MGMT (IPv6)** to configure an IPv6 address for the MGMT port. You can configure both IPv4 and IPv6 addresses for the MGMT port.
   Grid Manager adds a row for the MGMT port. For an HA pair, it adds two rows, one for each node.
4. Enter the following in the row of the MGMT port for a single Grid Master or independent appliance, and in the rows of the two nodes for an HA Grid Master or independent HA pair:
   - **Interface**: Displays the name of the interface. You cannot modify this.
   - **Address:** Type the IP address for the MGMT port, which must be in a different subnet from that of the LAN and HA ports.
   - **Subnet Mask (IPv4) or Prefix Length (IPv6):** For IPv4 address, specify an appropriate subnet mask for the number of management systems that you want to access the appliance through the MGMT port. For IPv6 address, specify the prefix length.

- **Gateway:** Type the default gateway for the MGMT port. If you need to define any static routes for traffic originating from the MGMT port—such as SNMP traps, syslog events, and email notifications—destined for remote subnets beyond the immediate subnet, specify the IP address of this gateway in the route.
- **Port Settings:** Choose the connection speed that you want the port to use. You can also choose the duplex setting. Choose **Full** for concurrent bidirectional data transmission or **Half** for data transmission in one direction at a time. Select **Automatic** to instruct the NIOS appliance to negotiate the optimum port connection type (full or half duplex) and speed with the connecting switch automatically. This is the default setting. You cannot configure port settings for vNIOS appliances.
- **DSCP Value**: Displays the Grid DSCP value. To modify, click Override and then enter the DSCP value. You can enter a value from 0 to 63. For information about DSCP and Implementing Quality of Service Using DSCP, see *Configuring Ethernet Ports*.

1. In the **Network** -> **Advanced** tab, make sure that the **Enable VPN on MGMT Port** checkbox is not selected.
2. Save the configuration and click **Restart** if it appears at the top of the screen.
3. Log out of Grid Manager.
4. Cable the MGMT port to your management system or to a switch or router to which your management system can also connect.
5. If your management system is in a subnet from which it cannot reach the MGMT port, move it to a subnet from which it can.
   The Infoblox Grid Manager GUI is now accessible through the MGMT port on the NIOS appliance from your management system.
6. Open an Internet browser window and enter the IP address of the MGMT port as follows: *https://<IP address of MGMT port>*.
7. Log in to Grid Manager.
8. Check the *Detailed Status* panel of the Grid member to make sure the status icons are green.

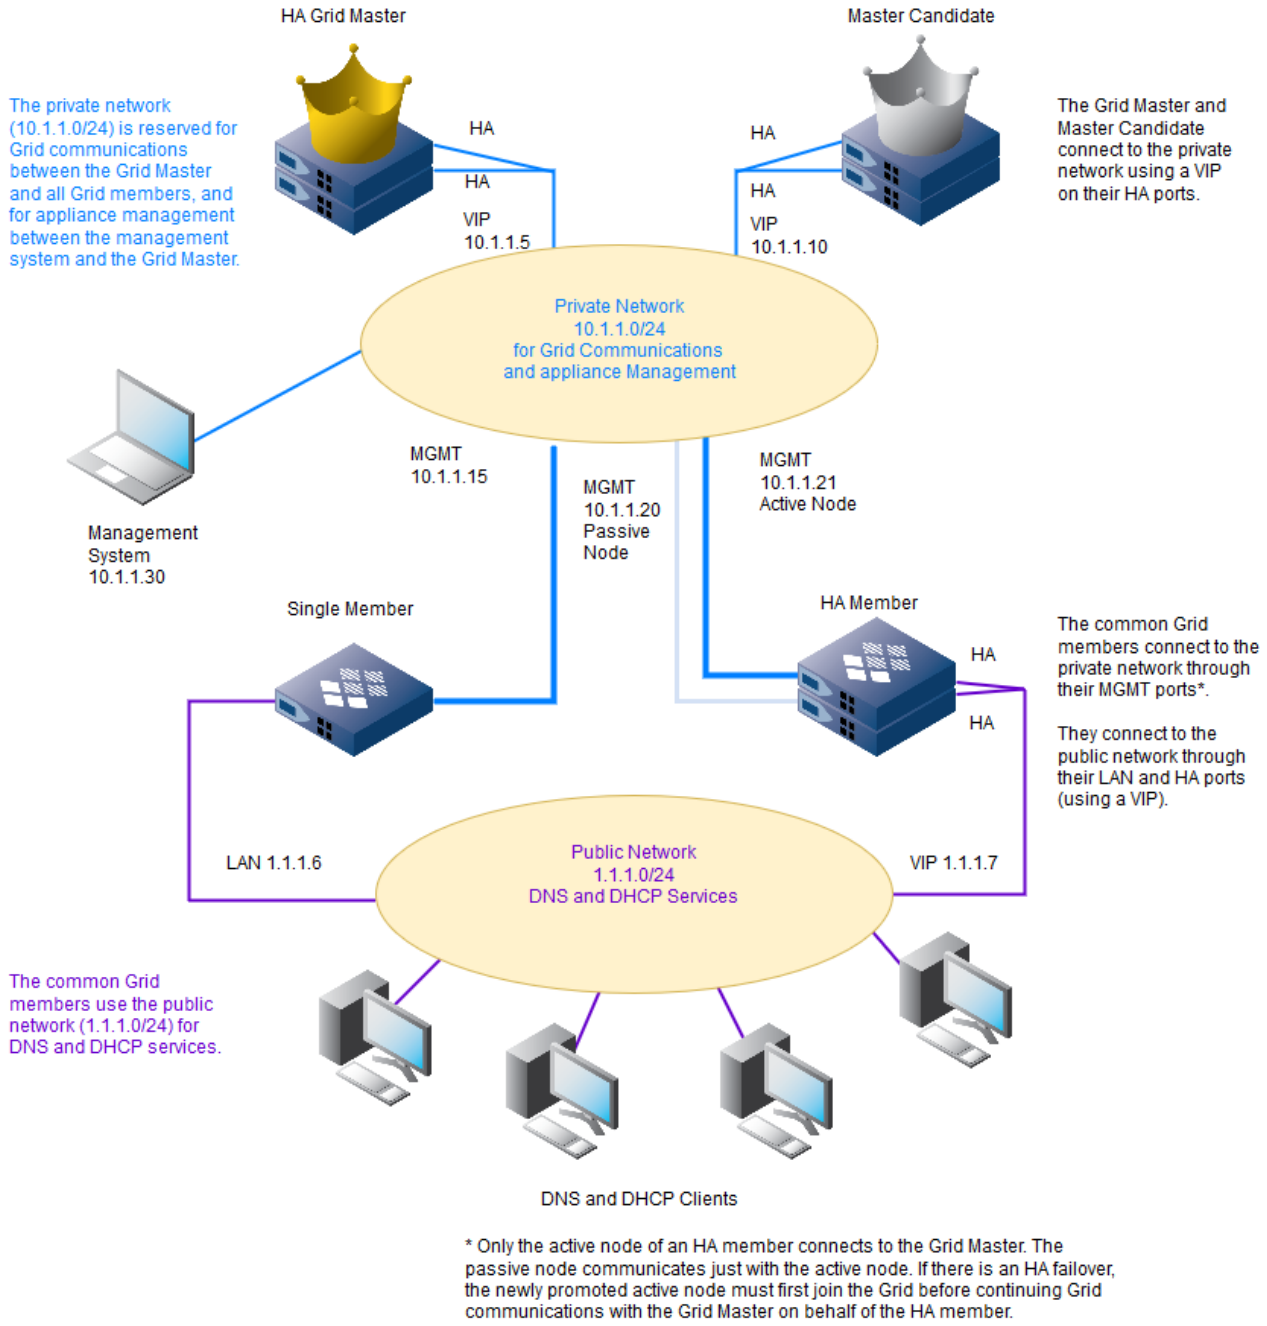
Grid Communications

You can isolate all Grid communications to a dedicated subnet as follows:

- For Grid communications from the Grid Master, which can be an HA pair or a single appliance, the master uses either the VIP interface on the HA port of its active node (HA master) or its LAN port (single master). Neither a single nor HA Grid Master can use its MGMT port for Grid communications. (This restriction applies equally to Master Candidates.)
- Common Grid members connect to the Grid Master through their MGMT port.

This ensures that all database synchronization and Grid maintenance operations are inaccessible from other network elements while the common Grid members provide network protocol services on their LAN ports.
The below figure shows how Grid members communicate to the master over a dedicated subnet.

Grid Communications



Enabling Grid Communications over the MGMT Port for Existing Grid Members

To enable the MGMT port for Grid communications on an existing single or HA Grid member:

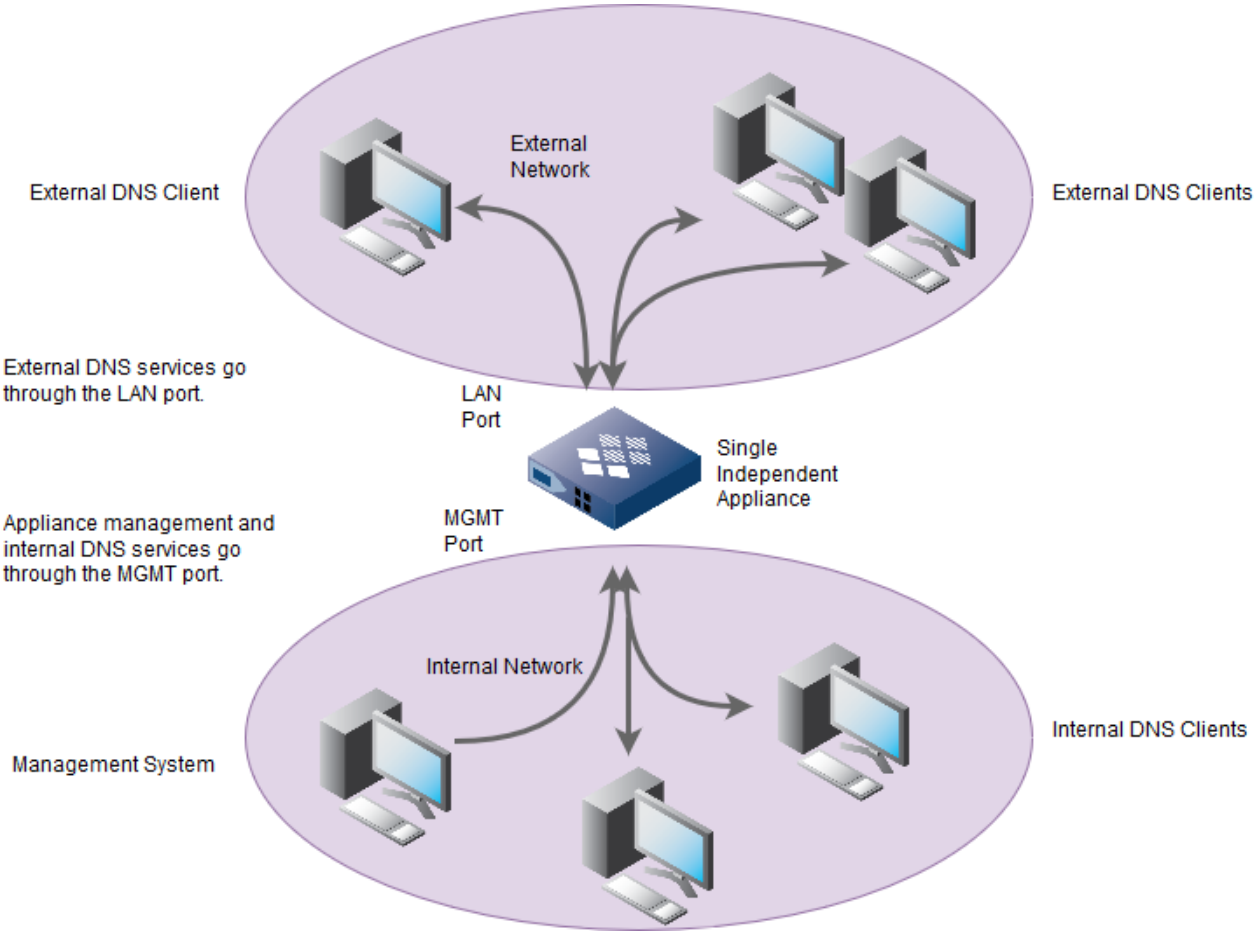
1. Log in to the Grid Master with a superuser account.
2. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
   Note that you must enable the MGMT port before modifying its port settings. See the Using the MGMT Port page.
3. In the **Network** -> **Basic** tab of the *Grid Member Properties* editor, add the MGMT port to the Additional Ports and Addresses table as follows:

4. Click the Add icon and select **MGMT (IPv4)** to configure an IPv4 address or select **MGMT (IPv6)** to configure an IPv6 address for the MGMT port. You can configure both IPv4 address and IPv6 address for the MGMT port. Grid Manager adds a row for the MGMT port. For an HA pair, it adds two rows, one for each node.
5. Enter the following in the row of the MGMT port for a single Grid Master or independent appliance, and in the rows of the two nodes for an HA Grid Master or independent HA pair:
    - **Interface**: Displays the name of the interface. You cannot modify this.
    - **Address:** Type the IP address for the MGMT port, which must be in a different subnet from that of the LAN and HA ports.
    - **Subnet Mask (IPv4) or Prefix Length (IPv6):** For IPv4 address, specify an appropriate subnet mask for the number of management systems that you want to access the appliance through the MGMT port. For IPv6 address, specify the prefix length.
    - **Gateway:** Type the default gateway for the MGMT port. If you need to define any static routes for traffic originating from the MGMT port—such as SNMP traps, syslog events, and email notifications—destined for remote subnets beyond the immediate subnet, specify the IP address of this gateway in the route.
    - **Port Settings:** Choose the connection speed that you want the port to use. You can also choose the duplex setting. Choose **Full** for concurrent bidirectional data transmission or **Half** for data transmission in one direction at a time. Select **Automatic** to instruct the NIOS appliance to negotiate the optimum port connection type (full or half duplex) and speed with the connecting switch automatically. This is the default setting. You cannot configure port settings for vNIOS appliances.
    - **DSCP Value**: Displays the Grid DSCP value. To modify, click **Override** and enter the DSCP value. You can enter a value from 0 to 63. For information about DSCP and Implementing Quality of Service Using DSCP, see *Configuring Ethernet Ports.*
6. In the **Network** -> **Advanced** tab, select the **Enable VPN on MGMT Port** checkbox.
7. In the **Security** tab, do the following:
    - **Restrict Remote Console and Support Access to MGMT Port:** Select this checkbox to restrict SSH (Secure Shell) v2 access to the MGMT port only. This restricts Infoblox Technical Support and remote console connections—both of which use SSH v2—to just the MGMT port. For an HA pair, you can make an SSH v2 connection to the MGMT port on both the active and passive nodes.
      Clear the checkbox to allow SSH v2 access to both the MGMT and LAN ports. For an HA pair, you can make an SSH v2 connection to the MGMT and LAN ports on both the active and passive nodes.
8. Save the configuration and click **Restart** if it appears at the top of the screen.
   The master communicates the new port settings to the member, which immediately begins using them. The member stops using its LAN port for Grid communications and begins using the MGMT port.
9. To confirm that the member still has Grid connectivity, check that the status icons for that member are green on the *Detailed Status* and *Grid* panels.

DNS Services

You can configure a single independent appliance or single Grid member to provide DNS services through the MGMT port in addition to the LAN port. For example, the appliance can provide DNS services through the MGMT port for internal clients on a private network, and DNS services through the LAN port for external clients on a public network. While providing DNS services on the MGMT port, you can still use that port simultaneously for appliance management. The figure below shows a management system communicating with a single independent appliance through its MGMT port while the appliance also provides DNS services on that port to a private network. Additionally, the appliance provides DNS services to an external network through its LAN port.

DNS Services on the LAN and MGMT Ports, and appliance Management on the MGMT Port



Like a single independent appliance, a single Grid member can also support concurrent DNS traffic on its MGMT and LAN ports. However, because you manage all Grid members through the Grid Master, a Grid member only uses an enabled MGMT port to send SNMP traps, syslog events, and email notifications, and to receive SSH connections.
In addition, the active node of an HA pair can provide DNS services through its MGMT port. To use this feature, you must enable DNS services on the MGMT ports of both nodes in the HA pair and specify the MGMT port IP addresses of both nodes on the DNS client as well, in case there is a failover and the passive node becomes active. Note that only the active node can respond to queries that it receives. If a DNS client sends a query to the MGMT port of the node that happens to be the passive node, the query can eventually time out and fail.
To enable DNS services on the MGMT port of an appliance:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
   Note:
   You must enable the MGMT port before modifying its port settings.
   You must mandatorily configure the LAN interface before joining the HA nodes to the Grid. If you join the nodes with VLAN tagging already enabled on HA, the new nodes must join with VLAN tagging only. If you join the nodes using the MGMT interface, you must enable VLAN tagging for the new nodes.
2. In the **Network** -> **Basic** tab of the *Grid Member Properties* editor, add the MGMT port to the Additional Ports and Addresses table as follows:
3. Click the Add icon and select **MGMT (IPv4)** to configure an IPv4 address or select **MGMT (IPv6)** to configure an IPv6 address for the MGMT port. You can configure both IPv4 and IPv6 address for the MGMT port.
   Grid Manager adds a row for the MGMT port. For an HA pair, it adds two rows, one for each node.
4. Enter the following in the row of the MGMT port for a single Grid Master or independent appliance, and in the rows of the two nodes for an HA Grid Master or independent HA pair:
   - **Interface**: Displays the name of the interface. You cannot modify this.

- **Address:** Type the IP address for the MGMT port, which must be in a different subnet from that of the LAN and HA ports.
- **Subnet Mask (IPv4) or Prefix Length (IPv6):** For IPv4 address, specify an appropriate subnet mask for the number of management systems that you want to access the appliance through the MGMT port. For IPv6 address, specify the prefix length.
- **Gateway:** Type the default gateway for the MGMT port. If you need to define any static routes for traffic originating from the MGMT port—such as SNMP traps, syslog events, and email notifications—destined for remote subnets beyond the immediate subnet, specify the IP address of this gateway in the route.
- **Port Settings:** Choose the connection speed that you want the port to use. You can also choose the duplex setting. Choose **Full** for concurrent bidirectional data transmission or **Half** for data transmission in one direction at a time. Select **Automatic** to instruct the NIOS appliance to negotiate the optimum port connection type (full or half duplex) and speed with the connecting switch automatically. This is the default setting. You cannot configure port settings for vNIOS appliances.
- **DSCP Value**: Displays the Grid DSCP value. To modify, click **Override** and enter the DSCP value. You can enter a value from 0 to 63. For information about DSCP and Implementing Quality of Service Using DSCP, see *Configuring Ethernet Ports*.

5. Click **Save & Close** to save your settings for the MGMT port.
6. From the **Data Management** tab, select the **DNS** tab -> -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
7. In the **General** -> **Basic** tab of the *Member DNS Properties* editor, do the following:
   - If you are running DNS service for IPv4, select the IPv4 checkbox for **MGMT** under **DNS Interfaces**.
   - If you are running DNS service for IPv6, select the IPv6 checkbox for **MGMT** under **DNS Interfaces**.
8. In the **General** -> **Advanced** tab, select one of the following from the **Send queries from** and the **Send notify messages and zone transfer requests from** drop-down lists:
   - **VIP**: The appliance uses the IP address of the HA port as the source for queries, notifies, and zone transfer requests.
   - **MGMT**: The appliance uses the IP address of the MGMT port as the source for queries, notifies, and zone transfer requests.
   - **LAN2:** The appliance uses the IP address of the LAN2 port as the source for queries, notifies, and zone transfer requests.
   - **Any**: The appliance chooses which port to use as the source for queries, notifies, and zone transfer requests.
     The **Send queries from** drop-down list also includes loopback IP addresses that you configured. You can select a loopback address as the source for queries.
9. Save the configuration and click **Restart** if it appears at the top of the screen.

To see that the appliance now also serves DNS on the MGMT port:

1. From the **Data Management** tab, select the **DNS** tab -> -> **Members** tab -> *Grid_member* checkbox.
2. Expand the Toolbar and click **View** -> **View DNS Configuration**.
3. Check that the IP address of the MGMT port appears in the address match list in the listen-on substatement.

About Lights Out Management

Infoblox LOM (Lights Out Management) is an implementation of the remote management and monitoring of Infoblox appliances that are LOM ready, such as the Trinzic 2010 appliances.
The LOM feature is useful when you want to monitor your platforms remotely or consolidate your data centers. When you monitor your systems remotely, you can avoid issues such as overheating of a problematic system by remotely powering down the system. To conserve energy, you can also power up and down any systems based on service requirements.
You can enable LOM for the entire Grid and override the Grid settings for specific members. You can also configure LOM on independent appliances and HA pairs.

> ⚠ Note
>
> You can configure LOM only on appliances that support LOM. This port automatically negotiates a speed of up to 1000 Mbps. Devices connected to the LOM port must be configured to auto-negotiate and must not have a fixed speed of 1000 Mbps.

LOM is disabled by default. Before you can configure LOM and remotely manage the appliance, ensure that the IPMI (Intelligent Platform Management Interface) port on your appliance is properly connected to the network. Consider the following security measures before you enable the IPMI interface for LOM:

- Use an authentication method other than the RAKP (Remote Authenticated Key-Exchange Protocol) for the IPMI interface. Any implementation that uses the RAKP can become vulnerable.
- Secure the network to which the IPMI interface is connected. Infoblox recommends that you use a separate and secure network for all IPMI traffic.
- Use strong passwords for all IPMI users. At least 10 random characters are recommended. Attacks are only effective against weak passwords.
- IPMI is disabled by default. DO NOT enable IPMI on the appliances if it is not being used.

By default, IPMI uses UDP port 623. You can then enable LOM and add LOM users through the Infoblox GUI. When you add LOM users, you can assign them specific roles so they can perform only certain functions. When you add a LOM user, you can configure the user to be an "operator" or a "user" depending on the functions you want the user to perform. An operator can access an appliance remotely and perform the following functions:

- Access the serial console
- Reset the appliance
- Power up and down the appliance
- Monitor system status, such as CPU usage and system temperature

A user role can only monitor system status. Users with this role cannot perform any other functions remotely.
After you set up and configure your appliance, perform the following tasks through Grid Manager to enable LOM and set up LOM users:

1. Enable LOM for the Grid or members that support IPMI, as described in Enabling LOM below.
2. Add LOM users based on your organizational needs, as described in Adding LOM User Accounts below.
3. Configure the IPMI network interface on the appliance, as described in Configuring the IPMI Network Interface, see *Configuring SNMP*.
4. After you have configured LOM and set up the IPMI interface, install a utility such as IPMItool on your Linux management system. For information about IPMItool, visit the IPMItool web site at *http://ipmitool.sourceforge.net*. For the most commonly used commands and examples, see IPMI Commands and Examples below.

You can also do the following from Grid Manager after you configure LOM:

- Enable and disable LOM for the Grid or members, as described in Enabling LOM below.
- Modify LOM settings, as described in Modifying LOM Settings below.
- View LOM users, as described in Modifying LOM Settings below.

Enabling LOM

Before you can add LOM users and manage Infoblox appliances remotely, you must enable LOM. When LOM is configured for the entire Grid, all members inherit the Grid settings. You can also override the Grid settings for specific members. For an HA pair, you can configure LOM on the node that supports IPMI.
To enable and disable LOM:

1. **Grid:** From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
   Independent appliance: From the **System** tab, select the **System Manager** tab, expand the Toolbar and click **System Properties** -> **Edit**.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the **LOM** tab, complete the following:
   - **Enable Lights Out Management:** LOM is disabled by default. Select this checkbox to enable LOM. When LOM is enabled or disabled for the Grid, all members inherit the same setting.
3. Save the configuration.

Adding LOM User Accounts

You can add up to eight LOM user accounts. Admins must use the configured user name and password to remotely log in to the appliance.
Note that when you add LOM user accounts at the Grid level, all members inherit them. You can configure user accounts specific to a member by overriding the Grid accounts. When you click **Override** to modify the inherited Grid accounts, the appliance creates copies of the Grid level user accounts and saves them at the member level. These are new accounts at the member level and do not affect the Grid accounts or any accounts configured on other Grid members. You can also reset member accounts to the Grid accounts by clicking **Inherit**. When you do that however, all changes you previously made to the member accounts are lost.
To add a LOM user account:

1. **Grid:** From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
   Independent appliance: From the **System** tab, select the **System Manager** tab, expand the Toolbar and click **System Properties** -> **Edit**.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the **LOM** tab, complete the following:
   - **User Accounts:** Click the Add icon and complete the following:
     - **Name:** Enter the name of the LOM user account.
     - **Password:** Enter the password for the LOM user account. Note that while the maximum length allowed for the password is 15 characters and the minimum length is 4 characters. If you are running NIOS on the IB-4000 or the ND-4000 platform, you must enter a minimum password length of 8 characters. Otherwise, an error message is displayed.
     - **Confirm Password**: Enter the password again.
     - **Role**: From the drop-down list, select the role for the LOM user account. **Operator** allows users to perform all supported LOM related functions. **User** allows admins to only monitor system sensors such as temperature and CPU usage.
   - **Disable**: Select this to deactivate the user account but keep a user profile.
   - Click **Add** to add the new user account.
3. Save the configuration.

Configuring the IPMI Network Interface

You must configure the IPMI network interface before you can access the appliance remotely. To configure the IPMI network interface:

1. **Independent appliance**: From the **System** tab, select the **System Manager** tab, expand the Toolbar and click **System Properties** -> **Edit**.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the **LOM** tab, complete the following in the Network Configuration table:
   - **Address**: Enter the IPMI interface address here.
   - **Subnet Mask**: Enter the subnet mask for the IPMI interface.
   - **Gateway**: Enter the gateway address for the IPMI interface.
3. Save the configuration.

Modifying LOM Settings

To modify LOM settings:

1. **Grid:** From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
   Independent appliance: From the **System** tab, select the **System Manager** tab, expand the Toolbar and click **System Properties** -> **Edit**.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.

2. Modify the following:
    - **Enable Lights Out Management:** LOM is disabled by default. Select this checkbox to enable LOM. When you enable or disable this for the Grid, all members inherit the same setting.
    - **Network Configuration**: Click the fields in the table to modify the IPv4 address, subnet mask, and gateway address for the IPMI interface. For an HA pair, the appliance displays information only for the nodes that support IPMI. Enter the information for the following fields: **Address**, **Subnet Mask**, and **Gateway**. The **Node** and **LAN Address** fields are read-only, and you cannot modify them. The LAN address is the IPMI interface address.
    - **User Accounts**: Click the Add icon to add new LOM users. You can also select an existing LOM user and click the Edit icon to modify the user settings, as described in Adding LOM User Accounts above.
3. Save the configuration.

Viewing LOM Users

To view information about LOM users:

1. **Grid:** From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
   Independent appliance: From the **System** tab, select the **System Manager** tab, expand the Toolbar and click **System Properties** -> **Edit**.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the **LOM** tab, Grid Manager displays the following information for each LOM user:
    - **Name**: The name of the LOM user.
    - **Role**: The user role to which the LOM user was assigned. This can be **Operator** or **User**.
    - **Disabled**: Indicates whether the LOM user account is disabled or not. When a LOM user account is disabled, the user cannot access the appliance remotely.

IPMI Commands and Examples

This section describes some of the most commonly used IPMITool commands and examples. For more information about the IPMI commands and usage, visit the IPMItool web site a *http://ipmitool.sourceforge.net*.
To use IPMI commands, complete the following:

1. Ensure that you have properly enabled and configured LOM and the IPMI network interface.
2. Install IPMITool on a Linux management system. For information, visit the IPMItool web site at*http://ipmitool.sourceforge.net*.
   Access IMPITool and enter an IPMI command to perform a specific task. The appliance displays the corresponding output.
   Following are some of the most commonly used IPMI commands and their sample outputs. Note that command outputs vary by appliances. The following sample commands were performed on a Trinzic 1415 appliance. All sample commands in this section use the following syntax:

```
ipmitool -H <LOMIPAddress> -U  username -P password -L [OPERATOR/USER] -I
lanplus
<supported commands>
```

> **Note**
>
> If you reset IB-2225 using LOM and the interval between power off and power on is lower than 10 minutes, a hardware watchdog timeout message may be displayed in the syslog and may reset the newly powered on system thus putting it in an unstable state. If the interval is longer, the watchdog timer is released before the system is up, and a restart will bring the system in a good state without the watchdog timeout messages.

Command to be Used with Caution

```
power reset variant
```

Caution: Using this command has the same effect as pulling the power cord off the appliance.

Checking Power Status with User Role

Command:

```
ipmitool -H 10.37.2.70 -U user -P infoblox -L USER -I lanplus power status
```

Command output:

```
Chassis Power is on
```

Checking Various Sensors [Temperature, Voltage, FANS, Physical Security, Power supply, OEM] with User Role

Command:

```
ipmitool -H 10.37.2.70 -U user -P infoblox -L USER -I lanplus sensor
```

Command output:

```

Printing System Event Log with User Role

Command:

```
ipmitool -H 10.37.2.70 -U user -P infoblox -L USER -I lanplus sel list
```

Command output: The appliance displays all event log entries (if any)

Getting FRU Information with User Role

Command:

```
ipmitool -H 10.37.2.70 -U user -P infoblox -L USER -I lanplus fru
```

Command output:

```
FRU Device Description : Builtin FRU Device (ID 0) Board Mfg Date : Sun Dec 31
15:00:00 1995
 Board Mfg : Supermicro Board Serial : Product Serial :
```

Powering Off the Appliance with Operator Role

Command:

```
ipmitool -H 10.37.2.70 -U operator -P infoblox -L OPERATOR -I lanplus power off
```

Command output:

```
Chassis Power Control: Down/Off
```

Powering On the Appliance with Operator Role

Command:

```
ipmitool -H 10.37.2.70 -U operator -P infoblox -L OPERATOR -I lanplus power on
```

Command output:

```
Chassis Power Control: Up/On
```

Activating the Serial Console Port using Operator role

Command:

```

ipmitool -H 10.37.2.70 -U operator -P infoblox -L OPERATOR -I lanplus sol
```

```
activate
```

Command output:

```

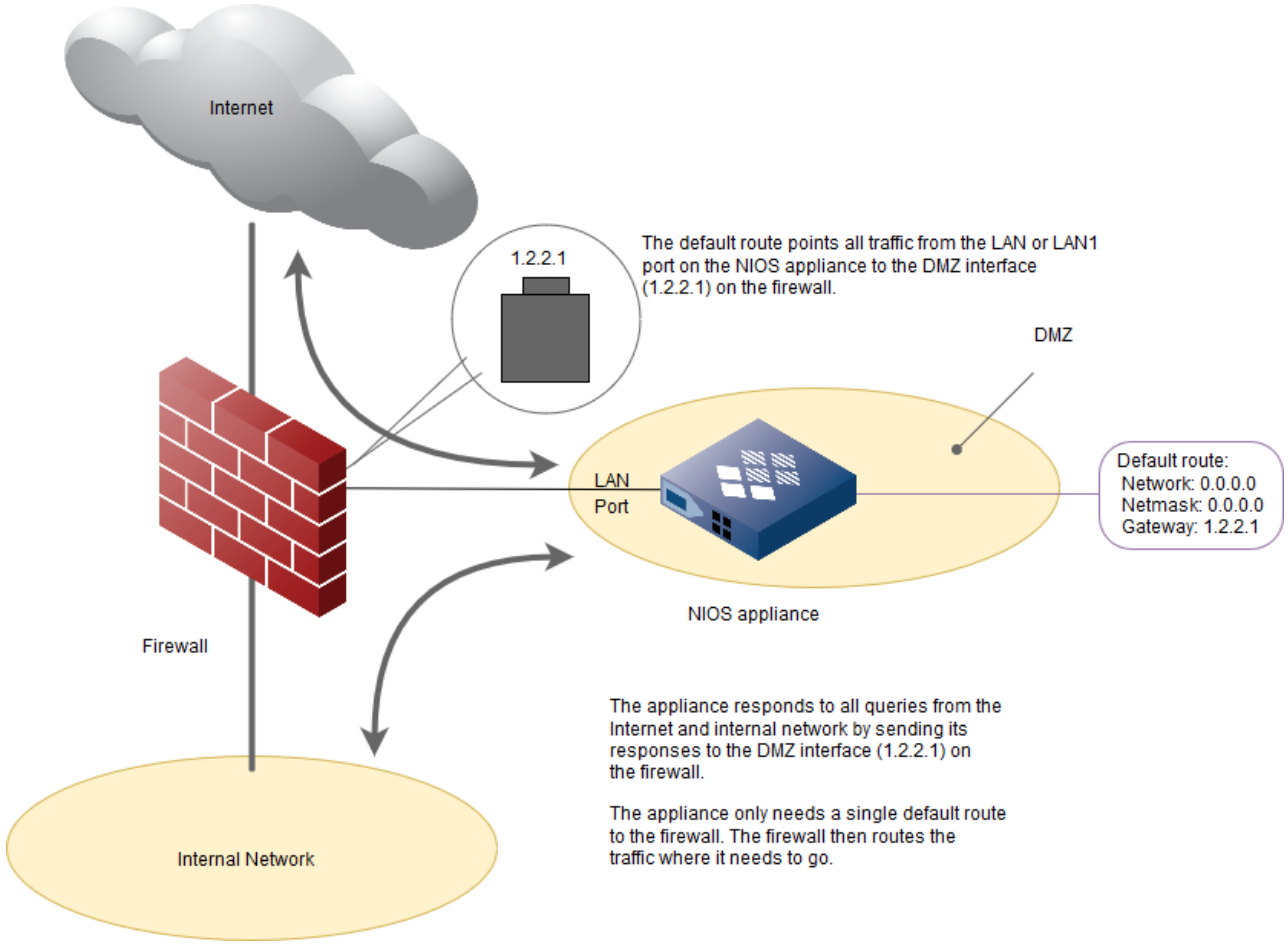
Setting Static Routes

When you put the NIOS appliance on a segment of the network where there is a single path to and from it, a single default route is sufficient. For example, in the figure Single Default Route below, the appliance is in the DMZ behind a firewall and connects to the rest of the network through the DMZ interface on the firewall. For example, when hosts send DNS queries from the Internet and the internal network to the appliance and when the appliance replies to those hosts, the firewall takes care of all the routing.

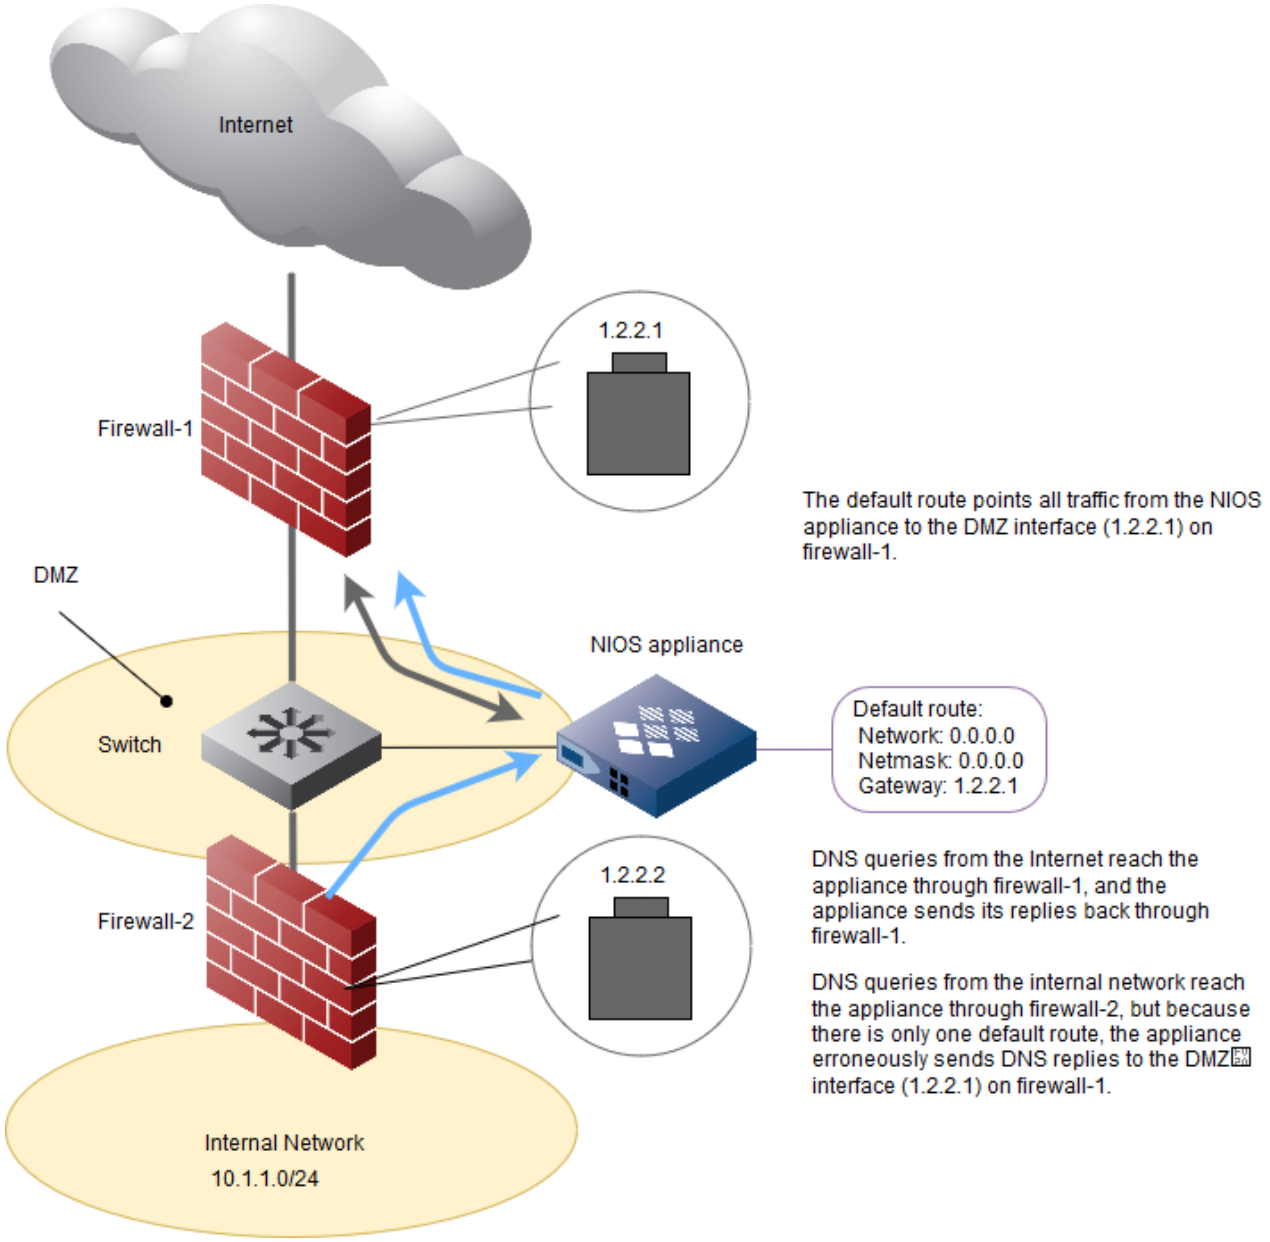
Single Default Route



When the NIOS appliance is on a segment of the network where there are multiple gateways through which traffic to and

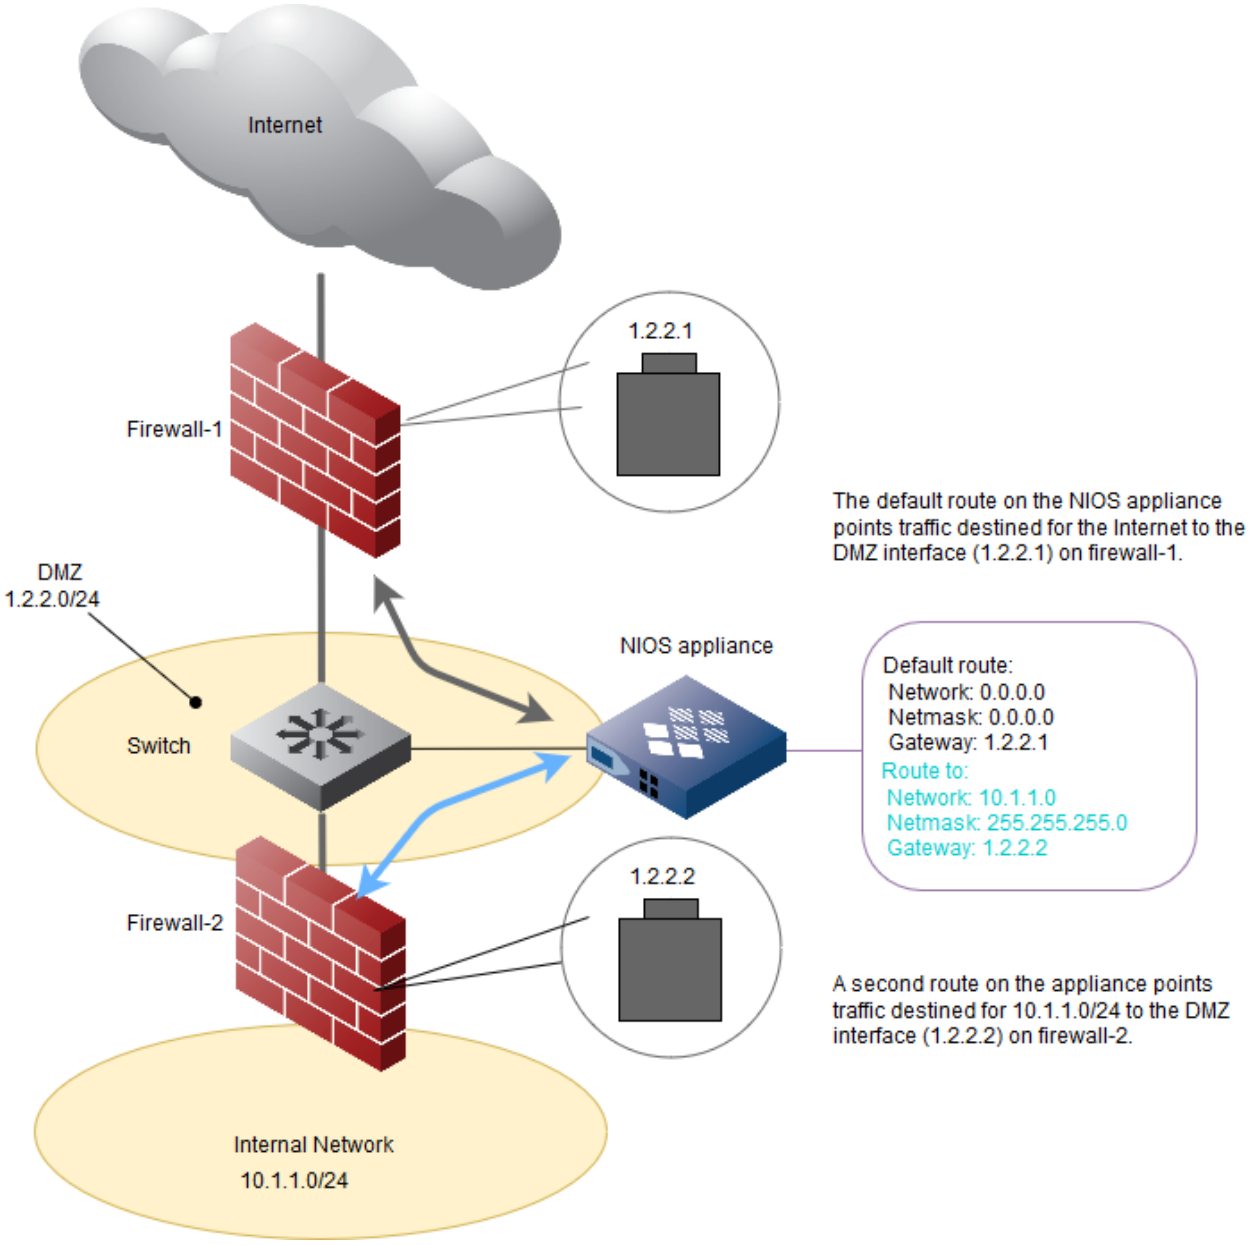
from the appliance can flow, a single default route is insufficient. For an example, see the below figure.

Erroneously Routed DNS Replies



To resolve the problem illustrated in the figure Erroneously Routed DNS Replies above, add a second route pointing traffic destined for 10.1.1.0/24 to use the gateway with IP address 1.2.2.2 on firewall-2. This is shown in the below figure.

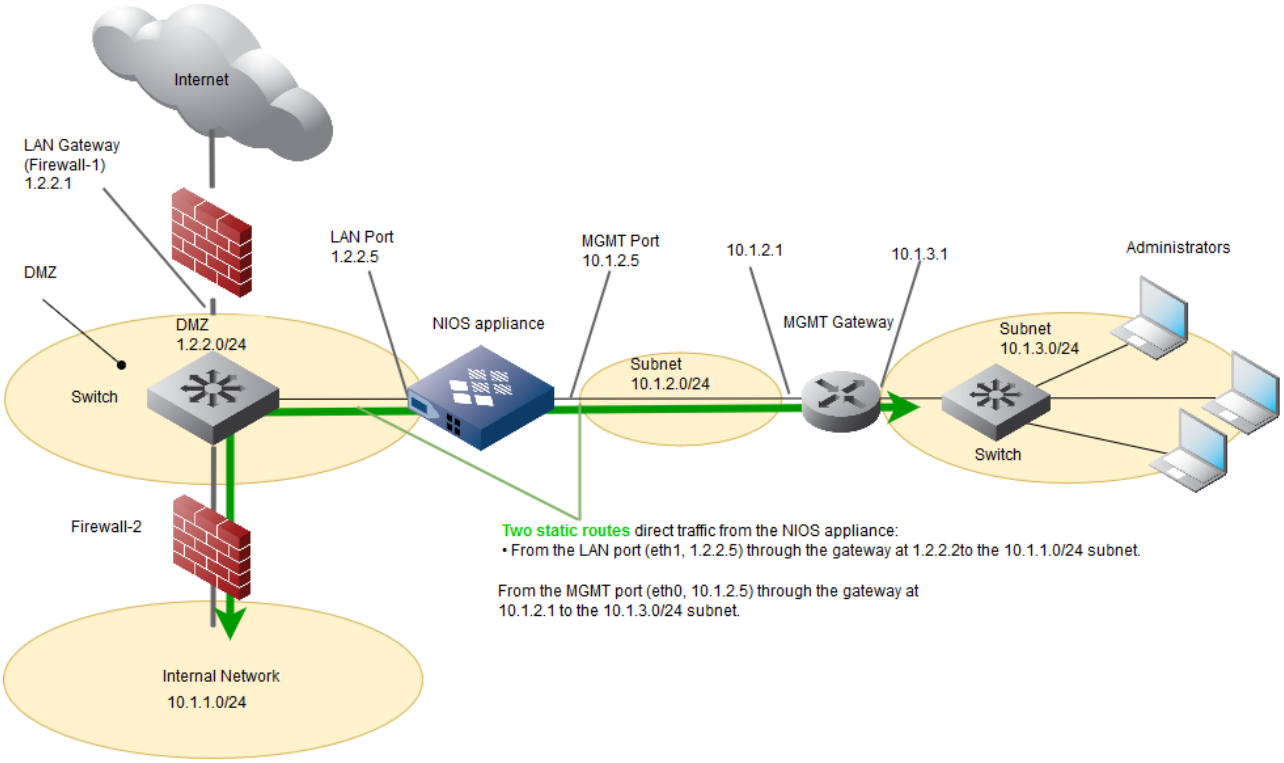
Properly Routed DNS Replies



Whenever you want the NIOS appliance to send traffic through a gateway other than the default gateway, you need to define a separate route. Then, when the appliance performs a route lookup, it chooses the route that most completely matches the destination IP address in the packet header.
When you enable the MGMT port, the gateway you reference in a static route determines which port the NIOS appliance uses when directing traffic to a specified destination.

- If a route definition references a gateway that is in the same subnet as the IP and VIP addresses of the LAN (or LAN1) and HA ports, the NIOS appliance uses the LAN (or LAN1) or HA port when directing traffic to that gateway.
- If a route definition references a gateway that is in the same subnet as the MGMT port, the NIOS appliance uses the MGMT port when directing traffic to that gateway

Static Routes for the LAN and MGMT Ports



Route Tables on the NIOS appliance

```
From LAN:
  1.2.2.0/24 dev eth1 scope link
  10.1.1.0/24 via 1.2.2.2 dev eth1
  default via 1.2.2.1 dev eth1

From MGMT:
  10.1.2.0/24 dev eth0 scope link
  10.1.3.0/24 via 10.1.2.1 dev eth0
  default via 10.1.2.1 dev eth0

From all:
  10.1.1.0/24 via 1.2.2.2 dev eth1
  10.1.3.0/24 via 10.1.2.1 dev eth0
  1.2.2.0/24 dev eth1 proto kernel scope link src 1.2.2.5
  10.1.2.0/24 dev eth0 proto kernel scope link src 10.1.2.5
default via 1.2.2.1 dev eth1
```

Note: There is a route table for each port as well as a comprehensive route table. For an HA pair, the LAN port route table is duplicated for the HA port.

In this illustration, the static routes are shown in green.

The need for routes can apply to any type of traffic that originates from the appliance, such as DNS replies, DHCP messages, SNMP traps, ICMP echo replies, Infoblox GUI management, and Grid communications.
To set a static route, do the following:

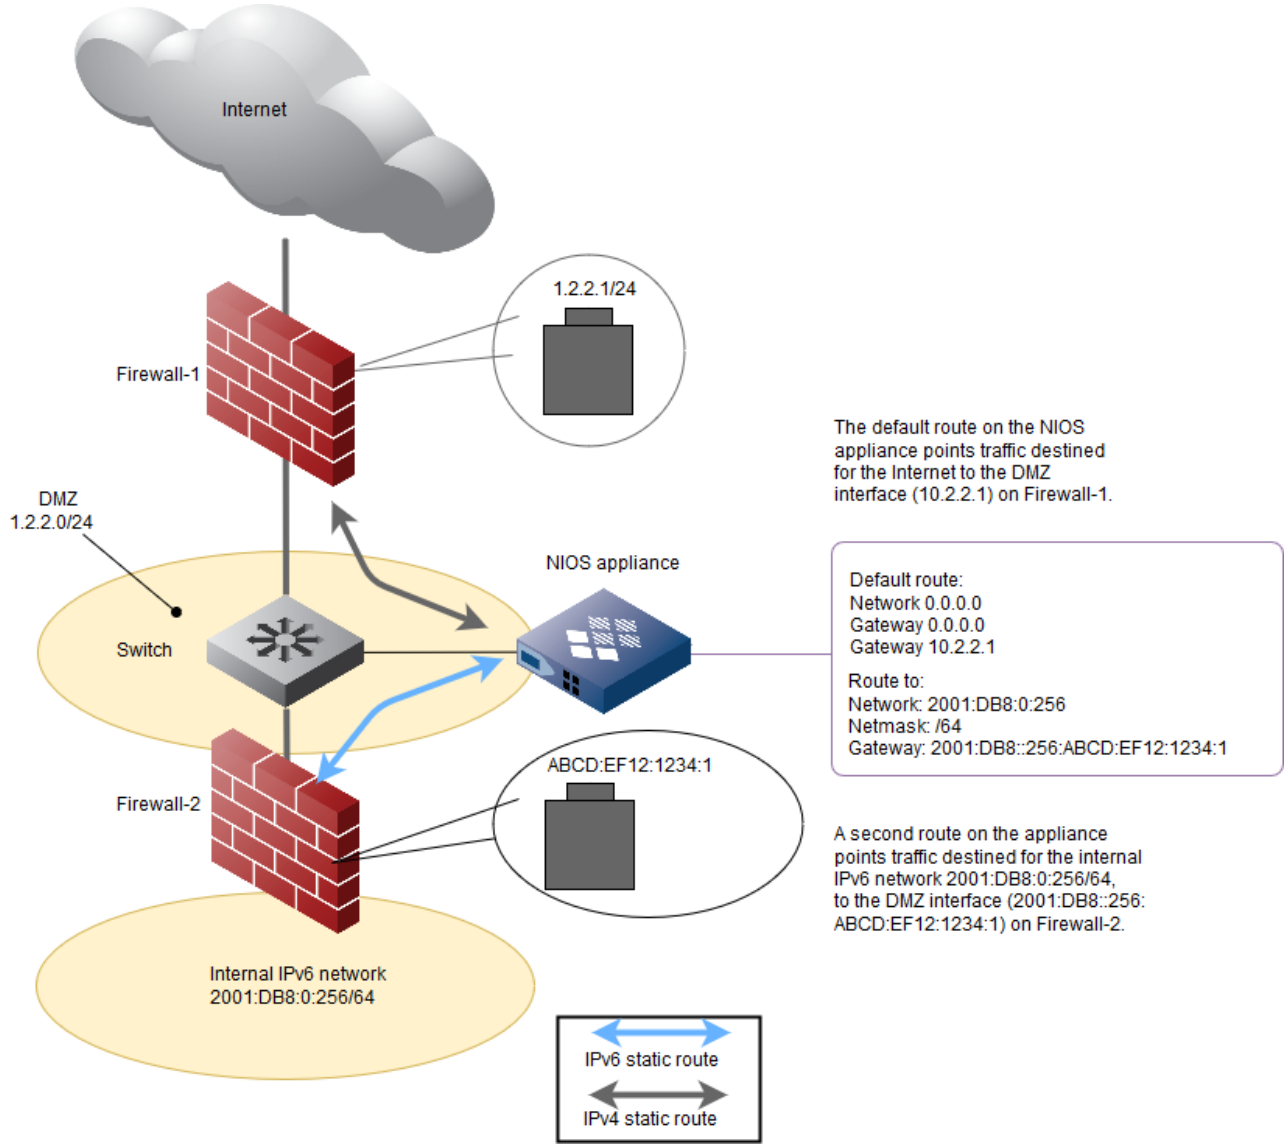
1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the **Network** -> **Advanced** tab of the *Grid Member Properties* editor, click the Add icon for the **IPv4 Static Routes** table, and then enter the following:
    - **Network Address:** Type the address and netmask of the remote network to which the NIOS appliance routes traffic.
    - **Gateway Address:** Type the IP address of the gateway on the local subnet through which the NIOS appliance directs traffic to reach the remote network. The gateway address must meet the following requirements:
        - It must belong to a working gateway router or gateway switch.
        - It must be in the same subnet as the NIOS appliance.
          Note to consult your network administrator before specifying the gateway address for a static route on the appliance. Specifying an invalid gateway address can cause problems, such as packets being dropped or sent to an incorrect address.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Defining IPv6 Static Routes

Principles and applications related to IPv4 static routing in this section apply equally to IPv6. In the figure Static Routes for IPv6 Traffic below, a NIOS appliance supports both IPv4 and IPv6 on its LAN1 port. IPv6 is routed to the internal network while the default IPv4 route remains to the outbound 10.2.2.1 address.
You can use prefix notation to enter an IPv6 network address; the full 128-bit gateway value must be entered. To set an IPv6 static route, do the following:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the **Network** -> **Advanced** tab of the *Grid Member Properties* editor, click the Add icon for the **IPv6 Static Routes** table, and then enter the following:
    - **Network Address:** Type the prefix and prefix length of the remote network to which the NIOS appliance routes traffic. As an example: 2001:DB8::256:/64. The double colon is required at the end of the prefix. NIOS performs validity checks on the address while it is being entered.
    - **Gateway Address:** Type the IP address of the gateway on the local subnet through which the NIOS appliance directs traffic to reach the remote network. As an example: 2001:DB8::256:ABCD:EF12:1234:1. The gateway address must meet the following requirements:
        - It must belong to a working gateway router or gateway switch.
        - It must be in the same subnet as one of the interfaces of the NIOS appliance.
        - The gateway address cannot be the same value as that for the VIP.
          Note to consult your network administrator before specifying the gateway address for a static route on the appliance. Specifying an invalid gateway address can cause problems, such as packets being dropped or sent to an incorrect address.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Static Routes for IPv6 Traffic



Enabling DNS Resolution

You can specify a network server to perform domain name queries and specify up to two name servers for resolving a DNS name. You can specify the IP address of a preferred name server and that of an alternate name server, plus use a search list for performing partial name resolution.
To enable DNS resolution for a Grid or for an independent appliance or HA pair:

1. **Grid:** From the **Grid** tab, select the **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
   Member: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* check box, and then click the Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the *Grid Properties* or *Member Properties* editor, select the **DNS Resolver** tab, and then enter the following:

- **Enable DNS Resolver:** Select the check box to enable the NIOS appliance to send DNS queries to the preferred or alternate name servers whose IP addresses you specify in the following fields.
  Click the Add icon and enter the IP addresses (IPv4 or IPv6) of the servers to which the appliance sends queries. The first address that you add is the primary DNS resolver and the second address that you add is the secondary DNS resolver. The appliance attempts to send queries to the servers in the order they are listed if it does not receive a response from a listed name server. To move a server up or down on the list, select it and drag it to its

new location or click the up and down arrows.
Note that if you are using the Infoblox Subscriber Parental Control feature, set the primary DNS resolver to a loopback address (127.0.0.1) to enable parental control.

- **Search List:** You can define a group of domain names that the NIOS appliance can add to partial queries that do not specify a domain name. For example, if you define a RADIUS authentication home server as "as1", and you list "corpxyz.com" and "hq.corpxyz.com" in the domain group list, then the NIOS appliance sends a query for as1.corpxyz.com and another query for as1.hq.corpxyz.com to the preferred or alternate name server. To specify domain names containing IDNs, manually convert it into punycode and specify domain names in punycode.
  To add a domain name, click the Add icon and type a domain name in the Search List field. To remove a domain name from the group, select it, and then click **Delete**.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing Licenses

You must install valid licenses for services and features to function properly in your Infoblox Grid. Different license types that are available are discussed in this topic. You can choose to obtain licenses for the desired features and services, and install them as static, dynamic, or Grid-wide licenses, depending on your network and business requirements.
After you install your licenses, you can monitor them from Grid Manager. Licenses are listed on the **Grid** tab -> **Licenses** tab. Grid Manager also displays the number of licenses that have expired and those that are expiring within the next 30 and 90 days respectively.
NIOS licenses are valid for Trinzic 2016 appliances, both physical and virtual. A NIOS license can be permanent or have an expiration date.

This topic includes the following sections:

License Types

Infoblox licenses are divided into the following classes:

- **Static**: Static licenses are member specific. They are installed and tied to the Grid Master or specific Grid members. Static licenses are mapped to the hardware ID for each individual NIOS or vNIOS appliance.

- **Dynamic**: These are floating licenses that are dynamically allocated to specific Grid members in the Grid. Dynamic licenses belong to a license pool, which is associated with the entire Grid. When not in use, they can be released back to the pool of licenses for further allocation. In an environment, such as a CMP (Cloud Management Platform), where you need to spin up multiple remote vNIOS appliances at different times based on business requirements, you can consider installing dynamic licenses.
- **Grid-wide**: Grid-wide licenses are associated with the entire Grid. They are not tied to any particular member. When installed, Grid-wide licenses are replicated to all members in the Grid. Although a Grid-wide license entitles all Grid members to run a particular feature, other conditions and factors determine whether the feature can be enabled on a particular member. For example, a member might not be able to run the Reporting and Analytics feature because it does not have the reporting appliance model. The currently supported Grid-wide licenses are **Security Ecosystem**, **Reporting Subscription**, **RPZ, Threat Analytics, Flex Grid Activation**, and **FireEye**. To configure Grid-wide licenses for RPZ, see *Grid-wide licenses for RPZ*.

The static, dynamic, and Grid-wide licenses can have one of the following terms of duration:

- **Perpetual**: Perpetual licenses are permanent licenses that do not have expiration dates.
- **Subscription** licenses: Unlike perpetual licenses, subscription licenses come with an expiry date and will be valid till the expiry of the contract. After subscription licenses expire, the renewed licenses must be downloaded from the support portal and applied. These licenses can be static or Grid-wide licenses. For more information about Subscription Licensing, see *Licensing Requirements*.
- **Temporary** licenses: You can enable one of several sets of temporary service licenses through the CLI command `set temp_license`. The duration for a temporary license is 60 days. They provide licensed features and functionality for the interim, while you wait for your permanent or subscription licenses to arrive. After these licenses expire, you cannot subscribe to the temporary licenses again. Note that pool licenses are not supported as temporary licenses.

Before any non-perpetual (subscription or temporary) licenses expire, an expiration warning appears during the Grid Manager login process. The warning reappears during each login until you renew the license. To renew a license, contact your accounts representative at Infoblox.

> ⚠ **Note**
> Grid Manager does not distinguish between subscription and temporary licenses.

Managing Static Licenses

Static licenses member-specific licenses that are mapped to the hardware IDs (also called as serial numbers) of individual NIOS or vNIOS appliances. Static licenses cannot be transferred among appliances. They come pre-installed on physical NIOS appliances according to the software packages you order at the time of purchase.
Static licenses can be perpetual or non-perpetual. A perpetual license does not have an expiration date. When you install a new static license with an expiration date beyond the existing license, it replaces the existing license. After you install static licenses on an appliance, you can view their status in Grid Manager.

Retrieving the Hardware ID of an Appliance

After you have set up or pre-provisioned a physical appliance or vNIOS virtual appliance, obtain the hardware ID or the virtual host hardware ID in case of a vNIOS virtual appliance:

1. Log in to the NIOS CLI, or open a terminal session for the VM and open the NIOS CLI.
2. Run the `show hwid` command as shown in the following example:

   ```
   nios-vm-ib-1420-gm > show hwid
    Hardware ID: 564d41e13a1cc55affb9bad4e3b5c48a
   ```

   Copy and paste the `Hardware ID` value for convenience.

   You can also run a `show license` command to obtain the same information:

   ```
   nios-vm-ib-1420-gm > show license
   ```

```
Version : 6.11.0-248090
Hardware ID : 564d41e13a1cc55affb9bad4e3b5c48a
```

> **Note**
> Make a note of the hardware IDs that you obtain during this procedure. Each of these unique Hardware ID values can be associated with a License Activation ID from your Contract Notification email. If a license key is installed for the current VM, that key value also appears in the output for the `show license` command.

Obtaining Static Licenses

You can retrieve a license key for a static license either in CSV (comma separated values) format or in .txt format. It includes the following information in the format: serial number, hardware ID, license type, end date, and license string.

You can either upload the CSV file to the appliance or copy the license information from the .txt file and paste it in the **Paste License(s)** field on the **Grid** tab -> **Licenses** tab -> **Member** tab -> **Add** dialog in Grid Manager. For more information, see the *Adding Permanent or Subscription Licenses* section.

To obtain permanent static licenses from Infoblox:

1. Log in to the support portal at *https://support.infoblox.com* using Google Chrome for best performance.
2. Click **My Products**.
   An overview page that contains the list of appliance (hosts) maintenance contracts, software entitlements (assigned and unassigned), and subscriptions is displayed.
3. For partners only: In the **Select Account** drop-down list, select the account for which you want to obtain licenses.
4. To obtain the license for a new VM:
   a. Click **Create Virtual Host**.
   b. In the *Create Virtual Host* dialog box, enter the virtual host hardware ID and choose the license technology as **DDI (for NIOS and BloxOne)** or **NetMRI**.
   c. Click **Save & Assign Software**.
   The *Manage Software of Host <host name>* page is displayed for the host you created.
   d. In the *Software available to be assigned to Host* section, enter the quantity to be assigned in the **Qty to Assign** field of the applicable license.
   e. Click **Assign Software** to assign the licenses.

   f. Click the **Download License Keys** button to download the licenses.
5. To obtain the license for a new physical appliance:
   a. Click the **Hosts** tab.
   b. In the search box, enter criteria to search for your appliance.
   c. In the **Manage** column of your appliance, select **Manage Software** from the drop-down list.
   The *Manage Software of Host <host name>* page is displayed.
   d. Assign licenses to the appliance or unassign them if not needed:
      i. In the *Software available to be assigned to Host* section, enter the quantity to be assigned in the **Qty to Assign** field of the applicable license, and click **Assign Software**.
      ii. In the *Software currently assigned to Host* section, enter the quantity to be unassigned in the **Qty to Unassign** field of the applicable license, and click **Unassign Software**.
   e. Click the **Download License Keys** button to download the licenses.
6. To obtain the license for an existing physical or a virtual appliance for which you are unsure of license entitlements or want to obtain a new listing of your license keys:
   a. Click the **Hosts** tab.
   b. In the search box, enter criteria to search for your appliance.
   c. In the **Manage** column of your appliance, select **Download License Keys** from the drop-down list.

d. Additionally, you may assign or unassign licenses and download them from the *Manage Software for Host <host name>* page as explained in step 5.

> **Note**
> Each VM License Activation ID should have a Hardware ID associated with it. As you install and spin up each virtual machine, establish written records for each Hardware ID with the VM License Activation IDs in a one-to-one ratio. These value pairs are necessary should you need to contact Infoblox Technical Support.

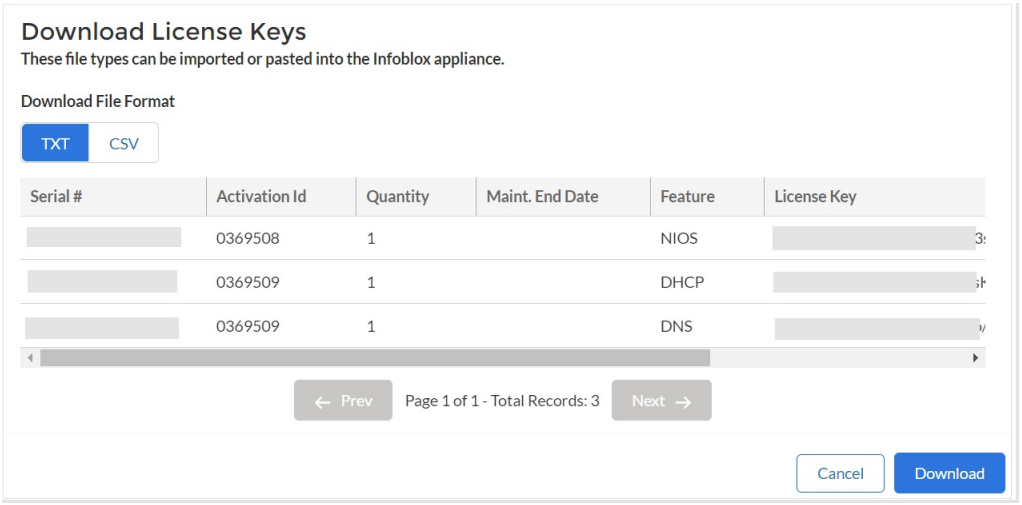
Downloading License Keys

You can download the license information either in CSV or TXT format. The following options are available in the *Support* portal:

- To download the license information for an individual appliance, click **Download License Keys** that is available on the **My Products** tab -> **Hosts** tab -> drop-down list, or on the *Manage Software for Host <host name>* page.
- To download the DDI license information for all your appliances at a time, click **Download All DDI License Keys** that is available on the **My Products** tab -> **Hosts** tab.

In the *Download License Keys* dialog that opens, complete the following steps:

1. Select between **TXT** or **CSV** format.
2. Click **Download**.



3. In the *Save as* dialog, choose the location where you want to save the file.
4. Click **Save**.

Managing Dynamic Licenses

Dynamic licenses are multiple licenses you obtain for NIOS appliances, both physical and virtual. You can install dynamic licenses in advance for different services and features and deploy them on demand, based on your business needs. The appliance stores these licenses in their respective license pools and allocates them when you deploy vNIOS virtual appliances. When you remove a vNIOS appliance from your Grid, the applicable licenses are automatically released back to the license pool. The appliance adjusts the total number of licenses accordingly. You can use dynamic licenses to automatically pre-provision and deploy vNIOS appliances. For more information about this feature, see *About Elastic Scaling*.

For a dynamic license, you can either upload the license file to the appliance or copy the information and paste it in the **Paste License(s)** field on the **Grid** tab -> **Licenses** tab -> **Pool** tab in Grid Manager. You must copy the entire string and save it to the text field. When you restore or perform a factory reset operation, you will lose the existing dynamic licenses.

License pools for a particular license type are an aggregate of the subpools that contain the respective license type. Subpools are either perpetual or non-perpetual with different expiration dates. NIOS displays non-perpetual and perpetual subpools with different expiration dates within the same pool.

Dynamic licenses can be allocated from a pool based on the aggregate install count. You can allocate licenses from a pool as long as the allocated count of perpetual and non-perpetual licenses does not exceed the count of perpetual and active non-perpetual licenses that are installed.

> **Note**
> You must install both the Grid and vNIOS licenses on a vNIOS appliance for it to join the Grid. You can add other licenses such as DNS, DHCP, or Cloud Platform depending on how you deploy your vNIOS virtual appliances.

Obtaining Dynamic Licenses

When you purchase licenses for specific features and services, you may deploy the licenses as dynamic licenses. License information is stored in a license file with the following information for each license: LSN-P (License Serial Number - Proxy), LK-P (License Key Proxy, LSN (License Serial Number) and LK (License Key). License keys are generated based on the LPC_UID (License Pool Container Unique ID) of the Grid Master. You must first obtain the LPC_UID of the Grid, also called the Grid license UID from the Grid Master and then contact Infoblox Technical Support to obtain dynamic licenses.
Infoblox stores information related to dynamic licenses in a license file. When you install dynamic licenses, you must upload the entire license file to the Grid Master, as described in the *Adding Permanent or Subscription Licenses* section.
To obtain dynamic licenses:

1. Log in to Grid Manager and obtain the LPC_UID from the Grid Master:
   a. From the **Grid** tab, select the **Licenses** tab -> **Pool** tab, and then click **Export All Licenses** in the Toolbar.
   b. Save the CSV file.
   c. Open the CSV file. The LPC_UID is displayed in the **SIGNATURE** row. Copy this ID. You will need this ID when contacting Infoblox Technical Support.
      Note that you can also use the show `license_pool_container` CLI command to display the `LPC_UID`.
2. Contact Infoblox Technical Support or your Infoblox representative to obtain the dynamic licenses.

Manually Allocating Dynamic Licenses

To allocate a particular feature license to a NIOS member:

1. From the **Grid** tab, select the **Licenses** tab -> **Pool** tab.
2. Select the feature license and click the Action icon ☰ next to the license, and then select **Allocate** from the list.
3. In the *Allocate Pool Licenses* dialog, click **Select Member Node**.
4. From the *Member Selector*, click the FQDN of the NIOS member on which you want to install the feature license. The appliance displays the member in the **To this member:** field.
5. Click **Allocate** to install this license on the selected member or click **Cancel** to cancel this action.
   NIOS allocates the license and adjusts the numbers in the **Assigned** and **Available** fields on the **Pool** tab.

Manually Deallocating Dynamic Licenses

To deallocate a particular feature license from a NIOS member:

1. From the **Grid** tab, select the **Licenses** tab -> **Member** tab.
2. Select the license and click the Action icon next to the checkbox, and then select **Deallocate** from the list.
3. In the *Deallocate Pool Licenses* dialog, select the licenses you want to deallocate from the Pool Licenses table.
4. Click **Deallocate** to remove the licenses from the members or click **Cancel** to cancel this action.
   NIOS deallocates the license from the respective members and adjusts the numbers in the **Assigned** and **Available** fields on the **Pool** tab.

Manually Revoking Dynamic Licenses

To remove a particular feature license from the pool:

1. From the **Grid** tab, select the **Licenses** tab -> **Pool** tab.
2. Select the feature license and click the Action icon next to the checkbox, and then select **Revoke** from the list.
3. In the *Remove Licenses* dialog, click the **Number** field and enter the number of licenses you want to remove for the selected license type.
4. Click **Remove Licenses** to remove the licenses or click **Cancel** to cancel this action.
   NIOS removes the licenses and adjusts the numbers in the **Assigned** and **Available** fields on the **Pool** tab.

Managing Grid-wide Licenses

NIOS supports Grid-wide licenses that are valid across the entire Grid. You can obtain Grid-wide licenses for features listed in this section. Although a Grid-wide license entitles all Grid members to run a particular feature, other conditions and factors determine whether the feature can be enabled on a particular member. For example, a member might not be able to run the Reporting and Analytics feature because it does not have the reporting appliance model.

For a Grid-wide license, you can either upload the license file to the appliance or copy the information and paste it in the text field on the **Paste License(s)** field on the **Grid** tab -> **Licenses** tab -> **Grid Wide** tab of Grid Manager. You must copy the entire string (license type, expiry date, and license string). The **Flex Grid Activation** license is bundled with the following licenses: Grid, Unbound, DNS Cache Acceleration, DNS, DHCP, DNS Traffic Control, Response Policy Zone, Software Threat Protection, Threat Protection Update, DNSFW, NXDOMAIN Redirect, Dual Engine DNS (only for recursive DNS), Microsoft Management, Threat Analytics, Security Ecosystem, and Cloud Network Automation.
Note the following about Grid-wide licenses:

- When you restore or perform a factory reset operation, you will lose the existing Grid-wide licenses.
- NIOS restores any Grid-wide licenses that are present in a restored database.
- When you restore a database from another Grid, NIOS replaces the UID of the Grid and the Grid-wide licenses from the other Grid.
- Static and Grid-wide licenses of the same type can co-exist in the same Grid.
- If a member is pre-provisioned for a specific feature, it is allowed to join the Grid that has the Grid-wide license for that feature even if the member does not have a license for that feature.
- To install a Cloud Network Automation license on an IB-FLEX appliance, it must be set up as a Grid Master.

About the Flex Grid Activation License

Flex Grid Activation is a permanent Infoblox license that you can implement as a NIOS Grid-wide license to enable the following features at the same time:

- Grid
- Unbound
- DNS Cache Acceleration
- DNS
- DHCP
- DNS Traffic Control
- Response Policy Zone
- Software ADP
- Threat Protection Update
- DNSFW
- NXDOMAIN Redirect
- Query rewrite
- Threat Analytics
- Security Ecosystem
- Captive Portal
- Microsoft Management
- Cloud Network Automation

For more information, see *About IB-Flex*. After you install the **Flex Grid Activation** license, you can view it on the **Grid** tab -> **Licenses** tab -> **Grid Wide** tab of Grid Manager.

You can install the **Flex Grid Activation** license on a Grid Master even if IB-FLEX is not a part of the Grid, but this license is effective only for an IB-Flex member. The Infoblox License Portal allows you to acquire any number of **Flex Grid Activation** license keys for each individual Grid. To install a temporary license, use the *set temp_license* CLI command.

About the Flex Grid Activation for Managed Services License

Flex Grid Activation for Managed Services is a combination of all existing Infoblox licenses that you can implement as a NIOS Grid-wide license. If you install this license, you do not need to install each license separately. The Flex Grid Activation for Managed Services license comprises the following licenses:

- Grid
- Unbound
- DNS Cache Acceleration
- DNS
- DHCP
- DNS Traffic Control
- Response Policy Zone
- NXDOMAIN Redirect
- Dual Engine DNS (only for recursive DNS)
- Software Threat Protection
- Threat Protection Update
- Threat Analytics
- Security Ecosystem
- Microsoft Management
- Cloud Network Automation

You can install the Flex Grid Activation for Managed Services license only on a Grid Master or a standalone appliance. To install a temporary license, use the *set temp_license* CLI command.

> **Note**
> If you install the Flex Grid Activation for Managed Services license, you cannot install the Flex Grid Activation license and if you install the Flex Grid Activation license, you cannot install the Flex Grid Activation for Managed Services license.

Obtaining Grid-wide Licenses

When you purchase licenses for specific features and services, the licenses may be Grid-wide licenses. License information is stored in a license file with the following information for each license: LSN-P (License Serial Number - Proxy), LK-P (License Key Proxy, LSN (License Serial Number) and LK (License Key).

License keys are generated based on the license UID of the Grid Master. You must first obtain the UID of the Grid and then contact Infoblox Technical Support to obtain the Grid-wide licenses.

> **Note**
> Ensure that you obtain the license UID of the Grid Master. If you use the license UID of a Grid member or an appliance that has not yet joined the Grid, you might not be able to properly install the Grid-wide license.

The license file (CSV) format for Grid-wide licenses are as follows:
GRID_WIDE,license_uid,license_type,[expiry_date],license_string

Infoblox stores information related to Grid-wide licenses in a license file. When you install Grid-wide licenses, you must upload the entire license file to the Grid Master, as described in the *Adding Permanent or Subscription Licenses* section.

To obtain Grid-wide licenses:

1. Log in to Grid Manager and obtain the license UID of the Grid Master as follows:
   a. From the **Grid** tab, select the **Licenses** tab -> **Grid Wide** tab, and then click **Export All Licenses** from the Toolbar.
   b. Save the CSV file.
   c. Open the CSV file. The UID is displayed in the **SIGNATURE** row. Copy this ID. You will need this ID when contacting Infoblox Technical Support.

Note to obtain the UID of the Grid, you can use the `show license_uid` command on the Grid Master. For more information, refer to the *Infoblox CLI Guide*.

2. Contact Infoblox Technical Support or your Infoblox representatives to obtain the Grid-wide licenses.

Adding Permanent or Subscription Licenses

To add permanent or subscription licenses:

1. From the **Grid** tab, select the **Licenses** tab -> **Member** tab or **Pool** tab or **Grid Wide** tab and click the Add icon.
2. Select one of the following:
   - **Upload License File**: Use this method to upload static, dynamic, and Grid-wide license files. Click **Select File**, navigate to the license file, and click **Open**.
   - **Paste License(s)**: Paste the license key in this text field. You must paste the entire string in CSV format: serial number, hardware ID, license type, end date (in the mm/dd/yyyy format), and license string. If you are pasting multiple licenses, start each string on a new line. For example, 564daaa3ef07e648a563434a2b412834,564daaa3ef07e648a563434a2b412834,DNS,12/05/2018,EwAAADU+PZEOjFsMAXxw4nlfHyZ6tdw
3. Click **Save License(s)**.
   The appliance validates the license and adds it to the table. Close the browser window and log in to Grid Manager. If you are activating licenses for an HA pair, you must follow this procedure for both nodes.

> **Note**
> - Once the NIOS license is installed, you must wait for NIOS to restart (if prompted) before you install other licenses.
> - To transfer licenses between vNIOS on VMware appliances, refer to the *Infoblox Installation Guide for vNIOS for VMware*.

Adding Temporary Licenses

Use the `set temp_license` command to generate and install temporary licenses. This can provide licensed features and functionality for the interim, while you wait for your permanent license to arrive.
To generate a temporary license:

1. Log in to the NIOS appliance through a remote console window.
   For more information on how to open a remote console window, refer to the *Infoblox CLI Guide*.
2. At the Infoblox command prompt, enter `set temp_license`.
   The appliance lists the available licenses, and you select those you need. For more information, see *set temp_license*.
3. Enter the number of licenses you want to install.
4. Confirm the selection when prompted, and the following message appears:
   `Temporary license is installed.`

> **Note**
> Once the NIOS license is installed, you must wait for NIOS to restart before you install other licenses.

Viewing Licenses

If the appliance is part of a Grid, you must log in to the Grid Master to view license information from Grid Manager. If the appliance is an independent appliance, log in to System Manager on the appliance. If you have transferred licenses from one vNIOS appliance to another, you can view information about the new and replaced licenses.
Grid Manager displays licenses on the **Grid** tab -> **Licenses** tab. You can view license information for all static and dynamic licenses (including temporary licenses) on the **Member** tab, and a summary of dynamic licenses on the **Pool** tab.

Viewing Member Licenses

To view the information about active licenses, including static and dynamic licenses that are currently assigned or allocated to NIOS and vNIOS appliances:

1. Log in to Grid Manager on the Grid Master or System Manager on an independent appliance.
2. Select the **Grid** or **System** tab -> **Licenses** tab -> **Member** tab. The appliance displays the following information:
    - **Type of License**: The license category. This can be **Static**, **Dynamic, Grid Wide,** or **Paid NIOS**. Static licenses are individual licenses you obtain and are currently assigned to specific appliances. These licenses are tied to specific hardware IDs and you cannot deallocate them. Dynamic licenses are pooled licenses that support the Elastic Scaling feature, which enables central tracking, granting, and management of NIOS feature licenses for vNIOS entities in the Grid. You can manually allocate and deallocate dynamic licenses. When installed, Grid-wide licenses are replicated to all members in the Grid. The currently supported Grid-wide licenses are **Security Ecosystem**, **Reporting Subscription**, **RPZ, Flex Grid Activation** and **FireEye**. Paid NIOS represents the pay-as-you-go licensing model for vNIOS virtual appliances. In the AWS Marketplace, when you use the Paid NIOS model to launch the vNIOS for AWS virtual appliance, the virtual appliance comes pre-installed with the following permanent licenses: **vNIOS**, **Grid**, **DNS**, and **CNA** (Cloud Network Automation). As long as the virtual appliance is up and running, you can use the NIOS features that these licenses provide. You cannot add, delete, import, or export Paid NIOS licenses. For information about the Paid NIOS in AWS Marketplace, refer to the *Installation Guide for vNIOS for AWS*.
    - **Feature**: Indicates the features for which the license was installed. For example, if the license was installed for DNS service, this shows **DNS**.
    - **Name**: The FQDN of the appliance.
    - **HA**: Indicates whether the appliance is an HA pair.
    - **IPv4 Address**: The IPv4 address of the appliance, if applicable.
    - **IPv6 Address**: The IPv6 address of the appliance, if applicable.
    - **Hardware ID**: The unique hardware ID of the appliance. The ID is highlighted in red if the license on the appliance was removed.
    - **Serial Number**: The serial number of the appliance.
    - **Type Context**: Depending on the license type, this field displays the attribute (such as **Model**) that the license controls. This field is blank if the license does not control any attribute type. This field can display one of the following:
        - **Leases**: Indicates that this DHCP license supports a specific number of DHCP leases. The number of leases supported is displayed in the **Type Details** field.
        - **Model**: Indicates that this vNIOS license supports a specific vNIOS virtual appliance model. The model supported is displayed in the **Type Details** field.
    - **Type Details**: Information about the attribute type that the license monitors. This field can display the following information for each attribute:
        - **Leases**: The number of DHCP leases that the DHCP license supports.
        - **Model**: The model of the NIOS virtual appliance, such as IB-V1410 or IB-V2215.
    - **Expiration**: The expiration date of the license.
    - **Replaced Hardware ID**: The hardware ID of the appliance whose license was removed.

Viewing Dynamic Licenses

You can install dynamic licenses on the Grid Master for future vNIOS appliance deployments. When you install dynamic licenses, the Grid Master store them in a license pool. You can view these licenses and evaluate license usage for vNIOS virtual appliances.
For a particular feature, such as DNS or DHCP, Grid Manager displays dynamic licenses in sub pools so you can view the number of permanent licenses, the number of licenses that are expiring on a particular date, and those that are expired. NIOS highlights the licenses that are going to expire soon using a yellow background. Licenses that are approaching expiry are highlighted with a pink background.

> ⚠ **Note**
> The overall license status for a particular feature reflects the most critical status among all licenses in the pool. For example, if there are expired licenses in the pool, the overall status for this license type appears as expired.

To view dynamic licenses in the pool and their usage information:

1. Log in to Grid Manager on the Grid Master.
2. Select the **Grid** tab -> **Licenses** tab -> **Pool** tab. The appliance displays the following information:
    - **Feature**: The feature for which you have obtained the license.
    - **Installed**: The number of licenses that have been installed for the specified feature.
    - **Assigned**: The number of licenses currently allocated to vNIOS virtual appliances.
    - **Available**: The number of licenses that are currently available for the specified feature.
    - **License Model**: For vNIOS license only. Indicates the model type of the vNIOS virtual appliance. Note that the vNIOS license you install on the vNIOS appliance must match the appliance model. You can use vNIOS license that has a higher capacity on a vNIOS appliance that has a smaller capacity, but not vice versa. For example, you can install a CP-V1405 license on a CP-V805 or CP-V1405 appliance, but not on a CP-V2205.
    - **Limit Context**: Depending on the license type, this field displays the attribute (such as **Model**) that the license controls. This field is blank if the license does not control any attribute type. This field can display one of the following:
        - **Leases**: Indicates that this DHCP license supports a specific number of DHCP leases. The number of leases supported is displayed in the **Type Details** field.
        - **Model**: Indicates that this vNIOS license supports a specific vNIOS virtual appliance model. The model supported is displayed in the **Type Details** field.
    - **Limit Value**: Information about the attribute type that the license monitors. This field can display the following information for each attribute:
        - **Leases**: The number of DHCP leases that the DHCP license supports.
        - **Model**: The model of the vNIOS virtual appliance, such as IB-V410 or IB-V2215.
    - **Expiration**: The expiration date and time of the license. It displays **Permanent** for permanent licenses and **Expired** for licenses that expired.
3. Click the arrow mark next to the checkbox of a specific feature to view the list of licenses and their respective expiration dates.

Viewing Grid-wide Licenses

Grid Manager displays the licenses that are configured for the respective Grid. To view Grid-wide licenses:

1. Log in to Grid Manager on the Grid Master.
2. Select the **Grid** tab -> **Licenses** tab -> **Grid Wide** tab. The appliance displays the following information:
    - **Feature**: The feature for which you have obtained the license.
    - **Limit Context**: Depending on the license type, this field displays the attribute (such as **Model**) that the license controls. This field is blank if the license does not control any attribute type. This field can display one of the following:
        - **Leases**: Indicates that this DHCP license supports a specific number of DHCP leases. The number of leases supported is displayed in the **Type Details** field.
        - **Model**: Indicates that this vNIOS license supports a specific vNIOS virtual appliance model. The model supported is displayed in the **Type Details** field.
    - **Limit Value**: Information about the attribute type that the license monitors. This field can display the following information for each attribute:
        - **Leases**: The number of DHCP leases that the DHCP license supports.
        - **Model**: The model of the vNIOS virtual appliance, such as IB-V1410 or IB-V2215.
    - **Expiration**: The expiration date and time of the license. It displays **Permanent** for permanent licenses.

You can do the following:

- Delete a Grid-wide license as explained in the *Removing Licenses* section.
- Click the Export icon to export the list of licenses to a .csv file.
- Click the Print icon to print the list of licenses.

To search for specific licenses on the **Member**, **Pool** and **Grid Wide** tabs, you can use filters and the **Go to** function (the **Go to** function is not supported in the Pool tab) to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches. You can also create a quick filter to save frequently used filter criteria. For information about Using Quick Filters, see *Using Quick Filters*.

Backing Up Licenses

You can back up all static licenses, dynamic licenses added in the license pool container, and Grid-wide licenses in case you need to re-install them at a later time. Infoblox recommends backing up the licenses before removing any of them.

> **Note**
> Dynamic licenses are not exported to this file. Dynamic licenses are automatically released and returned to the license pool on the Grid Master when a member leaves the Grid. Unallocated dynamic Licenses are available for allocations.

When you back up the licenses, Grid Manager creates a CSV file that lists the following information for each license: serial number, hardware ID, license type, end date, and license string.
To back up licenses:

1. From the **Grid** tab, select the **Licenses** tab.
2. Click **Export All Licenses** in the toolbar. Grid Manager generates a CSV file that contains all the licenses. Depending on the browser you use, you can then open the file or save it to a specified location.

Removing Licenses

You can remove licenses and reset a NIOS appliance to its factory default settings. For example, if you have a NIOS appliance running the DNSone package with the Grid upgrade, but you want to use it as an independent appliance, you can remove the Grid license. Infoblox recommends that you back up licenses before removing them, in case you decide to re-install them at a future time.
When you remove a Grid-wide license, the licensed feature is deactivated on all the members that are affected by the license. On the other hand, when you remove a Grid member from the Grid, the member no longer has the ability to run the feature associated with the Grid-wide license now that is it not part of the Grid.

> **Note**
> - Exercise caution when removing licenses; you may render an appliance unusable by removing the wrong license. Other feature sets may be affected once you remove a license; for example, removing licensing for DNS and DHCP services will also disable task packs on the **NIOS Dashboards –> Tasks** page.
> - Infoblox does not recommend deleting CNA temporary licenses as it may result in unexpected behavior. For example, after deleting a CNA temporary license, running a vRA workflow to create a reservation on a vNIOS setup followed by a vDiscovery job, can result in a VM affiliation conflict. To clear the conflict, as a workaround, you must install a CNA permanent license, and then delete it. For assistance, contact the Infoblox Technical Support.

To remove an active license:

1. From the **Grid** tab, select the **Licenses** tab -> **Member** tab or **Grid Wide** tab.
2. Select the license and click the Delete icon.
   Check the license that you are about to remove. Note that removing the wrong license can render an appliance unusable.
3. Click **Yes** when the confirmation dialog appears.
4. Close the browser window and log in to the Infoblox GUI.

NIOS Licenses

The following table lists NIOS licenses and the behavior when the subscription licenses expire:

License	Supported Features	When the License Expires
Advanced DNS Protection (ADP) / Threat Protection	Advanced DNS Protection / Threat protection	Existing functionality continues to work as is. You can add new custom rules and publish. You may not be able to upload new ruleset, but old rulesets remain functional.
Software Advanced DNS Protection / Threat Protection (software add-on)	Virtual advanced DNS protection / Threat protection	
Threat Protection Update	Receive and update threat protection rules and rule updates	
Threat Protection and Threat Protection Update	• Threat protection • Elastic scaling	
Security Ecosystem	Outbound Notification	Existing functionality continues to work as is with existing and new endpoints and notifications. Integrations such as the FireEye feed will stop functioning as it is dependent on RPZ.
FireEye	FireEye	Existing functionality continues to work as is.
DNS Cache Acceleration (DCA)	DNS Cache Acceleration	Existing functionality continues to work as is. Changes and new additions work fine.
DNS	DNS	Existing functionality continues to work as is. Allows addition of new zones and networks.
DNS Traffic Control (DTC)	DNS Traffic Control	Existing functionality continues to work as is.
Threat Analytics	Threat Insight/Threat Analytics	Existing functionality continues to work as is. New RPZ may not take effect as Named server does not restart after license expiry.
DHCP	DHCP	Existing functionality continues to work as is. Allows addition of new zones and networks.
Microsoft Management (MS MGMNT)	• Management of Microsoft DNS and DHCP servers from Infoblox Grid Manager. • Synchronization of DNS and DHCP data to the Grid database.	New data (new zone) added on Microsoft server is not synchronized to NIOS.
*Cloud Network Automation	Cloud network automation	Existing functionality continues to work as is.

License	Supported Features	When the License Expires
Cloud Platform	Cloud Platform	Existing functionality continues to work as is. The Cloud API is available. In Grid Manager, you can manage cloud objects from the **Grid** -> **Grid Manager** -> **Cloud-API** tab. You may not be able to add an A record on a zone that has Cloud Platform members assigned to it.
Response Policy Zone (RPZ)	Response Policy Zone	RPZ Feed zones and zone transfer continue to work. RPZ feeds will stop.
Dual Engine DNS (only for recursive DNS)	Unbound DNS	Functionality continues to work as is.
NIOS/vNIOS	NIOS services	Functionality continues to work as is.
Grid	• When installed on a member that has no other Infoblox licenses installed, you can Join the member to a Grid. • When installed on a Grid Master, you can get the UID required to obtain dynamic licenses.	Functionality continues to work as is with existing members. You may not be able to add new members to the Grid.
Query Redirection	Query Redirection/ NXDOMAIN Redirect	Functionality continues to work as is.
Reporting	Reporting	Reporting functionality continues to work as is and reports update. If the license related to FireEye expires, old data does not show in the *FireEye Alerts* report.
Multi-Grid Management (MGM)	Multi-Grid Management	Functionality continues to work as is.
Network Discovery (ND)	Network Discovery	Functionality continues to work as is.

* To install a Cloud Network Automation license on an IB-FLEX appliance, it must be set up as a Grid Master.

Licenses that are bundled with multiple licenses:

License	Supported Features	When the License Expires
DNSone includes the following licenses: • DNS • DHCP	• DNS • DHCP	-

License	Supported Features	When the License Expires
The Flex Grid Activation license includes the following licenses: • Grid • Unbound • DNS Cache Acceleration • DNS • DHCP • DNS Traffic Control • Response Policy Zone • NXDOMAIN Redirect • Dual Engine DNS (only for recursive DNS) • Software Threat Protection • Threat Protection Update • Threat Analytics • Security Ecosystem • Microsoft Management • *Cloud Network Automation	• Grid • Unbound • DNS Cache Acceleration • DNS • DHCP • DNS Traffic Control • Response Policy Zone • Software ADP • Threat Protection Update • DNSFW • NXDOMAIN Redirect • Query rewrite • Threat Analytics • Security Ecosystem • Captive Portal • Microsoft Management • Cloud Network Automation (only if IB-FLEX is used as a Grid Master).	Functionality continues to work as is for all features except for the Grid license, where functionality works for existing members. You may not be able to add new members to the Grid.
The Flex Grid Activation for Managed Services license installed only on Grid Master or a standalone appliance, includes the same set of licenses bundled with the Flex Grid Activation license.	Same features as the Flex Grid Activation license.	

* To install a Cloud Network Automation license on an IB-FLEX appliance, it must be set up as a Grid Master.

Note
NTLMv2 is the only authentication method supported for Microsoft servers managed from Infoblox Grids. For information about managing Microsoft Windows servers from Grid Manager, see *Managing Microsoft Windows Servers*.

About IB-FLEX

IB-FLEX is a virtual platform that is scalable based on the resource that you allocate to the virtual machine. NIOS automatically detects the capacity of the virtual machine and scales it to the appropriate platform after you provision the IB-FLEX member.
You must first install the Grid license on a non IB-FLEX appliance that is designated as the Grid Master to allow members to join the Grid, even if you have already installed an **Flex Grid Activation** license. This license does not affect a non IB-FLEX Grid Master.
An IB-FLEX appliance designated as a member does not require any license, either Grid or vNIOS, while joining the Grid. When you register an IB-FLEX member, the appliance checks for the Grid (enterprise) license and changes it to a non IB-FLEX member. For an IB-FLEX appliance, it checks for an **Flex Grid Activation** Grid-wide license before node registration.
IB-FLEX members can join the Grid through the MGMT interface when Software ADP is enabled. You can configure an IB-FLEX appliance to function as a Grid Master or a member. To enable reporting for a Grid member that is running Software ADP, you must configure the MGMT interface.
A non IB-FLEX appliance designated as a member requires either a Grid and/or vNIOS/NIOS licenses installed to join the Grid. Similarly, for a reporting appliance to join the Grid, you must install a Grid and/or vNIOS/NIOS licenses. You cannot assign pool licenses to an IB-FLEX appliance. IB-FLEX supports HA for appliances that are running Software ADP.
Infoblox supports elastic scaling on IB-FLEX members that use the **Flex Grid Activation** Grid-wide license. It also supports pre-provisioning for Software ADP on the supported platforms. You must add the new IB-FLEX model to the list of supported pre-provisioning hardware types, so that you can select it during the member pre-provisioning. To pre-provision a non IB-FLEX Grid member, you must have valid pool licenses and pre-provisioned those members in the Grid.

Important

To set up a supported virtual appliance as an IB-FLEX, you must first define the hardware type of the virtual appliance as IB-FLEX before you configure it. Depending on the platform or environment in which you are installing IB-FLEX, you can define the **hardware_type** parameter to **IB-FLEX** during the cloud-init process, or you can manually set the hardware type using the **set hardware-type** CLI command. For more information, see *set hardware-type*.

Limitations of IB-FLEX

- It is not compatible with the traditional node-based licensing and it supports capacity based licensing only.
- An IB-FLEX instance will not start if you do not configure the required minimum level of resources.
- The resources assigned to IB-FLEX for cores and memory must be equal to or exceed the minimum designated values for the platform. For more information about IB-FLEX platforms, see About IB-FLEX Instances and Platform Settings below.
- IB-FLEX does not support DNS64 on appliances running NIOS version 8.2.0.
- IB-FLEX on AWS does not support ADP and DCA features.
- To effectively use the IB-FLEX Grid Master Candidate, it is mandatory to install FLEX Grid Activation license / FLEX Grid Activation for Managed Services license, on the Grid Master.

Installing IB-FLEX

Depending on your network environment, you can install IB-FLEX just like how you install other Infoblox virtual appliances. Before you deploy an IB-FLEX, ensure that you set the hardware type of the appliance to IB-FLEX. You can do so either through the cloud-init process during deployment or manually through the **set hardware-type** CLI command.

For more information about installing IB-FLEX in the VMware environment, see *Deploying vNIOS Appliances on VMware*.

For information about installing IB-FLEX in the OpenStack environment, see *Deploying vNIOS for KVM in OpenStack Using Elastic Scaling*.

About IB-FLEX Instances and Platform Settings

An IB-FLEX instance supports capacity-based licensing only, but it is compatible with NIOS Grid Master that uses node-based licensing. You can upgrade an IB-FLEX instance from a low-end platform to a high-end platform by increasing the resource allocation of the virtual machine. An IB-FLEX instance selects the default internal settings for a respective instance platform based on the resource settings detected during the startup.
An IB-FLEX instance supports VMware ESXi with or without SR-IOV enabled and OpenStack with KVM both with or without SR-IOV. The table below provides information about the IB-FLEX platform resource specification:

IB-FLEX Platform Resource Specification

Resource Type	Allowed Range of Values	Recommended Value	Description
Virtual NUMA Nodes	1	1	Single virtual CPU socket
Disk Size	250 GB	250 GB	Fixed size virtual disk

The table below provides information about the IB-FLEX platform and various platform settings:

Total Resource Usage for Different Use Cases

Intended Use	Total CPU	Total Virtual Memory GB (Without Software ADP)	Total Virtual Memory GB (With Software ADP)	Database Object Count	Grid Master Capable
Small Authoritative DNS	4	8	10	100,000	No
Medium Authoritative DNS	8	16	22	600,000	Yes
Large Authoritative DNS	16	32	40	5,000,000	Yes
Recursive DNS (without acceleration)	6	14	18	200,000	Yes
Large Recursive DNS (without acceleration)	14	28	36	2,000,000	Yes
Small Grid Master	10	18	NA	1,000,000	Yes
Medium Grid Master	12	22	NA	2,000,000	Yes
Large Grid Master	16	32	NA	16,000,000	Yes
Small Recursive DNS (with acceleration)	10	12	20	100,000	No
Medium Recursive DNS (with acceleration)	16	20	28	100,000	No

Intended Use	Total CPU	Total Virtual Memory GB (Without Software ADP)	Total Virtual Memory GB (With Software ADP)	Database Object Count	Grid Master Capable
Large Recursive DNS (with acceleration)	26	30	38	100,000	No
Large Grid Master (with acceleration)	20	38	NA	16,000,000	Yes

Note the following about IB-FLEX:

- You cannot mark an IB-FLEX appliance as a Grid Master or Grid Master Candidate with resources that are intended for small authoritative DNS, small recursive DNS (with acceleration), medium recursive DNS (with acceleration), and large recursive DNS (with acceleration). For more information, see the *Total Resource Usage for Different Use Cases* table above.
- Infoblox recommends that you increase the memory to the following for IB-FLEX members to use certain features:
  - 16 GB, instead of the standard 14 GB, to use DNS analytics.
  - 20 GB, instead of the standard 18 GB, to use Threat analytics when RPZ is assigned to the IB-FLEX member.

Consider the following recommendations for VMs on IB-FLEX appliances deployed in KVM-based OpenStack environment and with virtual DNS Cache Acceleration (vDCA) and/or software Advanced DNS Protection (vADP) enabled:

1. vDCA and vADP are computational intensive features. Therefore, you must ensure that the vCPUs in each VM running vDCA and/or vADP does not exceed the total physical CPUs/cores of the NUMA node on which it is deployed. Refer to the following example configurations from: *Red Hat*, *VMware*, and *Oracle*.
2. Ensure that each vCPU of the VM is assigned to a separate physical core on the host and that it does not share the same physical core to avoid significant performance degradation that may occur.
3. For deployments using SRIOV, the number of RX queues on a VF is dependent on the underlying driver. Most of the drivers limit the number of queues to 1, 2, or 4. As such, a large IB-FLEX deployment with vDCA will not be fully utilized if only the LAN1 interface is used as only 1, 2, or 4 out of 8 vDCA cores will be assigned to each interface/VF. Other cores will mostly remain idle unless the traffic also arrives on the LAN2 interface. Refer to the example configuration from *Red Hat*.

Configuring DNS Cache Acceleration on IB-FLEX

When you enable virtual DNS cache acceleration on the IB-FLEX, the appliance acts as a high-speed DNS caching-only name server. This feature provides DNS cache acceleration support for recursive UDP DNS queries on the IB-FLEX. The DNS cache acceleration feature is bundled with the **Tiered licensing**. When you install this license, you are entitled to use the DNS cache acceleration feature on IB-FLEX.
IB-FLEX supports RPZ, but the response for RPZ queries are not cached by the DNS cache accelerator. Instead, these queries are bypassed to the host and you can configure cache expiry period for RPZ queries. Note that the maximum cache lifetime for DNS cache acceleration on IB-FLEX is set to 300 seconds if the RPZ license is installed.
You can also use Elastic Scaling to pre-provision DNS cache acceleration on IB-FLEX. IB-FLEX supports Intel x86_64 systems with IOMMU, Hugepages processors, virtio-net, and Intel 82599 10 G NIC and SRIOV with Intel 82599 ethernet controllers for DNS cache acceleration.
You can configure DNS cache acceleration on IB-FLEX using the Grid Manager or API. To view accelerated cache details, you can either log in to Grid Manager, or use CLI commands, or Infoblox API. If the tiered license usage is exceeded then a message is displayed in the Grid Manager. A warning message is displayed on the Grid Manager, if the QPS is going over the threshold on these platforms based on Tiered license installed.
Infoblox supports Auto Scaling that contains OpenStack packages to automatically scale the required number of resources based on your application. For more information, refer to *Auto Scaling for Virtual DNS Cache Acceleration*. For detailed information about configuring DNS Cache Acceleration, see *Configuring DNS Cache Acceleration*.

Reports for IB-FLEX

Infoblox supports a selected set of reports on IB-FLEX. To view all available reports, from the **Reporting** tab, select the **Dashboards** tab. The table below lists all the supported reports for IB-FLEX. For information about how to create and manage user-defined reports, see *Infoblox Reporting and Analytics*.

Supported Reports for IB-FLEX

DNS Reports	Security (DNS) Reports	System Reports
DNS Query Rate by Query Type	DNS Top RPZ Hits	SPLA Grid Licensing Features Enabled
DNS Query Rate by Member	DNS Top RPZ Hits by Client	CPU Utilization Trend
DNS Daily Query Rate by Member	DNS RPZ Hits Trend By Mitigation Action	Memory Utilization Trend
DNS Daily Peak Hour Query Rate by Member		
DNS Replies Trend		
DNS Cache Hit Rate Trend		
DNS Top Requested Domain Names		
DNS Top NXDOMAIN / NOERROR (no data)		
DNS Top Clients		
DNS Top Timed-Out Recursive Queries		
DNS Response Latency Trend		
DNS Top SERVFAIL Errors Sent		
DNS Top SERVFAIL Errors Received		
DNS Object Count Trend for Flex Grid License		
DNS Effective Peak Usage Trend for SPLA Grid License		

Configuring DNS Cache Acceleration

The software-based DNS acceleration feature supports IB-FLEX and non-IB-FLEX (IB-2215, IB-2225, IB-V2215, IB-V2225, IB-4015, IB-4025, IB-V4015, and IB-V4025) platforms. When you enable the virtual DNS cache acceleration feature on IB-Flex and non IB-Flex appliances, it acts as a high-speed DNS caching-only name server. This feature provides DNS cache acceleration support for recursive UDP DNS queries.

The DNS cache acceleration feature is bundled with tiered licensing for IB-FLEX appliances and for non-IB-FLEX appliances it is based on the type of tiered license that is installed. Only the Tier 1 (unlimited QPS up to capability) license can be installed on IB-2215 and IB-V2225 appliances. When you install the license, you are entitled to use the DNS cache acceleration feature. For non-IB-FLEX appliances, the warning message is based on the tiered license that is installed, and the QPS is rate-limited which is based on the type of license installed. If the tiered license and the QPS exceed the threshold, a warning message is displayed. For more information on the Tiered licensing feature, see the *Features on the Software DNS Cache Acceleration Platforms* table below for features on the Software DNS cache acceleration platforms.

All the appliances support RPZ, but the response for RPZ queries are not cached by the DNS cache accelerator. Instead, these queries are bypassed to the host. You can configure the cache expiry period for RPZ queries. Note that the maximum cache lifetime for DNS cache acceleration is set to 300 seconds if the RPZ license is installed. However, for IB-Flex appliances, you must configure RPZ zones for a member.

You can also use Elastic Scaling to pre-provision DNS cache acceleration. These appliances support Intel x86_64 systems with IOMMU, Hugepages processors, virtio-net, and Intel 82599 10 G NIC and SRIOV with Intel 82599 ethernet controllers for DNS cache acceleration.

You can configure DNS cache acceleration using the Grid Manager or API. To view accelerated cache details, you can either log in to Grid Manager, or use CLI commands, or Infoblox API. Infoblox supports Auto Scaling that contains OpenStack packages to automatically scale the required number of resources based on your application. For more information, refer to *Auto Scaling for Virtual DNS Cache Acceleration.*

Associated characteristics of the supported appliance include the following:

- Cache delete through the Grid Manager, CLI, or Infoblox API. For more information, see *Clearing DNS Cache*.
- ACL for IPv4 and IPv6.
- Sending SNMP traps for DNS cache acceleration service.
- SNMP queries for supported appliances.
- Fixed RRSET order for accelerated responses, for A and AAAA record types, for IPv4, and IPv6.
- Both non-accelerated recursive and authoritative DNS with Software ADP.

The following table lists the features that are either supported or not supported on the Software DNS cache acceleration platforms:

Features on the Software DNS Cache Acceleration Platforms

Features	IB-FLEX	IB-2215	IB-2225	IB-v2215	IB-v2225	IB-4015	IB-4025	IB-v4015	IB-v4025
Tiered licensing	Licensing is based on the Flex Grid Activation license on the Grid. Note that the queries per second are limited by the number of CPUs for IB-FLEX.	IB-40x5 appliances support four tiers of DNS QPS and the QPS levels are enforced by rate limiting							
RPZ	Yes, the maximum cache lifetime for DNS cache acceleration is set to 300 seconds if RPZ zones are configured for the member.	Yes, the maximum cache lifetime for DNS cache acceleration is set to 300 seconds if the RPZ license is installed.							
Caching (A, AAAA, MX, CNAME, PTR)	Yes	Yes							
Do not cache (EDNS, TCP, Any, TSIG)	Yes	Yes							

Features	IB-FLEX	IB-2215	IB-2225	IB-v2215	IB-v2225	IB-4015	IB-4025	IB-v4015	IB-v4025
Caching over additional interfaces (v4, v6)	Yes	Yes							
Dump Acceleration Cache (CLI, GUI, PAPI)	Yes	Yes							
Clear Acceleration Cache (CLI, GUI, PAPI)	Yes	Yes							
Cache pre-fetch and cache refresh	Yes	Yes							
ACLs (Allow-queries/ Responses, Match-Clients/Destination, Blackhole)	Yes	Yes							
AAAA Filtering (Bypassed but support configuring)	Yes	Yes							
Fixed RRSET ordering	Yes	Yes							
DNS64	Yes	Yes							
DNS monitoring feature (netmon)	Yes	Yes							
DNS Query logging (BIND only)	Yes	Yes							
DNS Views	Yes, it supports up to six DNS views.	Yes, it supports up to six DNS views.							
Forward/Stub zones	Yes	Yes							
Unbound as DNS resolver	Yes, unbound is supported through the Flex Grid Activation license.	Yes, unbound is supported if the Dual Engine DNS license is installed.							
DNS cache acceleration related restrictions for configuration	Yes, for NIOS version 8.2.0, restrictions are enforced based on whether the DNS cache acceleration feature is enabled or disabled.	No							
Reporting	Yes, for more information Reports for IB-FLEX, see *About IB-FLEX*.	Yes							

Features	IB-FLEX	IB-2215	IB-2225	IB-v2215	IB-v2225	IB-4015	IB-4025	IB-v4015	IB-v4025
VLAN	Yes	Yes							
DSCP	No, Infoblox does not support DSCP for virtual appliances.	Infoblox does not support DSCP for physical or virtual appliances only if DCA is enabled.							
Sort list	Yes	Yes							
Anycast (OSPF and BGP)	Yes	Yes							
BFD (Bidirectional Forwarding Detection)	Yes	Supported on all appliances							
HA Support	Yes, only for non-SRIOV.	Yes							
NIC Bonding	Yes	Yes							
Multiple-Interfaces on the same subnet	No	No							
IP Rate-limit and Response logging	No	No							
EDNS Client Subnet support	No	No							
NXDomain-redirection	Yes	Ye							
DNSSEC (Bypassed but support configuring)	Yes	Yes							
Debug enhancements	Yes	Yes							
SNMP Support for DCA service-related traps	Yes	Yes							
SNMP stats support for DNS QPS and CHR	Yes	Yes							
NX Mitigation	No	No							
NetFilter (Tracking tables)	No	Not supported on any appliance							

Features	IB-FLEX	IB-2215	IB-2225	IB-v2215	IB-v2225	IB-4015	IB-4025	IB-v4015	IB-v4025
Traffic-capture (All modes)	Yes, there is partial support. Note that tcpdump captures both queries and responses.	Yes, there is partial support. Note that tcpdump captures both queries and responses.							
No flush-mode support for DNS cache acceleration cache	Yes	Yes							
Per-interface UDP DNS cache acceleration response counters	Yes	Yes							
CLI commands	You can use the commands `set dns-accel` and `show dns-accel` to view and set DNS cache acceleration information. For more information, see *CLI Commands*.	You can use the commands `set dns-accel` and `show dns-accel` to view and set DNS cache acceleration information. For more information, see *CLI Commands*.							
DNS Query rewrite (Bypassed but supports configuring)	No	No							
Threat Protection	Supported on IB-FLEX platforms. Allows enabling Software ADP and DNS cache acceleration simultaneously on IB-FLEX platforms.	Supported on IB-FLEX platforms. Allows enabling Software ADP and DNS cache acceleration simultaneously.							
Subscriber Secure Policy	Yes	Yes							

Note

By default, all malformed packets are dropped early when the accelerated threat protection service is enabled.

Viewing Accelerated Cache Details

When you view cached contents of the DNS accelerator through the Grid Manager, there might be a slight impact on the DNS query performance of the selected member.

To view accelerated cache from the Grid Manager:

1. From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *Member* checkbox. Choose **View** from the Toolbar, and then click **View Cache**.
2. Click **Yes** in the *View Acceleration Cache* dialog box.
3. The system displays a *File Download was Successful* message and the cache data is displayed in table format in a new browser tab or browser window.

Limitations for Virtual DNS Cache Acceleration

- You cannot enable the DNS cache acceleration feature during a scheduled NIOS upgrade, but if you have already enabled this feature, it will function normally during the upgrade process.
- The appliance prompts for a reboot when you enable the DNS cache acceleration feature for the first time. You must accept it to start the service.
- You must disable the DNS cache acceleration feature and reboot the appliance manually to switch from virtual DNS cache acceleration to authoritative servers.
- The appliance prompts for a reboot when you enable virtual DNS cache acceleration and Software ADP on IB-FLEX, IB-22x5 and IB-40x5 platforms .
- DSCP is not supported if vDCA is enabled on IB-FLEX 22x5 and IB-40x5.
- DHCP license cannot be installed if the DCA license is installed and vice versa.
- DCA and Microsoft Management licenses cannot be installed and configured simultaneously.
- On all vNIOS appliances that support vDCA (virtual DNS Cache Acceleration) or vADP (virtual Advanced DNS Protection), you must run vDCA or vADP on a single virtual NUMA node. If the configuration of the virtual NUMA node and physical NUMA node are not the same, it may result in performance degradation.
- For virtual DCA appliances using virtio, it is recommended to increase the number of virtio queues to 2 for IB-v14x5, 4 for IB-v22x5, 4 for IB-v40x5, 2 for IB-FLEX Small, 4 for IB-FLEX Medium and 4 for IB-FLEX Large systems.

Limitations for DNS Cache Acceleration in Subscriber Services Parental Control

Enabling DNS Cache Acceleration for subscriber services in the **Parental Control** tab has the following limitations:

- The DNS Cache Acceleration subscriber site features, query count logging and blocked and allowed list support are applicable on Virtual DNS Cache Acceleration, and the features are available on IB-4030, however they are not supported.
- The DNS Cache Acceleration subscriber site features, query count logging and blocked and allowed list support and retains only unknown bits and does not support unknown policies (AVP).
- DNS Cache Acceleration uses BIND to process the guests behind Customer Premises Equipment (CPEs).
- The appliance prompts for a reboot when there is a configuration change.
- DNSTAP is required for query count logging.
- DNS Cache Acceleration does not cache blocked domains from BIND as it only uses category information for resolved domains.
- At Virtual DNS Cache Acceleration, the subscriber has access only to the primary MSP IP address.
- DNS Cache Acceleration subscriber site feature supports only 16 additional blocking policies.
- Before blocking another opt in subscriber at DNS Cache Acceleration, an opt in subscriber must resolve a domain.
- Proxy-All replies comes from DNS Cache Acceleration as long as the client connection status to MSP is "connected." If the client connection status is "disconnected," the first few queries goes to BIND, and future requests comes from DNS Cache Acceleration. Note that, TCP idle connections are closed every 20 seconds by MSP.
- The query name for the subscriber allowed and blocked list must contain a known TLD (top-level domain) and, if there are any prefixes, must conclude with a '.'.
- Only domain names are supported by the subscriber allowed and blocked lists, the wildcards and services are not supported.

For Information on Upgrading Parental Control at DNS Cache Acceleration, see *Upgrading Parental Control at DNS Cache Acceleration.*

IB-FLEX Platform Settings for DNS Cache Acceleration

When you enable the DNS cache acceleration feature on IB-FLEX, ensure that it has enough CPU and memory to start the service, and that it does not contain any authoritative zones. Note that you cannot start the service if the total CPU is less than 8 cores or if memory is less than 12G. To start the service, see the number of mandatory resources mentioned in the *Total Resource Usage for Different Use Cases* table.

If the DNS cache acceleration feature is enabled on a pre-provisioned member and fails to start due to insufficient resources on the member, the DCA status is displayed as failed. If you disable DCA on a member with insufficient resources, the member is not displayed in the **DCA** -> **Members** tab.

⚠ Note

- Under certain circumstances, the DNS cache acceleration feature may not function normally when you perform a product restart. This happens due to increased resource allocation on the virtual machine and the appliance does not log any entries in the syslog. Infoblox recommends that you restart or reboot the system and free up server resources if you encounter this issue.
- Before enabling DNS Cache Acceleration or ADP on virtual platforms, ensure that the ssse3, sse4_1, and sse4_2 CPU flags are set on the host server. For more information, see *https://help.ubuntu.com/lts/serverguide/DPDK.html.en*
- If you see the "/usr/bin/fast-path.sh: error starting /usr/bin/fp-rte. Check logs for details" error message in the infoblox.log file, ensure that the ssse3, sse4_1, and sse4_2 flags are set for the VM.

About Elastic Scaling

Elastic Scaling provides the capability to automatically pre-provision and deploy vNIOS appliances on-demand for IPAM (IP Address Management), DNS, and/or DHCP. Compared to standard appliance deployment and licensing management, you now have the flexibility to purchase multiple service and feature licenses and install them as dynamic licenses for future vNIOS or cloud deployments based on your evolving business needs and deploy them as needed. When you remove a vNIOS or cloud appliance from the Grid, the dynamic licenses on the appliance are automatically released and returned to the license pool on the Grid Master for reuse at a later time. Elastic scaling includes a full set of APIs for pre-provisioning, deployment, and de-provisioning vNIOS appliances, making it simple to add or remove DNS or DHCP capacity on-demand to meet changing infrastructure requirements, which is critical for realizing the benefits of dynamic Cloud environments. For information about the Infoblox cloud solution, see *Deploying Cloud Network Automation*.

You can purchase licenses of any type, such as vNIOS, DNS, DHCP, Enterprise (formerly Grid) and Cloud Platform, deploy them as dynamic licenses on the Grid Master , and allocate them to vNIOS virtual appliances manually or automatically through Elastic Scaling.

All dynamic licenses are tied to a specific Grid Master. You must first obtain the LPC_UID (License Pool Container Unique ID) of the Grid Master before obtaining the licenses from Infoblox Technical Support. For more information about Obtaining Dynamic Licenses, see *Obtaining Dynamic Licenses*.

When you use Elastic Scaling to pre-provision and launch vNIOS appliances, licenses are automatically installed on the newly spun-up appliances during the process as long as you have the correct vNIOS licenses in the license pools for the vNIOS models you plan to deploy. For example, you can install a CP-V1405 license on a CP-V1405 or CP-V805, but you cannot do so on a CP-V2205. If there are no licenses available in the pool for the specified appliance models, the Grid Master notifies you with an error message (for Cloud Platform Appliances, the API calls fail). Note that you cannot add a vNIOS Grid member when no dynamic licenses are available. When you spin down vNIOS appliances, its assigned licenses are released and returned to the NIOS license pool.

The Grid Master keeps track of dynamic licenses that are allocated to vNIOS members and adjusts the total number of available dynamic licenses for each feature and service. You can view the total number of dynamic licenses installed for each feature and service, the number of active and available licenses, their usage, and other related information in the **Grid** tab -> **Licenses** tab -> **Pool** tab of Grid Manager. For information about how to view dynamic licenses, see *Viewing Dynamic Licenses*.

Infoblox supports elastic scaling for Software ADP profiles on the supported platforms and provides the following pool licenses: **Threat Protection (Software add-on)** and **Threat Protection Update**. For more information about Software ADP profiles, see *Configuring Threat Protection Profiles*. Threat protection members use management port for IPv4 and IPv6 communication with the Grid. Infoblox supports cloud API calls for such members to join the Grid using MGMT port and VPN on the MGMT port. To know more about using the MGMT port, see *Using the MGMT Port*.

You can also manually allocate and deallocate dynamic licenses as your business requirements evolve. For more information about Manually Allocating Dynamic Licenses and Manually Deallocating Dynamic Licenses , see *Managing Licenses*.

Using Elastic Scaling to Pre-provision and Launch vNIOS Members

You can use Elastic Scaling to deploy on-demand vNIOS virtual members in a Grid and in your cloud environment and pre-provision them to manage networks and zones. For information about how to utilize Elastic Scaling to provision Cloud Platform Appliances and join them to the Grid using cloud API calls, see *Sample Cloud API Requests for Elastic Scaling.*
Complete the following tasks to pre-provision and launch vNIOS appliances:

1. Obtain dynamic licenses and install them on the Grid Master, as described in *Obtaining Dynamic Licenses.* You can also use a temporary license to spin up a Grid Master VM.
2. Create an offline Grid member or HA pair, as described in Adding a Single Member or Adding an HA Member, see *Adding Grid Members*.
3. Pre-provision the offline Grid member you just created, as described in Configuring Pre-Provisioned Members, see *Pre-Provisioning NIOS and vNIOS Appliances*. Note that there are a few guidelines that you might want to review before pre-provisioning your Grid member. For more information, see *Guidelines for Pre-provisioning Offline Grid Members.*
   Note that you must include the **Grid** and **vNIOS** provisional licenses for pre-provisioned vNIOS members in order to join them to the Grid.
4. Generate a token for the Grid member, as described in Generating Tokens for Grid Members below.
   Note for HA pairs, the appliance generates two tokens—one for each node of the HA pair.
5. Use cloud API calls to add network views, networks, or zones and then delegate the objects to the offline Grid member. For information about sample cloud API requests, see *Sample Cloud API Requests for Elastic Scaling.*
6. Use API requests to join the Grid member to the Grid. For sample API requests, see *Sample Cloud API Requests for Elastic Scaling*. If for any reasons the automated process of Elastic Scaling fails or if you are unable to send API calls, you can use CLI commands to join the Grid member to the Grid as a workaround. For more information, see Using CLI Commands to Join Grid Members below.
7. Verify the Grid member has successfully joined the Grid, as described in *Viewing Status*.
8. Verify the dynamic licenses have been allocated correctly by viewing the license usage, as described in *Viewing Dynamic Licenses.*

Generating Tokens for Grid Members

Before you can automatically allocate dynamic licenses to a pre-provisioned member, you must request a one-time token from the Grid Master. This token allows the member to register and authenticate itself to the Grid Master before a specified date and time (the default is 60 minutes from the time you generate the token). When the token is not used after the expiration date and time, it becomes invalid and you must generate another token for the member. You can configure the token usage timeout so the appliance can send syslog messages to alert you about the unused token. For information about how to set the token usage timeout value, see Configuring Token Usage Timeout below.
Using a one-time token eliminates the need for the Grid Master credentials to be exposed to other Grid members and the CMP (Cloud Management Platform) in the case of cloud implementation. Note that only superusers can generate and view the token for a pre-provisioned Grid member.

> ⚠ Note
>
> You can use API calls as part of the automated deployment process to generate a token for the vNIOS Grid member before joining it to the Grid. For information about sample API requests you can use to generate a token, see *Sample Cloud API Requests for Elastic Scaling.*. As a workaround, you can also generate a token through Grid Manager.

To generate a token through Grid Manager, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
2. Click the Action icon

next to the vNIOS member and select **Generate Token** from the list.

3. In the *Your Permission Token* dialog, the appliance displays the token and the **Expiration Date** of the token. You must generate a new token for the member if the token is not used before the expiration date.

> **Note**
>
> Copy this token and paste it at the CLI when you use the set token on command to set the token and generate the token file.

Configuring Token Usage Timeout

You can configure the appliance to send syslog messages to alert you about an unused token that has been generated for a pre-provisioned member. Depending on the timeout interval you configure, the appliance sends a syslog message for each timeout interval until the token expires.
To configure the token usage timeout value:

1. From the **Grid** tab -> **Grid Manager** tab, click **Grid Properties** -> **Edit** from the toolbar.
2. In the *Grid Properties* editor, select the **General** tab -> **Basic** tab and complete the following:
   - **Token usage timeout**: Enter the time interval (in minutes) for which the appliance sends a syslog message to alert you about the unused permission token for a pre-provisioned member. For example, if you enter 5 here, the appliance sends a syslog message every five minutes. The default is 10.
3. Save the configuration.

Using CLI Commands to Join Grid Members

> **Note**
>
> If for any reasons the automated process of Elastic Scaling does not function properly, you can use CLI commands to join Grid members to the Grid as a workaround.

When using Elastic Scaling, ensure that you have generated a token for the member, as described in Generating Tokens for Grid Members above, before joining the member to the Grid.
To join the vNIOS member to the Grid:

1. Access the Infoblox CLI using an SSHv2 connection through an SSHv2 client. You can also access the CLI by connecting a serial cable directly from the console port of a management system to the console port on the appliance, and then using a terminal emulation program such as Hilgraeve Hyperterminal® (provided with Windows® operating systems) and launch a session. The connection settings are:
   - Bits per second: 9600
   - Stop bits: 1
   - Data bits: 8
   - Flow control: Xon/Xoff
   - Parity: None
2. Log in using the default user name and password *admin* and *infoblox*. User names and passwords are case-sensitive.
3. To change the network settings from the default, enter the **set network** command. Then enter information as prompted to change the IP address, netmask, and gateway for the LAN1 port.

```
Infoblox > set network
NOTICE: All HA configuration is performed from the GUI. This interface is used only to configure a standalone node or to join a grid.
Enter IPv4 address [Default: n.n.n.41]: <Enter the LAN1 port IP address>
Enter netmask: [Default: 255.255.255.0]: <Enter the LAN1 port netmask>
```

```
Enter gateway address [Default: n.n.n.1]: <Enter the gateway IP address>
NOTICE: Additional IPv6 interface can be configured only via GUI.
Become grid member? (y or n): n
```

Note that you must enter **n** to use Elastic Scaling. If you enter y, the member becomes a Grid member and you will not be able to set token and join the pre-provisioned member to the Grid.

4. Use the `set token on` command to set the member token, the Grid Master IP address and certificate to the token file. Following is an example:

```
Infoblox > set token on
Enter GM-IP [Current: not defined]: <Enter the Grid Master IP address>
Enter Token [Current: not defined]: Copy token from the Your Permission
Token dialog in Grid Manager.
New Token Settings:
GM-IP: 1.1.1.1
Token: b25lLnZpcnR1YWxfbm9kZSQx
Is this correct? (y or n): y
Do you want to download the certificate form GM and validate (y or n): y
Is this correct and valid (y or n): y
Are you sure to apply and save settings to file?: y
The token and certificate are saved.
```

5. To verify the token:

```
Infoblox > show token
```

The CLI displays the current token setting and certification information. Verify this information.
Note if there is incorrect information, use set token off to remove the token file.

6. Use the `set token join` command to register the Grid member and get licenses from the license pool before joining the member to the Grid. Once the member joins the Grid, the token become invalid—you can use the token only once.

```
Infoblox > set token join
Are you sure to start Member registration Client? (y or no): y Starting
Member registration Client...
Connecting...
```

> ⚠ Note
>
> For HA pairs, repeat the CLI commands on both nodes.

Using OpenStack cloud-init template to configure Grid Master and join Grid members

You can use the following OpenStack cloud-init template to configure an IB-V815 as a Grid Master:

```
#infoblox-config remote_console_enabled: y default_admin_password: infoblox
 temp_license: nios IB-V815 dns dhcp enterprise
lan1:
```

```
    v4_addr: 10.2.0.132
     v4_netmask: 255.255.255.0
     v4_gw: 10.2.0.1

 mgmt:

     v4_addr: 10.1.0.69
     v4_netmask: 255.255.255.0
     v4_gw: 10.1.0.1
```

You can use the following OpenStack cloud-init template to join an IB-V815 member to the Grid:

```
#infoblox-config remote_console_enabled: y default_admin_password: infoblox
 temp_license: nios IB-V815 dns dhcp enterprise sw_tp tp_sub lan1:

     v4_addr: 10.2.0.140
     v4_netmask: 255.255.255.0
     v4_gw: 10.2.0.1
mgmt:
    v4_addr: 10.1.0.77
     v4_netmask: 255.255.255.0
     v4_gw: 10.1.0.1
gridmaster:
    token: xqyv+gEcPiUp9ETdHqmS2VcPIHEd81/U ip_addr: 10.39.8.109

     ha: fa:16:3e:25:43:8a
     lan2: fa:16:3e:8e:26:4c
```

Managing the Order of Match Lists

When you configure certain DNS and DHCP functions, you can create match lists that the appliance uses to filter specific IP addresses for specific operations. For example, you can create a DNS blackhole list for including and excluding DNS traffic to certain IP addresses, configure a list of IP addresses for allowing and denying DDNS updates, or define a Match Destinations list that identifies destination addresses and TSIG keys that are allowed access to a DNS view.
The appliance matches rules in these lists from top to bottom. Rules at the top always take precedence over those at the

bottom. Therefore, ensure that you put the most specific rules at the top of the list, and then put the more general rules at the bottom. For example, when you add network 10.10.0.0/24 to a DNS blackhole list, all 256 IP addresses in the network are put on the blackhole list. To allow DNS traffic to the specific IP addresses 10.10.0.55 and 10.10.0.88, you must add these two addresses at the top of the blackhole list before the network address 10.10.0.0/24, and then set their permissions to "Exclude." The same applies when you set up the list of clients for DDNS updates. If you want to deny DDNS updates from a specific client (10.0.0.99) and allow DDNS updates from all other clients in the 10.0.0.0/24 network, you must put 10.0.0.99 at the top of the list and configure the appliance to deny DDNS updates from this client. You then add network 10.0.0.0/24 for allowing DDNS updates from all other clients at the bottom of the list.

Managing NIOS Appliances

To reboot and shut down a NIOS appliance, you can use Grid Manager or the Infoblox CLI. To reset a NIOS appliance, you must use the Infoblox CLI. You can also restart a Grid member or restart a GUI session through Grid Manager. You can also force an HA failover using the GUI.

Restarting a Grid Member

You can restart a single Grid member or an HA pair on the NIOS appliance. When you restart a Grid member, the appliance logs the task in the audit log.
To restart a single Grid member:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox.
2. Expand the Toolbar and click **Control** -> **Restart**.
3. In the *Restart Product on Member* dialog box, click **OK** to restart the Grid member.

Rebooting a NIOS Appliance

You can reboot a single NIOS appliance, a single node in an HA pair, or both nodes in an HA pair. To reboot a single NIOS appliance or one or both nodes in an HA pair:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox.
2. Expand the Toolbar and click **Control** -> **Reboot**.
   For an HA pair, choose whether to boot one node (and which one) or both nodes, and then click **OK**. Depending on the browser you use, Grid Manager may display a dialog box that indicates the system is unavailable during a restart or reboot.

To reboot a single NIOS appliance using the CLI:

1. Log in to the Infoblox CLI using a superuser account for the NIOS appliance that you intend to reboot.
2. Enter the following CLI command: **reboot**

Shutting Down a NIOS Appliance

Under normal circumstances, you do not need to turn off or shut down a NIOS appliance. It is designed to operate continuously. However, if you want to turn off a NIOS appliance, use the GUI or the CLI to shut down the appliance, instead of turning it off by using the power switch.

Note

If there is a disruption in power when the NIOS appliance is operating, the NIOS appliance automatically reboots itself when power is restored.

To shut down a NIOS appliance:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox.

2. Expand the Toolbar and click **Control** -> **Shutdown**.
   For an HA pair, choose whether to shut down one node (and which one) or both nodes, and then click **OK**.
   The NIOS appliance shuts down. The fans might continue to operate until the appliance cools down.

To shut down a NIOS appliance using the CLI:

1. Log in to the Infoblox CLI using a superuser account.
2. Enter the following CLI command: `shutdown`

Forcing an HA Failover

If you want to change which node in an HA pair is active and which is passive, you can force a failover to occur. Within five seconds after initiating a failover, the previously passive node becomes active and assumes ownership of the VIP address. Note that a forced failover causes a temporary service disruption. To proceed with the forced failover, click **OK**. The appliance logs this task in the audit log.
To restart a single Grid member:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox.
   Note the Grid member that you select must be an HA pair.
2. Expand the Toolbar and click **Control** -> **Force HA Failover**.
3. In the *For HA Failover* dialog box, click **OK** to change the node in an HA pair.

Restarting GUI Sessions

You can restart a GUI session through Grid Manager. When you restart GUI on a specific member, the appliance logs off all other GUI sessions that are currently running even though they are opened in different browsers or another system. The appliance logs this task in the audit log.
To restart GUI sessions on a Grid member:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox.
2. Expand the Toolbar and click **Control** -> **Restart GUI**.
3. In the *Restart GUI* dialog box, click **OK** to restart the NIOS appliance.

Resetting a NIOS Appliance

There are three ways to reset a NIOS appliance:

- Resetting the Database
- Resetting a NIOS Appliance to Factory Settings
- Resetting the NIOS Appliance to Factory Settings and Removing Licenses You can perform these functions only through the CLI.

Resetting the Database
You can reset the database if you lose the administrator account and password or if you want to clear the database but preserve the log files to diagnose a problem. This function removes the configuration files, and the DNS and DHCP data from the appliance database. During this procedure, you are given the option to preserve the network settings of the appliance, which are the IP address and subnet mask, the IP address of the gateway, the host name, and the remote access setting.
To reset the database:

1. Log in to the Infoblox CLI using a superuser account.
2. Enter the following CLI command: `reset database`
   The appliance then displays a message similar to the following:
   ```
   The following network settings can be restored after reset: IP Address:
   10.1.1.10
   Subnet Mask: 255.255.255.0
   Gateway: 10.1.1.1
   ```

```
Host Name: ns1.corpxyz.com Remote Console Access: true
The entire database will be erased.
Do you wish to preserve basic network settings? (y or n)
```

3. Press the **Y** key to preserve the network settings or the **N** key to return the network settings to their default values (192.168.1.2, 255.255.255.0, 192.168.1.1).

Resetting a NIOS Appliance to Factory Settings

You can reset a NIOS appliance to its original factory settings. This removes the database, network settings, logs, and configuration files. Then, it reboots with its factory settings, which are the default user name and password, and default network settings. When you perform this procedure, the appliance does not give you the option to preserve your network settings.

> ⚠ Note
> If you have previously imported HTTPS certificates, the appliance regenerates the certificates and replaces them.

To reset the NIOS appliance to its factory settings:

1. Log in to the Infoblox CLI using a superuser account.
2. Enter the following CLI command: **reset all**

Resetting the NIOS Appliance to Factory Settings and Removing Licenses

You can also reset a NIOS appliance to its original factory settings and remove all the licenses installed on the appliance. This removes the database, network settings, logs, configuration files, and licenses. The appliance then reboots with its factory settings, which are the default user name and password, and default network settings.

> ⚠ Note
> If you have previously imported HTTPS certificates, the NIOS appliance regenerates the certificates and replaces them.

To reset the NIOS appliance to its factory settings and remove all its licenses:

1. Log in to the Infoblox CLI using a superuser account.
2. Enter the following CLI command: **reset all licenses.**

Managing the Disk Subsystem on the Infoblox-4010

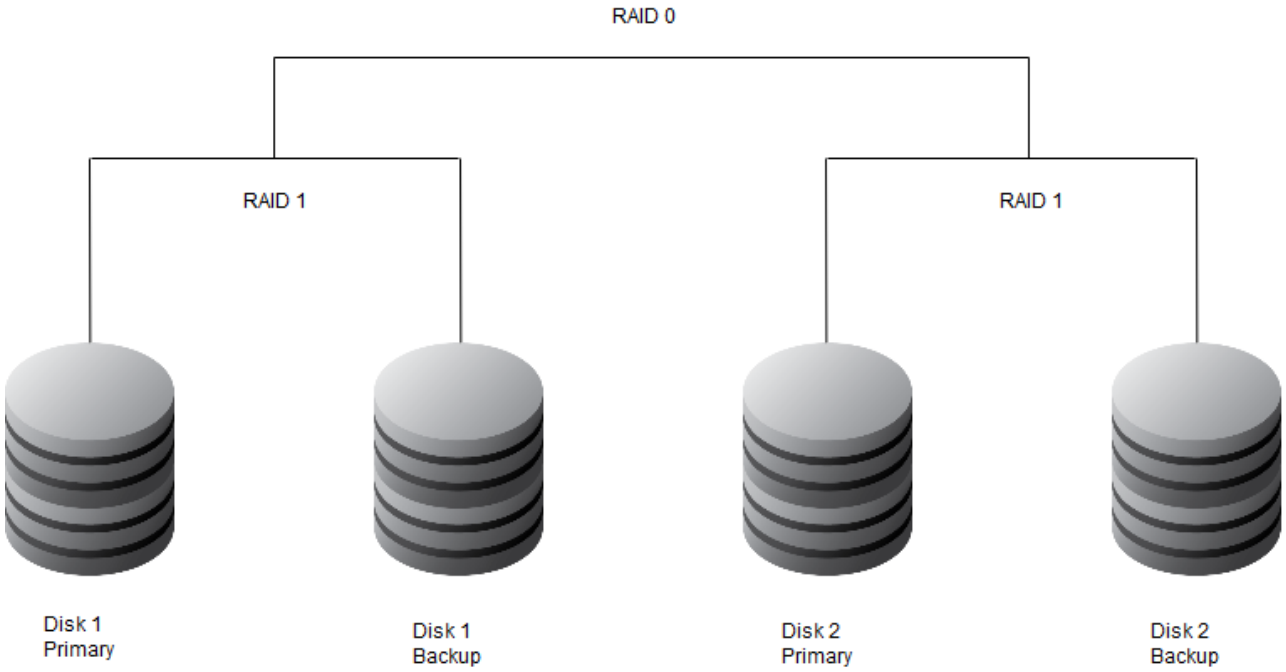
Among its many features, the Infoblox-4010 use a RAID (Redundant Array of Independent Disks) 10 array to provide the optimum mix of high database performance and redundant data storage with recovery features in the event of disk failures. The disk array is completely self managed. There are no maintenance or special procedures required to service the disk subsystem.

Caution: Never remove more than one disk at a time from the array. Removing two or more disks at once can cause an array failure and result in an unrecoverable condition. You should replace only one disk at a time, using a replacement disk from Infoblox. For information, see Replacing a Failed Disk Drive below.

About RAID 10

RAID 10 (or sometimes called RAID 1+0) uses a minimum of four disk drives to create a RAID 0 array from two RAID 1 arrays, as illustrated in RAID 10 Array Configuration below . It uses mirroring and striping to form a stripe of mirrored subsets. This means that the array combines—or stripes—multiple disk drives, creating a single logical volume (RAID 0). RAID 10 combines the high performance of RAID 0 and the high fault tolerance of RAID 1. Striping disk drives improves database write performance over a single disk drive for large databases. The disks are also mirrored (RAID 1), so that each disk in the logical volume is fully redundant.

RAID 10 Array Configuration



When evaluating a fault on the Infoblox-4010, it is best to think of the disk subsystem as a single, integrated unit with four components, rather than four independent disk drives. For information, see Evaluating the Status of the Disk Subsystem below.

Evaluating the Status of the Disk Subsystem

You can monitor the disk subsystem through the Infoblox Grid Manager GUI, the scrolling front panel LCD display, and four front panel LEDs next to the disk drives. In addition, you can monitor the disk status by using the CLI command `show hardware_status` . The following example displays the status of an Infoblox-4010 using the command:

```
Infoblox > show hardware_status
 POWER:Power OK
 Fan1:7258 RPM
 Fan2:6887 RPM
 Fan3:7258 RPM
 CPU1_TEMP: +20.0 C
 CPU2_TEMP: +24.0 C
 SYS_TEMP: +35 C
```

```
RAID_ARRAY: OPTIMAL
 RAID_BATTERY: OK READY Yes 103 HOURS
```

The *Detailed Status* panel provides a detailed status report on the appliance and service operations. To see a detailed status report:

- From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox -> Detailed Status icon in the table toolbar.

After displaying the *Detailed Status* panel, you can view the status of the selected Grid member. For more information on the *Detailed Status* panel, see *Status Dashboard*.
The RAID icons indicate the status of the RAID array on the Infoblox-4010.

Icon	Color	Meaning
	Green	The RAID array is in an optimal state.
	Yellow	A new disk was inserted and the RAID array is rebuilding.
	Red	The RAID array is degraded. At least one disk is not functioning properly. The GUI lists the disks that are online. Replace only the disks that are offline.

The appliance also displays the type of each disk. In the event of a disk failure, you must replace the failed disk with one that is qualified and shipped from Infoblox and has the same disk type as the rest of the disks in the array.
Infoblox-4010 uses only the IB-Type 3 disk type. All disk drives in the array must have the same disk type for the array to function properly. You can have either IB-Type 1, IB-Type 2, or IB-Type-3, but you cannot mix both in the array. When you have a mismatched disk in the array, you must promptly replace the disk with a replacement disk from Infoblox to avoid operational issues.

Disk Drive Front Panel LEDs

The disk drives of the Infoblox-4010 are located on the appliance front panel. To the right of each drive, two LEDs display connection and activity status. The below table lists the disk drive LED combinations and the states they represent.
Infoblox-4010 Disk Drive LED Combinations

Online/Activity LED (Green)	Fault/UID LED (Amber/Blue)	Description
On, off, or blinking	Alternating amber and blue	The drive has failed, or it has received a predictive failure alert; it also has been selected by a management application.
On, off, or blinking	Steadily blue	The drive is operating normally.
On	Amber, blinking regularly (1 Hz)	The drive has received a predictive failure alert. Replace the drive as soon as possible.
On	Off	The drive is online but it is not currently active.
Blinking regularly (1Hz)	Off	Do not remove the drive. The drive is rebuilding. Removing the drive may terminate the current operation and cause data loss.

Online/Activity LED (Green)	Fault/UID LED (Amber/Blue)	Description
Blinking irregularly	Amber, blinking regularly (1 Hz)	The drive is active, but it has received a predictive failure alert. Replace the drive as soon as possible.
Blinking irregularly	Off	The drive is active and operating normally.
Off	Steadily amber	A critical fault condition has been identified for this drive, and the controller has placed it offline. Replace the drive as soon as possible.
Off	Amber, blinking regularly (1 Hz)	The drive has received a predictive failure alert. Replace the drive as soon as possible.
Off	Off	The drive is offline, a spare, or not configured as part of an array.

Replacing a Failed Disk Drive

The Infoblox-4010 is designed to provide continuous operation in the event of a failed disk. Replace an original RAID disk only when there is a disk failure. Hot-swapping a disk drive is a simple process that does not require issuing commands or a GUI operation.
When you replace a failed disk, you must replace it with an Infoblox supplied disk. To ensure that you receive the correct replacement disk, report the disk type or part number of the failed disk. The appliance displays the disk type in the *Detailed Status* panel, and the Infoblox part number is printed on the disk. Installing disks that are not qualified and shipped from Infoblox could cause failures in the appliance.
To replace a disk drive, follow this procedure:

1. Identify and verify the failed drive via the Grid Manager, front panel LCD, or CLI.
2. Make sure you have identified the correct drive.
   Note: Do not remove a correctly functioning drive.
3. Push in the latch for the drive and pull the release lever out towards you.
4. When the drive disengages, wait about 30 seconds for the disk to completely stop spinning.
5. Slide it out of the slot.

Replacement drives are shipped as a complete unit, ready to insert into the appliance. There is no preparation required. To install a replacement drive, follow this procedure:

1. Insert the replacement drive into the drive bay slot.
2. Gently slide the drive into place. When you feel the release lever engage, continue applying gentle pressure to the drive while pushing the release lever towards the appliance.
3. The release lever locks into place and the LED next to the disk drive lights up. Note that if the alarm buzzer is sounding, it automatically turns off about 20 seconds after the drive is inserted.
4. The disk drive automatically goes into rebuild mode.

Disk Array Guidelines

Infoblox has designed the disk array to be completely self managed. There are no maintenance procedures required for a normally functioning disk array. Mishandling the disk array can cause an unrecoverable error and result in a failed appliance. Infoblox highly recommends that you observe the following guidelines:

- Remove only one disk at a time. Do not remove two or more disks from the appliance at the same time. Removing two or more disks at the same time might result in an appliance failure and require an RMA of the appliance. This rule applies to both powered and powered down appliances.
- If the status of the array is degraded, remove the failed or failing disk drive only. Do not remove an optimally functioning drive.
- If your acceptance procedure requires a test of the RAID hot swap feature, remove only one disk drive at a time. You can remove a second disk only after you replace the first disk and the array completes its rebuilding process.

- Do not remove a disk drive if the array is rebuilding. This could result in an appliance failure. Verify the status of the array before removing a disk drive.
- Use the following procedure to remove a spinning disk:
    a. Unlatch and pull the disk about two cm (one inch) to disengage contact.
    b. Wait about 30 seconds for the disk to completely stop spinning.
    c. Remove the disk and handle it with care. Do not drop the disk or ship it loosely in a carton.
- You can hot swap a drive while the appliance remains in production.
- There are some conditions that may require powering down the appliance to replace a failed unit. This normally happens if the RAID controller detects an error that could damage the array. If you insert a replacement drive into a live array and the controller doesn't recognize the drive, power down the appliance.
- If you inadvertently remove the wrong disk drive, do not immediately remove the disk drive that you originally intended to remove. Verify the status of the array and replace the disk drive that you removed earlier before removing another drive. Removing a second drive could render the appliance inoperable.
- Older appliances have an audio alarm buzzer that sounds if a drive fails. The alarm automatically stops about 20 seconds after a functional disk has been inserted into the array.
- All disks in the RAID array should have the same disk type for the array to function properly.
- In the unlikely event that two disk drives fail simultaneously and the appliance is still operational, remove and replace the failed disk drives one at a time.
- Rebuild time depends on a number of factors, such as the system load and Grid replication activities. On very busy appliances (over 90% utilization), the disk rebuild process can take as long as 40 hours. On a Grid Master serving a very large Grid, expect the rebuild process to take at least 24 hours.
- Replace a failed or mismatched disk only with a replacement disk shipped from Infoblox. When you request a replacement disk, report the disk type displayed in the *Detailed Status* panel of the GUI or the Infoblox part number on the disk.

Restarting Services

Whenever you make a change such as adding a zone or a network, Grid Manager notifies you that a service restart is required. You can enable the appliance to display the **Restart Banner** whenever it requires a service restart and prompt the administrator to input the user name before restarting the services. For information about how to enable the restart banner, see *Changing Grid Properties*. To view all pending activities that are waiting for service restart s , you can click **View Changes** in the restart banner at the top of Grid Manager.
The pending activities include additions, modifications, and deletions performed by all administrators. You can also view pending changes through the *Restart <Grid/ Member> Services* dialog box.
There are several ways to restart services on the affected Grid members. You can restart services at the Grid or member level, or you can restart services by groups, as described below:

- Restarting Grid Services
- Restarting Member Services
- Restarting Services by Groups

You can configure services restart settings such as restart timeout or delay as described in Configuring Restart Settings below.

> **Note**
>
> When you make configuration changes for DNS or DHCP and the service is enabled on at least one Grid member, Grid Manager suggests a restart even if the service is disabled on the member affected by the change.

User Permissions for Restarting Services

The following rules apply to superusers and limited-access users:

- You can cancel a schedule task that you create to restart a service. A superuser can cancel any scheduled restart task.

- Only superusers and administrators with read/write permission to all Grid members can schedule a Grid restart task.
- When a superuser schedules a Grid restart task, a limited-access user cannot schedule a member-level restart task.
- Limited-access users cannot cancel a superuser's scheduled tasks.
- Limited-access users cannot create or modify a scheduled restart task for a Grid member if a scheduled restart task for the member (created by another user) already exists.

The system writes every scheduled change action to the audit log as follows:

```
USER logon_id action service restart schedule 'schedule' on Grid (or member)
Grid name or member node id
```

For example:

```
USER jdoe insert service restart schedule '02/20/2007 01:30:00' on Grid
Infoblox USER jdoe deleted service restart schedule '02/22/2007 01:30:00' on
node id 3
```

For more information on the audit log, see *Using the Audit Log*.

Restarting Grid Services

Only superusers and administrators with read/write permission to all Grid members can schedule a Grid restart task. You can restart services at the Grid level either simultaneously or sequentially, and can also specify the restart time.
If you schedule the restart at a specific date and time, the system schedules the restart at the specified time on each Grid member.
To restart services at the Grid level:

1. From the **Data Management** tab, select the **DHCP**, **DNS**, or **Grid** tab, or select the **Administration** tab, and then click **Restart Services** from the Toolbar.

The *Restart Grid Services* dialog appears.

1. You can specify whether the member restarts services when necessary or you can force it to restart services. Select one of the following in the *RestartGridServices* section:
   - **Ifneeded**: Select this to restart all active DNS and DHCP services if there are any changes requiring a service restart.
   - **Forceservicerestart**: Select this to force a service restart even if it is not needed. A forced restart may be delayed if there are pending restarts for the same service.
2. Select one of the following in the *RestartMethod* section:
   - **RestartAllRestartGroups**: Restarts the services in the affected Grid members in the order defined for restart groups.
   - **Simultaneouslyforallmembers**: Restarts the services on all of the members in a Grid at the same time.
   - **Sequentiallyforallmembers**: Restarts the services on each Grid member one after one.
     AffectedMembersandServices: Click the Poll Members icon to display the affected members and services when the system restarts. Grid Manager displays the member names and one of the following for each service:
   - **YES**: The service is active and the system will restart the service upon execution of this task.
   - **NO**: The service will not restart unless the **Forceservicerestart** option is selected.
   - **DISABLED**: The service is currently disabled.
     ViewPendingChanges: You can view the list of pending changes that will take effect when you restart the services. You can use filters to look for specific objects and view the following information for each pending activity:
   - **Timestamp**: The timestamp of the operation.
   - **Admin**: The admin user who performed the operation.
   - **Action**: The type of operation that was performed by an administrator. This can be **Created**, **Modified**, **Deleted**, **Called**, or **Message**.

- **ObjectType**: Displays the object type. For example, DNS View, Named ACL, IPv4 MAC Filter, Blacklist Rule, and so on.
- **ObjectName**: The name of the object.
- **Message**: Description of the activity.

3. To schedule a service restart task, click the Schedule icon at the top of the wizard. In the *ScheduleChange* panel, complete the following:
   - **Now**: Restarts services upon clicking **Restart**.
   - **Later**: Enter the following information to schedule all Grid members to restart services at a certain date and time:
     - **Date**: Enter a date in YYYY-MM-DD (year-month-day) format. The appliance displays today's date. You can also click the calendar icon to select a date from the calendar widget.
     - **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. When you enter the time in a 24-hour format such as 23:00, Grid Manager displays 11:00:00 PM. You can also select a time from the drop-down list by clicking the time icon.
     - **TimeZone**: Select a time zone for the scheduled date and time from the drop-down list. This field displays the time zone of the browser that the admin uses to log in to Grid Manager.
4. Click **Restart** to restart services immediately or click **ScheduleRestart** to create a scheduled restart task.

> ⚠ Note
>
> When you restart services at the Grid level, the services are restarted only on those members for which you have permissions.

Restarting Member Services

The member restart time always supersedes the Grid restart time. If the member restart time is later than the Grid restart time, then the member restarts services at its scheduled time. If the member restart time is before the Grid restart time, then the member restarts services at its scheduled restart time, and again during the Grid restart time.
To restart member services:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox.
   or
   From the **Grid** tab, select the **Grid Manager** tab, and then select a member checkbox.
2. Click **Restart Services** from the Toolbar.
3. You can specify whether the member should restart services when necessary or you can force it to restart services. Select one of the following in the *Restart Member Services* section:
   - **If needed**: Select this to restart all active DNS and DHCP services, if there are any changes requiring a service restart.
   - **Force service restart**: Select this to force a service restart even if it is not needed. A forced restart may be delayed if there are pending restarts for the same service.
     Affected Services: This table displays the affected services when the system restarts. It can display one of the following for each service:
   - **YES**: The service is active and the system will restart the service upon execution of this task.
   - **NO**: The service will not restart unless the **Force service restart** option is selected.
   - **DISABLED**: The service is currently disabled.
     View Pending Changes: You can view the list of pending changes that will take effect when you restart the services. You can use filters to look for specific objects and view the following information for each pending activity:
   - **Timestamp**: The timestamp of the operation.
   - **Admin**: The admin user who performed the operation.
   - **Action**: The type of operation that was performed by an administrator. This can be **Created**, **Modified**, **Deleted**, **Called**, or **Message**.
   - **Object Type**: Displays the object type. For example, DNS View, Named ACL, IPv4 MAC Filter, Blacklist Rule, and so on.
   - **Object Name**: The name of the object.
   - **Message**: Description of the activity.

4. To schedule a service restart task, click the Schedule icon at the top of the editor. In the *Schedule Change* panel, complete the following:
    - **Now**: Restarts services immediately.
    - **Later**: Enter the following information to schedule the member to restart services at a certain date and time:
        - **Date**: Enter a date in YYYY-MM-DD (year-month-day) format. The appliance displays today's date. You can also click the calendar icon to select a date from the calendar widget.
        - **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
        - **Time Zone**: Select a time zone for the scheduled date and time from the drop-down list. This field displays the time zone of the browser that the admin uses to log in to Grid Manager.
5. Click **Restart** to restart services immediately or click **Schedule Restart** to create a scheduled restart task.

Restarting Services by Groups

You can use the group restart feature for the DHCP and DNS services. You do this by adding Grid members to groups and defining the restart order. Each service has a separate set of groups. You can specify whether a group is restarted sequentially or simultaneously and can also create a recurring schedule for restarts.
To access restart groups:

1. Click **Grid –> Grid Manager –> DHCP** or **DNS**.
2. On the **Services** tab, click **Toggle Restart Groups View**.

You can arrange group restart order for each service independently. Members in a group can restart simultaneously or sequentially, depending on your choice. When members are started sequentially, they are started in alphabetical order. When you have several restart groups, they all restart sequentially in the order that you define. For information, see Ordering Restart Groups below.
For each service, there exists the Default restart group in Grid Manager: Default DHCP group and Default DNS group. All Grid members belong to the Default group until you add them to another custom restart group. By default, the members of the Default group are restarted sequentially. The Default group is always restarted in the last place in the restart sequence for a service.

> ⚠ Note
>
> You can manage restart groups only if you are a superuser. If you are a limited-access user, you can see the restart groups and their restart status only if these groups include members for which you have permissions. When you restart services by groups, the services are restarted only on those members for which you have permissions.

For more information on how to create and manage restart groups, see the following sections. For how to restart services by groups, see Restarting Groups below.

Creating a Restart Group

You can add a member to a group if the member has a license for the corresponding service. Only members with the appropriate license are available for grouping. For pre-provisioned members, you can add them to groups, but the restart requests are not created for such members.
When you assign members to restart groups, Grid Manager checks if the restart may affect the service operation. If the restart with the current grouping configuration can lead to a service interruption, a warning message is displayed. For example, you cannot add two members from a DHCP failover association to the same group configured to restart its members simultaneously.
To create a restart group:

1. Click **Grid –> Grid Manager –> DHCP** or **DNS**.
2. On the **Services** tab, click **Toggle Restart Groups View**.
3. Click the **Add** icon.
4. Specify the general information for the group:
    - Name

- Comment
- Restart order for group members: simultaneously or sequentially
  Note that for how to delay service restarts, see Configuring Restart Settings below.

5. Click **Next**.
6. Add members by clicking the **Add** icon for each new member.
7. Click **Next**.
8. If you want to create a restart schedule for this group, select **Enable Restart Schedule** and specify the required parameters.
   Note that the restart schedule can run either once or on a recurring basis. It does not create scheduled tasks. If a schedule is configured for a restart group, you can still perform one-time restarts independently for Grid members or restart groups and create scheduled tasks for these restarts.
9. Select the restart type for the services on the affected members:
   - **If needed**: Select this to restart services only if there are changes requiring a service restart.
   - **Force service restart**: Select this to force a service restart even if it is not needed. A forced restart may be delayed if there are pending restarts for the same service.
10. Click **Next**.
11. If necessary, specify the extensible attributes.
12. Click **Save & Close**.

Editing a Restart Group

You can edit a restart group at any time, even when the restart process is running. The changes do not affect the current restart process.
To edit a restart group:

1. In the restart groups list, select the checkbox of the group to edit.
2. Click the Edit icon.
3. Edit the group properties as described in Creating a Restart Group above.
4. Click **Save** or **Save & Close**.

Deleting a Restart Group

Yo can delete any restart group, except the Default group. When you delete a group, all its members are automatically moved to the Default restart group. You can delete a restart group at any time, even when the restart process is running. The deletion does not affect the current restart process.
To delete a restart group:

1. In the restart groups list, select the checkbox of the group to delete.
2. Click the Delete icon.

Ordering Restart Groups

You can modify the order in which multiple groups are restarted. You cannot change the order for the Default group, as it always restarts in the last position by default.
To order restart groups:

1. Go to the restart groups view for the DNS or DHCP service.
2. In the toolbar, click **Order Restart Groups**.
3. Reorder the groups by using the drag-and-drop operation or by clicking the up and down arrows.
4. Click **OK**.

Restarting Groups

When you already have restart groups defined, you can restart services by specific groups at any time after you make configuration changes.
To restart services by groups:

1. Go to the restart groups view for the DNS or DHCP service.
2. Select the groups to restart.

3. In the toolbar, click **Restart –> Restart Groups**.
4. In the Restart Group Confirmation window, select the restart type for the services on the affected members:
    - **If needed**: Select this to restart services only if there are changes requiring a service restart.
    - **Force service restart**: Select this to force a service restart even if it is not needed. A forced restart may be delayed if there are pending restarts for the same service.
5. To schedule a service restart, click the Schedule icon at the top of the wizard. In the *Schedule Change* panel, complete the following:
    - **Now**: Restarts services immediately.
    - **Later**: Enter the following information to schedule the member to restart services at a certain date and time:
        - **Date**: Enter a date in YYYY-MM-DD (year-month-day) format. The appliance displays today's date. You can also click the calendar icon to select a date from the calendar widget.
        - **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
        - **Time Zone**: Select a time zone for the scheduled date and time from the drop-down list. This field displays the time zone of the browser that the admin uses to log in to Grid Manager.
6. Click **Restart** to restart services immediately or click **Schedule Restart** to schedule the restart.

⚠ Note
Normally, you cannot restart or schedule a restart of services when a scheduled full Grid upgrade is in progress. However, you can do so for the Default DNS or DHCP restart group. In this case, only the Grid Master is restarted. The other members of the group remain in the Timed Out status and are restarted after Grid Manager gets a response from them. For more information about the full Grid upgrades, see *Guidelines for Scheduling Full Upgrades*.

Configuring Restart Settings

To configure the service restart settings for the Grid:

1. Click **Grid–>Grid Manager–>DHCP** or **DNS** tab.
2. In the toolbar, click **Edit–>Grid DHCP Properties** or **Grid DNS Properties**.
3. Click **Toggle Advanced Mode–>Restart**.
4. If necessary, modify the service restart settings:

- **Delay between Restart Groups**. This is the delay between the restarts of separate restart groups. The default is 10 seconds.

⚠ Note

If the delay time from the previous group restart has not elapsed yet, the new restart requests are displayed with the Pending restart status. To speed up the new restarts, you change the delay between restart groups to a smaller value at any time.

- **Member Restart Timeout**. This is the amount of time that the appliance waits for a response from a member. The default is 1 minute.

5. Optionally, select the checkbox **Apply restart requests to offline members when they connect**.
6. Click **Save & Close**.

Canceling a Scheduled Restart Task

Limited-access users can only cancel a scheduled task that they created. Superusers can cancel a scheduled task that any user created. You can cancel scheduled restart tasks from **Task Manager**. For information, see *Viewing Tasks*.
When you delete a scheduled restart task, the system cancels the scheduled task to restart services on the member or Grid and does not restart services. To cancel a scheduled restart, see *Canceling Scheduled Tasks*.
You can also turn off the automatic service restart feature for other scheduled tasks. For example, if you set a recurring

automatic restart for a restart group, you may not need the automatic service restart which should normally happen after a scheduled change of an object. You can do so from the Infoblox CLI using the set scheduled command. For information, see the section *set scheduled* in the *Infoblox CLI Guide*.
Alternatively, administrator users with the approver role can cancel the automatic service restart for individual tasks when approving them. If you are an approver, you can do so by deselecting the **Enable automatic service restart** option for a task in the **Task Manager**. For information, see *Viewing Tasks*.

Configuring the Orphan Mode

After you enable NTP on a Grid, the Grid members including Grid Manager can function as NTP servers to clients. For information on how to configure a NIOS appliance as an NTP server, see *NIOS Appliances as NTP Servers*.

> **Warning**
>
> Setting a proper stratum value is important for time and service synchronization among Grid members. Unless a special configuration is required, use the default values. In case you configure the values, keep the configuration as simple as possible.

The NIOS NTP service is configured with external NTP servers, and the NTP service stratum is derived from these external NTP servers. Sometimes, in the absence of the external NTP servers, NIOS Grid members, through the disconnected NTP server deliver the NTP service to the clients. Depending on your admin permissions, you need to configure the NTP service stratum values for Grid Manager and Grid members to facilitate the disconnected NTP service. The disconnected NTP service uses the service stratum values to help Grid Manager or members act as NTP servers. Once the external NTP server is accessible, the Grid connects to the external NTP server and receives the stratum values from the external NTP server. When the NTP service is in a disconnected state, it is referred to as the orphan mode.

You can configure stratum values for Grid Manager and Grid member at the Grid level, and for individual member at Grid member level using Grid Manager or CLI commands. For information on how to configure orphan mode stratum values, see *Defining NTP Orphan Mode* and for information about admin permissions, see *About Administrative Permissions*.

> **Note**
>
> The Grid member value configuration takes precedence over Grid Manager value configuration.

Limitation of Orphan Mode

Note the following limitation of orphan mode:

- You can use the disconnected NTP service only if you have configured stratum values for NTP services on Grid Manager or a Grid member.
- When the member is offline and the Grid member and Grid Manager are at the default stratum, NIOS changes the stratum value of the local clock from 14 to 12.

Guidelines for Setting Stratum Values

The following is a list of guidelines for setting stratum values:

- Either use the default NTP stratum values for Grid Manager as well as Grid members, or configure the NTP stratum values for Grid Manager as well as Grid members.
- To avoid the scenario where Grid Manager does not have internet access for a long period of time, add an external NTP server for the Grid member.

- With the default NTP stratum values, when the external NTP server is not reachable, Grid Manager sets the stratum value of the fallback local source to 12 even though the actual NTP stratum value is 1 greater than the fallback local source's stratum value, 13.
- When a Grid member synchronizes with Grid Manager, the NTP stratum value of the Grid member is 1 greater than the NTP stratum value of Grid Manager, 14. However, if Grid Manager is not suitable as an NTP clock source, then the Grid member uses its fallback local source's stratum value, 14, and the actual NTP stratum value of the Grid member is 1 greater than the fallback local source's stratum value, 15.
- When you configure the NTP stratum values, Grid Manager uses the fallback local source's stratum value of 1 less than the set NTP stratum value. For example, if the NTP stratum value is set to 8, the fallback local source's stratum value of Grid Manager is set to 7; if the external NTP servers are not reachable, then the NTP stratum value of Grid Manager becomes 8.
- When the external NTP servers are either not reachable or not configured, Grid Manager uses its local source and sets the NTP stratum value. In this scenario, however, the following applies to Grid members:
    - If a Grid member is configured to synchronize with only Grid Manager, then
        - If Grid Manager is reachable, then the Grid member's stratum value is 1 greater than the NTP stratum value of Grid Manager.
        - If Grid Manager is not reachable, then the Grid member's stratum value is set to the member's stratum value configured either at the Grid level or member level.
    - If the Grid member is configured to synchronize with only a set of external NTP servers, then the Grid member's stratum value is set to 1 greater than the NTP stratum value of the server that has the best quality and the lowest stratum value. However, if none of the external NTP servers can be reached, then the Grid member's stratum value is set to the member's stratum value configured either at the Grid level or member level.
    - If the Grid member is configured to synchronize with external NTP servers as well as Grid Manager, then
        - If the NTP servers as well as Grid Manager are reachable, then the Grid member synchronizes with the best available NTP source according to its reachability, stratum values, jitter, and offset, by setting its stratum value to 1 greater than the NTP stratum value of the best source.
        - If the external NTP servers are not reachable but Grid Manager is reachable, then the NTP stratum value is set to 1 greater than the NTP stratum value of Grid Manager.
        - If the NTP servers and Grid Manager are not reachable, then the Grid member synchronizes with the local clock and the stratum value is set to the member's stratum value configured either at the Grid level or member level.

File Distribution Services

This section describes the file distribution services on the NIOS appliance. It contains the following topics:

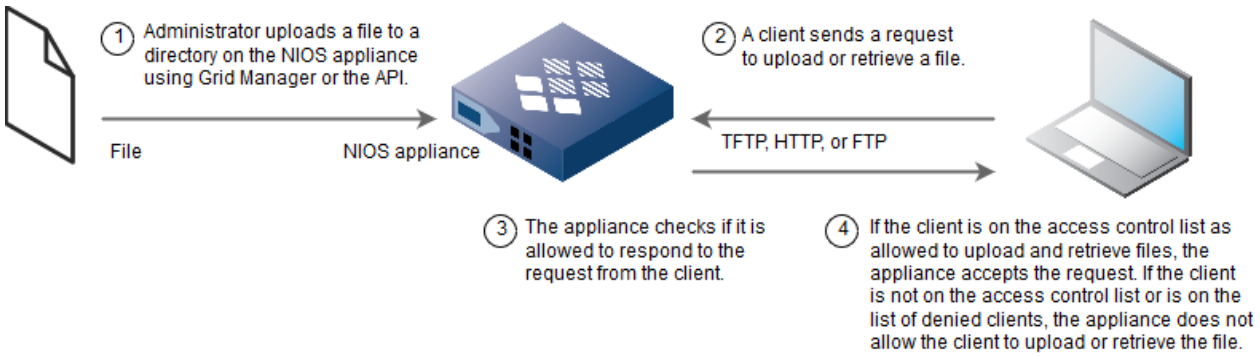
About File Distribution Services

You can upload files to the NIOS appliance and to individual Grid members using TFTP, HTTP, and FTP, clients. You can also upload files using the Grid Manager web interface or the API. Using access control lists, you can specify which network devices can upload files or retrieve files. You can use the **Group Results** function for file distribution services (TFTP, FTP, and HTTP) to group members by extensible attributes that contain the same values. For information about how to group members by extensible attributes, see *Adding Grid Members*.

> **Note**
>
> File distribution services using TFTP, HTTP, and FTP is not supported by IPv6-only appliances.

Network devices, such as VoIP phones, can use the DHCP services on the appliance for IP address assignments and use the file distribution services for IP device configuration downloads. Downloads can be accomplished with TFTP, HTTP, or FTP.

Uploading and retrieving files



File uploads and downloads by FTP and TFTP file distribution clients are logged in the syslog under the **Administration**-> **Logs** tabs. The logs store the following information:

- Client IP
- Date and Time
- Event type
- File(s) downloaded and/or uploaded

File Distribution Storage

This section describes the storage capacity for file distribution, and how to manage file distribution storage settings. Maximum storage space allowed for all file distribution services on a Grid is equal to the storage space allowed on the Grid member with the smallest amount of space allowed.

Maximum storage space is shown in the below table.

Maximum Storage Space by Platform Type

Member Type	Description	Max Limit
INFOBLOX_MEMBER	All Infoblox appliances	10GB
VNIOS_MEMBER	All virtual appliances (VMWare)	5GB
VM_MEMBER	Virtual IPAM member (IPAM Free Ware)	1GB

Usage Threshold Alerts

An SNMP trap generates an alarm message when a member nears storage capacity. The default threshold value is 90%, and the default reset value is 70%. If email notification is enabled, NIOS sends an email when either of these thresholds are reached.

- When the Grid member storage capacity reaches 100%, the SNMP trap generates a "High Usage" message. For information on how to modify the threshold values, see *Configuring SNMP*.

- File distribution clients will fail to PUT files if the file is large enough that it will put the member over the storage limit.

Modifying File Distribution Storage Limits

1. From the **Data Management** tab, select the **File Distribution** tab, and then click **Grid File Distribution Properties** from the Toolbar.
2. In the *Grid File Distribution Properties* editor, complete the following:
   - **Storage Limit (MB)**: Enter the maximum storage space in megabytes.
   - **Include files and directories in system backup**: This is selected by default to ensure that the appliance includes the uploaded files in the backup. You can clear this checkbox to improve the backup performance if you have stored these files separately.
3. Save the configuration and click **Restart** if it appears at the top of the screen.
   Note that to avoid data loss, after you change the storage limit FD services will be disrupted briefly and will take some time to resume. Wait until the File Distribution services are running again on the members before you upload any files.

Managing File Distribution Services

This section describes how to configure file distribution services such as TFTP, FTP and HTTP. This section also describes how to configure access control lists which determine which clients are granted access to the service, and which clients are denied access to the service.

Configuring the TFTP Service

The TFTP file distribution service is disabled on the appliance by default. To allow file distribution access using TFTP, you must specify the clients that are allowed to use the service and then enable the service on the appliance. If you do not specify this information or enable the service, the appliance denies access to all clients. The appliance provides read-only access to the files.

The TFTP service is supported only on LAN1 and MGMT interfaces. For more information, see *Configuring Ethernet Ports*.

To configure the TFTP file distribution service on a member:

1. From the **Data Management** tab, select the **File Distribution** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *Member File Distribution Properties* editor, select the **TFTP** tab, and then complete the following:
   - **Listen on Port**: Enter the number of the port on which the appliance receives TFTP file distribution requests.
     The default is port 69.
   - **Allow file transfers from**: Configure the appliance to grant or deny permissions to TFTP file distribution requests from clients, as described in Configuring Access Control for File Distribution below.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

After you configure the TFTP service, you must enable the service to allow file distribution access. For information, see Starting and Stopping File Distribution Services below.

Configuring the FTP Service
The FTP file distribution service is disabled on the appliance by default. To allow file distribution access using FTP, you must create at least one user (see *Managing Users*), specify the clients that are allowed to use the service, and then enable the FTP service on the appliance. If you do not specify this information or enable the service, the appliance denies access to all clients. User creation is not necessary to access the FTP service if anonymous is enabled at Grid level.The appliance provides read-only access to the files.
To configure the FTP file distribution service on a member:

1. From the **Data Management** tab, select the **File Distribution** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *Member File Distribution Properties* editor, select the **FTP** tab, and then complete the following:
    - **Listen on Port:** Enter the number of the port on which the appliance receives FTP file distribution requests. The default is port 21.
    - **Login Banner**: Enter your own login banner text that appears after you establish an FTP connection or use the default (**Restricted Access Only**).
    - **FTP Passive Mode**: By default, this is selected to enable FTP in passive mode; otherwise, it is in active mode. An FTP connection between a client and server can be in active or passive mode. In active mode, the server initiates the data connection. In passive mode, the client initiates the data connection. Depending on your firewall policy, firewalls can block active mode connections. There is no firewall filtering in passive mode.
    - **FTP File Listing**: Select this to allow users to list files and subdirectories on the appliance.
    - **Allow file transfers from**: Configure the appliance to grant or deny permissions to FTP file distribution requests from clients, as described in Configuring Access Control for File Distribution below.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Enabling FTP Anonymous User

The 'anonymous' FTP login is disabled by default, except when upgrading an earlier version in which case anonymous FTP is automatically enabled.

When you enable anonymous FTP at Grid level, you enable anonymous FTP on all Grid members running the FTP service. Anonymous user is only allowed to download files, even if the member is enabled to allow uploads.

1. From the **Data Management** tab, select Grid **File Distribution** Properties on the toolbar.
2. In the *Grid File Distribution Properties* dialog box, select the **Enable Anonymous FTP** checkbox.
3. Click **Save & Close**.

Configuring the HTTP Service

To allow file distribution access using HTTP, you must specify clients that can request the service and then enable the HTTP service on the appliance.

Before you enable the HTTP service, however, be aware of the following configuration rules:

- HTTP only runs on the active member of an HA pair.
- HTTP can run on the master or any member.
- HTTP always runs on the LAN port, never the MGMT port.
- HTTP to HTTPS redirect becomes non-functional if the file distribution service is enabled and all administrative access is run on the LAN port. For more information on HTTP redirect, see *Enabling HTTP Redirection.* For information on how to specify the MGMT port for HTTP, see *Using the MGMT Port.* To configure the HTTP file distribution service on a member:

1. From the **Data Management** tab, select the **File Distribution** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *Member File Distribution Properties* editor, select the **HTTP** tab, and then complete the following:
    - **Allow Any**: This is selected by default to allow HTTP file distribution requests from any client.
    - **Only these addresses**: Select this to configure the access control list for allowing HTTP file distribution requests from clients, as described in Configuring Access Control for File Distribution below.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring Access Control for File Distribution

You can select a named access control list (ACL) or create individual access control entries (ACEs) for each file distribution service (TFTP, FTP, HTTP) to control access to file distribution requests from specific clients. You can grant or deny access from specific IPv4 addresses and IPv4 networks, but you cannot do so for IPv6 addresses and IPv6 networks as well as TSIG key based ACEs.

> **Note**
>
> For HTTP service, you can grant permissions to all clients or specific clients, but you can deny permissions only to all clients, not specific clients.

When you grant access to a network for a specific file distribution service, all clients in the network are allowed to request file distribution service. You can deny services to specific IP addresses within the network by adding these addresses to an access control list and denying access to the service. Ensure that you list these IP addresses before the network address in the list because the appliance applies permissions to the addresses in the order they are listed. You can use the arrow keys to move the addresses up and down the list after you add them. For information about how to create a named ACL, see *Configuring Access Control*.
To configure an access control list for a file distribution service:

1. From the **Data Management** tab, select the **File Distribution** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *Member File Distribution Properties* editor, select a service tab: **TFTP**, **FTP**, or **HTTP**.
3. In the **Allow these clients to perform file transfers** section, select one of the following:
    - **Any**: Select this to allow any clients to use the HTTP file distribution service. This is selected by default.
    - **Named ACL:** Select this and click **Select Named ACL** to select a named ACL that contains only IPv4 addresses and networks. File distribution does not support IPv6 addresses/networks and TSIG key based ACEs. When you select this, the appliance allows clients that have the **Allow** permission in the named ACL to use the file distribution service. You can click **Clear** to remove the selected named ACL.
    - **Set of ACEs**: Select this to configure individual access control entries (ACEs). Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding.
        - **IPv4 Address:** Select this to add an IPv4 address. Click the **Value** field and enter the IP address. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
        - **IPv4 Network:** In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
            - **Address:** Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
            - **Permission:** Select **Allow** or **Deny** from the drop-down list.
        - **Any Address/Network:** For TFTP and FTP only. Select this to allow or deny access to all IPv4 addresses and networks. The default permission is **Allow**, which means that the appliance allows access to and from all IPv4 clients. You can change this to **Deny** to block access.
        After you have added access control entries, you can do the following:
        - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
        - Reorder the list of ACEs using the up and down arrows next to the table.
        - Select an ACE and click the Edit icon to modify the entry.
        - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Modifying Access Control Lists

1. From the **Data Management** tab, select the **File Distribution** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *Member File Distribution Properties* editor, select the tab of the service to which the list belongs.
3. In the **Allow file transfers from** section, modify the fields as described in Configuring Access Control for File Distribution above.

You can also do the following:

- Add a new permission. For information, see Configuring Access Control for File Distribution above.
- Delete a permission by selecting it and clicking the Delete icon.
- Reorder the list by selecting a permission and clicking an arrow next to the list to move the permission up or down the list.

Starting and Stopping File Distribution Services

You can enable and disable a file distribution service on a specific Grid member or on multiple members. You must have read/write permission to the Grid members to start and stop a service on them.

Starting a service on a member:

1. From the **Data Management** tab, select the **File Distribution** tab -> **Members** tab -> *member* checkbox, and then click the Start icon from the Toolbar. You can select multiple members by selecting their checkboxes.
2. From the Start drop-down menu, select the service you want to start.
3. In the *Start Service* dialog box, click **Yes**.
   Grid Manager enables the selected service on the selected member and displays the service status in the Status column in the panel.

Stopping a service on a member:

1. From the **Data Management** tab, select the **File Distribution** tab -> **Members** tab -> *member* checkbox, and then click the Stop icon from the Toolbar. You can select multiple members by selecting their checkboxes.
2. From the Stop drop-down menu, select the service you want to stop.
3. In the *Stop Service* dialog box, click **Yes**.
   Grid Manager disables the selected service on the selected member and displays the service status in the Status column in the panel.

> ⚠ Note
> When you start or stop a service, there may be a short delay before Grid Manager displays the correct status.

Monitoring File Distribution Services

To view the current status of the file distribution services:

1. From the **Data Management** tab, select the **File Distribution** tab -> **Members** tab.
2. Grid Manager displays the following information:
   - **Name**: The name of the Grid member.
   - **Address**: The IP address of the Grid member.
   - **Status**: The overall status of the file distribution services running on the member. You can mouse over on the field to view the status of each service. This field can display one of the following:
     - **Not Running**: All the file distribution services are disabled.
     - **Running**: One or more of the file distribution services are running properly.
     - **Warning**: The services are functioning properly. However, there are some issues, such as storage space has reached 90%, about the services.
     - **Error**: One or more of the services have service issues.
   - **Comment**: Information about the member.
   - **Site**: The location to which the member belongs. This is one of the pre-defined extensible attributes.

You can sort the information in ascending or descending order by columns. You can also print and export the information in this panel.

Managing Directories

You can create directories on the Grid Master and on Grid members, in which you can store your files. You can manage the directories in the following ways:

- Create a directory structure for file distribution, as described in Adding Directories below.
- Modify the directory name and permissions, as described in Modifying Directories below.
- Create a Virtual TFTP root directory, as described in Creating a Virtual TFTP Root Directory below.
- View the directories, as described in Viewing Directories From the Files Tab below.

Adding Directories

To add a directory:

1. From the **Data Management** tab, select the **File Distribution** tab -> **Files** tab.
2. Click the parent directory link, and then click **Add** -> **Directory** from the Toolbar.
3. Grid Manager adds a new directory to the parent directory and gives it the default name **NewDirectory**. You can modify the directory name and permissions, as described in Modifying Directories below.

Modifying Directories

1. From the **Data Management** tab, select the **File Distribution** tab -> **Files** tab.
2. Select a directory checkbox and click the Edit icon.
3. The *Directory* editor provides the following tabs from which you can modify data:
    - **General**: You can modify the directory name here, except for the Root directory.
    - **Virtual TFTP Root**: You can add an IP Address, a Network or a Range of IP addresses to support VMware ESX hosts who need different PXE boot images based on where they are in the network.
    - **Permissions**: You can add or delete admin permissions in this tab. For information, see *About Administrative Permissions*.
4. Save the configuration and click **Restart** if it appears at the top of the screen.
   You can also select a directory and click the Delete icon to delete it.

> **Note**
>
> When you delete a directory, the appliance automatically removes all its contents in that directory.

Creating a Virtual TFTP Root Directory

This section describes how to create a Virtual TFTP root directory for a specific IP address, network, or range of IP addresses. Note that Virtual TFTP root is supported only for file downloads, but not for file uploads using TFTP client.

> **Note**
>
> Root directory can not be a virtual TFTP root.

1. From the **Data Management** tab, select the **File Distribution** tab -> **Files** tab.
2. Select the directory checkbox and click the Edit icon.
3. In the *Directory* editor select **Virtual TFTP Root**. Click the Add icon and select one of the following:
    - **IP Address:** This creates a virtual TFTP directory that the clients from a specified IP address will see as the root directory.
    - **Network:** This creates a virtual TFTP directory that the clients on a specified network will see as the root directory.

    - **Range:** This creates a virtual TFTP directory that the clients in a specified range of IP addresses will see as the root directory.
4. From the drop-down in the **Member** column, select the member on which to make the virtual TFTP root directory.
5. In the **Address/Network** column, enter a value:
    - **IP Address:** Enter the IP address of the client that will have access to the virtual TFTP root directory. This IP address must be on the allow list in the TFTP access control list.
    - **Network:** Enter a network address using the format 10.0.0.0/24. This allows all clients in that network to access the virtual TFTP root directory. This network address must be on the allow list in the TFTP access control list.
    - **Range:** Enter the first IP address in the range Address/Network column, and the last IP address in the range in the End column. This allows all clients in that range to access the virtual TFTP root directory. This range must be on the allow list in the TFTP access control list.
6. Click Save & Close. Click **Restart** if it appears at the top of the screen.
7. To create more virtual TFTP root directories, repeat Steps 3 through 5.

Viewing Directories From the Files Tab

1. From the **Data Management** tab, select the **File Distribution** tab -> **Files** tab.
2. Grid Manager displays the following information in the Root directory.
    - **Name**: The name of the directory or file.
    - **Type**: Depending on the file type, this can be **Directory** or **File**.
    - **Size**: The file size in B, KB, or MB depending on whether the file size crosses the unit limit or not. For example, if the file size is 1023, Grid Manager displays 1023 B. If the file size is 1025, Grid Manager displays 1 KB. For a directory, Grid Manager displays a dash (-).
    - **Date Modified**: The timestamp when the directory was last created or when the file was last modified.
3. Click the directory link to view files and directories in a specific directory. You can also do the following in this panel:

- Sort the information in ascending or descending order by columns.
- Use the breadcrumb to go to a specific directory.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- Print and export the information in this panel.
- Add a directory or a file. For information, see Adding Directories and *Managing Files*.
- Open and edit a directory. For information, see Modifying Directories above.

Managing Files

This section describes how to upload files using the Grid Manager or a file transfer client. You can upload files to the Grid Master or to individual members.

Uploading Files

Some things to keep in mind when you upload files:

- When you use the Grid Manager to upload files, you can upload files only to the Grid Master, not to individual members of the Grid.
- To upload files to a member, you must use an FTP client, TFTP client or HTTP client. Files uploaded by file transfer clients to any member, will be synchronized back to Grid Master.
- The logs for file transfers using third party clients can be found in syslog.
- You can use a third party file transfer client to upload and retrieve files:
    - If the 'anonymous' login is enabled, you can retrieve files but this 'anonymous' user can not upload files even if the "Allow uploads" option is enabled.

    - If you create a user to use with a third party transfer client, this must be an FTP user with read/write permissions in their directory.
- You can upload a maximum of 10,000 files.
- If uploading a file exceeds the storage limit of 2 GB for a single file, NIOS logs a message and does not upload the file. For information about file distribution storage, see *Modifying File Distribution Storage Limits*.
- If you upload a file that has the same name and path as an existing file, NIOS automatically replaces the old file.

> **Note**
>
> Administrators with superuser privileges can manage uploading files. Limited-access admins with read/write permissions to specific directories can upload files to the directories. For information, see *Administrative Permissions for File Distribution Services.*

Enabling Upload to Grid Members

1. From the **Data Management** tab, select Grid **File Distribution** Properties on the toolbar.
2. In the *Grid File Distribution Properties* dialog box, select the **Allow Upload to Grid Members** checkbox.
3. Click **Save & Close**.

Uploading Files using Grid Manager

The Grid Manager uploads files only to the Grid Master. The Grid Master propagates the files to the members. You must use a third party file transfer client to upload files directly to an individual member:

- If the 'anonymous' login is enabled, you can retrieve files but this 'anonymous' user can not upload files even if the "Allow uploads" option is enabled.
- If you create a user to use with a third party transfer client, this must be an FTP user with read/write permissions in their directory.

1. From the **Data Management** tab, select the **File Distribution** tab -> **Files** tab.
2. Select the destination directory link.
3. Click the **Add** icon -> **File** from the Toolbar.
4. Select the **Extract files after upload (.zip, .tar, .gz, .tgz)** checkbox in the *Upload* dialog box if you are uploading .zip, .tar, .gz, or.tgz files and you want to automatically extract the files upon upload.
   Note that the directory structure in the compressed file is restored when the files are extracted. A directory that already exists it will be replaced by an extracted directory with the same name.
5. Click **Select to** navigate to the file you want to upload.
6. Select the file you want to upload, and then click **Open.**
7. If you want to upload more than one file, repeat Steps 4 and 6 until you have selected all the files you want to upload. You can upload a maximum of ten files at one time.
   Note you can delete an incorrect file selection by clicking the red icon next to the filename before you click Upload.
8. To verify the upload was successful. roll the mouse cursor over the green check mark next to the file name. If the upload was successful, the message "Upload succeeded." appears.

Uploading Files Using TFTP, FTP, or HTTP File Transfer Client

You can upload files to the Grid Master or to individual members using a third party FTP client. Files uploaded by file transfer clients to any member, will be synchronized back to Grid Master.
To upload files to a member, you must first enable the **Allow Upload to Grid Members** checkbox in the *Grid File Distribution Properties* dialog box. See Enabling Upload to Grid Members.
You must add an FTP user before you can upload files using a third party FTP client. This must be an FTP user. It is not the NIOS admin. For information see Adding FTP Users through Grid Manager.

Deleting Files From the Grid Master

If the FTP user has read/write permissions, then that user can delete files from the Grid member wherever that FTP user is connected. Only files can be deleted but not directories.

1. From the **Data Management** tab, select the **File Distribution** tab -> **Files** tab.
2. Grid Manager displays the files and folders in the Root directory. Click the directory link to see the files in a specific directory.
3. To delete a file, select the checkbox and then click the **Delete** icon.

Deleting Files From a Member

You can delete files from a member only if "**No**" appears in the *Synchronized with Grid Master* column.
If the FTP user has Read/Write permissions, then that user can delete files from the Grid member wherever that FTP user is connected. Only files can be deleted but not directories.

1. From the **Data Management** tab, select the **File Distribution** tab -> **Files** tab.
2. Grid Manager displays the files and folders in the Root directory. Click the directory link to see the files in a specific directory.
3. If "**No**" appears in the *Synchronized with Grid Master* column, select the checkbox, then click the **Delete** icon.

Viewing Files

You can view files from the Files Tab and from the Members Tab.

Viewing Files from the Files Tab

1. From the **Data Management** tab, select the **File Distribution** tab -> **Files** tab.
2. Grid Manager displays the following information in the Root directory.
    - **Name**: The name of the file.
    - **Type**: Depending on the file type, this can be **Directory** or **File**.
    - **Size**: The file size in B, KB, or MB depending on whether the file size crosses the unit limit or not. For example, if the file size is 1023, Grid Manager displays 1023 B. If the file size is 1025, Grid Manager displays 1 KB. For a directory, Grid Manager displays a dash (-).
    - **Date Modified**: The timestamp when the directory was last created or when the file was last modified.

You can view files and directories in a specific directory by clicking the directory link.

Viewing Files from the Members Tab

1. From the **Data Management** tab, select the **File Distribution** tab -> **Members** tab.
2. Grid Manager displays the following information in the Root directory.
    - **Name**: Member name.
    - **IPv4Address**: **Member's IP address**.
    - **Status**: State of the member, running or not running.
    - **Comment**: Additional comments about the member.
    - Site: User defined information about the site.
3. To see the files on the Grid Master, click on the name of the Grid Master. Grid Manager displays the following information:
    - **Name**: The name of the file.
    - **Type**: Depending on the file type, this can be **Directory** or **File**.
    - **Size**: The file size in B, KB, or MB depending on whether the file size crosses the unit limit or not. For example, if the file size is 1023, Grid Manager displays 1023 B. If the file size is 1025, Grid Manager displays 1 KB. For a directory, Grid Manager displays a dash (-).
    - **Date Modified**: The timestamp when the directory was last created or when the file was last modified.

Tip: When you drill down on the Grid Master from the Members tab, the Add icon is activated.

4. To see the files on a member, click on the name of the member. Grid Manager displays the following information:
   - **Name**: The name of the file.
   - **Type**: Depending on the file type, this can be **Directory** or **File**.
   - **Size**: The file size in B, KB, or MB depending on whether the file size crosses the unit limit or not. For example, if the file size is 1023, Grid Manager displays 1023 B. If the file size is 1025, Grid Manager displays 1 KB. For a directory, Grid Manager displays a dash (-).
   - **Date Modified**: The timestamp when the directory was last created or when the file was last modified.
   - **Synced with Grid Master**: You cannot delete files with a value other than "No". If this value is "No", you must delete the file.

     Note

     You cannot upload, modify, or delete a file or a directory when you drill down from the Members tab.

You can also do the following in this panel:

- Sort the information in ascending or descending order by columns.
- Use the breadcrumb to go to a specific directory.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters.*
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- Print and export the information in this panel.
- Add a directory or a file. For information, see *Adding Directories* and *Managing Files*.
- Open and edit a directory. For information, see *Modifying Directories.*
- You can enable "group by" function to organize your members in a meaningful way and quickly identify them based on common data. Complete the following to group members with the same extensible attribute value:
  - **Group Results**: Select this checkbox to enable the appliance to group members by extensible attributes.
  - **Group By**: From the drop-down list, select the first extensible attribute that you want the appliance to use for filtering members.
    Grid Manager displays data per group of members configured with the same extensible attribute value. For more information about grouping by extensible attributes, see *Grouping Members by Extensible Attributes*.

Managing Users

This section describes how to add and modify user accounts for use with an FTP client.
You must be a NIOS admin user with super user privileges to add, modify, or delete FTP users. FTP users are created at Grid level, so the same users will be available to access FTP service on all members.

- Each user must have unique Username.
- By default, the home directory with the user name is under the `/ftpusers` directory. However, the user can also choose to use an existing directory outside of `/ftpusers` as his home directory. If the admin specified home directory is not available then it will raise an error.
- Permission: Read-write or Read-only are assigned for each FTP user. Users with read-write permissions are allowed to upload files, delete files and list the files and directories under his home directory.
- You can have multiple users to use same home directory. One user may have read-only permissions while others have read-write permissions on same home directory.
- FTP users are not allowed to add, modify, or delete the directories, even with read-write permissions.

- If the "Allow uploads on the member" is disabled, then users with read-write permission also can not upload files to his home directory.

Users Default Home Directory

- FTP users default home directory is `/ftpusers`.
- The `/ftpusers` directory is created by default and listed in the 'Files' viewer under the root directory.By default, home directories for FTP users are under this directory.
- NIOS admin is allowed to upload and delete files to and from users home directories.
- Files uploaded by FTP users are visible in the Grid Manager.

Adding FTP Users through Grid Manager

1. From the **Data Management** tab, select the **File Distribution** tab -> FTP Users tab, and then click the Add icon.
2. In the *Add FTP User* dialog box, complete the following:
    - **Username**: Enter a name for the user. This is the username that the user uses to log in.
    - **Password**: Enter a password for the user to use when logging in.
    - **Confirm Password**: Enter the same password.
    - **Permissions**: From the drop down choose from the following:
        - **Read Only**: This allows the user to display files, but not to upload, or delete files using a third party FTP client.
        - **Read/Write**: This allows the user to upload, delete and list files using a third party FTP client.
    - Choose a directory for this user. This is the directory where files uploaded with this Username will go:
        - **Create Home DIrectory**: This creates a directory using the Username.
        - **Choose Specified Directory**: This allows the user to choose an existing directory.
3. Click **Save & Close**.

Adding FTP Users through CSV Import

You can add an FTP User by importing a CSV file with the headers in the following format:

```
version 1.0,,,,
 header-ftpuser,username*,password*,create_home_dir,home_dir,permission
ftpuser,user1,passwd1,True,/ftpusers/user1,RO
```

Modifying FTP Users

1. From the **Data Management** tab, select the **File Distribution** tab -> FTP Users tab.
2. Select the checkbox for the user you want to modify and click the Edit icon.
3. In the *FTP User Editor* you can modify the following:
    - **Password**: Enter a password for the user to use when logging in.
    - **Confirm Password**: Enter the same password.
    - **Permissions**: From the drop down choose from the following:
        - **Read Only**: This allows the user to display the files and their properties, but not to edit them.
        - **Read/Write**: This allows the user to display and edit the files and their properties.
4. Click **Save & Close**.

bloxTools Environment

The bloxTools environment provides a pre-installed environment for hosting custom web-based applications. This section includes the following topics:

- *About the bloxTools Environment*
- *Using the bloxTools Environment*

- *Monitoring the Service*

About the bloxTools Environment

The bloxTools environment provides tools for creating custom applications that facilitate the administrative tasks in your organization. It provides a pre-installed environment for running applications using Perl, Python, PHP, CGI scripting, and Infoblox API libraries. Note that no direct external remote user (telnet and ssh, for example) or shell access is available in this environment.
The bloxTools environment "borrows" resources such as CPU, memory, disk space, and networking from the host Infoblox appliance, but is logically separated from the NIOS. The logical separation ensures that any failure in the bloxTools service does not affect the other services running on the appliance.
The bloxTools environment can only be configured to run on an independent appliance or a Grid member. You cannot run the bloxTools service on a Grid Master or a Grid Master candidate.

> **Note**
>
> In previous NIOS releases, you could run the bloxTools service only on a Grid Master. If bloxTools has been configured to run on a Grid Master before an upgrade, the bloxTools service continues to run on the Grid Master after an upgrade. This configuration is preserved mainly for migration purposes only. Infoblox strongly recommends that you move the bloxTools service to a Grid member after the upgrade. For information about moving the bloxTools service, see *Using the bloxTools Environment.*

In a Grid, you can run the bloxTools service only on one Grid member at a time, and you cannot configure this member as a Grid Master candidate. However, you can move the bloxTools service from one member to another. For information about moving the bloxTools service, see *Using the bloxTools Environment.*
On an HA member, the bloxTools service runs on the active node. If there is an HA failover, the bloxTools service is automatically launched after the passive node becomes active. For information, see *About HA Pairs*.

> **Note**
>
> When you run the bloxTools service on an independent appliance or a Grid member, the performance of other services running on the appliance may be affected. Infoblox recommends that you run the bloxTools environment on a member that does not host critical services.

After you enable the bloxTools service and configure its built-in file transfer services, you can upload content to the bloxTools portal using either an FTP (File Transfer Protocol) or SFTP (SSH File Transfer Protocol) client. The uploaded content is included in system backups and you can restore it from the backups.
If you have further questions about bloxTools, visit the community site at *https://community.infoblox.com*.

System Requirements

The following table shows which Infoblox physical appliances support the bloxTools service.

Supported Infoblox Appliance
TE-815
TE-1415
TE-2215

The following table shows which Infoblox appliances support the bloxTools service and the memory requirement for each. The service "borrows" host resources such as CPU, memory, and disk space from the host Infoblox appliance.

Supported Infoblox Appliance	Memory Requirement
IB-V1410 IB-V1415 IB-V1420 IB-V1425	128 MB to 2048 MB The default is 256 MB
IB-V2210 IB-V2215 IB-V2220 IB-V2225	128 MB to 2048 MB The default is 256 MB
IB-V4015 IB-V4025	128 MB to 4096 MB The default is 256 MB

Using the bloxTools Environment

Complete the following tasks to upload custom applications to the bloxTools environment:

1. Log in to the appliance as a superuser and configure the bloxTools service, as described in Configuring the Service below.
2. Use an FTP or a SFTP client to upload content to the bloxTools environment.

In addition, you can schedule tasks as described in Scheduling Tasks below, and monitor the bloxTools service as described in *Monitoring the Service*.

WARNING: Resetting the Grid member using either the reset all or reset database CLI commands permanently deletes the content you uploaded to the bloxTools environment. Infoblox recommends that you backup the appliance before using any of these commands.

Configuring the Service

When you configure the bloxTools service, you can enable FTP, SFTP, and HTTPS, and set their operational parameters. FTP and SFTP are the services you use to upload data. You can disable these services when they are not in use. HTTPS must remain enabled to allow the web based bloxTools applications to run. Note that the bloxTools service uses the same SSL certificate as the host Infoblox appliance. For information on certificates, see *Managing Certificates*. You can configure the bloxTools service on port 443, 444 or on a port between 1024 to 63999. You can also enable HTTP to HTTPS redirection for the bloxTools service from the default HTTP port 80 to any specified HTTPS port. When you enable HTTP to HTTPS redirection, all the requests sent to the HTTP port are redirected to the HTTPS port configured for the bloxTools service. By default, NIOS appliance does not redirect HTTP requests to HTTPS.

Note

When you redirect HTTP to HTTPS, the connection is not as secure as compared to connecting directly through HTTPS.

Note the following when you configure the bloxTools service on port 443:

- HTTP to HTTPS redirection from Grid member to Grid Master is disabled.
- HTTP file distribution service is not allowed.

In previous NIOS releases, you could run the bloxTools service on a Grid Master or a Grid Master candidate. If you have not removed the bloxTools service from a member before you upgrade it to NIOS 6.11.0 or later, you cannot configure the bloxTools service on port 443 until you move the bloxTools service to an upgraded Grid member. For information, see *Moving the bloxTools Service*.
To configure the bloxTools service:

1. Log in as a superuser.
2. From the **Grid** tab, select the **Grid Manager** tab, and then click **bloxTools.** In the **Services** tab, click **Edit** -> **Grid bloxTools Properties** from the Toolbar.
3. In the *Grid bloxTools Properties* editor, complete the following:
   - **Enable Web Service:** Select **HTTPS Port** to enable users to access the applications through an HTTPS connection. The default port is 444. You can change the default HTTPS port to 443 or to a port between 1024 to 63999.
   - **Redirect Bloxtools HTTP to HTTPS:** Select this checkbox to enable redirection from the default HTTP port to the HTTPS port. The default HTTP port is 80. This is disabled by default.
   - **Enable FTP Service:** Select **FTP Port** to enable the FTP service. The default port is 26. You can change the port number to suit your environment.
   - **Enable SFTP Service**: Select **SFTP Port** to enable the SFTP service for secure file transfer. The default port is 28. You can change the port to a number between 1024 and 63999, provided that the port is not currently used for another purpose.
   - **Login:** Enter the username for the FTP and SFTP services. The username can contain lower case letters, numbers, underscores (_), and dollar signs ($), and it must begin with a letter, not a number.
   - **Set Password:** Enter the password for the FTP and SFTP services in this field.
   - **Retype Password**: Enter the same password.

   Note that the password is sent as clear text when you use the FTP service. To maintain security on the Infoblox appliance, this password should be different from the password set for the Infoblox appliance.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

When you configure the bloxTools service on an independent appliance, you can configure the allocated memory in the *System bloxTools Properties* editor. For information, see Allocating Memory below.

Allocating Memory

You can configure the memory you want to allocate to the bloxTools service. You must configure this at the member level. If you run the bloxTools service on an independent appliance, you can configure the allocated memory in the *System bloxTools Properties* editor.
To configure the allocated memory:

1. Log in as a superuser.
2. From the **Grid** tab, select the **GridManager** tab, and then click **bloxTools.** In the **Services** tab, click **Edit** -> **MemberbloxToolsProperties** from the Toolbar.
3. In the *MemberbloxToolsProperties* editor, complete the following:

- **Allocated Memory (MB):** The service "borrows" host resources such as CPU, memory, and disk space from the host Infoblox appliance. The default amount of memory the appliance allocates for the bloxTools environment is 256 MB. You can change this allocation, depending on the appliance platform. See *System Requirements* for the requirements and allowed values of each appliance.

Uploading Files

Use an FTP or a SFTP client to upload content, such as Perl modules, JavaScript files, PHP files, CGI files, and image files, to the bloxTools environment. You can upload a maximum of 4 GB of data. After you have uploaded content to your bloxTools environment, you should disable the FTP and SFTP services to prevent unauthorized or accidental changes.
To upload files using the FTP service:

1. Open an Internet browser window and log in to the FTP service by entering:
   `ftp://Grid_member_ip_addr:ftp_port`

For example, if the IP address of the Grid member is 10.1.1.1 and the FTP port number is 26, enter: ftp://10.1.1.1:26

2. In the *Authentication Required* dialog box, enter the username and password. This is the username and password you entered for the FTP service in the *bloxTools Environment* editor on the appliance.
3. Follow the instructions provided by your FTP client to upload the files.

To upload files using the SFTP service:

1. Open a terminal window and log in to the SFTP service by entering:
   `sftp -oPort=sftp_port sftp_user@Grid_member_ip_addr`
   For example, if the IP address of the Grid member is 10.1.1.1, the login username for the SFTP service is jdoe, and the SFTP port number is 28, enter:
   `sftp -oPort=28 jdoe@10.1.1.1`
2. Enter the password. This is the password you entered for the SFTP service in the *bloxTools Environment* editor on the appliance.
3. Follow the instructions provided by your SFTP client to upload the files.

Note

On a computer running Microsoft Windows, you can use WinSCP as the FTP or SFTP client for uploading files. The bloxTools environment stores the uploaded data in the /portal directory.

Scheduling Tasks

bloxTools includes support for the Perl module Config::Crontab so you can manage scheduler services. You can use the scheduler to execute commands in the future. You can also schedule recurring commands. For example, you can schedule the creation of a host record or schedule recurring reports. The scheduler allows default "user level" crontab access and you can use the user account 'nobody' to submit commands. The Grid Master replicates the crontab data to the Master Candidates.

Moving the bloxTools Service

In a Grid, you can move the bloxTools service from one Grid member to another. When you move the bloxTools service, the source member synchronizes data with the Grid Master, and the Grid Master synchronizes data with the destination member. The time to resynchronize the bloxTools data on to the destination member depends on the amount of data to synchronize and the Grid configuration. If the migration takes longer than two minutes, it becomes a long running task. This allows the move of the bloxTools service to run in the background while you perform other tasks. Note that on an independent appliance, you cannot move the bloxTools service to another member.
After an upgrade from previous NIOS releases, Grid Manager displays a warning message in the system message panel if you have previously configured to run the bloxTools service on the Grid Master. You can click **Move** in this panel to launch the *Move bloxTools* dialog box to move the bloxTools service to a Grid member.
To move the bloxTools Service:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, and then click **bloxTools** -> **Move** from the Toolbar.
2. In the *Move bloxTools* dialog box, complete the following:
   - **Source Member**: Displays the name of the Grid member that is currently running the bloxTools service. You cannot modify this field.
   - **Destination Member**: Click **Select**. In the *Member Selector* dialog box, select the member to which you want to move the bloxTools service. Grid Manager displays the name of the selected member here.
3. Click **Move**.

The appliance synchronizes data with the Grid Master, and the Grid Master synchronizes data with the destination member. This may take a while to complete depending on your Grid configuration and the amount of data.

Monitoring the Service

Infoblox provides several tools for monitoring the bloxTools Environment. The bloxTools Environment has its own syslog service which you can access to view logs generated by the bloxTools service and its processes. The *Detailed Status* panel also displays the status of the bloxTools Environment.

Viewing the Logs

The bloxTools Environment generates the following logs:

- access.log: The Apache access log
- error.log: The Apache error log
- syslog.log: The bloxTools Environment system log

These log files are included in the support bundle. You can download the log files using FTP. You can also connect to the CLI of the member running the bloxTools environment and use the following commands to view the logs:

- Use the `show file` command to view the list of log files.
- Use the `show bloxtools` command to view the status of the bloxTools Environment.
- Use the `show file bloxtools portal_access` command to view the web portal access log.
- Use the `show file bloxtools portal_error` command to view the web portal error log.
- Use the `show file bloxtools portal_log` command to view the web portal system log.

Viewing Detailed Status

You can view the status of the bloxTools Environment from the **Services** tab of the **Grid Manager** tab. To display the bloxTools service status, from the **Grid** tab, select the **Grid Manager** tab -> **Services** tab, and then click **bloxTools**. Grid Manager displays all Grid members that can host the bloxTools service. The name of the Grid Master is displayed only if you have completed an upgrade and previously configured the bloxTools service to run on the Grid Master. Though you can continue to run the bloxTools service on the Grid Master, Infoblox strongly recommends that you move the bloxTools service to a Grid member. For information, see *Moving the bloxTools Service*.
Grid Manager displays the following information about all Grid members:

- **Name**: The Grid member name.
- **Service Status**: Indicates the current operational status of the bloxTools service running on the member. This can include the migration status if you are moving the bloxTools service to another member.
- **IP Address**: The IP address of the member.
- **Comment**: Information about the bloxTools Environment.
- **Sit**: The location to which the member belongs. This is one of the predefined extensible attributes.

The service status icon indicates the operational status of the bloxTools Environment and the usage percentages for the CPU, memory and disk resources. The status icon can be one of the following:

Icon	Color	Meaning
	Gray	The bloxTools Environment is disabled or offline.
	Green	The CPU, memory, and disk usage is below 80%.
	Yellow	Usage of at least one of the following resources is greater than or equal to 80%: CPU, memory or disk. The description indicates the percentage of each resource.
	Red	The bloxTools Environment is down, or an essential service within the bloxTools Environment has failed.

RIR Registration Updates

This section explains how to configure the Infoblox Grid to manage RIR (Regional Internet Registries) allocated addresses and submit registration updates to the RIPE database. It includes the following topics:

RIR Address Allocation and Registration Updates

You can configure the Infoblox Grid to manage allocated IP address blocks that ISPs (Internet Service Providers) receive from their RIRs (Regional Internet Registries). An RIR is an entity that manages the Internet number resources, which include IP addresses and autonomous system numbers, within a specific region of the world. RIRs use SWIP (Share WHOIS Project) or RWhois (Referral WHOIS) servers to provide address allocation information for IP address blocks. Typically, an RIR determines the address blocks to be allocated for specific organizations (typically ISPs), while an ISP manages the allocated address blocks, associated organizations and corresponding RIR registrations. An organization can determine when to request for more address blocks from its RIR. Most ISPs manage multiple organizations and synchronize network address data with their RIRs every few months.

To leverage IPAM (IP Address Management) on the NIOS appliance, you can enable the Infoblox Grid to manage RIR allocated addresses and send registration updates to the RIPE (Réseaux IP Européens) database as often as you update RIR data on NIOS. RIPE is one of the five RIRs in the world that manages the allocation and registration of Internet number resources for Europe, Russia, the Middle East, and Central Asia.

> **Note**
>
> The RIR registration update feature is not supported in a Multi-Grid configuration.

About the RIPE Database

The RIPE database contains registration details of IP addresses and AS numbers originally allocated by the RIPE NCC (RIPE Network Coordination Center). The database contains information such as organizations that hold IP resources, where the allocations were made, and contact details for the networks. Organizations or individuals that hold the allocated address blocks are responsible for updating information in the database.

The NIOS appliance supports submitting registration and reassignment updates to the RIPE database, which can be accessed through the RIPE API interface or an email template. For more information, see *Configuring RIR Communication Settings*.

> **Note**

Before the NIOS appliance sends registration updates to the RIPE database, it does not validate the data you submit. Therefore, if you enter invalid information that cannot be mapped to the RIPE database, your updates will fail. In addition, the NIOS appliance does not synchronize data from the RIPE database

Requirements and Permissions

To manage RIR allocated addresses, organizations, and network utilization that contain RIR assignments, you must first enable support for RIR registration updates, and then configure the RIR communication method. Note that once you have enabled support for RIR registration updates, settings and fields that are relevant to this feature are enabled in Grid Manager. You do not need a special license to use this feature.

Only superusers can create, modify, and delete RIR organizations. Limited-access users can manage RIR allocated address blocks if they have the required permissions to the objects.

To view and manage RIR related data, admins must have permissions to the applicable resources. For example, to view RIR networks, admins must have read-only permission to the networks; and to edit them, admins must have read/write permission to them. For more information about admin permissions, see *About Administrative Permissions*.

Configuring RIR Registration Updates

To manage RIR allocated addresses and send registration updates through NIOS, you first add RIR organizations and create RIR allocated networks in NIOS. You can then reassign network addresses within the RIR allocated address block to other organizations based on your requirements, and then configure NIOS to send registration updates directly to the RIPE database. Any data you manage through the Grid is handled by the Grid Master.
When the Grid Master is an HA pair, the active node handles the submission of data. If an HA failover occurs during a submission, the failing node immediately aborts the submission. The new active node resumes the next submission. For information about HA pairs, see *About HA Pairs*.
To manage and submit updates to the RIPE database, you must first enable the Grid to support RIR registration updates. You can then enter RIR information, such as RIR organizations and RIR attributes.
To configure the Grid to manage RIR allocated addresses and submit updates to RIPE, complete the following:

1. Enable support for RIR registration updates, as described in Enabling Support for RIR Registration Updates below .
2. Define the method to communicate updates to RIPE, as described in Configuring RIR Communication Settings below.
3. Add and configure RIR organizations and RIR organizational attributes, as described in Adding RIR Organizations, see *Managing RIR Data*.
4. Add allocated address blocks and assign specific network addresses to RIR organizations, as described in Adding and Assigning RIR Networks, see *Managing RIR Data*.
5. Review and submit registration updates to RIPE, as described in Previewing Registration Updates, see *Managing RIR Data*. You can also perform the following tasks:

- View a list of RIR organizations, as described in Viewing RIR Organizations.
- Modify RIR organizations and RIR organizational attributes, as described in Modifying RIR Organizations.
- Monitor network utilization for networks that contain RIR assignments. For information about IPAM Home, see *Managing IPv4 Networks* or for more information about Viewing Networks, see *Configuring IPv4 Networks*.

Enabling Support for RIR Registration Updates

Before you can manage RIR data through Grid Manager, you must first enable support for RIR registration updates. To enable support for RIR registration updates:

1. From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar.
2. In the *Grid Properties* editor, select the **General** tab -> **Advanced** tab, and complete the following:
    - **Enable Updates of RIR Registrations**: Select this to enable the support for submitting RIR registration updates to the RIPE database. When you enable this feature, you can configure the appliance to send registration updates to RIPE for network reassignments and reallocations.

Note: Ensure that you configure DNS resolvers for the Grid when you enable this feature. For information about how to configure DNS resolvers, see *Enabling DNS Resolution*.

3. Save the configuration.

Configuring RIR Communication Settings

You can configure the appliance to send RIR address updates to RIPE through the RIPE REST API or through an email using the maintainer email address specified in the RIR organization. Note that when you use the API method to delete a registered address block, you do not need to submit RIR attributes that match the data in the RIPE database. However, when you use the email method, you must enter RIR attribute values that match the data in the database. Otherwise, your submission will fail. To view examples of registration updates that NIOS sends, see Previewing Registration Updates in *Managing RIR Data*.
To configure the RIR communication settings:

1. From the **Administration** tab, select the **RIR** tab, and then select **RIR Settings** -> **RIPE** from the Toolbar.
2. In the *RIR Communication Settings - RIPE* editor, select one of the following to determine how the appliance sends updates to RIPE. The default is **API**.
    - **API**: The appliance sends RIR updates to RIPE through the RIPE API. The default destination is *https://rest.db.ripe.net* for accessing the production database and *https://rest-test.db.ripe.net* for accessing the test database. Click **Override** and enter a different URL to override the default value. When you select this as the communication method, the registration status will be updated automatically after the registration update is completed. Note that RIPE supports only secure connections using HTTPS.
    - **Email:** The appliance sends RIR updates to RIPE through the email address displayed in the field. The default is *auto-dbm@ripe.net.* Click **Override** and enter a different email address to override the default value. The appliance uses a special email template that includes values of certain RIR attributes. If any of the RIR attribute values do not match the database in the RIPE database, your submission will fail. When you select **Email** as the communication method, ensure that you enable email notifications at the Grid level. For information how to enable email notifications, see Setting SNMP and Email Notifications in *Configuring SNMP*. Note that when you select this as the communication method, the registration status will not be automatically updated. You can manually change the status. For information, see Modifying RIR Network Data, in *Managing RIR Data*.
    - **None:** The appliance does not send RIR updates to RIPE.
3. Save the configuration.

Managing RIR Data

An RIR organization provides information about an entity that has registered a network resource in the RIPE Database. This entity can be a company (such as an ISP), a nonprofit group, or an individual. You can add RIR organizations defined in the RIPE database and start managing their data through NIOS.
After you have enabled support for RIR updates and configure the desired communication method for the updates, you can do the following to manage RIR data:

- Add RIR organizations and their associated data, as described in Adding RIR Organizations below.
- Add the RIR allocated addresses to NIOS and assign specific address blocks to ISP organizations, as described in Adding and Assigning RIR Networks below.
- View a list of organization objects, as described in Viewing RIR Organizations below.
- Review the reassignment information before sending the updates to RIPE, as described in Previewing Registration Updates below.
- Modify RIR organizational data and attributes, as described in Modifying RIR Organizations below.
- Modify RIR network data and attributes, as described in Modifying RIR Network Data below.
- Delete RIR organizations, as described in Deleting RIR Organizations below.
- Delete delegated addresses from an organization, as described in Deleting RIR Networks below.

Adding RIR Organizations

Before you can submit any RIR updates to the RIPE database, you must first add the RIR organization and its corresponding data to NIOS. You can also create additional organizations for ISP customers.
To add an organization:

1. From the **Administration** tab, select the **RIR** tab, and then click **Add** -> **RIPE Organization**.
2. In the *Add RIPE Organization* wizard, complete the following:
    - **Internet Registry:** The default is **RIPE**. This is the RIR that allocates address blocks to your organization. You cannot change this.
    - **Organization Name**: Enter the name of the organization that holds the resources allocated by RIPE NCC. You can enter up to 256 characters. Enter the name in this format: A list of words separated by white space. A word can be made up of letters, digits, the character underscore "_", and the character hyphen "-". The first character of a word must be a letter or digit and the last character of a word must be a letter, digit or a period. For example, you can enter `SPRINT REGION2.`
    - **Organization ID:** Enter the handle or ID of the organization. You can enter up to 23 characters. Enter the ID in this format: Start with **ORG-** followed by two to four characters, then followed by up to five digits and a source specification. Note that the first digit cannot be "0". The source specification starts with "-" followed by the source name that contains up to nine characters in length. For example, you can enter `ORG-CA1-RIPE` or `ORG-CB2-TEST`.
    - Maintainer: Enter the name of the maintainer for this organization. This is required. You can enter up to 256 characters; however, note that the RIPE database has an 80 characters limit for this field. A maintainer is any registrant or person to whom the authority to update has been delegated by another registrant either directly or indirectly, and who holds an identifier that allows updates to be authenticated and authorized. Data entered here must match exactly how the maintainer appears in RIPE.
      Enter the maintainer name in this format: Use letters, digits, the character underscore "_", and the character hyphen "". The first character must be a letter, and the last character must be a letter or a digit. You cannot use the following words (they are reserved by RPSL): any, as-any, rs-any, peer, as, and, or, not, atomic, from, to, at, action, accept, announce, except, refine, networks, into, inbound, outbound. Also note the following: Names starting with certain prefixes are reserved for certain object types. For example, names starting with "as" are reserved for as set names. Names starting with "rs-" are reserved for route set names. Names starting with "rtrs-" are reserved for router set names. Names starting with "fltr-" are reserved for filter set names. Names starting with "prng-" are reserved for peering set names. Names starting with "irt-" are reserved for irt names.
    - **Password:** Enter the maintainer password. This is required. You can enter up to 256 characters.
    - **Retype Password:** Enter the same password.
    - **Maintainer Email**: Enter the originating or source email address of the maintainer. This is required.

    RIR Organizational Attributes: This table lists all predefined RIR attributes associated with the RIR organization. Click the **Value** field of an attribute in the table to enter a value. The **Required** field indicates whether a value for the corresponding attribute is required.
    You can add custom attributes by clicking the Add icon and select an attribute from the drop-down list. You can also delete an RIR attribute by selecting its checkbox and clicking the Delete icon.
    For information about the RIR Organizational Attributes table, attributes and how to enter their values, see *Managing RIR Attributes*.
    Note that you cannot leave an optional RIR attribute value empty. If you do not have a value for an RIR attribute, you must delete it from the table. You can enter up to 256 characters for all RIR attributes.
3. Save the configuration. Note that you cannot schedule the creation, modification, or deletion of an RIR organization.

Modifying RIR Organizations

To modify an RIR organization:

1. From the **Administration** tab, select the **RIR** tab -> *rir_organization* checkbox, and click the Edit icon.
2. In the *Organization* editor, modify the organization information, as described in Adding RIR Organizations. You can also reorder the list of RIR organizational attributes using the up and down arrows.
3. Save the configuration.

Deleting RIR Organizations

You can delete an RIR organization that does not have any networks assigned to it. When you delete an RIR organization, the appliance moves it to the Recycle Bin, if enabled. You can later restore the network if needed. For information about the Recycle Bin, see *Using the Recycle Bin*.
To remove an RIR organization:

1. From the **Administration** tab, select the **RIR** tab -> *rir_organization* checkbox, and then click the Delete icon.
2. In the *Delete Confirmation (RIR Organization)* dialog box, click **Yes**.

Adding and Assigning RIR Networks

Before you can assign network addresses within an RIR allocated address block to an organization, you must first add the allocated address block to NIOS. Infoblox supports IPv4 and IPv6 network containers and networks. You can also create network templates that are specific for RIR networks. For information about creating network templates, see *About IPv4 Network Templates* and *About IPv6 Network Templates*.
Note that when you add network containers or networks to NIOS, the appliance does not validate whether the corresponding networks actually exist in the RIPE database. Even though you can create the networks in NIOS, the submission of updates for the network may fail. For example, if you create a child network and the parent network is not registered in RIPE, the registration update will fail.
In addition, each network can only be associated with an RIR in one network view. If you have a network address block registered with RIPE in a specific network view, you must not register the same address block in a different network view.
When you enable the support for updates of RIR registrations, Grid Manager displays the appropriate data fields that you can use to add or modify RIR related networks. You can do the following to add IPv4 and IPv6 networks:

- Add RIR allocated IPv4 networks to NIOS, or assign addresses to specific organizations. For information see *Adding IPv4 Networks*.
- Add RIR allocated IPv6 networks to NIOS, or assign addresses to specific organizations. For information, see *Adding IPv6 Networks*.
- Add IPv4 network templates that are specific to RIR address allocation. For information, see *About IPv4 Network Templates*.
- Add IPv6 network templates that are specific to RIR address allocation. For information, see *About IPv6 Network Templates*.

You can also do the following to modify specific data about the RIR networks:

- Modify RIR allocated or assigned IPv4 networks. For information see *Modifying IPv4 Networks*.
- Modify RIR allocated or assigned IPv6 networks. For information see *Modifying IPv6 Networks*.
- Modify IPv4 network templates that are specific to RIR address allocation. For information, see *Modifying IPv4 Network Templates*.
- Modify IPv6 network templates that are specific to RIR address allocation. For information, see *Modifying IPv6 Network Templates*.

You can preview the information before the appliance submits updates to the RIPE database. To preview registration updates, click **Preview RIR Submissions** in the *Add IPv4 Network* or *Add IPv6 Network* wizards. For more information, see *Previewing Registration Updates*.

Note

You can also add RIR networks through **Task Dashboard**. For information, see *The Tasks Dashboard*.

After you create an RIR network container or network, you can perform the following:

- Split a network that has an organization ID. A child network that is created does not contain an organization ID by default. You must assign an organization ID to the child network after splitting it. For information about splitting an RIR network, see *Splitting IPv4 Networks into Subnets* and *Splitting IPv6 Networks into Subnets*.
- Resize an IPv4 RIR network that contains an organization ID and has been registered with RIPE. For more information, see *Resizing IPv4 Networks*.

Viewing RIR networks

You can view a list of IPv4 and IPv6 RIR networks in the **Data Management** tab -> **IPAM tab** or the **Data Management** tab -> **DHCP** tab -> **Networks** tab -> **Networks** section. For more information, see *IPAM Home* and *Viewing Networks*.

Modifying RIR Network Data

You can modify certain RIR network information in the **RIR Registration** tab of the *IPv4 and IPv6 Network* editors. To modify RIR network information, complete the following:

1. From the **Data Management** tab, select the **IPAM** tab -> *network* checkbox, and then click the Edit icon.
   or
   From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network* checkbox, and then click the Edit icon.
2. In the *IPv4* or *IPv6 Network Container* or *Network* editor, click the **RIR Registration** tab, and then complete the following to modify RIR related data for the IPv4 or IPv6 network container or network:
   - **Internet Registry**: Displays the RIR that allocates RIR address blocks. The default is **RIPE**. You cannot change this.
   - **Organization ID**: Displays the organization ID with which this network is associated. You cannot change this.
   - **Registration Status**: Displays the current registration status. This can be **Registered** or **Not Registered**. **Registered** indicates that the network has a corresponding entry in the RIPE database. Note that when you select **API** as the communication method, the registration status will be updated automatically after the registration update is completed. However, when you select **Email** as the communication method, the registration status will not be automatically updated. You can modify this by selecting the appropriate status from the drop-down list.
   - **Status of last update**: Displays the registration status, communication method, timestamp of the last registration update. The status can be Pending, Sent, Succeeded, or Failed. The displayed timestamp reflects the timestamp used on the Grid Master. Each time you send a registration update to create, modify, or delete a network container or network, the updated status and timestamp will be displayed here. If you have selected not to send the registration update, the previous status and timestamp are retained.
   - **Registration Action**: From the drop-down list, select what you want to do with the RIR network updates. If you are creating a top-level network block that has already been assigned to the organization, select **None**. If you are creating a child network within the allocated address block, you can select one of the following:
     - **None**: The appliance does not submit the updates.
     - **Create**: The appliance creates the network container or network for the specified organization.
     - **Modify**: Modifies data for this network container or network.
     - **Delete**: Deletes the RIR network from the organization. When you select this, you must enter a reason for deleting this entry in the **Delete Reason** field.
   - **Do not update registrations**: By default, the appliance sends updates to RIPE if you specify **Create**, **Modify**, or **Delete** as the registration action. Select this if you do not want the appliance to submit updates to the RIPE database.

   RIR Network Attributes: Modify the value of RIR network attributes by clicking the **Value** field of an attribute and entering a new value. You can add a new RIR network attribute by clicking the Add icon and selecting an attribute from the drop-down list. You can also select any optional attributes and click the Delete icon to delete them. For information about RIR network attributes, see *RIR Network Attributes*.
   You can enter up to 256 characters for all RIR network attributes, unless otherwise noted.
   Preview RIR Submissions: Click this to view the updates before the appliance submits them to the RIPE database. This button is enabled only when the registration action is **Create**, **Modify**, or **Delete**, and the **Do not**

update registrations checkbox is not selected. For more information, see *Previewing Registration Updates.* To schedule this task, click the Schedule icon at the top of the wizard. In the Schedule Change panel, click **Later**, and then specify a date, time, and time zone.

3. Save the configuration.

Deleting RIR Networks

When you delete an RIR network or network container, the appliance moves it to the Recycle Bin, if enabled. You must enter the reason for deleting the RIR network or network container and indicate whether you want to send the deletion update to RIPE. You can delete multiple networks at the same time.
To delete an RIR network or network container:

1. From the **Data Management** tab, select the **IPAM** tab -> *network* checkbox, and then click the Delete icon. You can choose to delete the network immediately or schedule its deletion.
2. In the *Delete Confirmation (IPv4 or IPv6 Network)* or *Schedule Deletion* dialog box, complete the following:
   - **Justification**: Enter the reason for deleting this network.
   - **Do not update registrations**: Select this checkbox if you do not want the appliance to submit updates to RIPE.
3. Optionally, you can click **Preview RIR Submissions** to view the RIR network information before deleting the network. Grid Manager displays the preview data in a separate browser window. For information, see *Previewing Registration Updates*
4. Click **Yes**. If you are scheduling a deletion, enter the data and time for execution, and then click **Schedule Deletion**.

Managing RIR Attributes

Before you can successfully submit RIR data updates, you must ensure that all RIR required attributes contain valid values that can be mapped to data in the RIPE database. The appliance does not validate data with the RIPE database before you submit your updates. The appliance also does not synchronize data from the database.

> ⚠ Note
>
> RIPE does not support UTF-8 data in the **Description** and **Remarks** fields. After an upgrade, the NIOS appliance keeps the UTF-8 data in these fields. However, if you want to modify these fields after the upgrade, you must remove the UTF-8 data before you can save the changes.

When you enter a value for the following RIR attributes that cannot be mapped to a valid reference in the RIPE database, updates to the RIR database will fail. However, these values will still be displayed in the IPv4 or IPv6 network or network container panels of Grid Manager.

- RIPE Routes Maintainer
- RIPE Lower Level Maintainer
- RIPE Reverse Domain Maintainer
- RIPE Admin Contact
- RIPE Technical Contact
- RIPE Computer Security Incident Response Team

You can add multiple values for certain RIR attributes. When you add multiple values of the same attribute, the appliance groups the values in the order they are listed in the attribute table. You can also reorder the RIR attributes using the up and down arrows in the attribute tables.

RIR Organizational Attributes

The following table lists RIR organizational attributes, the format you must use to enter values, and whether they are required or optional.

Organizational Attribute	Corresponding RIPE Attribute	Description and Format	Required/ Optional
RIPE Description	descr	Enter a short description about the organization.	Optional
RIPE Country	country	From the drop-down menu, select the country name, followed by the two-letter ISO 3166 country code, of the country or area within the RIPE NCC service region or through Local Internet Registries.	Required
RIPE Admin Contact	admin-c	Enter the name of the on-site admin contact for the organization. Enter the name in this format: Start with two to four optional characters, followed by up to six optional digits, and then follow by a source specification. The first digit cannot be "0". The source specification starts with "-" followed by the source name that contains up to nine characters in length.	Required
RIPE Technical Contact	tech-c	Enter the name of the technical contact for the organization. Enter the name in this format: Start with two to four optional characters, followed by up to six optional digits, and then follow by a source specification. The first digit cannot be "0". The source specification starts with "-" followed by the source name that contains up to nine characters in length.	Required
RIPE Remarks	remarks	Enter remarks about the organization.	Optional
RIPE Notify	notify	Enter the email address to which notifications of changes to the organization will be sent.	Optional
RIPE Registry Source	source	From the drop-down list, select the registry at which the organization is registered. The default is RIPE. Select **RIPE** for the RIPE database, which is the authoritative database. Select **TEST** for the RIPE TEST database that operates in the same way as the RIPE database but contains only test data. Note that test data is cleaned out at the start of each month and a predetermined set of basic objects is re-inserted. You can use the RIPE TEST database to learn how to update the database and try out special scenarios. The RIPE TEST database has fewer restrictions which allows you to create encompassing or parent objects you may need for testing.	Optional
RIPE Organization Type	org-type	From the drop-down list, select one of the following organization type: • **IANA** for Internet Assigned Numbers Authority • **RIR** for Regional Internet Registry • **NIR** for National Internet Registry • **LIR** for Local Internet Registry • **WHITEPAGES** for special industry people • **DIRECT_ASSIGNMENT** for direct contract with RIPE NCC • **OTHER** for all other organizations **Note:** Only the RIPE database admin can set the organization type, and there are no NIRs in the RIPE NCC service region.	Optional
RIPE Address	address	Enter the organization address.	Optional

Organizational Attribute	Corresponding RIPE Attribute	Description and Format	Required/ Optional
RIPE Phone Number	phone	Enter the organization phone number in numeric format starting with the + character, followed by the country code, area code, and the phone number. For example, you can enter **+18089991000**. You can also use one of the following formats: • '+' <integer-list> • '+' <integer-list> "(" <integer-list> ")" <integer-list> • '+' <integer-list> ext. <integer list> • '+' <integer-list> "(" integer list ")" <integer-list> ext. <integer-list>	Optional
RIPE Fax Number	fax-no	Enter the organization fax number in numeric format starting with the + character, followed by the country code, area code, and the fax number. For example, you can enter **+16052529000**. You can also use one of the following formats: • '+' <integer-list> • '+' <integer-list> "(" <integer-list> ")" <integer-list> • '+' <integer-list> ext. <integer list> • '+' <integer-list> "(" integer list ")" <integer-list> ext. <integer-list>	Optional
RIPE Email	email	Enter the organization email address.	Required
RIPE Abuse Mailbox	abuse-mailbox	Enter the email address to which abuse complaints are sent.	Optional
RIPE Reference Notify	ref-nfy	Enter the email address to which notifications are sent when a reference to the organization object is added or removed.	Optional

RIR Network Attributes

When you create or edit an RIR associated network, ensure that you enter valid values for the RIR network attributes. The following table lists RIR network attributes, the format you must use to enter values, and whether they are required or optional:

Network Attributes	Corresponding RIPE Attribute	Descriptions and Formats	Required/ Optional
RIPE Admin Contact	admin-c	The name of the on-site admin contact for the network address. This attribute is populated from the organizational attribute. You can modify the value in this format: Start with two to four optional characters, followed by up to six optional digits, and then follow by a source specification. The first digit cannot be "0". The source specification starts with "-" followed by the source name that contains up to nine characters in length.	Required
RIPE Computer Security Incident Response Team	mnt-irt	The name of the Computer Security Incident Response Team (CSIRT) that handles security incidents for the network address. You can enter the value in this format: Use letters, digits, the character underscore "_", and the character hyphen "-". The value must start with "irt-", and the last character of a name must be a letter or a digit. You must enter a minimum of five characters.	Optional
RIPE Country	country	The two-letter ISO 3166 country code of the country within the RIPE NCC service region or through Local Internet Registries. This attribute is populated from the organizational attribute. You can select a different country code from the drop-down list.	Required

Network Attributes	Corresponding RIPE Attribute	Descriptions and Formats	Required/ Optional
RIPE Description	descr	Enter a short description about the network.	Required
RIPE IPv4 Status	status	The status of the IPv4 network address. From the drop-down list, select one of the following status: ALLOCATED PA ALLOCATED PI ALLOCATED UNSPECIFIED LIR-PARTITIONED PA LIR-PARTITIONED PI SUB-ALLOCATED PA ASSIGNED PA ASSIGNED PI ASSIGNED ANYCAST EARLY-REGISTRATION NOT-SET	Required
RIPE IPv6 Status	status	The status of the IPv6 network address. From the drop-down list, select one of the following: ALLOCATED-BY-RIR ALLOCATED-BY-LIR ASSIGNED ASSIGNED ANYCAST ASSIGNED PI	Required
RIPE Lower Level Maintainer	mnt-lower	Enter the name of the registered maintainer for hierarchical authorization purposes. This can protect the creation of networks directly (one level) below in the hierarchy of a network container or another network. The authentication method of the maintainer will be used upon creation of any network directly below the network that contains the "mnt-lower:" attribute. Enter the maintainer name in this format: Use letters, digits, the character underscore "_", and the character hyphen "-". The first character must be a letter, and the last character must be a letter or a digit. You cannot use the following words (they are reserved by RPSL): any, as-any, rs-any, peer, as, and, or, not, atomic, from, to, at, action, accept, announce, except, refine, networks, into, inbound, outbound. Also note the following: Names starting with certain prefixes are reserved for certain object types. Names starting with "as-" are reserved for as set names. Names starting with "rs-" are reserved for route set names. Names starting with "rtrs-" are reserved for router set names. Names starting with "fltr-" are reserved for filter set names. Names starting with "prng-" are reserved for peering set names. Names starting with "irt-" are reserved for irt names.	Optional
RIPE Network Name	netname	The name of the IP address range. You can enter up to 80 characters. Enter the network name in this format: Use letters, digits, the character underscore "_", and the character hyphen "-". The first character must be a letter, and the last character must be a letter or a digit.	Required
RIPE Notify	notify	Enter the email address to which notifications of changes to the object must be sent.	Optional
RIPE Registry Source	source	From the drop-down list, select the registry at which the organization is registered. The default is **RIPE**. Select **RIPE** for the **RIPE** database, which is the authoritative database. Select **TEST** for the RIPE TEST database that operates in the same way as the RIPE database but contains only test data. Note that test data is cleaned out at the start of each month and a predetermined set of basic objects is re-inserted. You can use the RIPE TEST database to learn how to update the database and try out special scenarios. The RIPE TEST database has fewer restrictions which allows you to create encompassing or parent objects you may need for testing.	Required
RIPE Remarks	remarks	Enter remarks about the network.	Optional

Network Attributes	Corresponding RIPE Attribute	Descriptions and Formats	Required/ Optional
RIPE Reverse Domain Maintainer	mnt-domains	Enter the name of a registered maintainer used for reverse domain authorization. This can protect domain objects. The authentication method of this maintainer will be used for any encompassing reverse domain object. Enter the maintainer name in this format: You can use letters, digits, the character underscore "_", and the character hyphen "-". The first character must be a letter, and the last character must be a letter or a digit. You cannot use the following words (they are reserved by RPSL): any, as-any, rs-any, peer, as, and, or, not, atomic, from, to, at, action, accept, announce, except, refine, networks, into, inbound, outbound. Also note the following: Names starting with certain prefixes are reserved for certain object types. Names starting with "as-" are reserved for as set names. Names starting with "rs-" are reserved for route set names. Names starting with "rtrs-" are reserved for router set names. Names starting with "fltr-" are reserved for filter set names. Names starting with "prng-" are reserved for peering set names. Names starting with "irt-" are reserved for irt names.	Optional
RIPE Routes Maintainer	mnt-routes	This attribute references a maintainer that is used in determining authorization for the creation of route objects. Enter the name in this format: Start with the reference to the maintainer, followed by an optional list of prefix ranges inside of curly brackets or the keyword "ANY". The default, when no additional set items are specified, is "ANY". For more information, refer to RFC-2622. Example: <mnt-name> [{ list of <address-prefix-range> } | ANY].	Optional
RIPE Technical Contact	tech-c	The name of the technical contact for the network. Enter the name in this format: Start with two to four optional characters, followed by up to six optional digits, and then follow by a source specification. The first digit cannot be "0". The source specification starts with "-" followed by the source name that contains up to nine characters in length.	Required

Monitoring RIR Data

You can view RIR organizations and networks you added to NIOS through Grid Manager. The appliances sends SNMP traps and email notifications about registration updates. It also logs RIR events in the Infoblox syslog. Note that sometimes due to network timeout from RIPE, your registration updates may fail.
You can do the following to monitor RIR data:

- View RIR update events in the syslog, as described in *Viewing the Syslog*.
- View RIR organizations, as described in Viewing RIR Organizations below.
- View RIR IPv4 and IPv6 network containers and networks, as described in *IPAM Home* and *Viewing Networks*.
- Preview RIR updates before submitting them to RIPE, as described in Previewing Registration Updates below.

Viewing RIR Organizations

You can view the list of RIR organizations that have received address allocation and the ones you have added associated networks.
To view RIR organizations:

1. From the **Administration** tab, select the **RIR** tab.
2. Grid Manager displays the following information for each RIR organization:
    - **Organization ID**: The RIR organization ID.
    - **RIR**: The RIR that allocates the address block to the organization.
    - **Maintainer**: The name of the maintainer for the organization.

You can also select **Organization Name** and RIR organizational attributes for display.
You can do the following in this tab:

- Modify some of the data in the table. Double click a row, and either modify the data in the field or select an item from a drop-down list. Click Save to save the changes. Note that some fields are read only.
- Sort the data in ascending or descending order by column.
- Select an organization and click the Edit icon to modify data, or click the Delete icon to delete it.

- Click the Permissions icon to configure permissions for the admin account.
- Use filters and the Go to function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the Go to field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information about quick filters, see *About the Grid Manager Interface*.
- Print and export the data in this tab.

Previewing Registration Updates

Before the appliance submits RIR updates to RIPE, you can preview the data in Grid Manager. The appliance uses the email template when displaying preview data in a separate browser window.
Preview data includes the subject line for the email, followed by the inetnum or inet6num template for the network and other associated data, such as network name, organization name, and others. When there are multiple operations involved, such as deleting multiple networks, the preview data includes a separate subject line for each operation.
You can preview registration updates when you create a new RIR network. In the Add Networks wizard, click **Preview RIR Submissions** in the wizard. For information about how to create or assign RIR networks, see *Adding and Assigning RIR Networks*.

Following is a sample preview for a network creation request:

```
Subject: CREATE inetnum 100.200.0.0 - 100.200.255.255 KEYWORDS: NEW inetnum:

```

Requirements and Permissions

To manage RIR allocated addresses, organizations, and network utilization that contain RIR assignments, you must first enable support for RIR registration updates, and then configure the RIR communication method. Note that once you have enabled support for RIR registration updates, settings and fields that are relevant to this feature are enabled in Grid Manager. You do not need a special license to use this feature.
Only superusers can create, modify, and delete RIR organizations. Limited-access users can manage RIR allocated address blocks if they have the required permissions to the objects.
To view and manage RIR related data, admins must have permissions to the applicable resources. For example, to view RIR networks, admins must have read-only permission to the networks; and to edit them, admins must have read/write permission to them. For more information about admin permissions, see *About Administrative Permissions*.

IP Address Management

IPAM (IP Address Management) is the allocation, administration, reporting, and tracking of IP addresses, network devices, and their associated data. This section provides information about IPAM and how to use the Infoblox tools to perform IPAM tasks and manage your entire IP network. It includes the following topics:

- *Managing IP Addresses*
- *IP Discovery and vDiscovery*
- *Infoblox Network Insight*

Managing IP Addresses

This section describes how to manage your networks and IP addresses through the Infoblox IPAM (IP Address Management) implementation. It contains the following topics:

- *About IP Address Management*
- *About Host Records*
- *Managing IPv4 Networks*
- *Viewing and Managing IPv4 Addresses*
- *Managing IPv6 Networks*

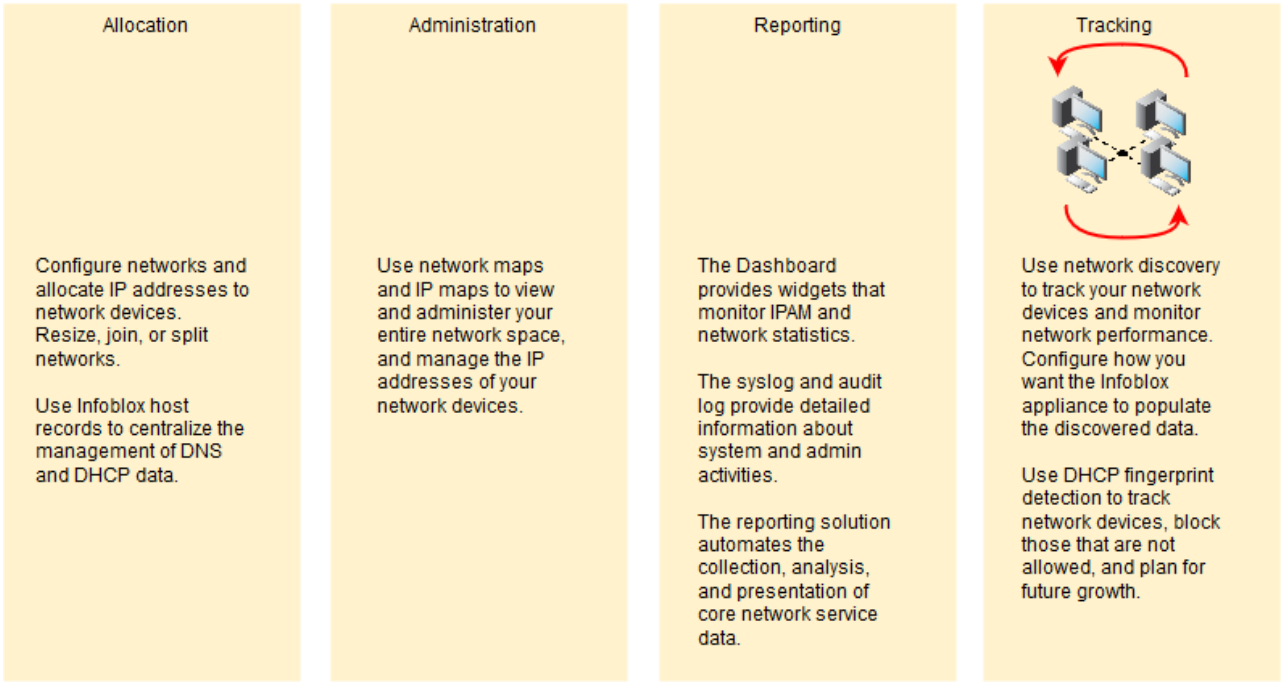
- *Viewing IPv6 Data*
- *Managing IPv4 and IPv6 Addresses*
- *Configuring Thresholds for IPAM Utilization*
- *Viewing Identity Mapping Information*

About IP Address Management

IPAM is the allocation, administration, reporting, and tracking of public and private IP spaces, network devices, and their associated data. It comprises the deployment of DNS and DHCP services and the monitoring of network devices and performance to ensure data integrity and security of your networks.

The Infoblox IPAM implementation is a feature-rich and easy-to-use solution that encompasses support for IPv4, IPv6, network discovery, and automated monitoring. Infoblox IPAM provides tools that integrate the allocation, administration, reporting, and tracking of your entire network space. The below figure highlights the Infoblox IPAM implementation.

Infoblox IPAM Features



You can perform the following IPAM tasks to effectively manage and control your network:

- Create host records. Host records integrate the DNS records and DHCP data of a network device. You can use a host record to manage a network device from one central point. For more information, see *About Host Records.*
- Create IPv4 and IPv6 networks. For information, see *About Network Containers.*
- Discover devices in IPv4 and IPv6 networks and other Objects created in IPAM. For more information about Adding IPv4 and IPv6 Network Containers and Networks and Adding Host Records, see *About Host Records*. View your IPv4 network and address utilization in a graphical mode. For information, see *IPv4 Network Map* and *IP Map*.
- When necessary, resize, join, or split networks. For information about Resizing IPv4 Networks, Splitting IPv4 Networks into Subnets, Joining IPv4 Networks see*, Managing IPv4 Networks.* For information about Splitting IPv6 Networks into Subnets, and Joining IPv6 Networks, see *Managing IPv6 Networks*.
- Manage IPv4 and IPv6 address data. For information, see *Viewing and Managing IPv4 Addresses, Viewing IPv6 Data* , and *Managing IPv4 and IPv6 Addresses*.

- Add and manage DNS resource records associated with IP addresses. For information, see *Configuring DNS Resource Records*.
- Monitor your core service network data using the Dashboard, audit log, syslog, and reports. For information, see *Infoblox Reporting and Analytics*.
- Discover and track network devices. For information, see *IP Discovery and vDiscovery* and *DHCP Fingerprint Detection.*

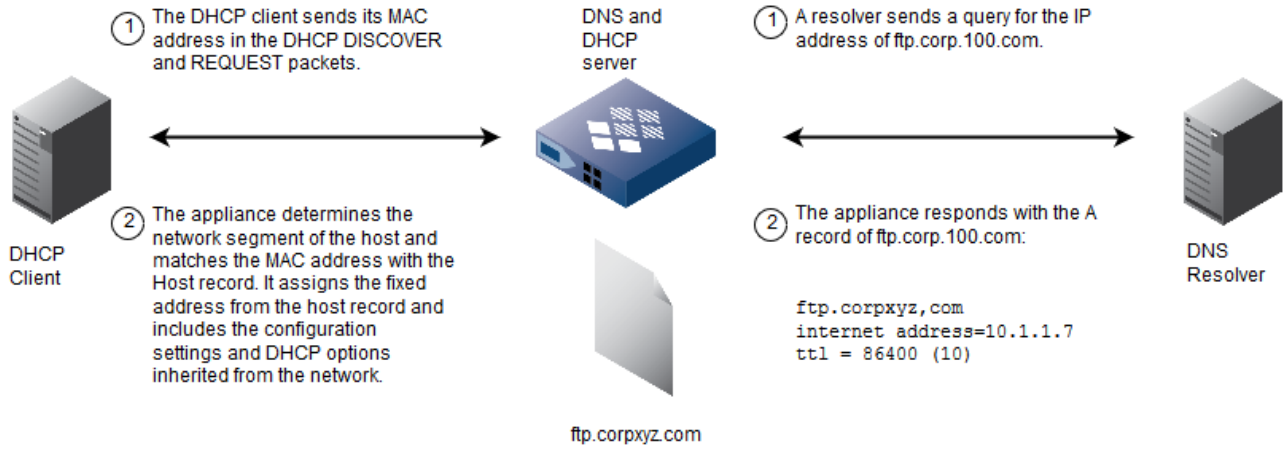
About Host Records

Host records provide a unique approach to the management of DNS, DHCP, and IPAM data. By using host records, you can manage multiple DNS records and DHCP and IPAM data collectively, as one object on the appliance.
When you create a host record, you are specifying the name-to-address and address-to-name mappings for the IP address that you assign to the host. The Infoblox DNS server then uses this data to respond to DNS queries for the host. When the server receives a name-to-address query, it responds with an A record for an IPv4 host or an AAAA record for an IPv6 host that contains the data from the host record. Likewise, when it receives an address-to-name query for the host, the appliance responds with a PTR record that contains data from the host record.

> ⚠ Note
>
> The appliance cannot respond if there is no PTR record and a PTR record is not created if there is no corresponding reverse-mapping zone.

Additionally, if you specify an alias in the host record, the appliance uses this data as a CNAME record to respond to queries with the alias. It maps the alias to the canonical name and sends back a response with the canonical name and IP address of the host. Thus, a single host record is equivalent to creating A, PTR, and CNAME resource records for an IPv4 address and AAAA and PTR records for an IPv6 address. The appliance supports IDNs for a host record. You can specify alias and domain names in the native character set. For information about IDN support, see .
Hosts also support prefix delegation for IPv6. For example, you can specify an IPv6 prefix in the host record of a router. The router then advertises this prefix on one of its interfaces, so hosts that connect to the interface can generate their IP addresses, using the stateless autoconfiguration mechanism defined in *RFC 2462, IPv6 Stateless Autoconfiguration*.
In addition, if the Infoblox DHCP server manages the IP address assigned to the host, the server uses it as a fixed address record as well. The DHCP server assigns the IP address to the host when it receives a DHCP request with the matching MAC address or DUID. Its response includes configuration information, and any DHCP options defined for the host or inherited from the network to which the fixed address belongs. You can also assign multiple IPv4 and IPv6 addresses to a host, as described in Assigning Multiple IP Addresses to a Host below.
You can copy an existing host record and turn it into a new one. When you copy a host record, other than the new host name and IP address, all DHCP and IPAM configuration including the MAC address and extensible attributes apply to the new record. You can also modify information, except for the host name and IP address, of an existing host record. For information about how to copy or modify a host record, see Copying and Modifying Host Records below. Note that you can also modify an IPv4 host record and turn it into a IPv4 reservation. For information, see *Configuring IPv4 Reservations*.
You can execute immediate discovery on a host record. This simple setting enables you to determine the precise type of device that is associated with the host, along with its IP addresses, its name and other information.
You can define extensible attributes for a host record to further describe the device. You can include information such as its location and owner for IP address management purposes. For information about extensible attributes, see *About Extensible Attributes*.
The below figure illustrates how the appliance uses the host record for both DHCP and DNS.

Using the Host Record for DHCP and DNS

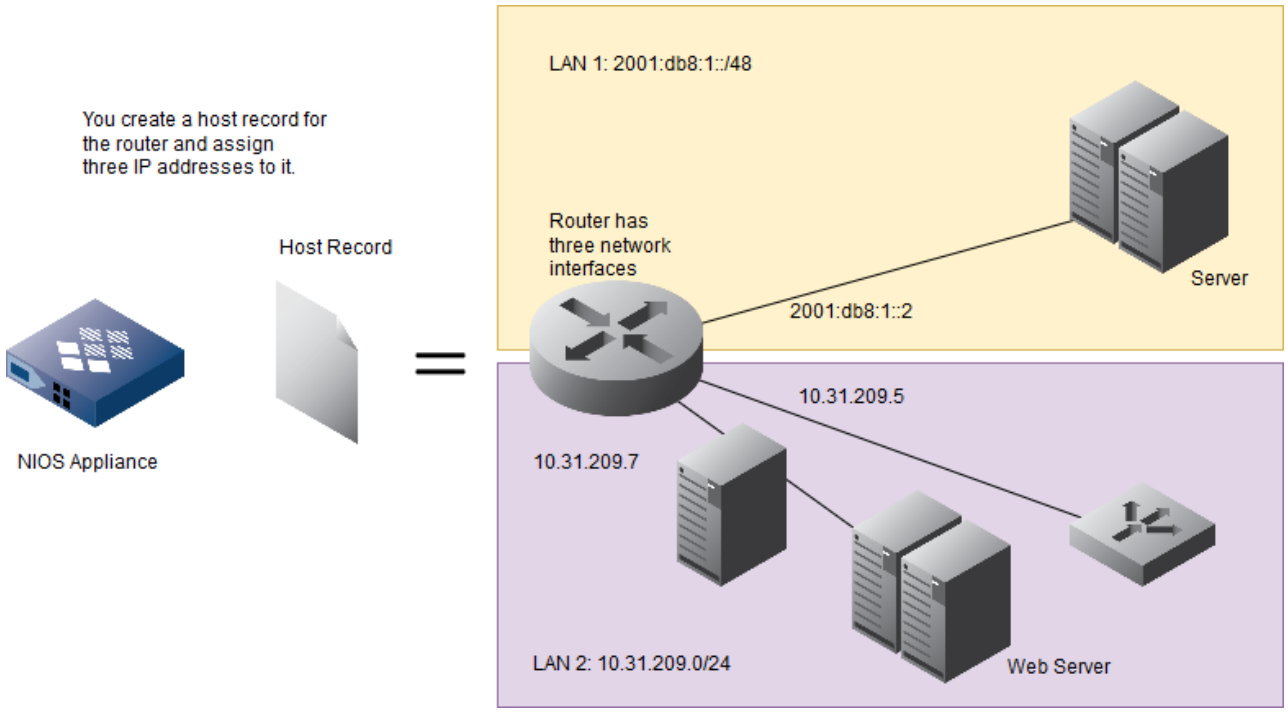


Note that If the zone of the host record is associated with networks, the IP addresses must belong to the associated networks. For example, if the host record is in the *corpxyz.com* zone, which is associated with 10.1.0.0/16 network, then the IP addresses of the host record must belong to the 10.1.0.0/16 network. For information about associating zones and networks, see *Associating Networks with Zones*.

Assigning Multiple IP Addresses to a Host

You can assign multiple IPv4 and IPv6 addresses to a host depending on the function of the device. For example, you can create a host record for a router that supports three network interfaces in two different networks, and assign IP addresses to each interface, as illustrated in the figure Assigning Multiple IP Addresses to one Host Record below. When the DNS server responds to DNS queries for the host, it includes an A or AAAA record for each IP address.
In addition, if the IP addresses belong to different networks, they can have different DHCP configurations and options. As shown in the figure Assigning Multiple IP Addresses to one Host Record below, the configuration information and DHCP options of the interface with the IPv6 address 2001:db8:1::2 may be different from the other two interfaces, 10.31.209.5 and 10.31.209.7, because it is in a different network.

Assigning Multiple IP Addresses to one Host Record



Adding Host Records

You can add host records from the Toolbar of the **IPAM**, **DHCP** and **DNS** tabs of the **Data Management** tab and from the Tasks Dashboard. For information about the Tasks Dashboard, see *Tasks Dashboard*.
When you create a host record, you must specify its zone and at least one IP address. If the zone of the host record is associated with one or more networks, the IP addresses must belong to one of the associated networks. If a zone of a host record contains IDNs, the appliance displays the zone name in the native character set.
For Cloud Network Automation, you can create host records within a delegated network view only when you enable DNS for the host record.
To add a host from the **Data Management** tab:

1. From the **IPAM**, **DHCP** or **DNS** tab of the **Data Management** tab, expand the Toolbar.
2. Click **Add** and select the option to add a host from the drop-down menu.
3. In the first page of the *Add Host* wizard, do the following:
    - **Name**: If Grid Manager displays a zone name, enter the host name here. The displayed zone name can either be the last selected zone or the zone from which you are adding the host. If no zone name appears or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click a zone name in the dialog box, and then enter a unique name for the host. The name you enter is prefixed to the DNS zone name that is displayed, and the complete name becomes the FQDN (fully qualified domain name) of the host. For example, if the zone name displayed is corpxyz.com and you enter admin, then the FQDN is admin.corpxyz.com.
    - **Enable in DNS**: This is selected by default. It enables DNS service for the host. If you clear this checkbox, DNS does not serve this host and you cannot assign it to a zone.
    - **Protected**: This is selected by default. To mark the record as protected in order to restrict DDNS updates to this record, select the Protected checkbox. This applies to both static and dynamic records.
      Note that if you select to protect the record, ensure that you also select the Prevent dynamic updates to RRsets containing protected records checkbox in the advanced updates properties of the Grid, view, zone, or Standalone appliance.

   Alternatively, you can protect records by selecting them, individually or in bulk, in the Resource Records Viewer and clicking Protect Records -> Enable Protection in the Toolbar.
    - **DNS View**: Displays the DNS view for the host record. This appears only when you enable the host record in DNS.
    - **Host Name Policy**: Displays the host name policy of the selected zone. This appears only when you enable the host record in DNS.
    - **RRset Order**: Select one of the following RRset orders that the appliance uses to return A and AAAA records of the host. This checkbox appears only when you have enabled the configuration of RRset order for the Grid and there are multiple IP addresses in this host record. For information about how to enable this feature, see *Enabling the Configuration of RRset Orders*.
        - **Cyclic**: The records are returned in a round robin pattern. This is the default.
        - **Fixed**: The records are returned in the order you specify in this host record. When you select this checkbox, the appliance displays up and down arrows next to the IPv4 and IPv6 address tables. You can use these arrows to reorder the address list. The appliance returns the A and AAAA records of this host based on the order you define in the address tables.
        - **Random**: The records are returned in a random order.
          Note that when you specify **Fixed** as the RRset order, the appliance places the resource records as follows:
        - A and AAAA records of the host in the fixed order you specify in the address tables. Note that the order of the returned A and AAAA records are independent of each other.
        - Other A and AAAA records in an undefined order.
        - Other record types in the default cyclic order.
          For more information about RRset order, see *Enabling the Configuration of RRset Orders*.
    - In the **IPv4 Addresses** and **IPv6 Addresses** sections, specify the IP addresses of the host record. Click the Add icon do one of the following:
        - Select **Next Available IP Address** to retrieve the next available IP address in a network. Infoblox recommends this option to ensure that you assign an IP address from the appropriate network.
          If the host record is in a zone that has one associated network, Grid Manager retrieves the next available IP address in that network.
          If the host record is in zone that has multiple associated networks, the *Network Selector* dialog

box lists the associated networks. If the zone has no network associations, the *Network Selector* dialog box lists the available networks. When you select a network, Grid Manager retrieves the next available IP address in that network.
If you want to enter a link-local IPv6 address, you must enter an IPv4 address and the host MAC address first, and then click the Add (**+**) icon again to enter the link-local IPv6 address. When you select the link-local IPv6 address, the MAC address is automatically filled in. For information, see *Understanding DNS for IPv6*.
Optionally, you can delete an IP address from the host by selecting an IP address in the table and clicking the Delete icon.
or

- Select **Add Address** to enter an IPv4 or IPv6 address. You can also enter an IPv6 prefix. Note that when you use this option, you could specify an IP address from a network that has not yet been defined. To avoid this, use the **Next Available IP Address** option instead.
- **MAC Address**: For an IPv4 address, enter the MAC address of the network device associated with this host IP address. Note that you must enter a MAC address if DHCP is enabled for the host IP address.
  or
- **DUID:** For an IPv6 address, enter the DHCP Unique Identifier (DUID) of the network device associated with this host IP address. Note that you must enter a DUID if DHCP is enabled for an IPv6 host address.
- **DHCP**: Select this to enable the DHCP services to manage the host IP address. If you do not select this option, the host IP address is not managed by the DHCP server.
- **Comment**: Optionally, enter additional information about the host record.
- **Disable:** Select this option to temporarily disable the host record. For example, you might want to disable a host when you need to update the network device.
  The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*. This section displays the following information:
- **Cloud Usage**: This field indicates whether this object is associated with any specific cloud extensible attributes or within a scope of delegation. It can be one of the following:
  - **Cloud from adapter**: Indicates that this object has been created by a cloud adapter and it may or may not be within a scope of delegation at the moment.
  - **Cloud from delegation**: Indicates that this object is within the scope of delegation or the object itself defines a scope of authority delegation, and it is not created by a cloud adapter.
  - **Used by cloud**: Indicates that this network or network container is associated with the extensible attribute **Is External** or **Is Shared** and the value is set to True, which implies the network is a private or shared network managed by the CMP, and it is not **Cloud from adapter** or **Cloud from delegation**.
  - **Non-cloud**: The object is a regular NIOS object and is not within the scope of any authority delegation nor is it associated with any of these extensible attributes: **Cloud API Owned, Is External** or **Is Shared**. NIOS admin users can modify this object based on their permissions.
- **Owned By**: A cloud object can be owned by the Grid Master or the cloud adapter. When the object is created by the Grid Master, this shows **Grid**. If the object is created by the cloud adapter, this shows **Adapter**.
  Delegate authority from the Grid Master
- **Delegate To**: This field indicates whether the authority for the object you want to create has already been delegated. If so, it displays the name of the delegation.

4. (*Applies only to Network Insight*) In the current Wizard step, you can optionally define the following identification values and settings for the new object's port reservation:
   - Choose the Device Type: Router, Switch-Router, Switch, MSFT (Microsoft) Server, **NetMRI**, **NIOS**, **VNIOS**, or ESX (VMware) Server.
     The values on this page are not required for defining the actual port reservation in a later wizard step.
   - Choose the Device Vendor: Cisco, Juniper, Aruba, Dell, **Infoblox**, or HP.
   - You can also enter a Location and a Description. These values are advisory and not required for configuration.
     After you define this group of settings, you will still need to define a device port reservation.

5. (*Applies only with Network Insight*) Click **Next** to initiate or disable discovery of the new host.
    - Choose either **Exclude from Network Discovery** or **Enable Immediate Discovery**. If you choose to Exclude, discovery will not execute on the host. If you choose **Enable Immediate Discovery**, discovery will execute on the host after you save your settings. You may also choose to leave both options disabled.
    - By default, the new host inherits its SNMP credentials from those defined at the grid level. Should you wish to override them for a local set of credentials, check the **Override Credentials** checkbox and select the **SNMPv1/SNMPv2** or **SNMPv3** option and enter the locally used credentials. For more information, see the sections *Configuring SNMP1/v2 Credentials for Polling* and *Configuring SNMPv3 Properties* for a complete description of SNMP credentials for discovery. (You can also test SNMP credentials to ensure they work before use.)
    - For the new object, you can check the **Override CLI Credentials** checkbox to override the inherited set of CLI credentials taken from the Grid level. This set of credentials may be used for the device that is directly associated with the new object (in this case, a Host) in its port reservation.
    - You can also click **Test CLI Credentials** to enter and test a set of CLI login credentials against a device based on its IP address.
      Port control operations require CLI credentials for the involved devices. (If you are not using port control for the new object, usage of CLI credentials is optional.) Because some IPAM and DHCP objects will use port control features as part of object creation, CLI credentials are automatically leveraged as part of discovery. Ensure you have the correct sets of CLI credentials for devices in your network. For more information, the section *Configuring CLI Discovery Properties*.
    - SSH is the default for CLI operations. Check the **Allow Telnet** checkbox if you know the device involved in the object assignment may support Telnet but may not support SSH, or if you want Telnet as an option.
6. (*Applies only with Network Insight*) Click **Next** to define switch port connectivity for the device that will be associated with the new host record. *This step is optional and not required for creating the new host record*. This feature set is also termed port control in Grid Manager. The device to which the new host record will be associated should already be discovered and managed from Grid Manager.
    - Begin by checking the Reserve Port checkbox. Note that reserving a switch port does not guarantee its availability.
      Optionally, you can skip connecting port configuration by clicking Next.
      Click the **Clear** button to remove the selected device from the configuration.
    - Click the Select Device button to choose the device for which the port reservation will be associated. You should know the identity of the device to whose interface the new object will be associated before taking this step. For more information, see the section *Using the Device Selector*.
    - After choosing the device, choose the Interface with which the port reservation will be bound. The drop-down list shows only interfaces that are most recently found to be available by Grid Manager during the last discovery cycle. This list will not include any ports that are Administratively Up and Operationally Up or that are otherwise already assigned to other networks or objects.
    - The Wizard page also shows a list of any VLANs that are currently configured in the chosen device (**The following VLANs are configured**). This Wizard page allows only the assignment of an existing VLAN in the chosen device to the new port reservation.
    - Check the Configure Port checkbox to define specific port control settings for the port reservation.
    - Choose the Data VLAN and/or the Voice VLAN settings you may need for the port assignment. Depending on the selected device, you may or may not be able to apply VLAN settings.
    - Set the Admin Status to Up if you need to activate the port after assignment in the current task.
      All port control operations require CLI credentials to be entered into Grid Manager. Because some IPAM and DHCP objects will use port control features as part of object creation, CLI credentials are automatically leveraged as part of discovery and configuration of port configurations such as Admin Up/Down status.
      Ensure you have the correct sets of CLI credentials for devices in your network.
    - Enter a Description for the port assignment. Infoblox recommends doing so to help other technicians to recognize the port assignment task.
7. Click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.
8. As the final step in the Add Host wizard, you define when Grid Manager creates the new object by scheduling it. As a separate task, you also schedule when the associated Port Configuration task executes.
    - To create the new Host and its associated port reservation immediately, select Now. The port control event is automatically synchronized to take place at the same time as the activation of the new host.
    - You can choose to have Grid Manager execute the port reservation at the same time as the host object creation. To do so, select **At same time as Host**.

- You can have Grid Manager execute the port reservation at a later time by selecting Later. Choose a **Selected time** by entering or selecting a Start Date (click the calendar icon to choose a calendar date) and a Start Time, and choose a Time Zone.

9. Choose one of the following from the **Save & ...** drop-down button menu:
   - Click **Save & Close** to add the Host object and close the wizard (this is the default).
   - Click **Save & Edit** to add the Host object and launch the editor.
   - Click **Save & New** to add the Host object and launch the wizard again to add another Host object.

Copying and Modifying Host Records

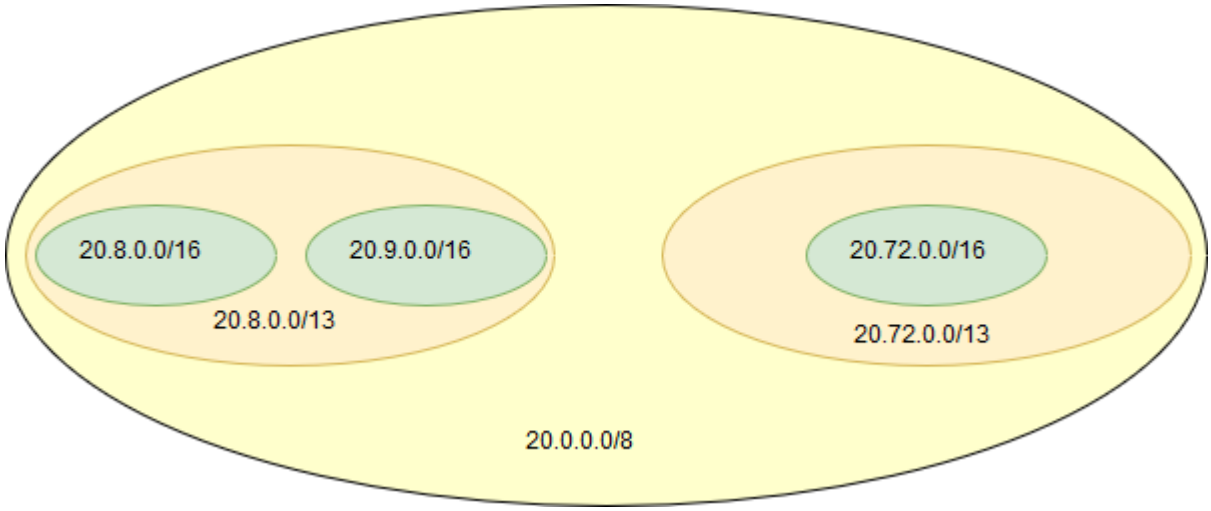
You can create a new host record by copying an existing one. When you copy a host record, other than the new host name and IP address, all DHCP and IPAM configuration including the MAC address and extensible attributes apply to the new record. You can also modify information, except for the host name and IP address, of an existing host record.
To copy or modify an existing host record:

1. From the **Data Management** tab, select the **IPAM**, **DHCP**, or **DNS** tab.
2. In the selected tab, search for or navigate to the host record that you want to copy or modify.
3. Do one of the following:
   - To copy a host record, select the record and expand the Toolbar, and then click **Add** -> **Host** -> **Copy Host**. Grid Manager displays the *Host Record* editor.
   - To modify a host record, select the record and click the Edit icon. Grid Manager displays the *Host Record* editor.
4. The *Host Record* editor provides the following tabs from which you can modify all the fields:
   - **General:** Enter the new hostname and specify at least one IP address. Optionally, you can modify the information you entered through the wizard as described in Adding Host Records above.
     Note that when you are modifying a DHCP enabled host address, you can apply IPv4 logic filters. To apply IPv4 logic filters, complete the following in the **IPv4 Addresses** section:
     - Select the IP address and click the Edit icon.
     - Click the **Filters** tab in the **Advanced** tab and complete the following:
       - **Filters**: You can keep the inherited IPv4 logic filters or override them and add a new IPv4 logic filter. For information, see *Applying Filters to DHCP Objects.*
   - **Device Information**: You can change advisory Device Information settings for the object's port reservation; settings are described in the section Adding Host Records above.
   - **TTL:** This tab displays the default TTL settings the record inherited from the Grid or the DNS zone, if you enabled override TTL settings at the zone level. You can keep the default settings or override them. To override the inherited value, click **Override** to enable the configuration. Specify how long the record is cached. Select the time period in seconds, minutes, hours, days, or weeks from the drop-down list. To enable the record to inherit the Grid or zone TTL settings, click **Inherit**.
   - **Aliases:** Click the Add icon. Grid Manager displays a new row in the table. Enter a fully qualified domain name (a CNAME record for the host) in the **Aliases** column. You can delete an alias by selecting the alias checkbox and clicking the Delete icon.
   - **IPv4 Discovered Data:** Displays the discovered data of the IPv4 addresses, if any, of the host record. For information, see *Viewing Discovered Data*.
   - **Port Reservation**: Review and edit any device port reservations that may be defined for the current object, or create a new port reservation and schedule it. For a closer look, see the section *Port Control Features in Network Insight*, and steps 4-8 in the section Adding Host Records above.
   - **IPv6 Discovered Data:** Displays the discovered data of the IPv6 addresses, if any, of the host record. For information, see *Viewing Discovered Data*.
   - **Extensible Attributes:** You can add and delete extensible attributes that are associated with a host record. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes.*
   - **Permissions:** This tab appears only if you belong to a superuser admin group. For information, see *About Administrative Permissions*.
5. Save the configuration.
6. Click **Restart Services** on the Toolbar for the changes to take effect.

About Network Containers

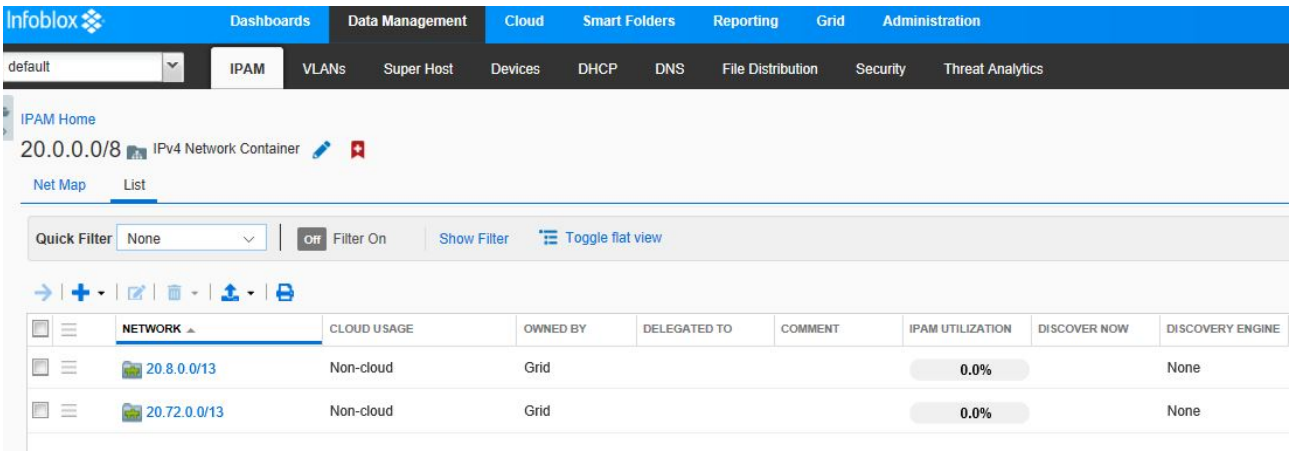
Grid Manager uses network containers to group IPv4 and IPv6 networks. A network container is a parent network that contain other network containers and leaf networks. A leaf network is a network that does not contain other networks. For example, the following figure illustrates the IPv4 20.0.0.0/8 network, which is a network container with two network containers, 20.8.0.0/13 and 20.72.0.0/13. The 20.8.0.0/13 network has two leaf networks, 20.8.0.0/16 and 20.9.0.0/16. The 20.72.0.0/13 network has one leaf network, 20.72.0.0/16.

IPv4 Network Container



From Grid Manager, you can click the link of the network container 20.0.0.0/8 in the IP List panel and drill down to the two network containers, 20.8.0.0/13 and 20.7.0.0/13, as shown in the below figure. You can click the network container links to drill down further to the leaf networks.

IP List View of Network Containers



In the **IPAM** tab, when you create an IPv4 or IPv6 network that belongs to a larger network, the appliance automatically creates a network container and puts the leaf network in the container. The appliance also creates network containers when you split IPv4 or IPv6 networks into smaller networks. For information, see *Splitting IPv4 Networks into Subnets* and *Splitting IPv6 Networks into Subnets*.

Adding IPv4 and IPv6 Network Containers and Networks

To add an IPv4 or IPv6 network container or network:

1. From the **Data Management** tab, select the **IPAM** tab.
2. Click the Add icon and select either **IPv4 Network** or **IPv6 Network**.
3. In the *Add Network* wizard, create a network as described in *Adding IPv4 Networks* or *Adding IPv6 Networks*.

Modifying IPv4 and IPv6 Network Containers and Networks

You can modify existing network settings, with the exception of the network address and subnet mask. To modify an IPv4 or IPv6 network container or network:

1. From the **Data Management** tab, select the **IPAM** tab -> *network* checkbox, and then click the Edit icon.
2. In the *DHCP Network* editor, modify the network settings as described in *Modifying IPv4 Networks* or *Modifying IPv6 Networks.*

Deleting Network Containers

Depending on the configuration, you may or may not be able to delete or schedule the deletion of a network container and all its contents. Contents in a network container can include other network containers, leaf networks, and associated objects. For recursive deletions, only network containers and networks are considered. Objects such as hosts are not considered for recursive deletions.
Superusers can determine which group of users are allowed to delete or schedule the deletion of a network container and all its contents. For information about how to configure the recursive deletion of network containers, see *Configuring Recursive Deletions of Networks and Zones*.
Note that you must have Read/Write permission to all the contents in order to delete a network container. When you delete a network container only, the appliance reparents the other network containers and leaf networks.
The appliance puts all deleted objects in the Recycle Bin, if enabled. You can restore the objects if necessary. When you restore a parent object from the Recycle Bin, all its contents, if any, are re-parented to the restored parent object. For information about the Recycle Bin, see *Using the Recycle Bin*.
To delete a network container:

1. From the **Data Management** tab, select the **IPAM** tab -> *network_container* checkbox. You can select multiple network containers for deletion.
2. Click the Delete icon.
3. Do one of the following in the *Delete Confirmation* dialog box:
    - Select one of the following. Note that these options appear only if you are allowed to delete the network container and all its contents. For information about how to configure this, *Configuring Recursive Deletions of Networks and Zones*.
        - **Delete only the network container and re-parent the subnets**: Select this to delete only the network container and re-parent its subnets.
        - **Delete the network container and all its subnetworks**: Select this to delete both the network and its contents.
    - Click **Yes**.

The appliance puts the deleted network container in the Recycle Bin, if enabled. You can also schedule the deletion for a later time. Click **Schedule Deletion** and in the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Deletions*. For information about scheduling recursive deletions of network containers, see *Scheduling Recursive Deletions of Network Containers and Zones*.

Managing IPv4 Networks

In Grid Manager, you use the Net Map (network map) and List panels to manage your IPv4 network infrastructure. After you select a network container from the IPAM tab, Grid Manager displays it in the Net Map panel, by default. The Net

Map panel provides a graphical view of your networks and has a number of features that simplify network management. The List panel displays the networks in table format.

You can always switch your view of a network container between the Net Map and List panels. Grid Manager keeps track of which panel you last used. When you select a network container, Grid Manager displays it in the Net Map or List panel, depending on which one you last used. For information about each panel, see IPv4 Network Map and IPAM Home below.

Use the IP Map and List panels to manage the IP addresses in leaf networks. For information, see *Viewing and Managing IPv4 Addresses*.

After you create an IPv4 network, you can modify its properties, resize it, use the split network feature to create subnets, enable discovery to discover routers, switches, firewalls, wireless access points and other device types within it, or join it to another network to create a larger network that encompasses adjacent subnets.

You can do the following from both the Net Map and List panels:

- Resize a network. For information, see Resizing IPv4 Networks below.
- Split a network into subnets. For information, see Splitting IPv4 Networks into Subnets below.
- Join a network. For information, see Joining IPv4 Networks below.
- Discover devices in the network. For information, see Discovering Networks (Under Network Insight only) below.

IPv4 Network Map

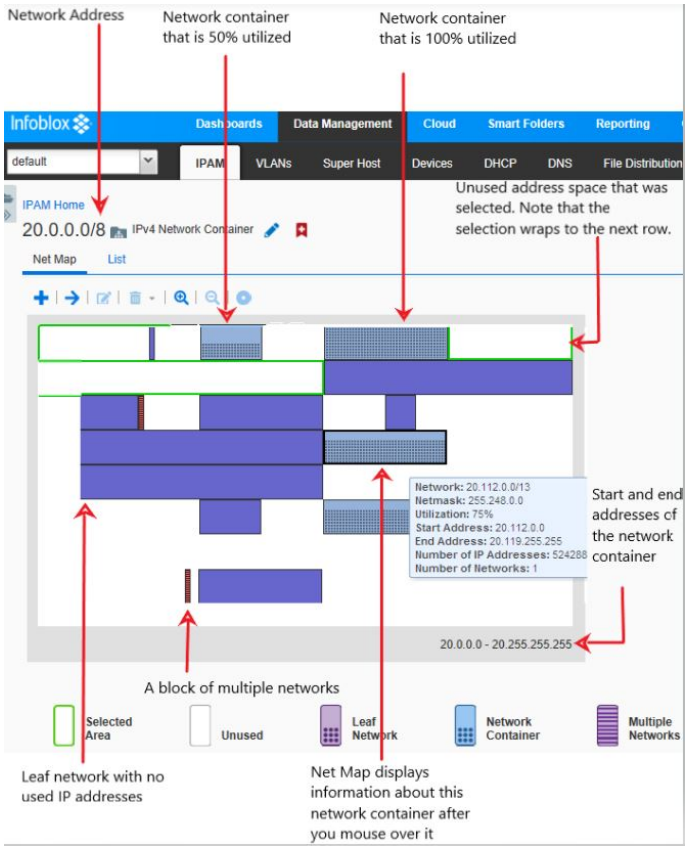
After you select an IPv4 network container from the IPAM tab, Grid Manager displays it in the Net Map (network map) panel, by default. Net Map provides a high-level view of your IPv4 network address space. You can use Net Map to design and plan your network infrastructure, configure and manage individual networks, and evaluate their utilization. Its unique display of the IPv4 network address space across multiple rows is similar to a road map that starts with the first IP address in the network and ends with the last address. Net Map displays the network address space across a maximum of eight rows, depending on the size of the network. It automatically scales the map so that it displays the entire address space of a network container.

The Net Map panel presents a complete view of the network space, including the different types of networks that are in it and its unused address space. IP addresses that belong to a network are blocked off. Each color-coded block represents a network container, a leaf network, or a block of networks that are too small to be displayed individually in the map. For example, in a /8 or /16 network, networks smaller than /20 or /28 respectively and that are beside each other are represented as a multiple network block. In addition, the fill pattern of the blocks indicates their utilization. Therefore, you can quickly evaluate how many and what type of networks are in a network container, their relative sizes, utilization, and how much space you have left.

As you mouse over areas of the map, it displays IP information about the area. Net Map also has a zoom feature that allows you to enlarge or reduce your view of a particular area.

The below figure displays the network map of a 20.0.0.0/8 network, which is a network container that has network containers and leaf networks.

20.0.0.0/8 Network Map



Displaying IP Information

As shown in 20.0.0.0/8 Network Map figure, as you mouse over the map, Net Map displays IP information about the area. When you mouse over an unused area, Net Map displays the following information:

- The start and end IP address
- The number of IP addresses that can fit in that space
- The largest possible network
- The number of /16 and /24 networks that can fit in that space

When you mouse over a network, Net Map displays the following information:

- Network address and netmask
- Utilization of the network. For a leaf network, Net Map reports the percentage of used IP addresses, except the broadcast and network addresses. For a network container, Net Map reports the percentage of the IP address space that has been allocated to either network containers or leaf networks.
- The first and last IP address of the network
- The total number of IP addresses in the network

When you mouse over a block of multiple networks, Net Map displays the following information:

- The start and end IP address of that block of networks
- The total number of IP addresses in that block of networks
- The number of networks in that block

Zooming In and Out

Use the zoom function to enlarge and reduce your view of a selected area. You can zoom in on any area in your network. You can zoom in on an area until it displays 128 addresses per row, for a total of 1024 addresses for the map. When you reach the last possible zoom level, the Zoom In icon in the Net Map task bar and the menu item are disabled.

After you zoom in on an area, you can click the Zoom Controller icon to track where you zoomed in. The Zoom Controller lists all the areas that you zoomed in and updates its list dynamically. You can click an item on the list to view that area again. Click the Zoom Controller again to close it.

To select an area and zoom in:

1. Right-click and select **Zoom In**, or click the Zoom In icon in the Net Map task bar. The pointer changes to the zoom in selector.
2. Select a starting point and drag to the end point. The starting point can be anywhere in the map. It does not have to be at the beginning of a network.
   Net Map displays a magnified view of the selected area after you release the mouse button. As you mouse over the zoomed in area, Net Map displays IP information about it.
3. You can do the following:
   - Select an area and zoom in again.
   - Add a network. If you zoom in on an area and click Add without selecting an open area first, Net Map selects the area where it can create the biggest possible network in that magnified area.
   - Select a network and perform any of the following operations:
     - Split the network.
     - Join it to another network.
     - Resize the network.
     - Edit its properties.
     - Open it to display its network or IP map.
   - Right-click and select **Zoom Out**, or click the Zoom Out icon in the Net Map task bar. Each time you click **Zoom Out**, Net Map zooms out one level and the Zoom Controller is updated accordingly.

Net Map Tasks

From Net Map, you can create IPv4 networks, and evaluate and manage your network resources according to the needs of your organization.

You can do the following:

- Zoom in on specific areas, as described in Zooming In and Out above.
- Add a network, as described in Adding a Network from Net Map below.
- Select a network and view either its network or Net Map, as described in Viewing Network Details below.
- Select a network and edit its properties, as described in *Modifying IPv4 and IPv6 Network Containers and Networks*.
- Split a network, as described in Splitting IPv4 Networks into Subnets below.
- Join networks, as described in Joining IPv4 Networks below.
- Resize a network, as described in Resizing IPv4 Networks below.
- (*Applies only with Network Insight*) Execute **vDiscovery** on the selected network, as described in *Configuring vDiscovery Jobs*.
- (*Applies only with Network Insight*) View **Discovery Status** for the selected network, as described in *Viewing Discovery Status*.
- (*Applies only with Network Insight*) Execute **Discovery Diagnostics** on the selected network, as described in *Executing Discovery Diagnostics*.
- (*Applies only with Network Insight*) Direct NIOS to discover devices on the selected network (**Discover Now**). The network must have discovery enabled before this button will be active. For more information about requirements and discovery features, see the topics under *About Network Insight*.
  Note If the **Discover Now** button and other associated discovery elements are disabled on the Toolbar, it indicates that discovery is not enabled for the parent network of the selected network or IP, or the network is not associated with a discovery appliance.
  Delete one or multiple networks, as described in Discovering Networks (Under Network Insight only) below.

- **Clear All Unmanaged Data** or **Clear All Discovered Data**, as described in the section *Clearing Discovered Data.*
- Switch to the List view of the network. For information, see IPAM Home below.
    - When you select one or more networks in Net Map and then switch to the List view, the list displays the page with the first selected network.
    - If you select one or more networks in the List view and then switch to the Net Map view, the first network is also selected in Net Map. If you select a network in the List view that is part of a Multiple Networks block in Net Map, it is not selected when you switch to the Net Map view.

Adding a Network from Net Map

When you create networks from Net Map, you can evaluate your network infrastructure and add networks accordingly. You can view the address space to which you are adding a network, so you can determine how much space is available and which IP addresses are not in use. When you mouse over an open area, Net Map displays useful information, such as the largest possible network that fits in that area and the total number of IP addresses. In addition, you can create networks without having to calculate anything. When you add a network, Net Map displays a netmask slider so you can determine the appropriate netmask for the size of the network that you need. As you move the slider, it displays network information, including the total number of addresses. After you select the netmask, you can even move the new network around the open area to select another valid start address.

To add a network from the Net Map panel:

1. Do one of the following:
    - Click the Add icon.
      Net Map displays the netmask slider and outlines the open area that can accommodate the largest network.
    - Select an open area, and then click the Add icon.
      Net Map displays the netmask slider and outlines the largest network that you can create in the open area that you selected.
2. Move the slider to the desired netmask. You can move the slider to the netmask of the largest network that can be created in the open area.
   As you move the slider, Net Map displays the netmask and its corresponding number of IP addresses. The outline in the network map also adjusts as you move the slider. When you mouse over the outline, it displays the start and end address of the network.
3. After you set the slider to the desired netmask, you can drag the new network block around the open area to select a new valid starting address. You cannot move the block to a starting address that is invalid.
4. Click **Launch Wizard** to create the network.
   The *Add Network* wizard displays the selected network address and netmask.
5. You can add comments, automatically create reverse mapping zones, and edit the extensible attributes. For information, see *Adding IPv4 Networks*. You cannot change the network address and netmask, but you can edit the description and enable or disable a network by selecting the network and clicking the Edit icon. To disable a network, you can double click the respective row, select the checkbox in the **Disabled** column and click **Save.** Grid Manager displays a warning message when you select the checkbox. Click **Yes** to confirm or **No** to cancel. You can also delete or restore a network. Grid Manager displays a warning message during deletion and when you restore the network indicating that the process may take a longer time if the amount of data is huge. Click **Yes** to continue or **No** to cancel the process.
6. Save the configuration and click **Restart** if it appears at the top of the screen. Grid Manager updates Net Map with the newly created network.

Viewing Network Details

From the Net Map panel, you can focus on a specific network or area and view additional information about it. If you have a network hierarchy of networks within network containers, you can drill down to individual leaf networks and view their IP address usage.

1. Select a network or area.
2. Click the Open icon.
    - If you selected a network container, Grid Manager displays it in the Net Map panel. You can drill down further by selecting a network or open area and clicking the Open icon again.

- If you selected a block of multiple networks, Grid Manager displays the individual networks in the Net Map panel. You can then select a network or open area for viewing.
- If you selected a leaf network, Grid Manager displays it in the IP Map panel.
- If you selected an open area, Grid Manager displays an enlarged view of that area in the Net Map panel.

This is useful when you are creating small networks in an open area.

IPAM Home

The IPAM Home panel is an alternative view of an IPv4 and IPv6 network hierarchy. For a given network, the panel shows all the networks of a selected network view in table format. This panel displays only the first-level subnets. It does not show further descendant or child subnets. You can open a subnet to view its child subnets. Subnets that contain child subnets are displayed as network containers. If the number of subnets in a network exceeds the maximum page size of the table, the network list displays the subnets on multiple pages. You can use the page navigation buttons at the bottom of the table to navigate through the pages of subnets.

The IPAM home panel displays the following:

- **Network**: The network address.
- **Comment**: The information you entered about the network.
- **RIR Organization**: This appears only if support for RIR updates is enabled. This displays the name of the RIR organization to which the network is assigned.
- **RIR OrganizationID**: This appears only if support for RIR updates is enabled. This displays the ID of the RIR organization to which the network is assigned.
- **RIR RegistrationStatus**: This appears only if support for RIR update is enabled. This field displays the RIR registration status. This can be **Registered** or **Not Registered**. **Registered** indicates that the network has a corresponding entry in the RIPE database.
- **Last Registration Updated**: Displays the timestamp when the last registration was updated. The displayed timestamp reflects the timestamp used on the Grid Master.
- **Status of Last Registration Update**: Displays the registration status and communication method of the last registration update. The status can be Pending, Sent, Succeeded, or Failed. Each time you send a registration update to create, modify, or delete a network container or network, the updated status will be displayed here. If you have selected not to send registration updates, the previous status is retained.
- **IPAM Utilization:** For a network, this is the percentage based on the IP addresses in use divided by the total addresses in the network. For example, in a /24 network, if there are 25 static IP addresses defined and a DHCP range that includes 100 addresses, the total number of IP addresses in use is 125. Of the possible 256 addresses in the network, the IPAM utilization is about 50% for this network.
  For a network container that contains subnets, this is the percentage of the total address space defined within the container regardless of whether any of the IP addresses in the subnets are in use. For example, when you define a /16 network and then 64 /24 networks underneath it, the /16 network container is considered 25% utilized even when none of the IP addresses in the /24 networks is in use.
  You can use this information to verify if there is a sufficient number of available addresses in a network. The appliance updates the IPAM utilization data immediately for a network container, but for a network it is updated every 15 minutes.
  The IPAM utilization data is displayed in one of the following colors:
- Red: The IPAM utilization percentage is above the configured Trigger value.
- Blue: The IPAM utilization percentage is below the configured Trigger value.
- **Active Users**: The number of active users on the selected network.
- **Discovery Engine**: Displays the discovery engine that performs the discovery process. This can be **Network Insight**, **NetMRI**, or **vDiscovery**. This field displays **None** if you have added or imported the network container or network manually.
- **Site**: The site to which the IP address belongs. This is a predefined extensible attribute.
- **Bridge Domain**: The name of the discovered bridge domain. This column will display values only for IP addresses that are discovered from Cisco APIC by Network Insight or NetMRI. If discovered by NetMRI, the value will be populated through IPAM Sync. Otherwise, this column will be blank. For information about how to configure Cisco APIC, see *Configuring Cisco Application Policy Infrastructure Controller (APIC)*.
- **Tenant**: The name of the discovered tenant. This column will display values only for IP addresses that are discovered from Cisco APIC by Network Insight or NetMRI. If discovered by NetMRI, the value will be populated

through IPAM Sync. Otherwise, this column will be blank. For information about how to configure Cisco APIC, see *Configuring Cisco Application Policy Infrastructure Controller (APIC).*

Additionally, you can select the following columns for display:

- **Disabled**: Indicates whether the network is disabled.
- **Leaf Network**: Indicates whether the network is a leaf network or not. A leaf network is a network that does not contain other networks.
- **Discovery Enabled**: (*Applies only with Network Insight*) Indicates whether discovery is allowed on the network container or the network.
- **Discover Now**: (*Applies only with Network Insight*) Indicates when the network is undergoing a current discovery process. A "Pending" icon appears in this column when you start the discovery and displays **Completed** after the completion of the discovery process.
- **Discovered VLAN ID**: (*Applies only with Network Insight*) The VLAN ID on the switch port.
- **Discovered VLAN Name**: (*Applies only with Network Insight*) The VLAN name on the switch port.
- **Assigned VLAN ID**: VLAN ID of the VLAN object assigned to the network.
- **Assigned VLAN Name**: VLAN name of the VLAN object assigned to the network.
- **VRF Name**: The name of the discovered VRF that uses IP addresses of the network, as discovered by Network Insight or NetMRI.
- **VRF Description**: The description of the discovered VRF.
- **VRF RD**: The address of the route distinguisher of discovered VRF.
  Note that as a general rule for the VRF-related columns, a column displays a specific value if there is a single non-empty value or several same values for the IP addresses in the network. Otherwise, the column displays “Multiple”. For example, if the VRF names for a network have the same value, the **VRF Name** column displays this value for the network. If more than one VRF are discovered for a network and their names are different, the **VRF Name** column displays “Multiple”. However, if for a number of VRFs there is only one VRF description or VRF RD value among other empty strings, the columns **VRF Description** and **VRF RD** display “Multiple” as this is regarded as distinct VRFs.
  To see values for each IP address in the network, click the network -> **List** tab.
- **BGP AS**: The number of the discovered BGP Autonomous System that uses IP addresses of the network.
  Note If more than one BGP AS are discovered for a network and their numbers are different, the **BGP AS** column displays “Multiple”. If the BGP AS numbers have the same value, the **BGP AS** column displays this value for the network. To see values for each IP address in the network, click the network -> **List** tab.
- **Managed**: (*AppliesonlywithNetworkInsight*) Indicates whether the network is set to Managed status under Grid Manager. For more information, see the section *Converting Unmanaged Networks under IPAM to Managed Status*.
- **First Discovered**: (*Applies only with Network Insight*) The date and timestamp of the first occasion that Grid Manager discovered the network.
- **Last Discovered**: (*Applies only with Network Insight*) The date and timestamp of the last occasion that Grid Manager performed discovery on the network. The timestamp is updated whenever any new IP from this network is discovered.
- **Extensible attributes and RIR attributes:** You can select the extensible attributes such as Building, Country, Region, State, and VLAN for display. When you enable support for RIR registration updates, you can also select associated RIR attributes for display. For information about RIR attributes, see *Managing RIR Attributes*.
- **Active Directory Sites**: You can also select Active Directory Sites for display. For information about Active Directory Sites, see *About Active Directory Sites and Services.*

The Toolbar and the Action menu provide access to actions you can take on the selected network where applicable, as follows:

- Click **Show Device View** to view the devices whose interfaces are in the selected network. To view device details and a list of all the interfaces associated with it, click the name of the device.
- Click **Convert** to change the status of an unmanaged network to managed status under IPAM.
- Click **Discover Now** to apply Network Insight discovery to a listed network.
- Click **Edit** to open the network editor.
- Click **Delete** to delete or schedule deletion of the selected network. To delete the network now, in the Delete Confirmation dialog box, click Yes. Grid Manager displays a warning message. Click Yes to continue or No to cancel the process.
- Click **Extensible Attributes** to open the network editor’s Extensible Attributes page for the selected network.
- Click **Permissions** to open the network editor’s Permissions page for the selected network.

- Click **Move Networks** to move a network to a destination Active Directory site.
- Click **Show Active Users** to view all the users who are currently active on the Active Directory domain.

You can sort the list of networks in ascending or descending order by columns. For information about customizing tables in Grid Manager, see *Customizing Tables*.

You can also modify some of the data in the table fields. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data inTables* .

Tip: If you select a network from the list and switch to the Net Map panel, the network is also selected in the network map.

Filtering the Network List

You can filter the network list, so it displays only the networks you need. You can filter the list based on certain parameters, such as network addresses, comments and extensible attributes. When you expand the list of available fields you can use for the filter, note that the extensible attributes are those with a gray background.

Resizing IPv4 Networks

You can resize a network to increase or decrease the network size and the number of IP addresses in the network. When you resize a network to a smaller netmask, you increase the number of IP addresses within that network. You can change the size of an IPv4 network when the operation does not affect existing objects in the network. You can resize an existing network only if the resized network does not exceed the upper network limit or create orphan objects, such as hosts and DHCP ranges. When a network has a parent network or subnets, the upper limit of the network size is marked in red in the resize network slider, and you cannot resize beyond this limit. For example, if a network has a /16 parent network, you cannot resize the network to a network that is larger than /16.

Before you resize an RIR allocated network block, ensure that the network block has already been registered at the corresponding RIR. Otherwise, when you reassign addresses within this block, the registration updates may fail. For information about RIR registration updates, see *RIR Registration Updates*.

To resize a network:

1. From the Net Map or List panel, select a network, and then click **Resize** from the Toolbar.
2. In the *Resize Network* editor, do the following:
    - **Address**: Displays the network address. You cannot modify this field.
    - **Netmask**: Displays the netmask of the network as you resize the network. You cannot modify this field.
    - **Resize slider**: Use the resize network slider to specify the appropriate subnet masks for the subnets. When you move the slider, Grid Manager displays the number of subnets and IP addresses within that subnet.
    - **Automatically create reverse-mapping zone**: This is enabled only when you resize a /8, /16, or /24 network. Select this checkbox to have the appliance automatically create reverse-mapping zones for the subnet. The appliance automatically creates reverse-mapping zones only for /8, /16, and /24 netmasks.
3. Click **OK**.

Splitting IPv4 Networks into Subnets

You can create smaller subnets simultaneously within a network by splitting it. You do not have to configure each subnet individually. You can create smaller subnets with larger netmasks. A larger netmask defines more networks with a smaller number of IP addresses.

These subnets inherit the address properties of the parent network, such as member assignments. The exceptions are the default router and broadcast address configuration. The default router and broadcast address configuration for address ranges and fixed address are disabled by default after splitting a network. You can enable these properties for each subnet after splitting the parent network.

Note that you cannot split a network that is part of a shared network.

To split a network:

1. From the Net Map or List panel, select the checkbox of a network, and then click **Split** from the Toolbar.
2. In the *Split Network* editor, do the following:
    - **Address**: Displays the network address. You cannot modify this field.
    - **Netmask**: Displays the netmask of the network. You cannot modify this field.
    - **Subnetworks**: Displays the number of subnets and IP addresses for each subnet.
    - **Split network slider**: Use the split network slider to specify the appropriate subnet masks for each subnet. When you move the slider, Grid Manager displays the number of subnets and the IP address range within that subnet.
    - **Immediately Add**: Select one of the following options.
        - **Only networks with ranges and fixed addresses and unmanaged**: Adds only the networks that have DHCP ranges, fixed addresses, and unmanaged addresses.
        - **All possible networks**: Adds all networks that are within the selected netmasks. The is enabled only when you split the /8 networks to /9 or /16 networks.
          Note that when you add a large number of networks, it could take a little longer for Grid Manager to display the networks.
    - **Automatically create reverse-mapping zone**: Select this checkbox to have the appliance automatically create reverse-mapping zones for the subnets.
3. Click **OK**.

Joining IPv4 Networks

Joining multiple networks into a larger network is the opposite of splitting a network. You can select a network and expand it into a larger network with a smaller netmask. A smaller netmask defines fewer networks while accommodating a larger number of IP addresses. Joining or expanding a network allows you to consolidate all of the adjacent networks into the expanded network. Adjacent networks are all networks falling under the netmask of the newly-expanded network. You can expand the selected network to a new size and add all other subnets into the new network. When you join networks, you need not define all small networks that cover the address spaces for a larger network.

Each of the adjacent networks join the expanded network and inherit the DHCP member configuration options of the selected network. The expanded network does not inherit the default router and broadcast address configurations of the adjacent networks. Those configurations are disabled by default.

Note

The member assignment for the expanded network combines all member assignments of the joining networks.

Note that the join and resize features work identically only when you have a single network. If the resize feature is disabled and if you have a single network object with additional new networks, then you must use the join feature to combine all networks.

To join or expand a network:

1. From the Net Map or List panel, select a network, and then click **Join** from the Toolbar.
2. In the *Join Network* editor, do the following:
    - **Address**: Displays the network address. You cannot modify this field.
    - **Netmask**: Displays the netmask of the network as you expand the network.
    - **Join Network slider**: Use the join network slider to specify the available subnet masks for the newly expanded network. Select a smaller netmask value, based on your requirements of the newly-expanded network. When you move the slider, a dialog box displays the total number of IP addresses and the IP address range of a selected subnet mask.

- **Automatically create reverse-mapping zone**: Select this checkbox to configure the expanded network to support reverse-mapping zones *Adding Grid Members*.

3. Click **OK**.

Discovering Networks (Under Network Insight only)

> **Note**
>
> When you add a new network and select the **Enable Discovery** option in the **Add IPv4 Network Wizard** window, network discovery begins automatically, and you do not need to click **Discover Now**.
> If the **Discover Now** button and other associated discovery elements are disabled on the Toolbar, it indicates that discovery is not enabled for the parent network of the selected network or IP, or that a discovery appliance (known as a Probe) is not associated with the network that you wish to discover.

To discover IPv4 or IPv6 networks:

- From the Net Map or List panel, select a network, and then click **Discover Now** from the Toolbar. NIOS asks you to confirm that you wish to launch discovery on the selected network.

In the Net Map panel, you can click on IP addresses in the network being discovered. As new data becomes available, NIOS updates the Discovered Data section of the panel with any information found on the device associated with the selected IP.

For more information about requirements and discovery features, see the topics under *About Network Insight*.

Deleting Networks

From the IPAM tab, you can delete multiple IPv4 and IPv6 networks. When you delete a network, all of its data, including all of its DHCP records, subnets, and records in its subnets, is deleted from the database and goes to the Recycle Bin, if enabled. Because of the potentially large loss of data that can occur when you delete a network, Grid Manager requires a confirmation to move the data to the Recycle Bin.

To delete IPv4 or IPv6 networks:

1. From the **Data Management** tab, select the **IPAM** tab -> *network* checkbox. You can select multiple checkboxes for multiple networks.
2. Select **Delete** or **Schedule Delete** from the Delete drop-down menu.
3. To delete the network now, in the *Delete Confirmation* dialog box, click **Yes**. To schedule a deletion, see *Managing Extensible Attributes*.
   The appliance puts the deleted network in the Recycle Bin, if enabled.

Viewing and Managing IPv4 Addresses

You can view and manage IPv4 address data in the IP Map and List panels. Grid Manager displays the IP Map and List panels for a specific network after you navigate through the network hierarchy, or when the selected network does not have subnets under it.

IP MAP

The IPv4 Map panel provides a graphical representation of all IPv4 addresses in a given subnet. IP Map displays cells that represent IPv4 addresses. Each cell in the map represents an IPv4 address, and its color indicates its status as described in the legend section. You can run a network discovery on the selected network, and the status of each IP address is updated accordingly. For information, see *About Discovery*.

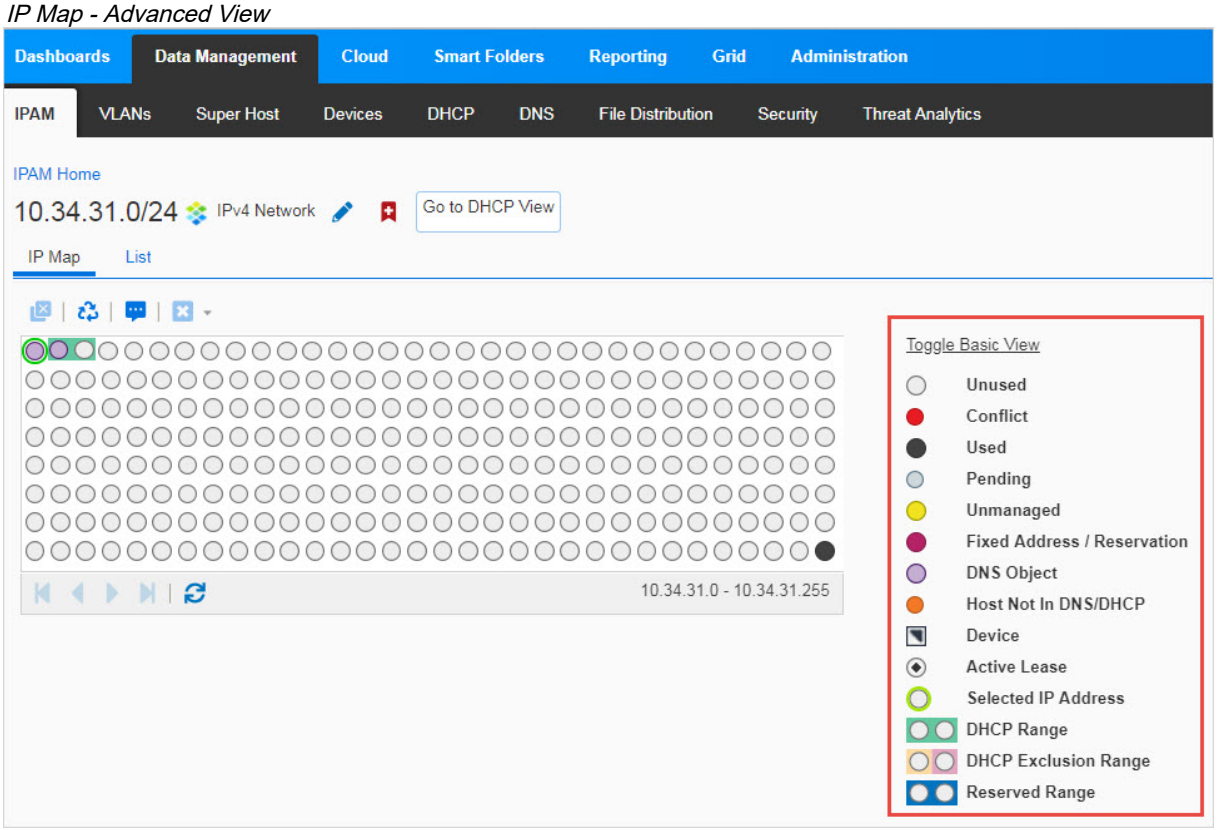
Each IP Map panel can accommodate up to 256 cells with each cell representing an IP address. If a given network has more than 256 addresses, additional IP addresses are displayed by paging to the next page. You can use the page navigation buttons to page through the IP addresses. To go to a specific IP address, you can enter the IP address in

the **Go to** field or click a specific cell in IP Map. IP Map has a basic and an advanced view. You can toggle between these views by clicking **Toggle Basic View** or **Toggle Advanced View**. As illustrated in the figure IP Map - Advanced View below, the status of an IP address is represented with a different color in the IP Map panel.

In the basic view, the IP Map panel displays the following IP address status:

- **Unused**: An IP address that has not been detected and is not associated with any network device or active host on the network.
- **Conflict**: An IP address that has either a MAC address conflict or a DHCP lease conflict detected through a network discovery.
- **Used**: An IP address that is associated with an active host on the network. It can be a resource record, fixed address, reservation, DHCP lease, or host record.
- **Pending**: An IP address that is associated with a scheduled task or approval workflow, and the associated operation has not been executed yet. This IP address is not considered when using the next available IP address function.
- **Selected IP Address**: The IP address that you selected.
- **DHCP Range**: The IP addresses within a DHCP range in the network. The appliance highlights the cells using a green background.
- **Reserved Rang**e: A range of IP addresses that are reserved for statically configured hosts. They are not served as dynamic addresses. You can allocate the next available IP from the reserved range when you create a static host.

IP Map - Advanced View



In the advanced view, the IP Map panel displays additional status as follows:

- **Unmanaged**: An IP address that has a discovered host, is not previously known to the appliance, and does not have an A record, a PTR record, fixed address, host address, lease, or is not within a DHCP range. You can change an unmanaged address to a host, DHCP fixed address, A record, or PTR record. You can also clear an unmanaged address. All existing administrator permissions apply to the unmanaged addresses.
- **Fixed Address/Reservation**: A host that is either a fixed address or reservation.
- **DNS Object**: An object that is configured for DNS usage.

- **Host Not in DNS/DHCP**: An IP address that is associated with a host record, but is not configured for DHCP or DNS services.
- **Active Lease**: An IP Address that has an active DHCP lease.
- **DHCP Exclusion Range**: A range of IP addresses within a DHCP range. The appliance cannot assign addresses in the exclusion range to a client. You can use these addresses as static IP addresses. This prevents address conflicts between statically configured devices and dynamically configured devices.
  Note that for a Microsoft split-scope range, the appliance highlights the cells using a combination of orange and pink background colors when the network is managed by two Microsoft servers. For a DHCP exclusion range, the appliance highlights the cells using an orange background.
- **Reserved Exclusion Range**: A range of IP addresses that are reserved for statically configured hosts. IP addresses residing within the exclusion range are excluded from the pool of available IP addresses and are not available for lease.

Under the IP map, Grid Manager displays the following information for the IP address that you have selected in the map:

- **Type**: The object type that is associated with the IP address. For example, this can be **Lease, IPv4 DHCP Range** or **Fixed Address**.
- **Comment**: Additional information about the IP address.
- **Lease State**: The lease state of the IP address. This can be one of the following: **Free**, **Backup**, **Active**, **Expired, Released**, **Abandoned**, **Reset**, **BootP**, **Static**, **Offered**, or **Declined**.
- **Name**: The name of the object type associated with the IP address. This field displays the name of the object type in the native character set if a host record contains IDNs. If a host record contains IDNs in punycode, this field displays the name in the punycode representation. For example, if the IP address belongs to a host record, this field displays the hostname. For IDNs, this field displays the name in the native character set. If punycode is used, then the appliance displays name in punycode.
- **MAC Address**: The discovered MAC address of the host. This is the unique identifier of a network device. The discovery acquires the MAC address for hosts that are located on the same network as the Grid member that is running the discovery. This can also be the MAC address of a virtual entity on a specified vSphere server. The appliance displays an **X** mark beside the MAC address if it is invalid. For more information about invalid MAC addresses, see *Synchronizing IP Addresses with Invalid MAC Addresses*.
- **DHCP Fingerprint**: The name of the DHCP fingerprint or vendor ID of the network device that was identified through DHCP fingerprint detection. This field displays **No Match** for devices that do not have any DHCP fingerprint information. For information about DHCP fingerprints, see *DHCP Fingerprint Detection*.

Depending on the selected object, you may also see information about neighboring devices, port, etc. For more information, see IP List Neighbor Information below.

You can do the following in the IP Map panel:

- Click **Go to DHCP View** to view DHCP properties of a selected network.
- Select an address range by clicking once on a start address and then use SHIFT+click on the end address. Click **Add -> Range** from the Toolbar to add the selected range as an IPv4 or IPv6 DHCP range or reserved range.
- Click the Resolve Conflict icon to resolve IP address conflicts. For information, see *Resolving Conflicting Addresses*.
- Click the Ping icon to ping a selected IP address. For information, see *Pinging IP Addresses*.
- Click the Reclaim icon to reclaim an IP address. For information, see *Reclaiming Objects Associated with IPv4 and IPv6 Addresses*.
- Click the Clear icon to clear an active lease. For information, see *Clearing Active DHCP Leases*. You can also select an IP address from the IP Map panel and view the following information:
- General information, as described in IP Address Header Panel below.
- Data retrieved through a network discovery or integrated from a PortIQ appliance and Trinzic NetMRI appliance. For information, see *Viewing Discovered Data*.
- The records associated with the IP address, as described in *Related Objects.*
- The audit history, as described in *Audit History.*
- Detailed lease information, as described in *Viewing Detailed Lease Information*.
- Click **DHCP View** to view DHCP properties of the selected network. For information, see *Modifying IPv4 Networks*.
- View active network users, as described in *Viewing Active Network Users*.

IP Address List

The IP address **List** panel displays all IPv4 addresses of a selected subnet in table format. The list provides information about the IP addresses in a hierarchy view. You can use this list to view detailed information about each IP address and its related objects in a selected network. This list provides information such as address status, object type, and usage.

You can configure filter criteria to display only IP addresses that you want to see in the table. For example, you can enter "MAC Address begins with 00" as the filter criteria to view only IP addresses that have associated MAC addresses that begin with 00. You can also enter a specific IP address in the **Go to** field to view information about the address.

Grid Manager can display the following information for the IP addresses. You can edit the columns to display information that is not shown by default.

- **IP Address**: The IP address of the corresponding record. The appliance highlights disabled DHCP objects in gray. A DHCP object can be an DHCP address range, fixed address, reservation, host configured for DHCP, or roaming host with an allocated IP address.
- **Name**: The name of the object type associated with the IP address. For example, if the IP address belongs to a host record, this field displays the hostname.
- **MAC Address**: The discovered MAC address of the host. This is the unique identifier of a network device. The discovery acquires the MAC address for hosts that are located on the same network as the Grid member that is running the discovery. This can also be the MAC address of a virtual entity on a specified vSphere server.
- **Bridge Domain**: The name of the discovered bridge domain. This column will display values only for IP addresses that are discovered from Cisco APIC through Network Insight or NetMRI. If discovered by NetMRI, the value will be populated through IPAM Sync. Otherwise, this column will be blank. For information about how to configure Cisco APIC, see *Configuring Cisco Application Policy Infrastructure Controller (APIC)*.
- **Tenant**: The name of the discovered tenant. This column will display values only for IP addresses that are discovered from Cisco APIC through Network Insight or NetMRI. If discovered by NetMRI, the value will be populated through IPAM Sync. Otherwise, this column will be blank. For information about how to configure Cisco APIC, see *Configuring Cisco Application Policy Infrastructure Controller (APIC)* .
- **EPG**: The name of the end point group. This column will display values only for IP addresses that are discovered from Cisco APIC through Network Insight or NetMRI. If discovered by NetMRI, the value will be populated through IPAM Sync. Otherwise, this column will be blank. For information about how to configure Cisco APIC, see *Configuring Cisco Application Policy Infrastructure Controller (APIC)*.
- **DHCP Client Identifier**: For an IPv4 address, the DHCP Unique Identifier of the host.
- **Port Reservation**: Lists any Port Reservation from Network Insight that is associated with the IP address. The information takes the form of *device name*:*interface name*.
- **VIP**: Indicates when the IP address is operating as a Virtual IP and operates in router redundancy.
- **Status**: The current status of the corresponding record. This can be **Used** or **Unused**.
- **Type**: The object type that is associated with the IP address. For example, this can be **Broadcast**, **Lease, IPv4 DHCP Range** or **Fixed Address**.
- **Discover Now**: Indicates when the network is undergoing a current discovery process. A "Pending" icon appears in this column when you start the discovery and displays **Completed** after the completion of the discovery process.
- **Usage**: Indicates whether the IP address is configured for DNS or DHCP.
- **Lease State**: The lease state of the IP address. This can be one of the following: **Free**, **Backup**, **Active**, **Expired, Released**, **Abandoned**, **Reset**, **BootP**, **Static**, **Offered**, or **Declined**.
- **User Name**: The name of the user who received the lease for the IP address.
- Task Name: The name of the task that collected the discovered data. It is usually the ID or task name that collected the data. It is defined on the corresponding Trinzic NetMRI appliance when you import the discovered data to the NIOS appliance. The task name should be defined in the vDiscovery task manager for vDiscovery.
- **Comment**: Additional information about the IP address.
- **First Discovered**: The timestamp when the IP address was initially discovered. This data is read-only.
- **Last Discovered**: The timestamp when the IP address was last discovered. This data is read-only.
- **OS**: The operating system of the discovered host. Sometimes this field also displays the percentage of certainty about the discovered OS. The OS value can be one of the following:
    - **Microsoft**: This value is displayed for all discovered hosts that have a non-null value in the MAC addresses using the NetBIOS discovery method.
    - A value that a TCP discovery returns.
    - The OS of a virtual entity on a vSphere server.

    - DHCP fingerprint.
    - Information about the device OS from Network Insight. For network devices, OS information is collected by SNMP. Depending on the device SNMP settings, this field can display the OS version or remain empty (rarely).
      For end hosts, the OS information is collected using active TCP fingerprint scanning by nmap. To enable this, select the following checkboxes in the Grid basic discovery properties: **Port Scanning** and **Profile Device**.
      For Windows end hosts, you can enable Network Insight to use the SMB v1 protocol during fingerprinting. To enable this, go to **Grid Discovery Properties** -> **Advanced** and add port 445 with smb1 service and TCP type.
      If nmap fails to detect the OS precisely, a list of most likely guesses is displayed. The end host's **Device Type** field always displays the OS family.
- **NetBIOS Name**: The returned NetBIOS name from the last discovery.
- **Device Type(s)**: The type of device associated with the IP address, if any: Router, Switch-Router, and other types.
- **Open Port(s)**: Lists any TCP/UDP ports that are open on the current IP address.
- **VRF Name**: The name of the discovered VRF to which the interface with this IP address belongs, as discovered by Network Insight or NetMRI.
- **VRF Description**: The description of discovered VRF.
- **VRF RD**: The address of the route distinguisher of discovered VRF.
- **BGP AS**: The number of the discovered BGP Autonomous System that uses the IP address.
- **Discovered Name**: The name of the discovered IP address, if any was previously assigned by an administrator.
- **Discoverer**: The identity of the appliance that discovered the IP address.
- **Fingerprint**: The name of the DHCP fingerprint or vendor ID of the network device that was identified through DHCP fingerprint detection. This field displays **No Match** for devices that do not have any DHCP fingerprint information. For information about DHCP fingerprints, see *DHCP Fingerprint Detection*.
- **Site**: The site to which the IP address belongs. This is a predefined extensible attribute.

Disabled (hidden): Indicates whether the DHCP or DNS record is disabled.

> ⚠ Note
>
> For an IP address that falls within a DHCP range, Grid Manager displays extensible attribute values for the DHCP range and fixed address or host record. When you view the same IP address in the **DHCP** tab however, Grid Manager displays only the extensible attribute values associated with the fixed address or host record, but not the DHCP range. For example, when you define extensible attribute **State** with the value **California** for DHCP range 1.0.0.1 – 1.0.0.5, and then define extensible attribute **State** with the value of **Alaska** for fixed address 1.0.0.3, Grid Manager displays both **California** and **Alaska** in the **State** field for IP address 1.0.0.3 in the IP Address List view. However, when you view 1.0.0.3 from the **DHCP** tab, the **State** field displays **Alaska** only

IP List Neighbor Information

Other values are available for display in the IP list. Most of the hidden columns consist of information discovered by Grid Manager, to identify devices connected to the network interfaces neighboring the listed IP addresses. These data columns are hidden and must be enabled for display by selecting the **Visible** checkbox for each field when editing the columns for the table. Most of this information does not appear unless a device is recognized in IPAM or is in managed state under IPAM. Additional IP list neighbor information includes:

- **Discovered Name**: The discovered name of the device bound to the IP address. The IP address may be just one of several or many IP addresses bound to the device on a specific interface.
- **Discovered MAC Address**: The discovered MAC of the interface bound to the IP address.
- **Discoverer**: Name of the Infoblox appliance that discovered the IP address and its associated information.
- **Attached Device Description**: Listing of the device neighboring to the IP address.
- **Attached Device Address**: The IP address of the device neighboring to the current IP.
- **Attached Device Name**: The host name of the device neighboring to the current IP.
- **Attached Device Vendor**: The vendor of the device neighboring to the current IP address.
- **Attached Device Model**: The vendor's model number for the device neighboring to the current IP address.

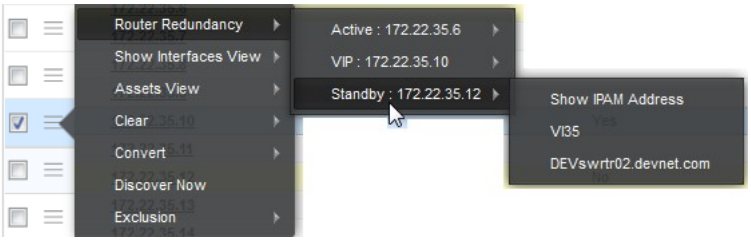
- **Attached Device Port Description**: An admin-provided description for the neighboring IP address, if any is discovered.
- **Attached Device Port Name**: The name of the switch port or port channel connected to the end device. For Cisco devices with virtual port channel configured, this field also displays the list of physical interfaces that form the virtual port channel. The first vPC peer's IP address is displayed in the field **Attached Device Address** mentioned above, and other vPC data is displayed in the **Attached Device Port Name** field in the following format:
  virtual port channel name: list of physical interfaces of the first device, IP address of the second device/virtual port channel name: list of physical interfaces of the second device
  Example:
  An end device is connected to devices 192.168.1.2 and 192.168.1.3 using vPC. The first vPC peer's IP address 192.168.1.2 is displayed in the **Attached Device Address** field. Other vPC data is displayed in the **Attached Device Port Name** field:
  `port-channel-1: Ethernet4/11, Ethernet5/11, 192.168.1.3/port-channel-1: Ethernet3/12, Ethernet4/12`
- **Attached Device Type**: Indicates the device type for the neighboring device: **Router**, **Switch-Router**, **Switch**, and other types.
- **Port Duplex**: Discovered Duplex setting for the neighboring port, when applicable.
- **Port Link**: Indicates the state of the link: **Connected** or **Disconnected**.
- **Port Speed**: Indicates the speed of the network connection.

Using the List Panel Action Menu

The IP address **List** panel provides an Action icon with a series of menu options for features related to IP address management and IP data management under IPAM. Menu choices change based upon the context and the current state of IP addresses in the table; features available in the List panel action menu include the following:

- (*Applies only with Network Insight*) View **Router Redundancy** information for discovered IP addresses in an IPv4 network. For active VIPs, you will see several sets of related information:

Virtual IPs and discovered redundancy information



- **Active**: lists the active interface in the redundancy pair;
- **VIP**: The Virtual IP for the router redundancy pair;
- **Standby**: The standby IP interface for the router redundancy.

Discovery of all three IP components of the Router Redundancy instance also provides related information for all three IP entities:

- **Show IPAM Address**: opens the IPAM page to the listed IP address;
- **VIP**: Opens the virtual interface in the host device's Interfaces page;
- **Associated router**: The third item lists the hostname router for each of the three IP address entities comprising the redundancy instance. The currently active router will be identified with the **Active** and **VIP** objects; the second **Standby** router is identified with the **Standby** IP address.
- **Show Interfaces View**: Displayed only if there is a device interface associated with this IP address. It displays the interface name. Clicking the interface name opens the interfaces list view for that device. The interfaces list view is pre-populated with the interface name.

- **Assets View –> Show Assets**: Opens the IP address's list of network assets that are connected to the IP address or reachable through the IP address in some way, such as through a routable path. Provides a quick look at basic connectivity provided by the selected IP address; for more information about Assets views, see *Viewing Assets Associated with Discovered Devices*.
- **Clear**: Allows you to remove data associated with the currently selected IP address, form three categories:
  - **Clear Lease**: If the IP interface gets its configuration from a DHCP lease, choosing this option will clear the IP's DHCP configuration. Applies only to IP addresses that are fully managed through IPAM;
  - **Clear Unmanaged Data**: Clears the discovered data for an unmanaged IP address;
  - **Clear Discovered Data**: Clears discovered data from the IPAM object, and re-launches discovery afterwards if necessary.
- **Convert**: Conversion feature to convert the currently unmanaged IP address to an object fully managed by IPAM: **Network**, **To Host**, **To A Record**, **To PTR Record**, or **To Fixed Address**. (For related information, see *Managing Discovered Data*, *About Host Records*, *Managing A Records* and *Managing PTR Records.*)
- **Discover Now**: Requests Grid Manager to execute discovery on the selected IP address.
- **Exclusion**: Exclude or disable exclusion of the current IP address from discovery. For related information, see *Excluding IP Addresses from Discovery*.
- **Show Active Users**: Displays all the users who are currently active on the selected network. For information, see *Viewing Active Network Users*.

Additional IP List Information

You can display all available extensible attributes. You can also sort the list of IP addresses in ascending or descending order by **IP Address** only. If you enabled the IP Discovery feature, you can configure the IP List panel to display discovered data and fields imported from NetMRI appliances. For information about integrating discovered data from NetMRI, see *Integrating Discovered Data From NetMRI*.
You can select an IP address from the List panel and view the following information about it:

- General information, as described in *IP Address Header Panel*.
- Data retrieved through a network discovery or integrated from a PortIQ appliance, as described in *Viewing Discovered Data*.
- The records associated with the IP address, as described in *Related Objects.*
- Audit history, as described in *Audit History*.
- Detailed lease information, as described in *Viewing Detailed Lease Information*.

You can also do the following from the IP List panel:

- Click **Go to DHCP View** to view DHCP properties of a selected network. For information, see *Modifying IPv4 Networks*.
- Click the Ping icon to ping a selected IP address. For information, see *Pinging IP Addresses*.

Filtering the IP Address List

You can filter the IP address list, so it displays only the IP addresses you need. You can filter the list based on any combination of extensible attributes and the parameters displayed in the IP address list, such as usage and type. When you expand the list of available fields you can add to the filter, note that the extensible attributes are those with the gray background.

IP Address Header Panel

When you select an IP address from the IP Map or List panel, Grid Manager displays information about the highest priority object associated with the IP address. Depending on the object type, Grid Manager displays all or some of the following information. For example, if the highest priority object is a fixed address, Grid Manager displays only the object type, MAC address, lease state, and comment of the object.

- Type: The object or record type, such as A record, PTR record, or host record.

- Name: The name of the object. For example, if the IP address belongs to a host record, this field displays the hostname. The appliance highlights disabled DHCP objects in gray. A DHCP object can be a DHCP address range, fixed address, reservation, host configured for DHCP, or roaming host with an allocated IP address.
- MAC: The MAC address of the network device associated with the IP address.
- **Lease Sate**: The current status of the DHCP lease.
- Comment: Comments about the IP address.

Discovered Data

The **Discovered Data** tab displays discovered data through a network discovery or integrated from PortIQ and NetMRI appliances. For information about viewing discovered data, see *Viewing Discovered Data*.

Related Objects

The Related Objects tab displays the following information about the records associated with the IP address:

- **Name**: The name of the object. For example, if the IP address belongs to a host record, this field displays the hostname. The appliance highlights disabled DHCP objects in gray. A DHCP object can be a DHCP range, fixed address, reservation, host configured for DHCP, or roaming host with an allocated IP address.
- **Type**: The object type, such as DHCP lease, host, A record, and bulk host.
- **Comment**: Information about the object. You can also select the following for display:
- **DNS view**: The DNS view to which the object belongs. You can do the following in this tab:
- Add a resource record. You can select the following from the drop-down list:
    - Host Record—For information, see *Adding Host Records*.
    - Range—For information, see *Adding IPv4 Address Ranges.*
    - Fixed Address—For information, see *Adding IPv4 Fixed Addresses.*
    - Reservation—For information, see *Adding IPv4 Reservations.*
    - A Record—For information, see *Adding A Records.*
    - PTR Record—For information, see *Adding PTR Records*.
- Edit the properties of the selected object. Depending on the type of object, Grid Manager displays the corresponding editor for the object. For example, if the selected object is a fixed address, Grid Manager displays the fixed address editor. When you select a lease object, Grid Manager displays the lease viewer.
- You can also modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*. Delete a selected object or multiple objects.
- When you select a lease object and click the Show Details icon, you can view the lease start and end dates.
- Depending on the object type, you can convert a selected object to one of the following:
    - **Reservation**
    - **Host**
    - **Fixed Address**
- View detailed lease information about the IP address, as described in *Viewing Detailed Lease Information.*
- Print and export the information in the Related Objects table.

Audit History

By default, the Audit History tab displays the following information about the last five actions performed on the selected IP:

- **Timestamp**: The day, date, and time of the operation.
- **Action**: The type of operation that was performed by the administrator.
- **Object Type**: The object type of the entry.
- **Object Name**: The name of the object.
- **Admin Name**: The name of the administrator who performed the operation.
- **Message**: The description of the administrative activity.

⚠ Note

If you change the IP address of an existing record to a new one in the **IP MAP** tab when the Grid **Audit Logging** is set to *Brief*, then NIOS will not display modification or transition details about the new IP address in this tab. You can only view subsequent modifications and deletions to the new IP address. However, you can view the audit log history and transition details of the old IP address, but you cannot view the initial transition from an old IP address to the new IP address.

Managing IPv4 Addresses

You can do the following from the IP Map and List panels:

- Add IP addresses to existing hosts. For information, see Adding IP Addresses to Existing Host Records below.
- Clear unmanaged IP addresses. For information, see Clearing Unmanaged Data see below.
- Convert objects to other object types. For information, see *Converting Objects Associated with IP Addresses.*
- Reclaim IP addresses. For information, see *Reclaiming Objects Associated with IPv4 and IPv6 Addresses.*
- Ping IP addresses. For information, see *Pinging IP Addresses*.
- Configure and run a network discovery. For information, see *IP Discovery and vDiscovery*.
- Resolve discovery conflicts. For information, see *Resolving Conflicting Addresses*.
- Clear discovered data. For information, see *Clearing Discovered Data.*

Adding IP Addresses to Existing Host Records

You can add unused and unmanaged addresses, including all their information, to existing host records. When you add an unmanaged address to a host record, the appliance adds the discovered data to the host record. You can select the desired host to which you want to add the unmanaged address.
To add an unmanaged IP address to an existing host record:

1. From the IP Map or List panel, select an IP address, and then click **Add** -> **Add to Existing Host** from the Toolbar.
2. In the *Select Host* dialog box, do the following:
    - In the table, select the host to which you want to add the selected IP address. You can also use the filters or the **Go To** field to narrow down the host list. For information, see *Using Filters* and *Using the Go To Function*.
    - Click the Select icon.
      Grid Manager displays the *Host Record* editor.
3. In the *Host Record* editor, update the host properties.
4. Save the configuration and click **Restart** if it appears at the top of the screen. To close the editor without saving the changes, click the **Close** icon.

Clearing Unmanaged Data

You can clear the status of unmanaged data at the network and IP address levels. When you clear an unmanaged address, the status of the IP address changes to **Unused**. An unmanaged address is an IP address with a discovered host, is not previously known to the appliance, and does not have an A record, PTR record, fixed address, host address, lease, or is not within a DHCP range. You can change an unmanaged address to a host, a DHCP fixed address, an A record, or a PTR record. You can also clear the unmanaged data associated with the address.
To clear unmanaged data:

1. From the IP Map or List panel, select the IP address for which you want to clear unmanaged data, and then click **Clear** -> **Clear Unmanaged Data** from the Toolbar. You can select multiple IP addresses.
2. In the *Clear Unmanaged data* dialog box, click **Yes**.

Viewing Router Redundancy Information for Virtual IPs (VIPs)

1. From the **Data Management** tab, click **CSV Job Manager** from the Toolbar.
2. In **CSV Job Manager**, click the **CSV Import** tab and select the import job that you want to delete. Click the Action icon

and select **Delete** or click the Delete pending job icon.

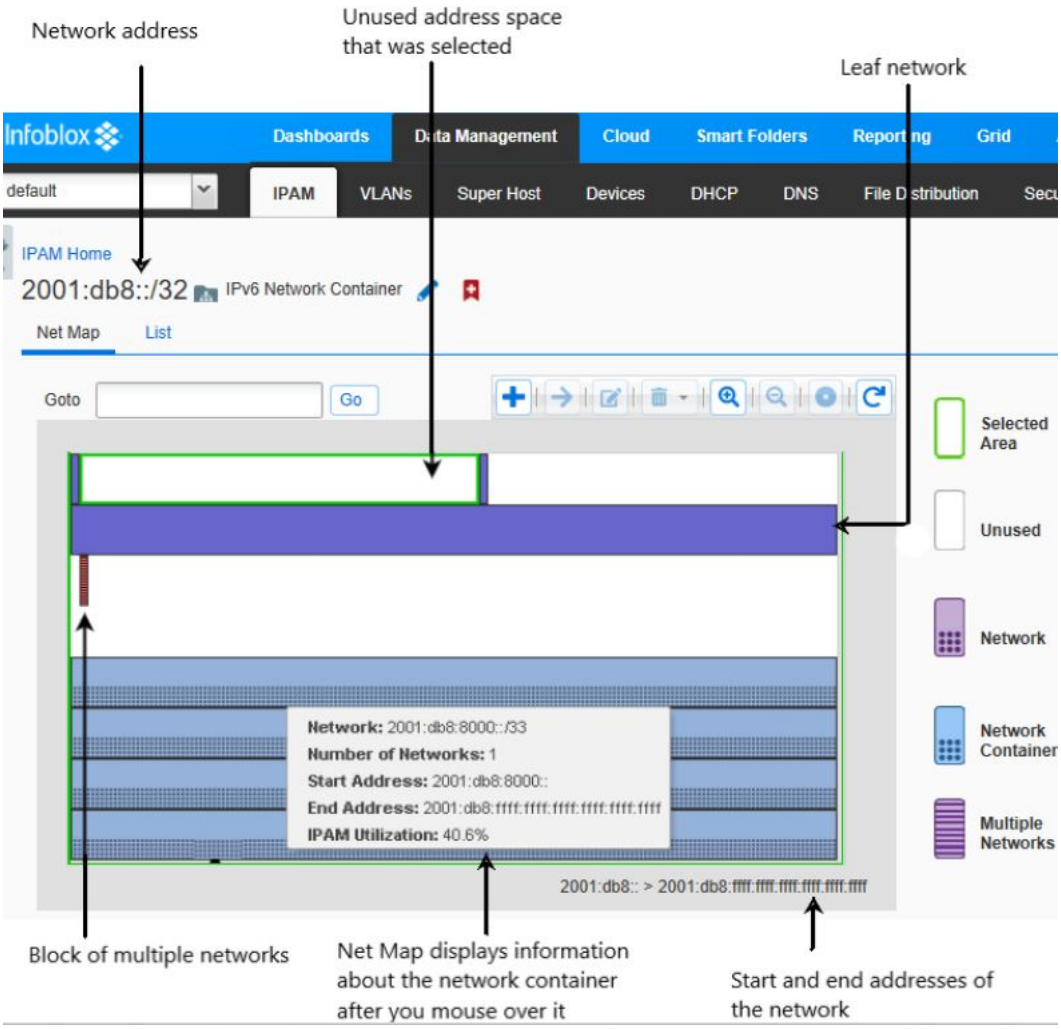
Managing IPv6 Networks

In Grid Manager, you can use the IPv6 Net Map (network map) and List panels to manage your IPv6 network infrastructure. After you select a network container from the IPAM tab, Grid Manager displays it in the Net Map panel, by default. The Net Map panel provides a graphical view of your networks and has a number of features that simplify network management. The List panel displays the networks in table format.
You can always switch your view of a network container between the Net Map and List panels. Grid Manager keeps track of which panel you last used. When you select a network container, Grid Manager displays it in the Net Map or List panel, depending on which one you last used. For information about each panel, see *IPv4 Network Map* and *IPAM Home*.
You can use Grid Manager to manage IPv6 networks and their AAAA, PTR and host resource records. You can configure IPv6 networks and track IP address usage in those networks. You can also split and join IPv6 networks, when necessary.

IPv6 Network Map

After you select an IPv6 network container from the IPAM tab, Grid Manager displays it in the IPv6 Net Map (network map) panel, by default. Just like the IPv4 Net Map, the IPv6 Net Map provides a high-level view of the network address space. You can use Net Map to design and plan your network infrastructure, and to configure and manage individual networks.
The Net Map panel presents a complete view of the network space, including the different types of networks that are in it and its unused address space. IP addresses that belong to a network are blocked off. Each color-coded block represents a network container, a leaf network, or a block of networks that are too small to be displayed individually in the map. For example, in a /64 or /96 network, networks smaller than /76 or /108 respectively and that are beside each other are represented as a multiple network block. In addition, the fill pattern of the blocks indicates their utilization. Therefore, you can quickly evaluate how many networks are in a network container, their relative sizes, utilization, and how much space you have left.

As you mouse over areas of the map, it displays IP information about the area. Net Map also has a zoom feature that allows you to enlarge or reduce your view of a particular area.
The below figure displays the network map of a 1111::/16 network, which is a network container that has network containers and leaf networks.
IPv6 Network Map



Displaying Network Information

As shown in the figure IPv6 Network Map above, as you mouse over the map, Net Map displays IP information about the area. When you mouse over an unused area, Net Map displays the following information:

- The start and end IP address
- The largest possible network
- The number of /64 networks that can fit in that space

When you mouse over a network container, Net Map displays the following information:

- Network address and netmask
- The first and last IP address of the network
- The number of networks in that block
- IPAM utilization

When you mouse over a network, Net Map displays the following information:

- Network address and netmask
- The first and last IP address of the network

When you mouse over a block of multiple networks, Net Map displays the following information:

- The start and end IP address of that block of networks
- The number of networks in that block

Zooming In and Out

Use the zoom function to enlarge and reduce your view of a selected area. You can zoom in on any area in your network. You can zoom in on an area until it displays 128 addresses per row, for a total of 1024 addresses for the map. When you reach the last possible zoom level, the Zoom In icon in the Net Map task bar and the menu item are disabled.
After you zoom in on an area, you can click the Zoom Controller icon to track where you zoomed in. The Zoom Controller lists all the areas that you zoomed in and updates its list dynamically. You can click an item on the list to view that area again. Click the Zoom Controller again to close it.
To select an area and zoom in:

1. Right-click and select **Zoom In**, or click the Zoom In icon in the Net Map task bar. The pointer changes to the zoom in selector.
2. Select a starting point and drag to the end point. The starting point can be anywhere in the map. It does not have to be at the beginning of a network.
   Net Map displays a magnified view of the selected area after you release the mouse button. As you mouse over the zoomed in area, Net Map displays IP information about it.
3. You can do the following:
   - Select an area and zoom in again.
   - Add a network. If you zoom in on an area and click Add without selecting an open area first, Net Map selects the area where it can create the biggest possible network in that magnified area.
   - Select a network and perform any of the following operations:
     - Edit its properties.
     - Open it to display its IP List.
     - Delete it immediately, or schedule its deletion.
   - Right-click and select **Zoom Out**, or click the Zoom Out icon in the Net Map task bar. Each time you click **Zoom Out**, Net Map zooms out one level and the Zoom Controller is updated accordingly.

Net Map Tasks

From Net Map, you can create IPv6 networks, and evaluate and manage your network resources according to the needs of your organization. You can do the following:

- Zoom in on specific areas, as described in Zooming In and Out above.
- Use the **Go to** function to find a network in the current zoom level of Net Map.
- Add a network, as described in Adding a Network from Net Map below.
- Select a network and view IP address list, as described in *Viewing IPv6 Data.*
- Select a network and edit its properties, as described in *Modifying IPv4 and IPv6 Network Containers and Networks*.
- Split a network, as described in Splitting IPv6 Networks into Subnets below.
- Join networks, as described in Joining IPv6 Networks below.
- Delete one or multiple networks, as described in *Discovering Networks (Under Network Insight only)*.
- Switch to the List view of the network. For information, see IPv6 Network List below.
  - When you select one or more networks in Net Map and then switch to the List view, the list displays the page with the first selected network.
  - If you select one or more networks in the List view and then switch to the Net Map view, the first network is also selected in Net Map. Although, if you select a network in the List view that is part of a Multiple Networks block in Net Map, it is not selected when you switch to the Net Map view.

Adding a Network from Net Map

When you create networks from Net Map, you can view the address space to which you are adding a network, so you can determine how much space is available and which IP addresses are not in use. When you mouse over an open area, Net Map displays useful information, such as the largest possible network that fits in that area. In addition, you can create networks without having to calculate anything. When you add a network, Net Map displays a netmask slider so you can determine the appropriate netmask for the size of the network that you need. As you move the slider, it displays network information, including the total number of addresses. After you select the netmask, you can even move the new network around the open area to select another valid start address.
To add a network from the Net Map panel:

1. Do one of the following:
    - Click the Add icon.
      Net Map displays the netmask slider and outlines the open area that can accommodate the largest network.
    - Select an open area, and then click the Add icon.
      Net Map displays the netmask slider and outlines the largest network that you can create in the open area that you selected.
2. Move the slider to the desired netmask. You can move the slider to the netmask of the largest network that can be created in the open area. You can also move the slider to the smallest network that can be placed in the current zoom level of Net Map.
   As you move the slider, Net Map displays the netmask. The outline in the network map also adjusts as you move the slider. When you mouse over the outline, it displays the start and end address of the network.
3. After you set the slider to the desired netmask, you can drag the new network block around the open area to select a new valid starting address. You cannot move the block to a starting address that is invalid.
4. Click **Launch Wizard** to create the network.
   The *Add Network* wizard displays the selected network address and netmask.
5. You can add comments, automatically create reverse mapping zones, and edit the extensible attributes. (For information, see *Adding IPv6 Networks*.)
6. Save the configuration and click **Restart** if it appears at the top of the screen. Grid Manager updates Net Map with the newly created network.

Viewing Network Details

From Net Map, you can focus on a specific network or area and view additional information about it. If you have a network hierarchy of networks within network containers, you can drill down to individual leaf networks and view their IP address usage.

1. Select a network or area.
2. Click the Open icon.
    - If you selected a network container, Grid Manager displays it in the Net Map panel. You can drill down further by selecting a network or open area and clicking the Open icon again.
    - If you selected a block of multiple networks, Grid Manager displays the individual networks in the Net Map panel. You can then select a network or open area for viewing.
    - If you selected a leaf network, Grid Manager displays it in the Network List panel.
    - If you selected an open area, Grid Manager displays an enlarged view of that area in the Net Map panel. This is useful when you are creating small networks in an open area.

IPv6 Network List

The Network list panel is an alternative view of an IPv6 network hierarchy. For a given network, the panel shows all the networks of a selected network view in table format. A network list displays only the first-level subnets. It does not show further descendant or child subnets. You can open a subnet to view its child subnets. Subnets that contain child subnets are displayed as network containers. If the number of subnets in a network exceeds the maximum page size of the table, the network list displays the subnets on multiple pages. You can use the page navigation buttons at the bottom of the table to navigate through the pages of subnets.
The IPAM home panel displays the following:

- **Network**: The network address.
- **Comment**: Information you entered about the network.
- **IPAM Utilization:** For a network, this is the percentage based on the IP addresses in use divided by the total addresses in the network. You can use this information to verify if there is a sufficient number of available addresses in a network. The IPAM utilization is calculated approximately every 15 minutes.
- **Site**: The site to which the IP address belongs. This is a predefined extensible attribute.
- **Active Users**: The number of active users on the selected network. You can select the following columns for display:
- **Disabled**: Indicates whether the network is disabled.
- **Leaf Network**: Indicates whether or not the network is a leaf network.
- Other available extensible attributes

You can sort the list of subnets in ascending or descending order by columns. For information about customizing tables in Grid Manager, see *Customizing Tables*.
You can also modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.

Tip: If you select a network from the list and switch to the Net Map panel, the network is also selected in the network map.

Filtering the Network List

You can filter the network list, so it displays only the networks you need. You can filter the list based on certain parameters, such as network addresses, comments and extensible attributes. When you expand the list of available fields you can use for the filter, note that the extensible attributes are those with a gray background.

Splitting IPv6 Networks into Subnets

You can create smaller subnets simultaneously within a network by splitting it. You do not have to configure each subnet individually. You can create smaller subnets with larger netmasks. A larger netmask defines a larger number of network addresses and a smaller number of IP addresses.
Note that you cannot split a network that is part of a shared network. To split an IPv6 network:

1. From the **Data Management** tab, select the **IPAM** tab -> *network* checkbox, and then click **Split** from the Toolbar.
2. In the *Split Network* editor, do the following:
    - **Address**: Displays the network address. You cannot modify this field.
    - **Net mask**: Specify the appropriate netmask for each subnet.
    - **IPv6 Prefix Collector Network**: If you split a network with prefix delegations that are not tied to specific addresses, specify the network in which all prefix delegations are assigned. If you leave this field blank, the server assigns all prefix delegations that are not tied to specific addresses to the first network.
    - **Immediately create**: Select one of the following:
        - **Only networks with ranges and fixed addresses**: Adds only the networks that have DHCP ranges and fixed addresses.
        - **All possible networks**: Adds all networks that are within the selected netmasks. You can select this option only when you increase the CIDR by 8 bits.
    - **Automatically create reverse-mapping zone**: Select this checkbox to have the appliance automatically create reverse-mapping zones for the subnets. This function is enabled if the netmask of the network is a multiple of four, such as 4, 12 or 16.
3. Click **OK**.

Joining IPv6 Networks

Joining multiple networks into a larger network is the opposite of splitting a network. You can select a network and expand it into a larger network with a smaller netmask. A smaller netmask defines fewer networks while accommodating a larger number of IP addresses. Joining or expanding a network allows you to consolidate all of the adjacent networks into the expanded network. Adjacent networks are all networks that fall under the netmask of the newly-expanded network.
To join or expand a network:

1. From the **Data Management** tab, select the **IPAM** tab -> *network* checkbox, and then click **Join** from the Toolbar.
2. In the *Join Network* editor, do the following:
    - **Address**: Displays the network address. You cannot modify this field.
    - **Netmask**: Enter the netmask of the expanded network.

- **Automatically create reverse-mapping zone**: Select this checkbox to configure the expanded network to support reverse-mapping zones . The appliance automatically creates reverse-mapping zones only if the netmask is between /4 through /128, in increments of 4 (that is, /4, /8, /12, and so on until /128).

3. Click **OK**.

Viewing IPv6 Data

To the configured IP addresses in an IPv6 network:
by selecting an IPv6 leaf network from the Network List panel

- For a leaf network that is not in a network container, from the **Data Management** tab, select the **IPAM** tab, and then click the IPv6 network you want to view.
- For a leaf network that is in a network container, from the **Data Management** tab, select the **IPAM** tab → *network_container -> network*.

Grid Manager lists the configured IPv6 addresses. You can export and print the list. It displays the following information about each IP address:

- **IP Address:** The name of the IPv6 DHCP object, which can be a DHCP range, fixed address, host configured for DHCP, or a roaming host with an allocated IP address.
- **Name:** The name of the record associated with the IP address.
- **DUID:** The DHCP Unique Identifier (DUID) of the device that was assigned the IP address.
- **Status:** The status of the IPv6 object, such as Used or Unused.
- **Type:** The object type associated with the IP address, such as **AAAA record**, **IPv6 Fixed Address**, or **Unmanaged**.
- **Usage:** Indicates whether the IPv6 address is configured for DNS or DHCP.
- **Exclude**: (*Applies only with Network Insight*) Denotes whether the IP is excluded from discovery.
- **Lease State:** (*Applies only with Network Insight*) The lease state of the record, such as Active.
- User Name: The name of the user who received the lease for the IP address.
- **First Discovered**: (*Applies only with Network Insight*) The date and timestamp of the first occasion that NIOS discovered the IP address.
- **Last Discovered**: (*Applies only with Network Insight*) The date and timestamp of the last occasion that NIOS discovered the IP address.
- **OS**: The operating system of the IP.
- **NetBIOS Name**: The returned NetBIOS name from the last discovery.
- **Device Type(s)**: Shows the device type for the device associated with the IP address.
- **Fingerprint**: The name of the DHCP fingerprint or vendor ID of the network device that was identified through DHCP fingerprint detection. This field displays **No Match** for devices that do not have any DHCP fingerprint information. For information about DHCP fingerprints, see *DHCP Fingerprint Detection*.
- **Comment:** Displays comments about the record.
- **Site**: The site to which the IP address belongs. This is a predefined extensible attribute.

You can display all available extensible attributes. You can also sort the list of IP addresses in ascending or descending order by **IP Address** only.
You can drill down further and view the records associated with an IP address. To view the associated records of an IP address, select it and Grid Manager displays information about the IP address in the **Related Objects** and **Audit History** tabs.

Related Objects

Grid Manager displays the following information about the records associated with the IP address:

- **Name**: The record name. For example, if the IP address belongs to a host record, this field displays the hostname.
- **Type**: The object type. For example, AAAA Record, PTR Record, Host Record, IPv6 Fixed Address.
- **Comment:** Additional information that was entered in the record about the IP address.

Audit History

Grid Manager displays the following information about the last five actions performed on the selected IP:

- **Timestamp**: The day, date, and time of the operation.
- **Action**: The type of operation that was performed by the administrator.
- **Object Type**: The object type of the entry.
- **Admin Name**: The name of the administrator that performed the operation.
- **Message**: Description of the administrative activity.

Filtering the IP Address List

You can filter the IP address list, so it displays only the IP addressees you need. You can filter the list based on any combination of extensible attributes and the parameters displayed in the IP address list, such as usage and type. When you expand the list of available fields you can add to the filter, note that the extensible attributes are those with the gray background.

Managing IPv4 and IPv6 Addresses

Grid Manager uses IP addresses as the entry point to the data set containing Infoblox host, DNS, DHCP, and other information related to that address. You can view the data, modify it, assign extensible attributes to the objects associated with the address, and convert DHCP lease types, such as changing a currently active dynamic lease to a fixed address or host record.
You can view and manage IPv4 address data in the IP Map panel, and view and manage IPv4 and IPv6 data in the IP List panel. You can do the following for IPv4 and IPv6 data from the IP List panel:

- Convert objects to other object types.
- Reclaim IP addresses.
- Ping IP addresses.
- Clear DHCP leases.

You can also print and export in CSV format the information displayed in any panel that supports these functions.

Converting Objects Associated with IP Addresses

The NIOS appliance provides a simple mechanism for converting unmanaged IP addresses to resource records, such as host records and A or AAAA records. You can also convert the active lease of a dynamically assigned IPv4 or IPv6 address to a fixed address or host, and convert an IPv4 lease to an IPv4 reservation. Using the conversion mechanism, you can keep the existing information of a network device during the conversion.
The appliance supports the following conversions for IPv4 objects:

- DHCP leases to fixed addresses, reservations, or host records
- Fixed addresses to reservations or host records
- Unmanaged addresses to host records, A records, PTR records, or fixed addresses
- A records to host records
- PTR records to host records

The appliance supports the following conversions for IPv6 objects:

- DHCP leases to fixed addresses or host records
- Fixed addresses to host records
- AAAA records to host records
- IPv6 PTR records to host records

Note

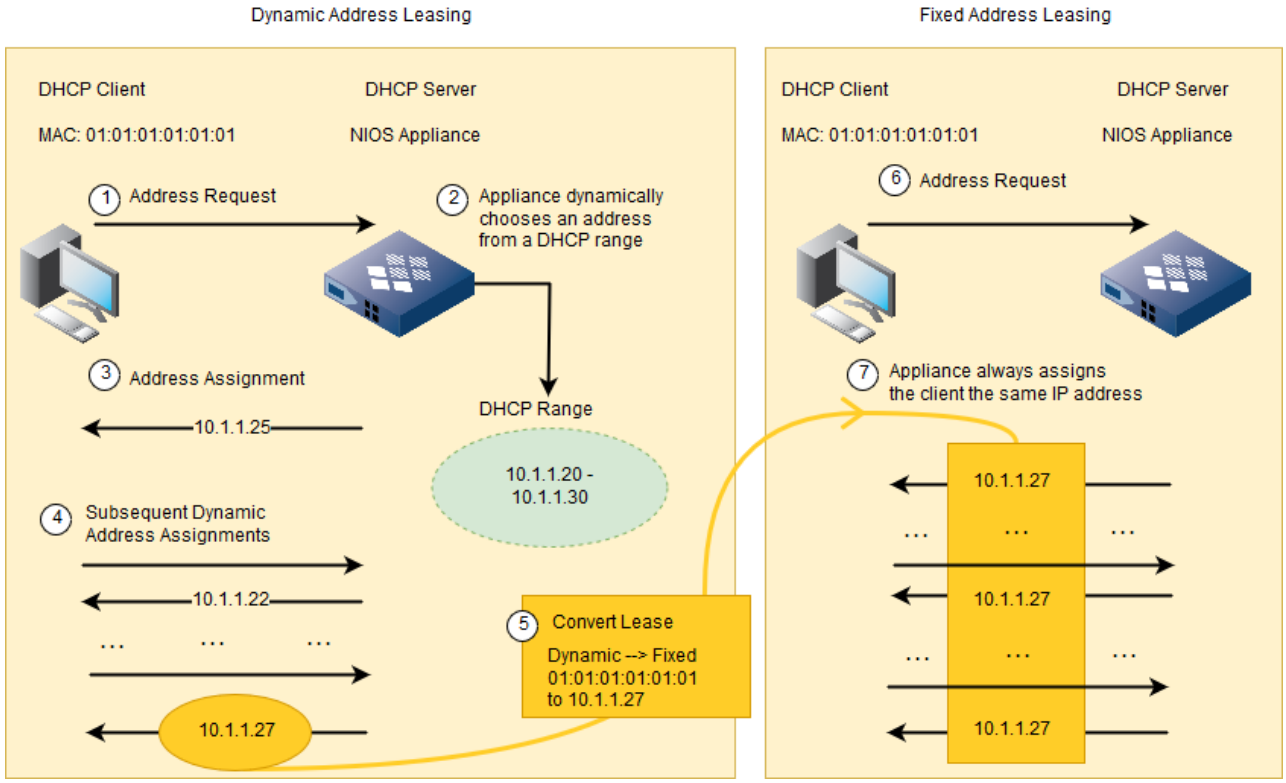
You cannot convert unmanaged IP addresses or leases served by Microsoft DHCP servers to host records.

Converting DHCP Leases

To create a fixed address, you bind an IPv4 address to a MAC address or an IPv6 address to a DUID. You can make that binding by converting an active dynamically leased address to a fixed address. The lease conversion transforms the temporary binding between the IPv4 address and MAC address or the IPv6 address and DUID in the dynamic lease to a persistent one. The lease must be active so that the NIOS appliance has an IPv4-to-MAC address or IPv6-to-DUID binding to convert into a fixed address.
The appliance uses the following rules when converting a DHCP lease:

- If an IPv4 DHCP lease is converted to a fixed address, the appliance copies the client identifier to the fixed address, based on information in the lease. If the appliance finds the client identifier in the lease information, the appliance includes it when it creates the host. If it finds the MAC address, the appliance includes it when it creates the host. If it finds both, the appliance includes only the MAC address (default) when it creates the host.
- If an IPv6 DHCP lease is converted to a fixed address, the appliance copies the DUID to the fixed address.
- If you try to convert an IPv4 DHCP lease or a fixed address with a client identifier, not a MAC address, to a host, the appliance displays an error message in the host editor. This ensures that you do not attempt this operation and lose the data.
- You cannot create two IPv4 fixed addresses with the same client identifier or MAC address in the same network. You cannot create two IPv6 fixed addressed with the same DUID in the same network.
- If the appliance receives a second IPv4 DHCP request with the same client identifier, it provides the same fixed IP address if the lease is still binding.

The below figure illustrates converting a dynamic IPv4 lease to a fixed lease.
Converting a Dynamic IPv4 Lease to a Fixed Lease



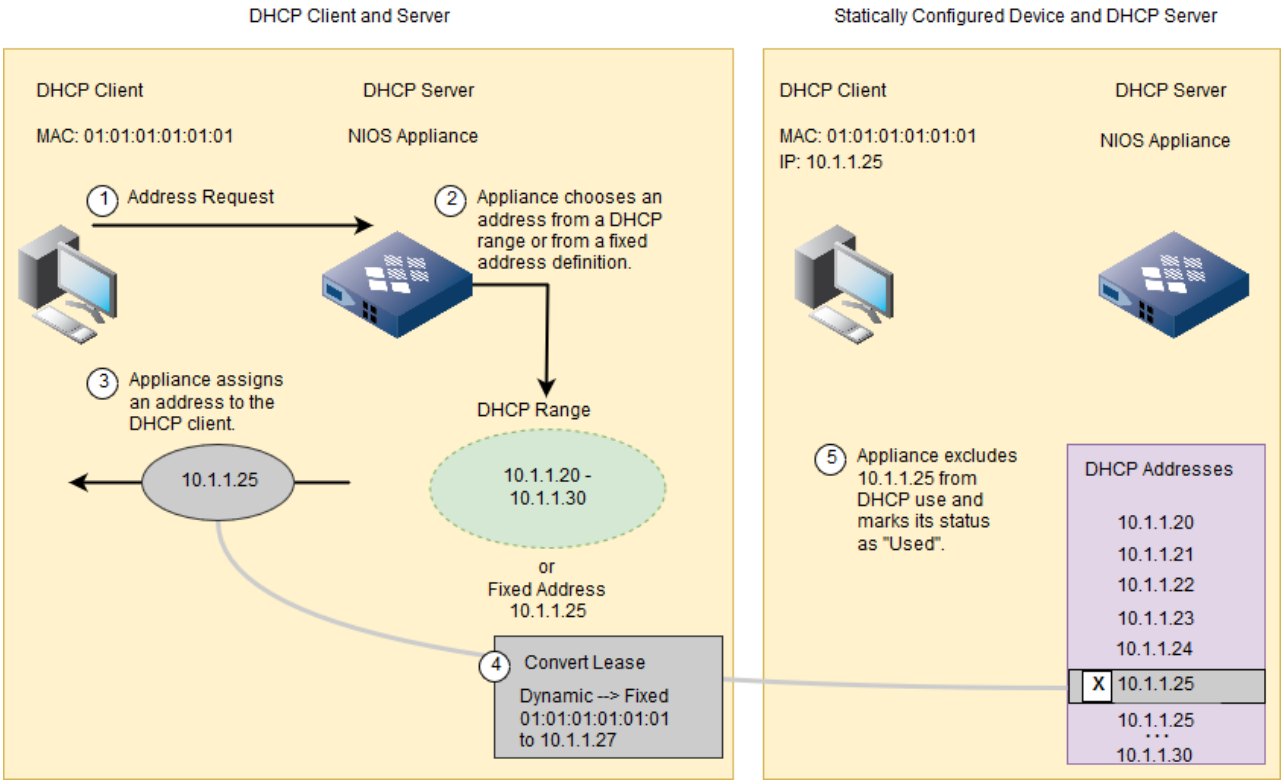
An advantage of converting an active dynamic lease is that you do not need to learn the MAC address or DUID of the device to which you want to assign an IP address and manually enter it in the fixed address configuration.
An IPv4 reservation is an address that you exclude from DHCP use because you intend to configure that address manually on a device, such as a firewall, router, or printer. You can also convert an IPv4 fixed address or a dynamic address with an active lease to a reservation.
When you convert an address in a DHCP range to a reservation, you reduce the total number of dynamically assignable

addresses in that range by one. Correspondingly, this reduces the number of allocated addresses needed to exceed a high or low watermark threshold for that range.

> **Note**
> To return an IP address to its place in a DHCP range after converting it from an active dynamic lease to a fixed address, reservation, or Infoblox host, delete the fixed address, reservation, or host to which you previously converted the IP address. The IP address then becomes part of the DHCP range to which it first belonged.

You can convert IPv4 fixed addresses to reservations, as shown in the below figure.

Converting an IPv4 Dynamic Lease or Fixed Address to a Reservation
DHCP Client and Server Statically Configured Device and DHCP Server



To convert an object:

1. From the IP Map, select an IPv4 address or from the IP List panel, select an IPv4 or IPv6 address.
2. In the Related Objects tab, select the checkbox of the object, and then click **Convert** from the Toolbar or navigation bar.
3. Select the object type to which you want to convert the object. Grid Manager displays the corresponding editor for the object type.
4. For all IPv4 conversions, Grid Manager populates the discovered information in the corresponding editor. Depending on the type of conversion, do one of the following:
   - For host record conversions, see *About Host Records*.
   - For IPv4 reservation conversions, see *Modifying IPv4 Reservations*.
   - For fixed address conversions, see *Modifying IPv4 Fixed Addresses.*
   - For A record conversions, see *Modifying A Records.*
   - For PTR record conversions, see *Modifying PTR Records*.

> **Note**

When you select an object for conversion, Grid Manager displays only the available conversion types for the object. You must save the changes in the editor for the conversion to take place.

Reclaiming Objects Associated with IPv4 and IPv6 Addresses

You can use the reclaim IP function to delete all objects, except the active DHCP lease, that are associated with a selected IP address. To delete a DHCP lease, use the clear lease function as described in Clearing Active DHCP Leases below. When you reclaim an IP address, Grid Manager deletes the associated objects and puts them in the Recycle Bin, if enabled. You can reclaim any used and unmanaged IP addresses. You can also select multiple IP addresses for this function. After you reclaim an IP address, the address status changes to Unused. You can then reassign the IP address to other objects. For example, when you reclaim a fixed address, Grid Manager deletes the fixed address object and puts it in the Recycle Bin. When you reclaim an IP address that is associated with a host record and the address is the only address in the host, Grid Manager deletes the host record.
Grid Manager deletes all the objects that are associated with the selected IP addresses and puts them in the recycle bin, with the following exceptions:

- When you reclaim IP addresses that are in a DHCP range, all the objects that are associated with the IP addresses are deleted and the IP addresses remain in the DHCP range.
- When you select an IP address that is part of a host record, only the selected IP address is deleted from the host. However, if the selected address is the only address in the host, Grid Manager deletes the host record.

Grid Manager does not reclaim the following:

- Unused IP addresses
- Bulk hosts

To reclaim an IP address:

1. From the IP Map or List panel, select the IP address you want to reclaim, and then click **Reclaim** from the Toolbar. You can select multiple IP addresses.
2. In the *Delete Confirmation* dialog box, click **Yes**.

Grid Manager puts the deleted objects in the Recycle Bin, if enabled.

Pinging IP Addresses

You can find out whether an IP address is accessible and active by pinging the address. Grid Manager sends a packet to the selected IP address and waits for a reply when you ping the address. You can ping individual IP addresses from the IP Map and IP List panels. You can ping all IP addresses from the IP Map panel and all IP addresses on the selected page from the IP List panel.
To ping an IPv4 or IPv6 address:

- From the IP Map or IP List panel, select the IP address that you want to ping, and then click **Ping** from the Toolbar.

To ping all IPv4 addresses:

- From the IP Map panel, click **Multi-ping** from the Toolbar. Grid Manager pings all IP addresses displayed in the IP Map panel and displays the ping status in the panel. When the ping or multi-ping is complete, the status bar displays the number of active IP addresses detected through the ping. To close the ping status bar, click the Close icon.
- From the IP List panel, click **Multi-ping** from the Toolbar. Grid Manager pings all IP addresses visible on the selected page. When the ping or multi-ping is complete, the status bar displays the number of active IP addresses detected on the selected page. To close the ping status bar, click the Close icon.

Clearing Active DHCP Leases

A DHCP lease specifies the amount of time that the DHCP server grants to a network device the permission to use a particular IP address. You may sometimes need to terminate an active lease. The following are some of the reasons for clearing active DHCP leases:

- When a network device is moved to another network.
- Reset a DHCP lease to fix other problems.

In Grid Manager, you can select multiple IP addresses and clear their active DHCP leases.
To clear an active lease:

1. From the IP Map or List panel, select the IP address for which you want to clear a DHCP lease, and then click **Clear** -> **Clear Lease** from the Toolbar. You can select multiple IP addresses.
2. In the *Clear DHCP Lease Confirmation* dialog box, click **Yes**.

Configuring Thresholds for IPAM Utilization

You can define thresholds for IPAM utilization in a network or network container and configure the appliance to send SNMP trap and email notifications to a designated destination when IPAM utilization in a network or network container crosses the configured threshold. IPAM utilization for a network is the percentage based on the IP addresses in use divided by the total addresses in the network and for a network container that contains subnets, it is the percentage of the total address space defined within the container regardless of whether any of the IP addresses in the subnets are in use. The appliance sends an SNMP trap and email notification only once when the IPAM utilization in a network or network container exceeds the Trigger value and when it drops below the Reset value. The default Trigger value is 95% and the default Reset value is 85%. The IPAM utilization notifications are sent for IPv4 networks and IPv4 network containers only. The appliance updates the IPAM utilization data immediately for a network container, but for a network it is updated every 15 minutes.
You can define thresholds for IPAM utilization at the Grid level and network level. The appliance applies the settings hierarchically in a parent-child structure. By defining thresholds at a higher level, all networks can then inherit the same settings and you do not have to redefine them for each network. For example, if you set the thresholds for IPAM utilization at the Grid level, then the settings applies to all the network containers and networks in any network view. However, if you override these settings at the network container or network level, then the settings applies to that network or network container and any network within that network or network container in the same network view. If you set the thresholds for an individual network, then it overrides settings at a higher level.

Note

Infoblox recommends that you do not enable SNMP traps and email notifications for IPAM utilization during an upgrade, because if you have configured notifications you may have to unconfigure them during an upgrade.

You can configure the thresholds for IPAM utilization at the Grid level and override them at the network level. To configure the IPAM utilization thresholds at the Grid level, see *Defining Threshold for Traps*.
To configure the IPAM utilization thresholds for a IPv4 network, network container, or network template, complete the following:

1. **Network Container**: From the **Data Management** tab, select the **IPAM** tab -> *network_container* checkbox, and click the Edit icon.
   Network: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and click the Edit icon.
   Network Template: From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab -> *DHCP_template* checkbox, and click the Edit icon.
2. In the editor, click **Toggle Advanced Mode**, select the **IPv4 IPAM Utilization Notification** tab, and then complete the following:
   - **IPAM Utilization Notification**: Click **Override** to override the inherited property, and specify the following:
     - **Enable SNMP Notifications**: Select this for the appliance to send an SNMP trap to the trap receiver that you define for the Grid when IPAM utilization crosses the configured threshold.
     - **Enable Email Notifications**: Select this for the appliance to send an email notification to a designated destination if IPAM utilization crosses the configured threshold.
   - **IPAM Threshold Settings**: Click **Override** to override the inherited property, and specify the following:
     - **Trigger**: Enter a Trigger value between 0 to 100. The appliance sends an SNMP trap and—if configured to do so—sends an email notification to a designated destination when the IPAM utilization exceeds the Trigger value. The default Trigger value is 95.

- **Reset**: Enter a Reset value between 0 to 100. The appliance sends an SNMP trap and —if configured to do so—an email notification to a designated destination when the IPAM utilization drops below the Reset value. The default Reset value is 85.
- **Email Addresses**: Click **Override** to override the inherited property. Click the Add icon, and then enter an email address to which you want the appliance to send email notifications when IPAM utilization for the network or network container crosses the configured threshold. You can create a list of email addresses.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Viewing Identity Mapping Information

You can view user information associated with networks, end-host devices, Active Directory domains, routers and switches when you enable the **Identity Mapping** feature on the appliance. Access to user information related to networks and devices help network administrators to understand how the network resources are consumed and by whom. Each network user being mapped can use different devices to access their network environment. So using the identity mapping feature and synchronizing servers, such as Microsoft servers and Cisco ISEs, on the Infoblox appliance provide visibility of user interaction with their environments. By enabling this feature, you can monitor domain users, the IP addresses they log on to, the login status, and the time duration of their current status in the **IPAM** tab. For information about Identity Mapping for Active Directory users, see *Configuring Identity Mapping* and how to collect about user and device information from Cisco ISEs, see *Configuring Cisco ISE on NIOS*. You can generate the user login history report to monitor user login activities in a given time frame. For information, see *User Login History Report.*
You can do the following in the **Network Users** tab:

- View active network users, as described in Viewing Active Network Users below.
- View user login history, as described in Viewing Network Users Login History below.

Enabling Identity Mapping

You must first enable the Identity Mapping feature to view user information of a network or device. Complete the following to enable this feature:

1. From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar.
2. In the *Grid Properties Editor*, select the **General** tab -> **Advanced** tab, and then complete the following:
   - **Enable Network Users feature**: Select this checkbox to enable the Identity Mapping feature on the appliance. Note that the **Network Users** tab is available only after you enable this feature.
     Note on an Infoblox appliance, the **Enable Network Users Feature** option is disabled by default for all new installations.
3. Save the configuration.

Viewing Active Network Users

You can view all the users who are currently active on a network in the **Active Users** tab. Using the Action icon ☰, you can do the following in the **Active Users** tab:

- **Go To IPAM IP Address Details**: Select this to open the IPAM Home page to view the network address of the device. This option is greyed out for devices that have an IP address and is not part of an IPAM network.
- **Go To DHCP Network Details**: Select this to open the **DHCP** > **Networks** tab to view the network address of the device. This option is greyed out for devices that have an IP address and not managed by the Grid.
- **Go To IPAM Network Details**: Select this to open the IPAM Map for the selected user. The page shows network information in graphical format. This option is greyed out for devices that have an IP and not managed by the Grid.

To view active users:

1. From the **Data Management** tab, select the **Network Users** tab > **Active Users** tab.
   or
   You can use the Action icon

   in the following tabs to open the *Active Users* dialog box:
   IPAM tab: From the **Data Management** tab, select the **IPAM** tab, click the Action icon

next to the respective network and select **Show Active Users**.
DHCP tab: From the **Data Management** tab, select the **DHCP** tab > **Networks** tab, click the Action icon

next to the respective network and select **Show Active Users**.
Cloud tab:

- In the **Networks** tab, click the Action icon

  next to the respective network and select **Show Active Users**.
- In the **VMs** tab, click the Action icon

  and select **Show Active Users**.
  DNS tab: From the **Data Management** tab, select the **DNS** tab > **Zones** tab > **Records** tab, click the Action icon

  and select **Show Active Users**.

The **Active Users** tab or *Active Users* dialog box displays the following information:

- **User Name**: Displays the logon name of the user. When the same user logs in to the domain from multiple clients, entry for each IP address is displayed separately. If multiple users logs in to the same domain, entry for each user is listed separately.
- **Domain**: The name of the domain.
- **First Seen**: The timestamp when the user logged in to the network for the first time.
- **IP Address**: The IP address of the client.
- **Data Source**: The IP address of the Microsoft server or the API method.
- **Data Source IP Address**: Displays the source from which the data is collected. It can be Cisco ISE, Microsoft server or the API method.
- **Last Seen**: The timestamp when the user was last seen accessing the network.
- **Last updated**: Displays the timestamp when the user information was last updated.

Viewing Network Users Login History

You can view the login history of end-host devices, networks, and Active Directory domain users. You must first enable the identity mapping feature to view user login information. For information about enabling Identity Mapping feature, see Enabling Identity Mapping above.
To view network user login history:

1. From the **Data Management** tab, select the **Network Users** tab -> **User History** tab. Grid Manager displays the following information:
   - **User Name**: The logon name of the user. When the same user logs in to the Active Directory domain from multiple clients, entry for each IP address is displayed separately. If multiple users logs in to the same Active Directory domain, entry for each user is listed separately.
   - **Domain**: Name of the Active Directory domain.
   - **First Seen**: The timestamp when the user logged in to the Active Directory domain for the first time.
   - **Log Out Time**: Displays the log out time of the user.
   - **IP Address**: The IP address of the client.
   - **Data Source**: The IP address of the Microsoft server or the API method.
   - **Status**: Displays the status of the user. The status can be one of the following: **Active** (logged in), **Logged Out**, and **Timed Out**.
     - **Active**: The user is logged in and active.
     - **Logged Out**: The user has logged out of the system.
     - **Timed Out**: The user is logged in but has been idled for a certain period of time. The default is two hours. You can configure this time interval, as described in Configuring Active User Timeout Session below.
   - **Last Seen**: The timestamp when the user was last seen accessing the network.
   - **Last updated**: The timestamp when the user information was last updated.

Configuring Active User Timeout Session

You can configure the amount of time that an active session of a user changes to timed out. When the idle session time is reached, the user status changes to inactive status. The default idle time is 2 hours. You can change it to minutes, hours, or days. The user status can be one of the following: **Active**, **Logged Out**, and **Timed Out**.
To configure active user timeout interval:

1. From the **Grid** tab -> **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
2. Select **Microsoft Integration** tab in the *Grid Properties Editor* and complete the following in the **Basic** tab:
    - **Assumed Network Users Time Out:** Specify the time period after which the user status changes to **Timed Out**. Select the time period in minutes, hours, or days from the drop-down list.
3. Save the configuration.

IP Discovery and vDiscovery

This section provides information about the Infoblox IP discovery and vDiscovery, and how you can use them to detect, collect, and manage information about active hosts in predefined networks as well as virtual entities in private, public, and hybrid clouds managed through CMPs (Cloud Management Platforms) such as VMware vCenter servers and vSphere Hypervisor, OpenStack, and AWS (Amazon Web Services). It also explains how to integrate and view discovered data from the NetMRI appliances.

This chapter includes the following topics:

About Discovery

Note

The discovery features described in this chapter apply to NIOS Grid deployments that do not use the Discovery license and its accompanying features under Network Insight. Network Insight provides the ability to discover, query, and catalog routed and switched networks and the devices within them, including infrastructure routers, enterprise switches, security devices such as firewalls, wireless access points, end host computer systems, and more. For more information about Network Insight, see *Infoblox Network Insight*.

Infoblox provides IP discovery for detecting and obtaining information about active hosts in predefined networks, and vDiscovery for discovering virtual entities and interfaces (such as vSwitch and vRouter) in private, public, and hybrid clouds managed through CMPs (Cloud Management Platforms) such as VMware vCenter servers and vSphere Hypervisor, OpenStack, and AWS (Amazon Web Services). You can configure multiple discovery tasks on one or more discovering members.

- IP discovery: You execute an IP discovery (**Data Management** tab -> **IPAM** tab -> **Discovery** from the Toolbar) to detect active hosts on specified networks in a network view. You can configure the appliance to perform an IP discovery using one of the following protocols: ICMP (Internet Control Message Protocol), NetBIOS (Network Basic Input/Output System), and TCP (Transmission Control Protocol). For more information, see *Supported IP Discovery Methods*. You can start an IP discovery immediately after you configure it, schedule it for a later date

and time, or configure a recurring discovery based on a recurrence pattern. For information about how to configure an IP discovery, see *IP Discovery and vDiscovery.*

- vDiscovery: This is an extension to the former VM discovery, in which the NIOS appliance only discovers virtual entities on VMware vCenter and vSphere servers. A vDiscovery job (from the **Data Management** tab -> **IPAM** tab -> **vDiscovery** from the Toolbar, or **Cloud** tab -> any sub tab -> **vDiscovery** from the Toolbar) now detects virtual entities and interfaces in private, public, and hybrid clouds that are managed through VMware vCenter servers and vSphere Hypervisor, OpenStack, Azure, or AWS. You can define vDiscovery jobs through the *vDiscovery Job* wizard and manage all configured vDiscovery jobs through the **vDiscovery Job Manager**. Note that for a specific vDiscovery job, NIOS synchronizes successive discovered data (not the associated NIOS objects) with the data in the targeted CMP. For example, if you change the IP address of a VM, this information is reflected in the next discovery of the same vDiscovery job. If you terminate a VM, the VM is deleted from the NIOS database. If you delete certain information on the CMP, the respective discovered data is removed from the NIOS database. Be aware that if you change the parameters of a vDiscovery Job, the last discovered data from this job will be automatically cleaned up so that the appliance can continue to synchronize data from one discovery to the next. If you do not want to lose discovered data for a specific vDiscovery job, you should create a new vDiscovery job for this new collection instead of modifying the current job. For information about how to configure vDiscovery jobs for specific CMPs and how to manage them, see *Configuring vDiscovery Jobs* and *Managing vDiscovery Jobs*.

Note

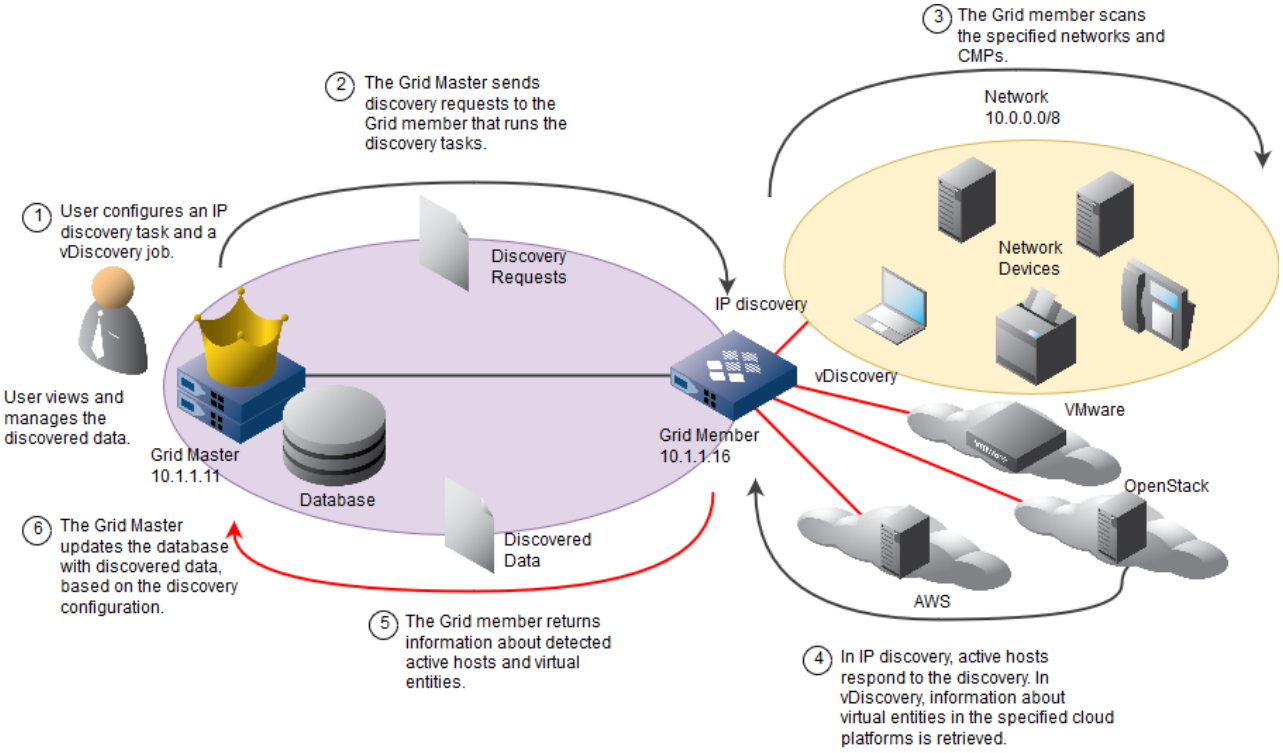
For new installations, an IP discovery task is automatically created by default. You can choose to disable the IP discovery after you have set up your appliance. However, you must configure and manually schedule vDiscovery jobs in order for the appliance to detect and collect information about virtual entities in the clouds. When you upgrade from a previous NIOS release to NIOS 7.2 and later, former VM Discovery tasks are divided into separate vDiscovery jobs based on the server endpoints defined in the VM Discovery tasks. All new vDiscovery jobs inherit the same discovery schedule from the old tasks. You must manually enable the new vDiscovery schedules in order for the appliance to perform vDiscovery jobs. For information about how to enable the vDiscovery schedule, see *Scheduling vDiscovery Jobs*.

After a discovery, the appliance updates the database with the discovered data based on the discovery configuration. For example, you can configure the appliance to merge newly discovered data, consolidate managed data, or update unmanaged data. The appliance also identifies unmanaged and conflict data after a discovery. Unmanaged data is discovered data that is not configured for DNS or DHCP and has no associated NIOS objects. Conflict data is discovered data that is configured for DNS or DHCP and has associated NIOS object or objects, but certain key values are different than those in the NIOS database. For information about guidelines the appliance uses to update discovered data, see *Guidelines Before Starting a Discovery* and *Guidelines for Configuring vDiscovery Jobs*.

Grid Manager displays discovered data in the **Discovered Data** section of the IP address properties panel when you drill down to individual IPs. For information about how to view and manage discovered data, see *Viewing Discovered Data* and *Managing Discovered Data*. The appliance records admin operations in the audit log and discovery operations in the syslog.

The figure High-Level Discovery Process below shows a high-level perspective of the discovery processes. You can configure and initiate an IP discovery from the *Discovery Manager* wizard and a vDiscovery from the *vDiscovery Job* wizard. You must first select a Grid member that runs the discovery tasks. After you configure an IP discovery task and a vDiscovery job, the Grid Master sends the discovery requests to the selected member. Based on the configuration of the discovery tasks, the selected member runs the discovery and collects information about discovered hosts and virtual entities from the specified networks and cloud platforms. The Grid member then reports the discovered results to the Grid Master. Based on the discovery configuration, the Grid Master updates the database with discovered data.

High-Level Discovery Process



Administrative Permissions

You can initiate a discovery and manage discovered data based on your administrative permissions. You must have read/write permission to "Network Discovery" to initiate and manage IP discovery and vDiscovery. You must have at least read-only permission to "All Tenants" and "All Network Views" to view discovered data in the **VMs (by IP Address)** tab in the **Cloud** tab. To take actions on discovered data, such as resolving conflicts or clear unmanaged data, you must have read/write permissions. For information about how to configure admin permissions, see *About Administrative Permissions*.

Following are permission guidelines for initiating and controlling a discovery:

- Superusers can initiate and control a discovery on all networks and CMPs.
- Administrators with read/write permission to "Network Discovery" can initiate and control a vDiscovery job or an IP discovery. For IP discovery, only the objects with IP addresses to which the administrators have read/write permission are updated to include the discovered data.

After a discovery is completed, the following permission guidelines apply to viewing and managing discovered data:

- Superusers can view and manage all discovered data.
- Administrators with read/write permission to networks can view all discovered data. They can also add unmanaged data to existing hosts, and resolve IP address conflicts.
- Only administrators with read/write permission to a DNS zone or specific record type can convert unmanaged data to a host, fixed address, reservation, A record, or PTR record.
- Administrators with read-only permission to networks can only view discovered data. They cannot change any discovered data.

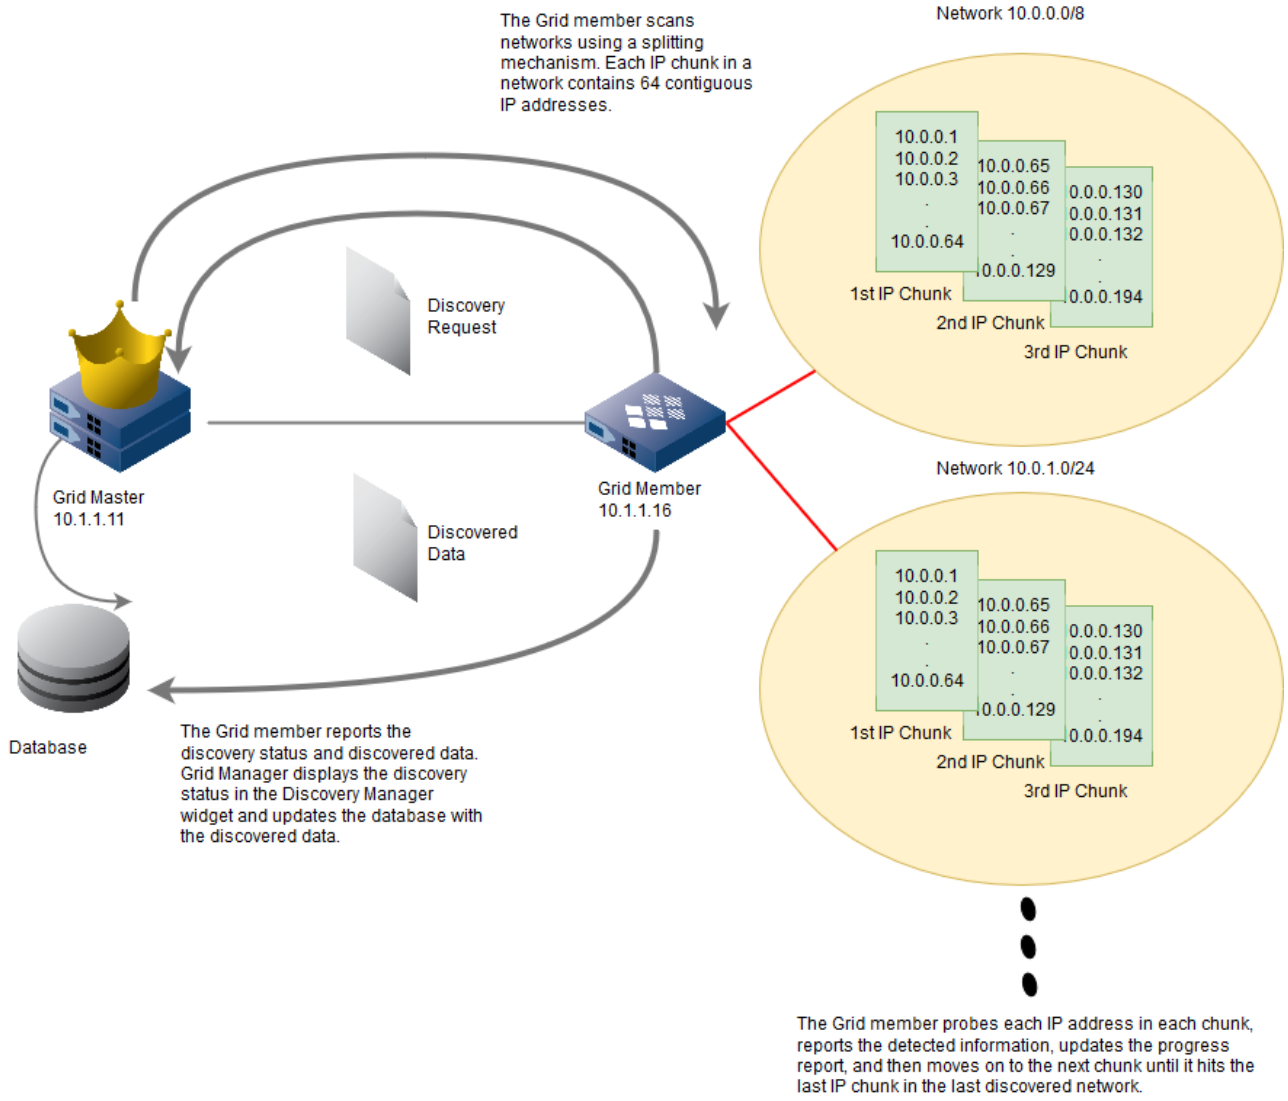
IP Discovery Process

Once an IP discovery starts, the Grid member reports the discovery status, such as **Completed**, **Running**, **Paused**, **Stopped**, or **Error**, in the *Discovery Manager* wizard and the *Discovery Status* widget on the Dashboard. In the *Discovery Status* widget, Grid Manager reports the time when the discovery status was last updated and the numbers of each type of discovered data. For information, see *Managing Discovery*.

When an IP discovery starts, the appliance divides the IP addresses in a network into chunks, with each chunk containing 64 contiguous IP addresses. The discovery process probes each IP address in parallel and in ascending

order, reports the detected information, updates the progress report, and then moves on to the next chunk until it hits the last chunk of IP addresses. The appliance then updates the database with the discovered data.
An IP discovery scans the selected networks in the order the networks appear in the *Discover Manager* wizard.
You can configure discovery processes on the same network, but the same configuration cannot be shared between two discovery processes.
The below figure illustrates how an IP discovery works.

IP Discovery Process



Supported IP Discovery Methods

When you perform an IP discovery, you can choose one of the following discovery methods:

- ICMP
- NetBIOS
- TCP
- Full

These methods actively scan predefined networks and probe IP addresses. The Grid member listens for responses from the IP addresses as proof of activities. The IP discovery scans through the specified network ranges and probes IP addresses (except for the network, broadcast, and multicast address types) in each network, including the /31 and /32

subnets. Note that the possible addresses in the /31 and /32 subnets can be used only as source addresses for point-to-point links. In these cases, there are no broadcast or network addresses in the /31 and /32 subnets, and the appliance can discover source addresses in these subnets.

ICMP

This method detects active hosts on a network by sending ICMP echo request packets (also referred to as pings) and listening for ICMP echo responses. The ICMP discovery is a simple and fast discovery that detects whether an IP address exists or not. It returns only the IP address and MAC address (only if the Grid member running the discovery is on the same discovered network) of a detected host. The ICMP discovery might miss some active hosts on the network due to security measures that are put in place to block ICMP attacks.
You configure the timeout value and the number of attempts in the *Discovery Manager* wizard. The ICMP discovery method returns the following information for each detected host:

- IP address: The IP address of the host.
- MAC address: The discovery returns the MAC address only if the Grid member running the discovery is on the same discovered network.

To use the ICMP discovery method, the ICMP protocol between the Grid member performing the discovery and the target networks must be unfiltered.

NetBIOS

The NetBIOS method queries IP addresses for an existing NetBIOS service. This method detects active hosts by sending NetBIOS queries and listening for NetBIOS replies. It is a fast discovery that focuses on Microsoft hosts or non-Microsoft hosts that run NetBIOS services.
You configure the timeout value and the number of attempts in the *Discovery Manager* wizard. This method returns the following information for each detected host:

- IP address: The IP address of the host.
- NetBIOS name: This value is set to the name returned in the NetBIOS reply.

To use the NetBIOS discovery method, ports 137 (UDP/TCP) and 139 (UDP/TCP) between the Grid member performing the discovery and the target networks must be unfiltered.

TCP

The TCP discovery probes each active host on a list of TCP ports using TCP SYN packets. This method detects all active hosts that generate SYN ACK responses to at least one TCP SYN. The discovery can determine the OS on a host by analyzing how the host reacts to the requests on opened and closed ports. It then uses the TCP fingerprints to guess the OS. To obtain a TCP fingerprint, IP discovery provides two scanning techniques, SYN and CONNECT.
When you use the SYN technique, the discovery sends a TCP SYN packet to establish a connection on a TCP port. If the port is open, the host replies with a SYN ACK response. The discovery does not close the port connection.
The CONNECT technique is a three-way TCP handshake. The discovery starts with the same process as the SYN technique by sending the TCP SYN packet. If the host replies with a SYN ACK response, the discovery then sends a RST packet to close the connection. If the response contains a RST flag, it indicates that the port is closed. If there is no reply, the port is considered as filtered. The TCP discovery is a deliberate and accurate discovery method. It can basically detect all active hosts on a network provided that there are no firewalls implemented on the network.
You can select the TCP ports, the TCP scanning technique, and configure the timeout value and the number of attempts in the *Discovery Manager* wizard. This method returns the following information for each detected host:

- IP address: The IP address of the host.
- MAC address: The discovery returns the MAC address only if the Grid member running the discovery is on the same discovered network.
- OS: This is set to the highest probable OS reported in the response.

To use the TCP discovery method, the TCP port and a specific set of ports between the Grid member and the discovered networks must be unfiltered. The default set of ports is defined by the factory settings.

Full

The full discovery method is a combination of an ICMP discovery, a NetBIOS discovery, a TCP discovery, and a UDP scan. This method starts by sending an ICMP echo request. If no IP address on the network responds to the ICMP request, the discovery ends. If there is at least one response to the ICMP echo request, a NetBIOS discovery starts. A TCP discovery then follows by skipping through the active hosts that the NetBIOS discovery detects. The TCP discovery also handles the NetBIOS-detected hosts that have no MAC addresses. This method also performs a UDP scan to determine which UDP ports are open.
You configure the timeout value and the number of attempts in the *Discovery Manager* wizard. The full discovery method returns the following information for each detected host:

- IP address
- MAC address
- OS
- NetBIOS name

To use the full discovery, all the filter and firewall requirements in the ICMP, NetBIOS, and TCP discovery methods apply. The following is a summary of the supported IP discovery methods:

Discovery Type	Returned Data	Guideline	Mechanism
ICMP	• IP address • MAC address	Use ICMP for a rough and fast discovery	ICMP echo request and reply
NetBIOS	• IP address • NetBIOS name	Use NetBIOS for discovering Microsoft networks or non-Microsoft networks that run some NetBIOS services	NetBIOS query and reply
TCP	• IP address • MAC address • OS	Use TCP for an accurate but slow discovery	TCP SYN packet and SYN ACK packet
Full	• IP address • MAC address • OS • NetBIOS name	Use Full for a general and comprehensive discovery	1. ICMP echo request and reply 2. NetBIOS query and reply 3. TCP SYN packet and SYN ACK packet

The method you select to run an IP discovery determines the kind of information the discovery returns and the time it takes to complete an IP discovery. If time is a concern, the following are factors you may consider when configuring an IP discovery:

- The timeout value
- The number of attempts
- The number of ports the discovery scans
- The size of network you want to discover

Guidelines Before Starting a Discovery

Consider the following guidelines before you start a discovery.

Database Updates

After the Grid Master receives discovery data from the Grid member, it integrates the data based on the following rules:

- For a discovered host with a new IP address, the appliance marks the IP address "unmanaged."
- For a discovered host associated with one of the following, the appliance updates the data of the associated object:
    - A fixed address reservation or host address reservation
    - A host address not configured for DHCP services
    - A fixed address or host address with the same MAC address as that of the discovered host
    - An A or PTR record
    - A DHCP lease with the same MAC address as that of the discovered host
- For a DHCP lease that does not have any associated object, such as a fixed address or host record, the appliance updates the IP address with the discovered data. When the lease expires and the IP address has no associated objects, the appliance marks the IP address "unmanaged". When the lease expires and the IP address is associated with the same MAC address, the appliance preserves the discovered data.
- For a discovered host associated with one of the following, the appliance updates all data except the MAC address and marks the IP address as a conflict. For information about resolving conflicting addresses, see *Managing Discovered Data*.
    - A fixed address with a different MAC address than that of the discovered host
    - A DHCP lease with associated objects and with a different MAC address than that of the discovered host
    - An Infoblox host address configured for DHCP services and with a different MAC address than that of the discovered host
- For a discovered host that is part of a DHCP range but does not have a fixed or leased address or is not within an exclusion range, the appliance assigns a DHCP range conflict to the IP address.
- For a discovered host through a vDiscovery, the appliance adds the discovered data to the database. The data is displayed in the IP Map and IP List panels, the **Discovered Data** tab of an object editor, and the Discovered Data section of the IP Address panel.
- The OS of an IP address obtained by an IP discovery supersedes that obtained by a vDiscovery, and the newly discovered name of a host supersedes the last discovered data.
- When a vDiscovery cannot obtain the IP address of a virtual entity, it does not return any discovered data for the entity.
- Only the objects with IP addresses to which the administrators have read/write permission are updated to include the vDiscovery data.

Database Capacity

When the Grid Master database reaches its maximum capacity (the maximum capacity varies based on the appliance model), the Grid Master stops updating the database and requests that the Grid member stop the discovery. When the discovering Grid member database reaches its capacity, the Grid member pauses the discovery. The appliance displays a dialog to inform you that the discovery pauses. The Grid member resumes the discovery once the database falls below its capacity. When a discovery pauses because of capacity issues, you cannot resume the discovery or start a new discovery. You can check the capacity of your appliance database before starting a discovery.

HA Failover

In an HA pair, if the Grid Master fails over to the passive node, the passive node takes over and continues with the discovery from the last known state. If an independent appliance fails, the appliance stops the discovery process and keeps the discovery in a paused state. The appliance resumes the discovery once it starts up again.

Configuring IP Discovery

You must have read/write permission to Network Discovery to initiate a discovery. After you start a discovery, you cannot change the configuration of the discovery, but you can start the discovery process immediately or schedule it for a later date. You can also configure a recurring discovery that repeats on a regular basis. For information, see Configuring and Starting an IP discovery and Scheduling IP Discovery below. The appliance saves the configuration of the last discovery. When you start an IP discovery from the IPAM Home, Net Map or Network List panel, you can select the networks on which you want the discovery to run. When you start an IP discovery from the IP Map or IP List panel, the discovered network is the one to which the IP addresses belong. You can include additional networks when you configure the IP discovery from the *Discovery Manager* wizard. You can run an IP discovery on multiple networks in one network view.

Guidelines for Starting and Scheduling IP Discovery

After you configure a discovery, you can start the discovery process immediately or schedule it for a later date. You can also configure a recurring discovery that repeats on a regular basis. When you start a discovery immediately or schedule for a later date after you configure it, the discovery happens only once and it will not be repeated. To repeat a discovery regularly, you can configure a recurring discovery. A recurring discovery occurs repeatedly based on the schedule you have configured. For more information about how to start a discovery immediately or schedule it for a later date, see Configuring and Starting an IP discovery and Scheduling IP Discovery below.
You can configure IP discovery tasks independent of each other and each one contains a specific set of networks and discovery settings.
Note the following guidelines about immediate, regular and recurring IP discovery tasks:

- You cannot run regular and recurring discovery processes concurrently.
- If a recurring discovery is scheduled to start when a discovery is in progress, the recurring discovery will be postponed to the next schedule time. The current recurring discovery will not be performed.
- You can pause and resume all discovery tasks.
- You cannot start a discovery when another one has been paused.
- You cannot use the start command to start a recurring discovery.
- Discovery permissions are applicable to all discovery tasks.
- When you start an IP discovery, only the available IP addresses in the network are discovered. The discovered data through a specific Discovery job can only be modified or deleted by the same Discovery job. When you start a different Discovery job to discover IP addresses in the same network and if some of the information in the network is changed, the newly discovered data and the originally discovered data (now old data) co-exist in the database. When you run the original Discovery job again, the old data is deleted or modified, or the new data is added depending on the information discovered.

Configuring and Starting an IP discovery

To start an IP discovery immediately after you configure it:

1. From the **Data Management** tab, select the **IPAM** tab, and then select **Discovery** -> **Discover Now** from the Toolbar.
2. In the *Discovery Manager* wizard, click the **General** tab, and then complete the following in the **Basic** tab:
    - **Current Status:** Displays the last discovery status and timestamp. This data is read-only.
    - **Member Name**: Click **Select Member**. In the *Member Selector* dialog box, select the Grid member from which you want to run the discovery. You can also use filters or the Go to function to find a specific member. For information, see *Using Filters* and *Using the Go To Function*.
    - **Merge the discovered data with existing data:** When you select this checkbox, the appliance merges the discovered data with the existing data. It appends newly discovered data to existing data and preserves the existing data when there is no newly discovered data. This checkbox is selected by default.
      Note if you clear this checkbox, the appliance replaces the existing data with the newly discovered data and if there are no newly discovered values for some fields, the appliance removes the existing values for these fields and the fields become empty.
    - **Update discovered data for managed objects:** Select this checkbox if you want the appliance to update the data of existing managed objects such as A records, PTR records, host records, and fixed addresses,

with the discovered data. If you clear this checkbox, the appliance updates only the unmanaged objects. This checkbox is selected by default.

3. Click **Save** to save the discovery configuration. Note that you must save the configuration before you can start a discovery.
4. Click **Start** to start the IP discovery. You can also do one of the following:
    - **Restore to Defaults**: Restore the discovery configuration using the default values.
    - **Pause**: Stop a running discovery.
    - **Resume**: Resume the discovery that has been stopped.
    - **Save**: Save the discovery configuration.
    - **Close**: Cancel the configuration. If you have started a discovery, the discovery runs in the background when you click **Close**. For information, see *Running Tasks in the Background*.

> ⚠ Note
>
> Once you start a discovery, you cannot change the discovery configuration. After you click **Start**, the button changes to **Pause**. You can click **Pause** to pause a discovery. When the discovery is paused, the button changes to **Resume**. You can click **Resume** to continue the paused discovery.

Defining IP Discovery Method

To configure the IP discovery method you want to use:

1. From the **Data Management** tab, select the **IPAM** tab, and then select **Discovery** -> **Discover Now** from the Toolbar.
2. In the *Discovery Manager* wizard, click the **IPv4 Device Discovery** tab, and then complete the following in the **Basic** tab:
    - **Mode**: Select the IP discovery method you want to use. For information, see *Supported IP Discovery Methods* . If you select **TCP** or **FULL**, ensure that you configure the TCP ports in the **Advanced** tab. The default is **FULL**.
    - Click the Add icon to add networks. In the *Network Selector* dialog box, select the network view and networks. Use SHIFT+click and CTRL+click to select multiple networks. You can also use filters or the Go to function to find a specific network. For information, see *Using Filters* and *Using the Go To Function*. . You can do the following in the table:
        - Click the Add icon again to add more networks.
        - Select a network or multiple networks in the network table and click **Delete** to delete them.
        - Click the Export icon to export the data in CSV format.
        - Click the Print icon to print the data.
    - **Disable**: Select this to exclude an IP discovery task. IP discovery is enabled by default.
3. If you select **TCP** or **FULL** in **Mode**, click the **Advanced** tab and complete the following:
    - **TCP Scan Technique**: Select the TCP technique you want to use for the discovery. The default is SYN. For information, see *TCP*.
    - In the port table, select the checkbox of the port you want to configure. You can select all ports by clicking the checkbox in the header.
      Optionally, you can click the Add icon and complete the following to add a new service to the list.
        - Port: Enter the port number you want to add to the list. You must enter a number between 1 and 65535.
        - Service: Enter the name of the service.

      You can also delete a specific TCP port in the list. You can select multiple ports for deletion.
    - **Timeout (ms)**: Enter the timeout value in milliseconds for the discovery. The timeout value determines how long the discovery waits for a response from an IP address after probing it. The minimum is 5 and the maximum is 4000. The default is 1000.
    - **Attempts**: Enter the number of times you want the discovery to probe an IP address when scanning a network. The minimum is 1 and the maximum is 5. The default is 2.
4. Click **Save** to save the discovery configuration. Note that you must save the configuration before you can start a discovery.
5. Click **Start** to start the IP discovery. You can also do one of the following:

- **Restore to Defaults**: Restore the discovery configuration using the default values.
- **Pause**: Pause a running discovery.
- **Resume**: Resume the discovery that has been stopped.
- **Save**: Save the discovery configuration.
- **Close**: Cancel the configuration. If you have started a discovery, the discovery runs in the background when you click **Close**. For information, see *Running Tasks in the Background*.

You can do the following after a discovery is complete:

- View the discovery status. You can view the current discovery status in the *Discovery Status* widget on the Dashboard. For information, see *Dashboards*.
- View the discovered data. For information, see *Viewing Discovered Data.*
- Manage the discovered data. For information, see *Managing Discovered Data.*

Scheduling IP Discovery

After you configure a discovery (as described in Configuring and Starting an IP discovery above), you can schedule to run a one-time IP discovery at a later date and time. You can also schedule a recurring IP discovery by configuring a recurrence pattern. The appliance automatically starts a recurring discovery based on the configured schedule and detects any newly added or removed networks. Note that you can only schedule the start of a discovery, you cannot schedule it to pause, stop, or resume. After a scheduled discovery starts, you can then pause, stop, or resume it.
You can schedule only one IP discovery at a time. Once you schedule a discovery, you cannot change the configuration until the task is cancelled or executed. You can however disable a recurring discovery. When you disable a recurring discovery, it will not recur during the scheduled interval.

To schedule a one-time IP discovery for a specific date and time:

1. From the **Data Management** tab, select the **IPAM** tab, and then select **Discovery** -> **Discover Now** from the Toolbar.
   or
   From the *Discovery Status* widget, select **Discover Now** from the drop-down list, and then click **Discovery Manager.**
2. In the *Discovery Manager* wizard, click the Schedule icon at the top of the wizard. In the *Schedule Change* panel, click **Later**, and then specify a date, time, and time zone. Click **Schedule Start** to schedule the discovery. If applicable, you can select **Click here to view/manage the scheduled items to reschedule a discovery or view all scheduled discoveries**.

To schedule a recurring IP discovery:

1. From the **Data Management** tab, select the **IPAM** tab, and then select **Discovery** -> **Schedule Discovery** from the **Toolbar**.
   or
   From the *Discovery Status* widget, select **Schedule Discovery** from the drop-down list, and then click **Discovery Manager.**
2. In the *Discovery Manager* wizard, complete the following in the scheduler:
   - **Disable:** Select this checkbox to disable recurring IP discovery. When you select this checkbox, IP discovery will not recur during the scheduled interval. Clear the checkbox to enable recurring IP discovery.

   If you select **Hourly**, complete the following:
   a. **Schedule every hour(s) at**: Enter the number of hours between each update instance. You can enter a value from 1 to 24.
   b. **Minutes past the hour**: Enter the number of minutes past the hour. For example, enter 5 if you want to schedule the rule update five minutes after the hour.
   c. **Time Zone**: Select the time zone for the scheduled time from the drop-down list.

   If you select **Daily**, you can select either **Everyday** or **Every Weekday** and then complete the following:

- **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
- **Time Zone**: Select the time zone for the scheduled time from the drop-down list.

If you select **Weekly**, complete the following:

- **Schedule every week on**: Select any day of the week.
- **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
- **Time Zone**: Select the time zone for the scheduled time from the drop-down list.

If you select **Monthly**, complete the following:

- **Schedule the day of the month**: Enter the day of the month and the monthly interval. For example, to schedule the rule update on the first day after every 2 months, you can enter Day 1 every 2 month(s).
- **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
- **Time Zone**: Select the time zone for the scheduled time from the drop-down list.

3. Click **Save** to save the configuration.

If the discovery task fails during a scheduled interval, the task stops and will not continue for the corresponding occurrence. The scheduled task resets and the discovery starts at the next scheduled time. For example, when you configure a recurring discovery to occur every five hours, discovery starts at the following hours on each day: 00:00, 05:00, 10:00, 15:00, and 20:00. If the discovery scheduled for 05:00 fails, the discovery starts at the next recurrence, which is at 10:00. For information about failed discovery, see Guidelines for Starting and Scheduling IP Discovery.
The following examples explain when a recurring discovery starts based on your configuration:
Example 1
When you configure a recurring discovery to occur every five hours, the discovery starts at the following hours on each day: 00:00, 05:00, 10:00, 15:00, and 20:00. The first occurrence on each day starts at 00:00.
Example 2
When you configure a recurring discovery to occur every two days during a week, the discovery starts on the following days every week: Monday, Wednesday, Friday, and Sunday. The first occurrence starts on Monday of each week.

Monitoring IP Discovery Status

You can monitor IP discovery status through the *Discovery Status* widget on the Dashboard. You can also start, pause, resume, and stop a discovery from the widget. For information, see *Discovery Status*.

Configuring vDiscovery Jobs

A vDiscovery job retrieves information about virtual entities in cloud environments that are managed through cloud management platforms (CMPs) such as VMware, OpenStack, AWS, Azure, and GCP. The current vDiscovery feature supports tenants, networks, and compute VMs only. It does not support data that is retrieved from load balancer networks, load balancer VMs, Kubernetes platform VMs, application gateways, service VMs, SQL VMs, or any other VMs that are created using cloud services such as Kubernetes service or analytics service, where the IPAM is handled by the respective orchestration engines of the cloud provider.
Note that if the vDiscovery job retrieves unsupported data from AWS, Azure, or GCP, then it impacts the performance of the vDiscovery process.

You must first select a member to run the vDiscovery job. To ensure that the job is executed properly, verify the connection between the discovering member and the discovered endpoint. If you select HTTPS as the protocol for communication, you must upload either an SSL CA (Certified Authority) certificate or a self-signed SSL certificate to the Grid. If the certificate has expired, ensure that you delete the expired certificate and then upload a new certificate. For more information about uploading certificates, see *Managing Certificates*.

> ⚠ Note
>
> After you upload a new certificate, wait for two minutes before running a vDiscovery job. This is because the newly uploaded certificate takes some time to be reflected in the NIOS database.

Note that when you disable any virtual entities or interfaces on the CMP, the appliance excludes them from the vDiscovery job. In situations where the discovering member you select to perform vDiscovery jobs is disconnected from the Grid Master, the member continues to execute vDiscovery jobs based on the configured schedule. Newly discovered

data replaces previously discovered data. The last set of discovered data is considered the most up-to-date and is sent to the Grid Master when the member reconnects with the Grid Master.

When you configure vDiscovery jobs, you can enable the Infoblox NIOS appliance to automatically create DNS records for discovered IP addresses of VM instances that are served by the NIOS appliance. You can configure the appliance to add DNS records for specific DNS views associated with the network view defined for public and private IP addresses of VM instances served by the appliance. For more information about this feature, see Creating DNS Records for Newly Discovered VMs below.
Before you configure and start a vDiscovery job, there are a few guidelines to consider.

Sections covered in this topic are:

Guidelines for Configuring vDiscovery Jobs

Consider the following guidelines before starting a vDiscovery job:

- Discovered data through a specific vDiscovery job can only be modified by the same vDiscovery job. If you create a different vDiscovery job to discover the same network and some of the information in the network has changed, the newly discovered data and the original discovered data (now old data) co-exist in the database. For example, vDiscovery job "AWSJob1" discovers IP address 10.0.0.11 with VM name "corpxyz." This discovered data is stored in the NIOS database. You subsequently create a new vDiscovery Job "AWSJob2" to discover the same IP but now the VM name has been changed to "corp200." The discovered VM name for 10.0.0.11 is now "corp200." Both VM names "corpxyz" and "corp200" exit in the database until you run AWSJob1 again, and "corpxyz" will be removed from the database.
- If the "ERROR: PycURL" error is displayed when you run a vDiscovery job, it is possible that the cloud provider has updated their certificate. You need to download the latest certificate from the cloud provider website and upload it to NIOS. For example, for AWS, download the certificates from *https://www.amazontrust.com/repository/*. For more information see Error while running job below.
- Cloud Extensible Attributes:
  - To merge discovered cloud extensible attributes into NIOS, you must have at least one cloud license (Cloud Network Automation or Cloud Platform) installed in the Grid. However, if you want to view the discovered cloud data in the **Cloud** tab of Grid Manager, you must have the Cloud Network Automation license installed on the Grid Master. Otherwise, even though the cloud data is merged into the NIOS database, you cannot view it through Grid Manager. For more information about Cloud Network Automation, see *Deploying Cloud Automation Network*.
  - In addition, ensure that you select the auto consolidation options when defining policies for how to handle the discovered cloud extensible attributes, as described in *Defining Policies for Handling Discovered Data*. Note that only cloud extensible attributes for managed objects are updated. To update cloud extensible attributes for unmanaged objects, you can first convert the unmanaged objects to managed objects. For more information about Managing Unmanaged Data, see *Managing Discovered Data*.
- When you select **VMware** as the endpoint server for the vDiscovery job, consider the following:
  - Typically, vDiscovery does not collect data about "Network" from VMware vSphere and vCenter servers. Therefore, you must first define a network in NIOS in order to discover IPs in the network.
  - However, if you use vCenter to define a network as "IP_Pool," which contains the CIDR for the network, vDiscovery is able to collect this data and translate it into a network. NIOS then creates the network and updates it with corresponding Cloud extensible attributes.

- If you use an AWS Elastic IP address and select **AWS** as the endpoint server for the vDiscovery job, you must first manually create the network in NIOS before launching the vDiscovery job in order to discover the Elastic IP.
- Properties of a VM address (such as interface name, network encapsulation, segmentation, VLAN ID) can only be updated through cloud extensible attributes, depending on the policies you select when configuring a vDiscovery task. To properly integrate discovered VM address properties with NIOS, ensure that you do one of the following:
    - Define cloud extensible attributes for these properties through your cloud adapter. For information about how to define cloud extensible attributes, refer to the *Quick Start Guide* for your cloud adapter, available on the Support site.
    - Convert unmanaged VM addresses to managed so discovered cloud extensible attributes can be merged into NIOS. For more information, see *Converting Unmanaged Data*.
    - Unmanaged objects in NIOS are updated with newly discovered data and stay as unmanaged objects. Managed objects in NIOS that have no conflict with newly discovered data are updated and stay as managed objects.
    - If there is conflict between managed objects in NIOS and newly discovered data, the managed objects are not updated and stay as managed objects while a conflict is flagged for these objects. For more information about how to resolve the conflict, see *Resolving Conflicting Addresses*.
    - NIOS does not automatically remove unmanaged objects that were discovered in the past but do not exist in current discoveries. This can happen if your network topology has changed in between discoveries. You can manually remove these unmanaged objects if you do not want them to stay in the database. For more information about how to remove these objects, see *Clearing Unmanaged Data* and *Clearing Discovered Data.*
    - For delegated DNS and DHCP objects, changes are handled by the delegated Cloud Platform Appliance based on the scope of delegation. Discovered data is still updated by the Grid Master.
- You cannot delete discovered tenants, networks, and VMs through the vDiscovery process. Conflict management is not supported for these objects. Note the following:
    - Discovered subnets are always created as managed networks. Pools of IP addresses (public pools) when discovered are translated into managed networks. Any discovered public IP that is not linked to a pool is marked as unmanaged data in NIOS, unless there is a corresponding network already created.
    - Tenant and VM information is merged into NIOS through cloud extensible attributes, only if there is a cloud license (Cloud Network Automation or Cloud Platform) installed in the Grid. Properties for unmanaged tenants and VMs are always updated while properties for managed tenants and VMs are updated only if auto-consolidation of tenant and VM information is selected when you configure the vDiscovery job.
- If a newly created vDiscovery job fails, first ensure that no control characters or permanently undefined Unicode characters such as non-breaking space, non-breaking hyphen, and so on are present in the job name.

Creating a new vDiscovery Job

To create a new vDiscovery job, complete the following tasks:

1. Name the new job and select a member to perform the vDiscovery, as described in Selecting the vDiscovery Member below. Do not use control characters or undefined Unicode characters in your job name.
2. Select a cloud platform for the vDiscovery, as described in SelectingtheEndpointServer below.
3. Define network views for public and private IP addresses, as described in Defining Network Views below.
4. Define policies for handling discovered data, as described in Defining Policiesfor HandlingDiscovered Data below.
5. Optionally, you can enable NIOS to automatically create DNS records for newly discovered VMs using their IP addresses, as described in CreatingDNSRecords for Newly DiscoveredVMs below.
6. Schedule the vDiscovery job, as described in SchedulingvDiscoveryJobs below.

Selecting the vDiscovery Member

To create a new or modify an existing vDiscovery job:

1. For a new vDiscovery job: From the **Data Management** tab, select the **IPAM** tab, then select **vDiscovery** -> **New** from the Toolbar; or from the **Cloud** tab, select **vDiscovery** -> **New** from the Toolbar.
   or
   To modify an existing job: From the **Data Management** tab, select the **IPAM** tab and click **vDiscovery** -> **Discovery**

Manager from the Toolbar, or from the **Cloud** tab, select **vDiscovery** -> **Discovery Manager** from the Toolbar. In the **vDiscovery Job Manager** editor, click the Action icon

next to a selected job and select **Edit** from the menu.

2. In step one of the v*Discovery Job* wizard or in the **General** tab of the *vDiscovery Job Properties* editor, complete the following:
    - **Job Name**: Enter the job name for this vDiscovery. It might be helpful to use a name that is unique to this specific discovery if you plan to configure multiple vDiscovery jobs. You cannot update the job name after the vDiscovery job is run for the first time.
    - **Member**: Click **Select** to choose the Grid member that will perform the vDiscovery job. If only a single member is active, the appliance name automatically appears here. When you select a Cloud Platform Appliance to perform vDiscovery, it communicates directly with the CMPs to obtain information that is not available through the provisioning process from the cloud adapter.
    - **Comment**: Enter information to describe this discovery.
      The new job will not execute until you have completed all configuration steps in the wizard. You will not be able to save this job until you have completed all job settings.
3. Click **Next** to select an endpoint server on which you want to perform the vDiscovery job, as described in SelectingtheEndpointServer below, or save the configuration after you have modified data in this tab.

Selecting the Endpoint Server

⚠ Note

- You might lose some discovered data if you modify any of the following parameters for an existing vDiscovery job. To avoid this, create a new vDiscovery job instead.
- Azure Government Cloud uses different service endpoints for its services. For more information about Azure service endpoints, refer to the *Infoblox Installation Guide for vNIOS for Azure* .
- Updates to the root CAs of Azure services installed by Microsoft, can cause vDiscovery to fail.
  If vDiscovery fails with ERROR: PycURL error: (60, 'SSL certificate problem: unable to get local issuer certificate'):
    a. Download the **DigiCert Global Root G2** Certificate from *DigiCert Root Certificates*.
    b. Upload the certificate to NIOS as described in *Uploading CA Certificates*.
- From NIOS 8.4.2 onward, each GCP vDiscovery job can utilize only one uniquely named service account file.
- You can use the same service account file for different GCP vDiscovery jobs in earlier NIOS releases (such as 8.4.0, 8.4.1). However, deleting one vDiscovery job causes the other vDiscovery job with the same name to be stuck in "Job in Progress" state. It is recommended to use only one uniquely named service account file for each vDiscovery job.
- You cannot edit an existing GCP vDiscovery job to upload a different service account file.
- Auto created networks and VM instances having IP address of auto created networks cannot be discovered by GCP vDiscovery.

1. In step two of the v*Discovery Job* wizard, or in the **Endpoint** tab of the *vDiscovery Job Properties* editor, complete the following:

- **Server Type**: Choose one of the following server types for this vDiscovery:
    - **AWS**: Collects information available for the AWS service endpoint. You can perform vDiscovery jobs through a proxy server in an AWS deployment, including Amazon Route 53. For more information, see *Configuring Proxy Servers*.
    - **Azure**: Collects information available for virtual entities in the specified VNets (Azure virtual networks) within the Microsoft Cloud.
    - **OpenStack**: When you select this server type, vDiscovery discovers network information stored in Neutron servers, VM instance information in Nova servers, and tenant or project information in Keystone servers.
    - **VMware**: Supports VMware vCenter and vSphere servers v5.0 and later. Collects information for all virtual entities running on the specified servers.
    - **GCP**: Collects information available for virtual entities in the specified GCP project.

Depending on the server type you select, other options in this step change accordingly, as follows:

For **AWS**, complete the following:

- **Service Endpoint**: This is typically the regional service endpoint for the desired Amazon region. Example: ec2.us-west-1.amazonaws.com. For more information about AWS service endpoints, refer to the *Infoblox Installation Guide for vNIOS for AWS*, available on the Infoblox Support site. For a list of available AWS service endpoints, see *https://docs.aws.amazon.com/general/latest/gr/ec2-service.html*
- **Port**: Enter the port you want to use for the vDiscovery job.
- **Protocol**: The protocol used for AWS is always over SSL. AWS provides certificates that is linked to the CA. By default, this certificate is embedded in NIOS and used as a reference for the CA when connecting to AWS. You can also upload a new certificate as described in *Managing Certificates*. If you upload a new certificate, the embedded certificate will be overwritten by the new one.
- **Allow unsecured connection**: This option is not applicable for AWS connection.

Credentials: Select the method you want to use to authenticate the connection between the Grid member and AWS for discovery jobs. You can select one of the following:

- **Use instance profile**: An instance profile is a container for an IAM role that you use to pass role information to an EC2 instance when the instance is up and running. Select this option if you want to collect information from AWS by waiving a user's credentials and by using configuration of a predefined IAM role to get a temporary token that allows API calls. Note that you must first configure the option for "instance profile" in AWS, define an IAM role in the instance profile, and then set permissions for this role before you can select this option. Otherwise, this option is disabled. When you select this, you do not need to provide user credentials.
  Note: Multiple vDiscovery jobs are required for multiple accounts irrespective of the scope of the instance profile.
- **Use IAM credential**: Select this if you want to authenticate by using IAM roles to grant secure access to AWS resources from your EC2 instances. Click **Select** to choose the IAM role and use its credentials to access AWS resources from your EC2 instances when they are up and running.
  - **Access Key ID** and **Secret Access Key**: Enter the Access Key ID and Secret Access Key for the AWS service endpoint. This is the secret key pair for the administrator account that executes the discovery job. For more information, refer to the *Infoblox Installation Guide for vNIOS for AWS*, available on the Infoblox Support site.

For more information about instance profiles and IAM roles, refer to the AWS documentation.

For **Azure**, complete the following:

- **Service Endpoint**: This is the service endpoint for the desired VNet in the Microsoft Cloud. For more information about Azure service endpoints, refer to the *Infoblox Installation Guide for vNIOS for Azure*.
- **Port**: Enter the port you want to use for the vDiscovery job.
- **Protocol**: The protocol used for Azure is always over SSL. Azure provides certificates that is linked to the CA. By default, this certificate is embedded in NIOS and used as a reference for the CA when connecting to Azure. You can also upload a new certificate as described in *Managing Certificates*. If you upload a new certificate, the embedded certificate will be overwritten by the new one.
- **Allow unsecured connection**: This option is not applicable for Azure connection.
- **Client ID** and **Client Secret**: Enter the client ID and client secret for the Microsoft Azure account. When you configure the client account, ensure that you have authorization to obtain device information on a wide network basis. If you replace the client secret of the vDiscovery job with the existing client ID, you must restart the vDiscovery job for the changes to take effect. For information about Azure client ID and client secret, refer to Microsoft Azure documentation.

For **OpenStack**, complete the following:

- **Keystone Server IP**: Enter the Keystone Server IP address.
- **Keystone Server Port**: Select this checkbox If you are using Identity Endpoint for the connection, else enter the Keystone Server Port number.
- **Protocol**: Select **HTTP** or **HTTPS** as the protocol. When you select **HTTPS**, you must upload the corresponding SSL CA certificate to the Grid in order for NIOS to communicate with OpenStack, as described in *Managing Certificates*.
- **Allow unsecured connection**: This option is enabled when you use HTTPS as the protocol. When you select this, the appliance bypasses remote SSL certificate validation. Select this option only if security for the HTTPS

connection between the discovering member and OpenStack is irrelevant, or if the connection is protected by other security measure besides TSL/SSL, such as an isolated private circuit.
- **Username** and **Password**: Enter the username and password of the administrative account that was configured on OpenStack. When you configure the administrative account, ensure that you have authorization to obtain device information on a wide network basis.
- **Identity Version**: Select the Keystone server identity service version from the drop-down list. You can select one of the following: **Keystone v2** and **Keystone v3**. By default, **Keystone v2** is selected.
- **Domain Name**: Enter the domain name. This field is displayed only if you select **Keystone v3** as the identity version.

For **VMware**, complete the following:

- **Host**: Enter the host name of the VMware server.
- **Port**: Enter the port number of the VMware server.
- **Protocol**: Select **HTTP** or **HTTPS** as the protocol. When you select **HTTPS**, you must upload the corresponding SSL CA certificate in order for NIOS to communicate with the VMware server, as described in *Managing Certificates*.
- **Allow unsecured connection**: This option is enabled when you use HTTPS as the protocol. When you select this, the appliance bypasses remote SSL certificate validation. Select this option only if security for the HTTPS connection between the discovering member and VMware is irrelevant, or if the connection is protected by other security measure besides TSL/SSL, such as an isolated private circuit.
- **Username** and **Password**: Enter the username and password of the administrative account that was configured on the specified VMware server. When you configure the administrative account, ensure that you have authorization to obtain device information.

For **GCP**, complete the following:

- **Service Account File**: Click **Upload** to select and upload the GCP service account file from your local disk. For more information about creating a GCP Service Account, see *Creating GCP Service Account*.

Click **Next** to define the network views to which discovered data belongs for both public and private IP addresses, as described in Defining NetworkViews below.

Defining Network Views

To track overlapping networks and IP address ranges so you can discover specific networks and IP addresses, you can associate one or more network views with a Grid member or Cloud Platform Appliance that is selected to run the vDiscovery. You can then define a specific network view to which discovered data for public and private IP addresses belongs if the network view is not automatically detected. If no network view is specified, the default network view is used.
For Network Insight, when you discover networks using multiple discovery interfaces, you must configure network views so you can associate each discovery interface with an available network view. Note that on the same discovering member, each discovery interface must have a unique network view association.

1. For a new vDiscovery job: From the **Data Management** tab, select the **IPAM** tab, then select **vDiscovery** -> **New** from the Toolbar; or from the **Cloud** tab, select **vDiscovery** -> **New** from the Toolbar.
   or
   To modify an existing job: From the **Data Management** tab, select the **IPAM** tab and click **vDiscovery** -> **Discovery Manager** from the Toolbar, or from the **Cloud** tab, select **vDiscovery** -> **Discovery Manager** from the Toolbar. In the **vDiscovery Job Manager** editor, click the Action icon next to a selected job, and then select **Edit** from the menu.
   Action icon
   
2. In step three of the v*Discovery Job* wizard, or on the **Network View** tab of the *vDiscovery Job Properties* editor, complete the following:
   - Under the **For Public IP Addresses** section, select one of the following options the appliance uses if the network view is not automatically detected:
     - **This Network View**: From the drop-down list, specify a network view to which discovered data for public IP addresses belongs. The default is the default network view. You cannot create a new network view for this option.

- **The tenant's network view (if it does not exist, create a new one)**: Select this only if at least one cloud license is installed in the Grid. When you select this, discovered data for public IP addresses belongs to the tenant's network view. If the network view does not exist, the appliance creates it (only if a cloud license is installed in the Grid). The appliance uses tenant information of a discovered public IP address to create a new NIOS network view for all discovered objects (primarily subnets) for that tenant. For example, AWS tenants by default are associated with the user account's 12-digit account number (such as 2233441247523), which is the identifier for all objects that are created by that account in AWS. That tenant value becomes the identifier for the new network view as its objects are discovered by NIOS.

- Under the **For Private IP Addresses** section, select one of the following options the appliance uses if the network view is not automatically detected:
  - **This Network View**: From the drop-down list, select a network view to specify a network view to which discovered data for private IP addresses belongs. The default is the default network view. You cannot create a new network view for this option.
  - **The tenant's network view (if it does not exist, create a new one)**: Select this only if at least one Cloud Platform Appliance is active or a cloud license is installed in the Grid. When you select this, discovered data for private IP addresses belongs to the tenant's network view. If the network view does not exist, the appliance creates it (only if a cloud license is installed in the Grid). The appliance uses tenant information of a discovered private IP address to create a new NIOS network view for all discovered objects (primarily subnets) for that tenant. For example, AWS tenants by default are associated with the user account's 12-digit account number (such as 2233441247523), which is the identifier for all objects that are created by that account in AWS. That tenant value becomes the identifier for the new network view as its objects are discovered by NIOS.

3. Configure filtering options for vDiscovery as described in the *Defining Filtering Options* section.

Defining Filtering Options (for AWS and GCP only)

Configure a vDiscovery job with CIDR-based filters to restrict vDiscovery to discover data only in included networks or skip vDiscovery in excluded networks. The maximum number of networks you can include in or exclude from a vDiscovery job is 10.

> **Note**
> You can enable the vDiscovery filter options only for private networks, not for public networks.

To define the filtering options for a vDiscovery job, complete the following steps:

1. Do one of the following:
   - To create a new vDiscovery job:
     - On the **Data Management** tab -> **IPAM** tab, from the Toolbar, select **vDiscovery** -> **New**.
       or
     - On the **Cloud** tab, from the Toolbar, select **vDiscovery** -> **New**.
   - To modify an existing job:
     i. Do one of the following:
        - On the **Data Management** tab -> **IPAM** tab, from the Toolbar, select **vDiscovery** -> **Discovery Manager**.
          or
        - On the **Cloud** tab, from the Toolbar, select **vDiscovery** -> **Discovery Manager**.

     ii. In the *vDiscovery Job Manager* editor, click the **Action** icon next to a selected job, and then select **Edit** from the menu.
2. In step three of the v*Discovery Job* wizard, do the following in the **Filtering Options** section:
   a. Select **Enable Filter**.
   b. In the **Network** drop-down list, do one of the following:
      - Select **INCLUDE** to include networks in which the vDiscovery job must discover resources. All other networks will be excluded from vDiscovery.
      - Select **EXCLUDE** to specify networks that must be excluded from vDiscovery. All other networks will be included in vDiscovery.

c. Click the **Add** icon and, for networks to be included in or excluded from vDiscovery, enter a valid IP address range in the CIDR notation.

3. Click **Next** to configure the appliance to handle discovered data as described in the *Defining Policies for Handling Discovered Data* section.

Defining Policies for Handling Discovered Data

In this step, you define how the appliance handles discovered data.

1. For a new vDiscovery job: From the **Data Management** tab, select the **IPAM** tab, then select **vDiscovery** -> **New** from the Toolbar; or from the **Cloud** tab, select **vDiscovery** -> **New** from the Toolbar.
   or
   To modify an existing job: From the **Data Management** tab, select the **IPAM** tab and click **vDiscovery** -> **Discovery Manager** from the Toolbar, or from the **Cloud** tab, select **vDiscovery** -> **Discovery Manager** from the Toolbar. In the **vDiscovery Job Manager** editor, click the Action icon

   next to a selected job and select **Edit** from the menu.
2. In step four of the v*Discovery Job* wizard, or in the **Data Consolidation** tab of the *vDiscovery Job Properties* editor, complete the following:
   Under **When inserting discovered into NIOS**, select one or both of the following:
   - **Merge the discovered data with existing data:** When you select this checkbox, the appliance merges the discovered data with the existing data. It appends newly discovered data to existing data and preserves the existing data when there is no newly discovered data. This checkbox is selected by default. If you clear this checkbox, the appliance replaces the existing data with the newly discovered data and if there are no newly discovered values for some fields, the appliance removes the existing values for these fields and the fields become empty.
   - **Update discovered data for managed objects:** Select this checkbox if you want the appliance to update discovered data for all corresponding NIOS objects (if they exist in NIOS). If you do not select this checkbox, the appliance updates only the discovered data for unmanaged objects. None of the managed data will be updated. This checkbox is selected by default.
   - **For every newly discovered IP address, create**: Select this checkbox to enable NIOS to automatically create or update DNS records for discovered network entities and VM instances. It does not include cloud adapters such as AWS or DDNS. This is applicable if the records were originally created by vDiscovery. If you select this checkbox, NIOS considers all records created in a zone as one and calculate it as one serial number change.
     - **Host**: Select this to automatically create Host records for discovered entities.
     - **A & PTR Record**: Select this to automatically create A and PTR records for discovered entities. Note that the DNS zones and reverse-mapping zones to which the records belong must exist in NIOS before the vDiscovery job is executed. Otherwise, vDiscovery does not create the records.
     - **The DNS name will be computed from the formula**: Enter the formula that NIOS uses to create the DNS records for each discovered VM address. For example, if there are two IP addresses associated with a VM, NIOS creates two DNS records, or a host record with two IP addresses, depending on your configuration. You must use the syntax of `${parameter name}` for the formula.
       For AWS, Azure, GCP, OpenStack, and VMware cloud platforms, this field supports the following parameters:
       `vm_id, vm_name, discovered_name, tenant_id, tenant_name, subnet_id, subnet_name, network_id, network_name, vport_name, ip_address, ip_address_octet1 or 1, ip_address_octet2 or 2, ip_address_octet3 or 3, ip_address_octet4 or 4`. Note that it does not support IPv6 addresses.
       For example, when you enter `${vm_name}.corpxyz.com` and the discovered vm_name = XYZ, the DNS name for this IP becomes `XYZ.corpxyz.com`

. When you enter `${discover_name}` here and the discovered name for the IP is `ip-172-31-1-64.us-west-1.compute.internal`, the DNS name for this IP is `ip-172-31-1-64.us-west-1.compute.internal`.

- Under **Select the DNS view to which the DNS records are being added**, select one or both of the following:
  - **Use this DNS view for public IPs**: Select this checkbox to add DNS records to a specific DNS view for public IPs. Select a DNS view from the drop-down list. If you do not select a DNS view, the DNS records are added to the default DNS view.
  - **Use this DNS view for private IPs**: Select this checkbox to add DNS records to a specific DNS view for private IPs. Select a DNS view from the drop-down list. If you do not select a DNS view, the DNS records are added to the default DNS view.
    If you are changing the DNS view, ensure that the **Merge the discovered data with existing data** checkbox is not selected.
    Note that the **Use this DNS view for public IPs** and **Use this DNS view for private IPs** fields will be disabled, if you select **The tenant's network view (if it does not exist, create a new one)** option when you define the network views to which discovered data belongs for both public and private IP addresses, as described in Defining Network Views above.
    Under **When discovered data is linked to managed data**, select any combination of the following. Tenants and VMs are managed objects when they have NIOS objects, such as host records or fixed addresses, associated with them. Otherwise, they are unmanaged objects. The appliance always updates properties for all unmanaged objects.
  - **Auto-consolidate on managed Tenant's properties:** When you select this checkbox, the appliance updates properties with discovered data for managed tenants, as well as unmanaged tenants (NIOS always updates unmanaged tenants). When you clear this checkbox, the appliance does not update discovered data for managed tenants. This checkbox is selected by default.
  - **Auto-consolidate managed VM's properties:** When you select this checkbox, the appliance updates properties and extensible attributes with discovered data for managed VMs, as well as unmanaged tenants (NIOS always updates unmanaged tenants). When you clear this checkbox, the appliance does not update discovered data for managed VMs. This checkbox is selected by default.
  - **Auto-consolidate Cloud EAs on managed data:** When you select this checkbox, NIOS updates discovered extensible attribute values for managed objects that contain cloud extensible attributes, only if a cloud license is installed in the Grid. This includes the update of the extensible attribute **VM ID** (which links the NIOS object to the VM) whenever a VM is added, updated or removed depending on the information collected. As a result, when a VM instance reuses an IP address or when a VM instance is deleted in the Cloud, the DNS Records or fixed address tied to that IP address are also updated, reflecting the new value of the VM instance ID. To update cloud extensible attributes for unmanaged objects, convert the objects to managed objects in NIOS. For more information, see *Managing Unmanaged Data*.
    The extensible attribute **VM ID** is not updated if you do not enable the **Auto-consolidate Cloud EAs on managed data** checkbox, which leads to a conflict on that IP address. The NIOS object does not link to the same VM as the newly discovered IP. In such cases, you can use the **Resolve Conflicts** option to update either your NIOS objects or your discovered data. For information about resolving conflicts, see *Resolving Conflicting Addresses*.

3. Click **Next** to schedule this vDiscovery job and specify when the job should start, as described in Scheduling vDiscovery Jobs below.

Creating DNS Records for Newly Discovered VMs

When you configure the policies NIOS uses to handle discovered data, you can enable NIOS to automatically create or update DNS records for discovered IP addresses of VM instances. NIOS automatically adds Host records or A and PTR records for the discovered VMs based on your configuration. You can also enter a formula that NIOS uses to create the

DNS name for the discovered IP based on its VM parameters such as VM name or discovered name. By doing so, NIOS is able to discover public and private IP addresses by looking up the corresponding DNS names.
Discovered data includes IP addresses for the VMs and the associated information such as VM ID, VM Name, Tenant ID, and others. Note that corresponding zones must already exist in order for NIOS to add DNS records. Otherwise, NIOS does not add any DNS records and it logs a message in the syslog. For information about how to enable this feature, see Defining Policies for Handling Discovered Data above.
NIOS automatically adds DNS records based on the following conditions:

- The corresponding DNS zones must already exist in the NIOS database. NIOS does not automatically create DNS zones for the records.
- To create a PTR record, the corresponding reverse-mapping zone must exist.
- A DNS zone cannot be associated with more than one DNS view. NIOS does not create DNS records for zones that are associated with multiple DNS views.
- NIOS adds new DNS records only if the VM name for the discovered IP address is available and there is no conflict with information about the associated network view.

On subsequent vDiscovery, if an IP for a VM is removed, the corresponding DNS records are removed. If the IP for a VM is changed, the IP address in the corresponding DNS record is changed accordingly. If the DNS record name template is changed, all the DNS recorded are replaced with the DNS records using the new template. All administrative actions for these changes are recorded in the Audit log. Summary of the changes are logged in the syslog.
The following table captures some scenarios about how vDiscovery handles various actions and what the outcome is for the information on the Cloud Platform appliance and in the NIOS database. All the scenarios in the table use the following template: $(discovered_name).

> ⚠ Note
> vDiscovery updates only records that are created by the vDiscovery process. It does not create or update DNS records that are originally created by other admin users.

Actions and Conditions	Cloud Platform Data before vDiscovery	Cloud Platform Data after vDiscovery	NIOS Data before vDiscovery	NIOS Data after vDiscovery
• Add new VM (vma) on Cloud Platform appliance • Automatic creation of Host records • **In NIOS**: existing zone corpxyz.com; no DNS records	No data for vma	10.10.10.1 vma.corpxyz.com	**Zone**: corpxyz.com	**Zone**: corpxyz.com **Host record**: vma.corpxyz.com (10.10.10.1)
• Add new VM (vma) on Cloud Platform appliance • Automatic creation of Host records • **In NIOS**: existing zone corpxyz.com; existing Host record (*originally created by vDiscovery or admin*)	No data for vma	10.10.10.1 vma.corpxyz.com	**Zone**: corpxyz.com **Host record**: vma.corpxyz.com (10.10.10.1)	**Zone**: corpxyz.com **Host record**: vma.corpxyz.com (10.10.10.1)

Scheduling vDiscovery Jobs

You can enable the appliance to start a vDiscovery immediately after you configure it, schedule it for a later date and time, or configure a recurring discovery based on a recurrence pattern. Note that all scheduled vDiscovery jobs are executed in queue based on the order of the schedule in the **vDiscovery Job Manager**. Therefore, a scheduled vDiscovery might be delayed if there are other jobs being executed before its scheduled start time.

1. For a new vDiscovery job: From the **Data Management** tab, select the **IPAM** tab, then select **vDiscovery** -> **New** from the Toolbar; or from the **Cloud** tab, select **vDiscovery** -> **New** from the Toolbar.
   or
   To modify an existing job: From the **Data Management** tab, select the **IPAM** tab and click **vDiscovery** -> **Discovery Manager** from the Toolbar, or from the **Cloud** tab, select **vDiscovery** -> **Discovery Manager** from the Toolbar. In the **vDiscovery Job Manager** editor, click the Action icon

   next to a selected job and select **Edit** from the menu.
2. In step five of the v*Discovery Job* wizard, or in the **Schedule** tab of the *vDiscovery Job Properties* editor, complete the following:
   - **Enable**: To ensure that the scheduled vDiscovery job takes place, select this checkbox. When you upgrade from a previous version of NIOS, you must select this checkbox after the upgrade to ensure that the previously configured discovery tasks are being executed at the scheduled time.
     If you select **Once**, complete the following:
   - Choose a **Start Date** using the date picker.
   - **Time Zone**: Select the time zone for the scheduled time from the drop-down list.
     If you select **Hourly**, complete the following:
     - **Schedule every hour(s) at**: Enter the number of hours between each update instance. You can enter a value from 1 to 24.
     - **Minutes past the hour**: Enter the number of minutes past the hour. For example, enter 5 if you want to schedule the rule update five minutes after the hour.
     - **Time Zone**: Select the time zone for the scheduled time from the drop-down list.

   If you select **Daily**, you can select either **Every day** or **Every Weekday** and then complete the following:
   - **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
   - **TimeZone**: Select the time zone for the scheduled time from the drop-down list. If you select **Weekly**, complete the following:
   - **Scheduleeveryweekon**: Select any day of the week.

- **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
- **TimeZone**: Select the time zone for the scheduled time from the drop-down list. If you select **Monthly**, complete the following:
- **Schedulethedayofthemonth**: Enter the day of the month and the monthly interval. For example, to schedule the rule update on the first day after every 2 months, you can enter Day 1 every 2 month(s).
- **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
- **TimeZone**: Select the time zone for the scheduled time from the drop-down list.

3. Save the vDiscovery job. The appliance lists all vDiscovery jobs in the **vDiscovery Job Manager**, from which you can manage jobs that have not been executed, including modifying selected jobs or deleting some.

Managing vDiscovery Jobs

You can view all configured vDiscovery jobs or modify some of the settings for selected ones in the **vDiscovery Job Manager**. You can also add a new vDiscovery job by clicking the Add icon.
To view or modify vDiscovery jobs:

1. From the **Data Management** tab, select the **IPAM** tab, then select **vDiscovery** -> **Discovery Manager** from the Toolbar; or from the **Cloud** tab, select **vDiscovery** -> **Discovery Manager** from the Toolbar.
2. The appliance displays the following information in the **vDiscovery Job Manager**:
   - **Name**: The name of the vDiscovery job.
   - **Status:** The current status of the vDiscovery job. Grid Manager displays an icon and descriptive information about the status. You can hover you mouse over the icon to view the current status, as follows:
     - **Job created**: The configured job has been created.
     - **Job starting**: Starting the configured job.
     - **Job in progress**: The job is being executed at the moment.
     - **Job completed**: The job is completed successfully.
     - **Cancelled**: The job was cancelled while it was being executed.
     - **Error while running job**: The job has failed.
       If the "ERROR: PycURL error: (60, 'SSL certificate problem: unable to get local issuer certificate')" error message is displayed, it means that the certificate has expired or is invalid. You need to remove the expired or invalid certificate and upload a new one. If the error is displayed for an AWS vDiscovery job, download the certificates from *https://www.amazontrust.com/repository/* and upload them. If it is displayed for an Azure vDiscovery job, follow the instructions in the Azure documentation to generate a root certificate for Azure and upload it to NIOS. For information about uploading certificates, see *Managing Certificates*.
   - **Schedule**: Displays the configured schedule for the selected job.
   - **Public IP's Network View**: The name of the network view to which discovered data for public IP addresses belongs.
   - **Private IP's Network View**: The name of the network view to which discovered data for private IP addresses belongs.
   - **Member**: The Grid member that performs the vDiscovery job.
   - **Last Run**: The timestamp when the selected vDiscovery job was last performed.
   - **Comment**: Comments added when the vDiscovery job was created
3. Click the Action icon

   next to a selected job, and you can do one of the following:
   - **Edit**: Modify the vDiscovery job settings in the *vDiscovery Job Properties* editor. The editor displays the following tabs: **General**, **Endpoint**, **Network View**, **Data Consolidation**, and **Schedule**. Click the tab that contains information you want to modify, and then modify the information as described in Configuring vDiscovery Jobs above.
   - **Delete**: Remove the vDiscovery job from the list.
   - **Start**: Start vDiscovery now for the selected job. The appliance might display an AMQP error when you first start a newly created vDiscovery job. This is due to the start-on-demand mechanism experiencing a delay in executing the job. Wait a few seconds and start the job again.
   - **Stop**: Stop and terminate the vDiscovery job that is in progress. You cannot resume this discovery once you stop it. All discovered data remains intact in the database.

4. Click **Close** to close the **vDiscovery Job Manager**.

Viewing Discovered Data

After an IP discovery and a vDiscovery, you can view discovered data in the Discovered Data section when you drill down to a specific IP address in the Net Map, Net List, IP Map or IP List panel. For information about IP Map and IP List, see *Viewing and Managing IPv4 Addresses.*
You can also view discovered data for Cloud specific VMs in the Cloud tab. Note that you must install the Cloud Network Automation license on the Grid Master to view the Cloud tab.

Viewing IPAM Discovered Data

To view discovered data in the **IPAM** tab:

1. In the top navigation bar, select the network view to which discovered data belongs.
2. From the **Data Management** tab, select the **IPAM** tab.
3. In the IPAM home page, select the network you want to view discovered data and click the link.
4. In the IP List of IP Map panel, click the IP address link to drill down to the IP address properties panel.
5. In the **Discovered Data** section, click the Configure icon to specify data to be displayed in the **Discovered Data** tab.
6. Select fields from the **Available** list and click the arrow key to move them to the **Selected** list and vice versa. You can use CTRL+Click or SHIFT+Click to select multiple fields at one time.
   You can also change the order in which the fields are displayed by moving the fields up and down in the **Selected** list. To move a field up in the list, select it and click the Up arrow. To move a field down, select it and click the Down arrow.
7. Click the Configure icon again, and the **Discovered Data** section displays the fields you have specified. Note the fields you select appears for all IP addresses in the network.

Depending on the source of the discovered data, when you modify certain DNS and DHCP objects, Grid Manager can display some of the following discovered data (if any) in the **Discovered Data** tab:

- **NetBIOSName**: The name returned in the NetBIOS reply or the name you manually register for the discovered host.
- **OS**: The operating system of the detected host or virtual entity. The OS can be one of the following:
- **Microsoft** for all discovered hosts that have a non-null value in the MAC addresses using the NetBIOS discovery method.
- A value that a TCP discovery returns.
- The OS of a virtual entity on a vSphere server.
- **Discovered MAC Address**: The discovered MAC address for the host. This is the unique identifier of a network device. The discovery acquires the MAC address for hosts that are located on the same network as the Grid member that is running the discovery. This can also be the MAC address of a virtual entity on a specified vSphere server.
- **AP Name**: The name of the access point for the device. This column is displayed only for wireless devices. If discovered by NetMRI, the value will be populated through IPAM Sync as well.
- **AP IP Address**: The IP address of the access point for the device. This column is displayed only for wireless devices. If discovered by NetMRI, the value will be populated through IPAM Sync as well.
- **SSID**: The unique name of the WLAN (Wireless Local Area Network). If discovered by NetMRI, the value will be populated through IPAM Sync as well.
- **Discovered DUID**: For IPv6 address only. The DHCP unique identifier of the discovered host. This is an optional field, and data might not be included.
- **Last Discovered**: The timestamp when the IP address was last discovered.
- **First Discovered**: The timestamp when the IP address was first discovered.
- **Task Name**: The name of the task that collected the discovered data. It is usually the ID or task name that collected the data. It is defined on the corresponding NetMRI appliance when you import the discovered data to the NIOS appliance. The task name should be defined in thevDiscoverytask managerforvDiscovery.
- **Discovered Name**: The name of the network device associated with the discovered IP address.
- **Discoverer**: Specifies whether the IP address was discovered by NetMRI or NIOS discovery process.

If you imported data from NetMRI appliances, Grid Manager displays the following information, if available. For information about the data imported from NetMRI appliances, see *Integrating Discovered Data From NetMRI*.

- **Attached Device Description**: A textual description of the switch that is connected to the end device.
- **Attached Device Address**: The IPv4 or IPv6 address of the switch that is connected to the end device.
- **Attached Device Model**: If a reverse lookup was successful for the IP address associated with this switch, the device model is displayed here.
- **Attached Device Name**: If a reverse lookup was successful for the IP address associated with this switch, the host name is displayed here.
- **Attached Device Port Description**: A textual description of the switch port that is connected to the end device.
- **Attached Device Port Name**: The name of the switch port or port channel connected to the device. For Cisco devices with virtual port channel configured, this field also displays the list of physical interfaces that form the virtual port channel. For more information, see *IP List Neighbor Information*.
- **Attached Device Vendor**: The vendor name of the switch port connected to the end device.
- **Attached Device Port**: The number of the switch port connected to the end device.
- **Attached Device Type**: Identifies the switch that is connected to the end device.
- **Attached Device Location**: The physical location of the network device to which the end host is connected/attached, as detected from the device during discovery.
- **Attached Device Contact**: The contact details for the network device to which the End Host is connected/attached, as detected from the device during discovery.
- **Device Vendor**: The vendor name of the end device.
- **Device Model**: The device model of the end device.
- **Device Location**: The physical location of the network device on which the IP Address is configured, as detected from the device during discovery.
- **Device Contact**: The contact details for the network device on which the IP Address is configured, as detected from the device during discovery.
- **Device Management IP**: The IPv4 or IPv6 address of the end device that is connected to the switch.
- **Device Port Type**: The port type for the end device.
- **Device Port Name**: The port name for the end device.
- **Device Type(s)**: Identifies the device type.
- **Port Duplex**: The negotiated or operational duplex setting of the switch port connected to the end device. You can modify this in the IPv6 fixed address and AAAA record editors.
- **Port Link**: The link status of the switch port connected to the end device. Indicates whether it is connected.
- **Port Speed**: The interface speed, in Mbps, of the switch port. You can modify this in the IPv6 fixed address and AAAA record editors.
- **Port Type**: The switch port type.
- **Port Status**: The operational status of the switch port. Indicates whether the port is up or down.
- **Open Port(s)**: Ports that are open.
- **VLAN Name**: The name of the VLAN of the switch port.
- **VLAN ID**: The ID of the VLAN of the switch port.

For IP addresses discovered through a vDiscovery, Grid Manager displays the following additional information, if available:

- **Virtual Host Adapter**: The name of the physical network adapter through which the virtual entity is connected to the appliance.
- **Virtual Datacenter**: The name of the vSphere datacenter or container to which the virtual entity belongs.
- **Virtual Cluster**: The name of the VMware cluster to which the virtual entity belongs.
- **Virtual Entity Name**: The name of the virtual entity.
- **Virtual Entity Type**: The virtual entity type. This can be blank or one of the following: Virtual Machine, Virtual Host, or Virtual Center. Virtual Center represents a VMware vCenter server.
- **Virtual Host**: The name of the VMware server on which the virtual entity was discovered.
- **Virtual Switch**: The name of the switch to which the virtual entity is connected.
- **Virtual Machine Name**: The name of the VM instance.
- **Virtual Machine ID**: The ID of the VM.
- **Virtual Machine Tenant ID**: The tenant ID to which the VM belongs.
- **Virtual Machine Port Group**: The port group to which the VM belongs.
- **Attached Virtual Switch Name**: The name of the virtual switch to which the VM is connected.
- **Attached Virtual Switch ID**: The ID of the virtual switch to which the VM is connected.
- **Attached Virtual Switch Type**: The type of the virtual switch. This can be standard or distributed.

- **Attached Virtual Switch IPv6 Enabled**: Indicates that virtual switch that has IPv6 enabled.
- **Attached Virtual Port Name**: The name of the virtual adapter on the virtual switch to which the VM is connected.
- **Attached Virtual Port MAC Address**: The MAC address of the virtual adapter on the virtual switch to which the VM is connected.
- **Attached Virtual Port Link Status**: The link status of the virtual adapter on the virtual switch to which the VM is connected.
- **Attached Virtual Port Configured Speed**: The configured port speed of the virtual adapter on the virtual switch to which the VM is connected.
- **Attached Virtual Port Configured Mode**: The configured mode of the virtual adapter on the virtual switch to which the VM is connected.
- **Attached Virtual Port Configured Speed**: The actual port speed of the virtual adapter on the virtual switch to which the VM is connected.
- **Attached Virtual Port Configured Mode**: The actual mode of the virtual adapter on the virtual switch to which the VM is connected.
- **Network Segment Type**: The type of network segment to which the VM is connected.
- **Network Segment Name**: The name of the network segment to which the VM is connected.
- **Network Segment ID**: The ID of the network segment to which the VM is connected.
- **Network Segment Port Group**: The port group of the network segment to which the VM is connected.
- **Network Segment Available Ports**: The number of available ports reported by the virtual switch to which the VM is connected.
- **Attached Virtual Switch VTEP Type**: The type of VTEP (Virtual Tunnel Endpoint) in the virtual switch that is connected to the VM. This can be VXLAN or STT.
- **Attached Virtual Switch VTEP IP**: The IP address of the VTEP in the virtual switch that is connected to the VM.
- **Attached Virtual Switch VTEP Port Group**: The port group of the VTEP in the virtual switch that is connected to the VM.
- **Attached Virtual Switch VTEP VLAN**: The VLAN of the VTEP in the virtual switch that is connected to the VM.
- **Attached Virtual Switch VTEP DHCP Server**: The DHCP server of the VTEP in the virtual switch that is connected to the VM.
- **Attached Virtual Switch VTEP Multicast**: The multicast address of the VTEP in the virtual switch that is connected to the VM.
- **Physical Host IP Address**: The IP address of the physical node on which the VM is hosted.
- **Physical Host Name**: The name of the physical node on which the VM is hosted.
- **Physical Host MAC Address**: The MAC address of the physical node on which the VM is hosted.
- **Physical Host CIDR Subnet**: The subnet mask of the physical node on which the VM is hosted.
- **Physical Host 's NIC Names**: The list of all physical port names used by the virtual switch on the physical node on which the virtual machine is hosted. Valid values are eth1, eth2, eth3, and so on.

Viewing Discovered Data for Cloud VMs

You can view discovered data for cloud specific VMs after performing a vDiscovery job. Note that you must have at least read-only permission to "All Tenants" and "All Network Views" to view the **VMs** tab.
To view discovered data for cloud VMs, see *Viewing All Cloud VMs*.

Managing Discovered Data

In addition to viewing the discovered data, you can perform the following to manage the discovered data:

- Manage an unmanaged address by adding it to a host, converting it to managed data, or clearing its unmanaged status. Note that for Cloud Network Automation, you can convert discovered data to NIOS objects within a delegated scope.
- Resolve conflicting addresses.
- Clear discovered data for a network view, network, IP address, or cloud tenant.
- You can also clear all discovered data collected by a specified vDiscovery job.

This section covers the following:

Managing Unmanaged Data

You can manage unused and unmanaged addresses by performing one of the following:

- Add to an existing host, as described in Adding to an Existing Host below.
- Convert to a fixed address, host, A record, or PTR record, as described in Converting Unmanaged Data below. Note that for Cloud Network Automation, you can convert discovered data to NIOS objects within a delegated scope.
- Clear the unmanaged status, as described in Clearing Unmanaged Data below.

> ⚠ Note
>
> You cannot convert unmanaged IP addresses that are being served by Microsoft DHCP servers to host records.

Adding to an Existing Host

You can add an unmanaged address, including all its information, to an existing host. You can select the desired host to which you want to add the unmanaged address.
To add an unmanaged address to an existing host, perform the following:

1. From the *IP Map* or *List* panel, select an unmanaged address you want to add to a host, and then click **Add** -> **Add to Existing Host** from the Toolbar.
2. In the *Select Host* dialog box, select a host from the table. You can also search for a host using filters or the Go to function. For information Using filters and Using the go to Function , see *Finding and Restoring Data*. Click the Select icon to select the desired host.
   Note that depending on the page size configuration, the search results are limited to the page size that you set. If the search results exceed the page size limit, the appliance displays an error message to inform you to refine your search criteria or to change the page size limit. In the *Host Record* editor, complete the information.
3. Save the configuration, and then click **Restart** if it appears at the top of the screen.

Converting Unmanaged Data

You can convert an unmanaged address to a host, an A or AAAA record, a PTR record, or a fixed address. To convert an unmanaged address:

1. In the *IP Map* or *List* panel, select an unmanaged address you want to convert, and then select **Convert** from the Toolbar.
2. In the drop-down list, select the type of address to which you want to convert the unmanaged address. For IPv4 addresses, you can select **To Host**, **To A Record**, **To PTR Record**, or **To Fixed Address**. For IPv6 addresses, you can select **To Host**, **To AAAA**, **To PTR Record**, or **To IPv6 Fixed Address**.
   Depending on the record type you select, Grid Manager displays the corresponding editor. It also populates the attributes of the unmanaged address in the editor. Enter the appropriate information in the editor.
3. Save the configuration, and then click **Restart** if it appears at the top of the screen.

Note
After the conversion, the status of the unmanaged address changes to **Used**.

The following are some conditions for a conversion:

- **A and AAAA records**: You must select a DNS zone when converting an unmanaged address to an A or AAAA record.
- **PTR record**: You must select a DNS zone when converting an unmanaged address to a PTR record.
- **IPv4 and IPv6 Fixed Address**: Grid Manager displays a confirmation dialog box to ensure that you want to create a fixed address for the unmanaged address.
- **IPv4 and IPv6 Host record**: You can use the unmanaged address to enable a host record for DNS or DHCP.

Clearing Unmanaged Data

Unmanaged objects are objects that are not configured for DNS or DHCP and do not have any corresponding NIOS objects such as fixed addresses, DNS records, or host records. You can clear unmanaged data if you do not want it to appear in the discovered data. Any unmanaged data that was discovered in a previous discovery can be removed. When you clear an unmanaged IP address, the status of the IP address changes to **Unused**.
Note that for cloud deployments, you can remove an unmanaged VM only when all the VM related properties are removed first. When the VM is removed, the tenant pointing to this VM will also be removed automatically. For information about cloud deployments, see *Deploying Cloud Network Automation*.
To clear unmanaged data, complete the following steps:

Method 1

1. **For IP addresses**: From the **Data Management** tab -> **IPAM** tab, select an unmanaged IP address in the *IPMap* or *List* panel.
   For networks: From the **Data Management** tab -> **IPAM** tab -> *IPMap* or *List* panel, select a network in which you want to clear all unmanaged addresses.
   For Cloud tenants: From the **Cloud** tab -> **Tenants** tab, select a tenant for which you want to clear unmanaged data.
   For Cloud VMs: From the **Cloud** tab -> **VMs** tab, select a VM for which you want to clear unmanaged data.
2. Click **Clear** -> **Clear Unmanaged Data** or **Clear All Unmanaged Data** from the Toolbar.
3. In the *ClearUnmanagedData* confirmation dialog box, click **Yes**. The appliance clears data that has no corresponding NIOS objects such as fixed addresses, DNS records, or host records.

Method 2

1. From the **Cloud** tab -> **VM** tab, select **Discovery Manager** from the Toolbar.
2. In the *vDiscoveryJobManager* dialog, click the Action icon

   next to the selected vDiscovery job, and then select **Clear Unmanaged Data**.
3. In the *ClearUnmanagedData* confirmation dialog box, click **Yes**. The appliance clears data that has no corresponding NIOS objects such as fixed addresses, DNS records, or host records.

Note
After you clear all the unmanaged data, you should navigate to the **Data Management** tab and clear all the associated networks. When you clear unmanaged addresses in a given network view, all unmanaged IPv4 and IPv6 addresses of all networks in the network view are cleared. When you select an entire network or a specific network in the *IP Map* or *List* panel, all the unmanaged addresses in the network are cleared. After you clear the unmanaged data, the status of the IP addresses changes to **Unused**.

Resolving Conflicting Addresses

Conflicts happen when discovered data does not match existing IP address data. The *IP Map* panel and the **Cloud** tab -> **VMs** tab display conflicting addresses with a red background. The *IP List* panel displays **Conflict** as the status for all

conflicting addresses. For objects that have multiple conflicts, Grid Manager lists each of them in a bulleted list in the *Resolve multiple conflicts* dialog. You can select a conflict, in any order, to begin resolving each issue. After you resolve the selected issue, Grid Manager returns to the *Resolve multiple conflicts* dialog so you can resolve other issues. Depending on the conflict, you can do one of the following to resolve it:

- For a DHCP lease conflict, you can clear the existing lease and create either a fixed address or a reservation for the IP address. You can also keep the existing data and clear the discovered data. For more information, see Resolving DHCP Lease Conflicts below.
- For a fixed address conflict, you can either keep the existing fixed address data or update the existing data with the discovered data. For more information, see Resolving Fixed Address Conflicts below.
- For a DHCP range conflict, you can create a fixed address, create a reservation, or clear the discovered data. For more information, see Resolving DHCP Range Conflicts below.
- For a host conflict, you can either keep the existing host record data or update the existing data with the discovered data. For more information, see Resolving Host Conflicts below.
- For a VM affiliation conflict, you can either update all the displayed objects to be affiliate with the discovered data or keep the current affiliation and clear the conflict. For more information, see Resolving VM Affiliation Conflicts below.

You must resolve conflicting addresses individually. You cannot resolve multiple conflicts at the same time.

Note

After the conflict is resolved, the status of the IP address changes depending on how you resolved the conflict.

To resolve a conflict:

1. In the *IP Map* or *List* panel, select a conflicting address, and then click **Resolve Conflict** from the Toolbar.
2. The *Resolve Conflict* dialog box displays the reason of the conflict and lists the existing information and discovered information of the address in the **Description** field. Depending on the type of conflict, the appliance displays the corresponding resolution options. You can compare the existing and discovered data and decide how you want to resolve the conflict.

Resolving DHCP Lease Conflicts

When an IP address has a DHCP lease and the discovered MAC address is in conflict with the existing MAC address, the IP address has a DHCP lease conflict.
To resolve a DHCP lease conflict, perform the following:

1. In the *Resolve Conflict* or *Resolve multiple conflicts* dialog, Grid Manager displays the nature of the conflict and the discovered data versus the current data. Select one of the following to resolve the conflict:
   - **Clear lease and create fixed address from discovered data**: Clears the existing DHCP lease and creates a fixed address with the discovered data. The *Fixed Address* editor appears with the discovered data populated.
   - **Clear lease and create a reservation from discovered data**: Clears the existing DHCP lease and creates a new reservation using the discovered data. The *Reservation* editor appears with the discovered data populated.
     This option does not apply to leases served by Microsoft DHCP servers because they do not support Infoblox reservations.
   - **Keep the existing and ignore this conflict**: Keeps the current DHCP lease for the address and ignores the lease conflict.
2. Click **OK** or **Resolve** (when you have multiple conflicts). If you have multiple conflicts, Grid Manager returns to the *Resolve multiple conflicts* dialog so that you can resolve other conflicts.

Resolving Fixed Address Conflicts

When the discovered MAC address of an IPv4 address does not match with its existing MAC address, or when the DUID of an IPv6 address does not match with its existing DUID, the IP address has a fixed address conflict.
To resolve a fixed address conflict, perform the following:

1. In the *Resolve Conflict* or *Resolve multiple conflicts* dialog, Grid Manager displays the nature of the conflict and the discovered data versus the current data. Select one of the following to resolve the conflict:
    - **Keep fixed address and clear discovered data**: Keeps the existing fixed address and clears the discovered data.
    - **Update fixed address with discovered data**: Updates the existing fixed address data with the discovered data.
2. Click **OK** or **Resolve** (when you have multiple conflicts). If you have multiple conflicts, Grid Manager returns to the *Resolve multiple conflicts* dialog so that you can resolve other conflicts.

Resolving DHCP Range Conflicts

When an IP address is in a DHCP range and does not match an existing DHCP lease, fixed address, or exclusion range and it shows an active state during a discovery, the IP address has a DHCP range conflict.
To resolve a DHCP range conflict:

1. In the *Resolve Conflict* or *Resolve multiple conflicts* dialog, Grid Manager displays the nature of the conflict and the discovered data versus the current data. Select one of the following to resolve the conflict:
    - **Create a fixed address**: Creates a fixed address with the discovered data.
      If the fixed address is served by a Microsoft server, but is outside of a scope, you must then navigate to the *Fixed Address* editor and assign the fixed address to the appropriate Microsoft server.
    - **Create a reservation**: Creates a reservation with the discovered data. This creates an Infoblox reservation, and therefore cannot be used for IP addresses that are served by Microsoft servers. Note that you cannot convert an IPv6 address to a reservation.
    - **Clear discovered data**: Clears the discovered data and no object is created for the IP address.
2. Click **OK** or **Resolve** (when you have multiple conflicts). If you have multiple conflicts, Grid Manager returns to the *Resolve multiple conflicts* dialog so that you can resolve other conflicts.

Resolving Host Conflicts

When the MAC address of an IPv4 address that belongs to a host record does not match with its existing MAC address, or when the DUID of an IPv6 address that belongs to a host record does not match with its existing DUID, the IP address has a host conflict.

1. In the *Resolve Conflict* or *Resolve multiple conflicts* dialog, Grid Manager displays the nature of the conflict and the discovered data versus the current data. Select one of the following to resolve the conflict:
    - **Keep host record and clear discovered data**: Keeps the existing data and clears the discovered data.
    - **Update host record with discovered data**: Updates the existing host record data with the discovered data.
2. Click **OK** or **Resolve** (when you have multiple conflicts). If you have multiple conflicts, Grid Manager returns to the *Resolve multiple conflicts* dialog so that you can resolve other conflicts.

Resolving VM Affiliation Conflicts

When an IP address contains objects that are affiliated with a VM that is not the same as the discovered VM, this IP address has a VM affiliation conflict.
To resolve a VM affiliation conflict:

1. In the *Resolve Conflict* or *Resolve multiple conflicts* dialog, Grid Manager displays the nature of the conflict and the discovered affiliation versus the current affiliation. Select one of the following to resolve the conflict:
    - **Update all the displayed objects to be affiliate to the discovered affiliation**: Updates all associated objects in this IP address to affiliate with the discovered affiliation.
    - **Keep the current affiliation(s) and clear the conflict**: Keeps the existing data and clears the conflict.
2. Click **OK** or **Resolve** (when you have multiple conflicts). If you have multiple conflicts, Grid Manager returns to the *Resolve multiple conflicts* dialog so that you can resolve other conflicts.

Resolving MAC Address Conflicts

When the MAC address of an existing IP address does not match the MAC address of the discovered data, the object has a MAC address conflict.
To resolve a MAC address conflict:

1. In the *Resolve Conflict* or *Resolve multiple conflicts* dialog, Grid Manager displays the nature of the conflict and the discovered data versus the current data. Select one of the following to resolve the conflict:
    - **Change the configured MAC address to be the same as the discovered MAC address**: Changes the MAC address to the discovered MAC address.
    - **Keep fixed address and ignore this conflict**: Keeps the fixed address and ignores the discovered data.
2. Click **OK** or **Resolve** (when you have multiple conflicts). If you have multiple conflicts, Grid Manager returns to the *Resolve multiple conflicts* dialog so that you can resolve other conflicts.

Clearing Discovered Data

You can clear previously discovered managed data for selected IPv4 or IPv6 networks. This action is useful, for example, if your network topology has changed since the last discovery and you want to discover new data on the network or cloud platform. You may perform this action whether or not the network is in a managed or unmanaged state.

> ⚠ Note
>
> This action clears only the discovered data that is supported in the **Discovered Data** section for an IP address. It does not clear any NIOS objects or information such as tenants, networks, or VMs for a cloud platform. If a discovered IP address has the same IP as an existing NIOS object (such as a fixed address, DNS record, or host record), the appliance removes this IP address.

To clear discovered data:

1. In the *IP Map* or *List* panel, select a network, and then click **Clear** -> **Clear Discovered Data** from the Toolbar.
2. In the *Clear Discovered Data* dialog box, click **Yes**.
3. Navigate to the **Data Management** tab → **DNS** tab, delete all the associated zones.
4. After you clear all the discovered data, you should navigate to the **Data Management** tab and clear all the associated networks.

You can also clear discovered data on all networks in a network view by performing the following steps:

1. In the *IP Map* or *List* panel, select a network, and then click **Clear** -> **Clear Discovered Data** from the Toolbar.
2. In the *Clear Discovered Data* dialog box, click **Yes**.
3. Navigate to the **Data Management** tab → **DNS** tab, delete all the associated zones.
4. After you clear all the discovered data, you should navigate to the **Data Management** tab and clear all the associated networks.

> ⚠ Note
>
> When you clear all discovered data in a given network view, all imported discovered data for managed addresses, in all IPv4 and IPv6 networks in the network view, are cleared.

You can also clear discovered data for a specific discovery job, as follows:

1. From the **Cloud** tab -> **VM** tab, select **DiscoveryManager** from the Toolbar.
2. In the *vDiscoveryJobManager* dialog, click the Action icon

    next to the selected vDiscovery job, and then select **ClearDiscoveredData**.
3. In the *ClearDiscoveredData* dialog box, click **Yes**. The appliance clears all the discovered managed data that is collected by the specified vDiscovery job.
4. Navigate to the **Data Management** tab → **DNS** tab, and then delete all the associated zones.
5. After you clear all the discovered data, you should navigate to the **Data Management** tab and clear all the associated networks.

Note

If you delete an associated zone before you clear the discovered data, the **Clear** option gets disabled from the **Cloud** tab -> **VM** tab. The **Clear** option can be accessed from the **Cloud** tab -> **Tenants** tab. This is applicable when you use WAPI calls to clear all discovery data.

Clearing All Discovery Data

You can clear all the discovered data, whether managed or unmanaged, for a specific vDiscovery job. This action removes only the discovered data, not the associated NIOS objects, collected by the specified vDiscovery job only. It does not remove any discovered data collected through Network Insight or other non vDiscovery tasks.

Note

If the same data is collected by the specified vDiscovery job and another non vDiscovery job such as Network Insight or IP discovery, the discovered data remains intact and will not be removed.

To clear all discovered data for a specific vDiscovery job, perform the following:

1. From the **Cloud** tab -> **VM** tab, select **Discovery Manager** from the Toolbar.
2. In the *vDiscoveryJobManager* dialog, click the Action icon

   next to the selected vDiscovery job, and then select **Clear All Discovery Data**.
3. In the *ClearDiscoveredData* dialog box, click **Yes**. The appliance clears all the discovered managed and unmanaged data that is discovered by the specified vDiscovery job.

Note

If you delete all the networks from the **Data Management** tab before you clear all the discovered data, the data gets cleared only from the NIOS user interface and not from the NIOS database which results in stale VM to be fetched when WAPI calls are made.

Integrating Discovered Data from NetMRI

The NetMRI appliances discover and track IPv4 and IPv6 network devices and provide information about the discovered IP addresses. You can integrate IPv4 and IPv6 discovered data into the NIOS appliance database, and then view the data in the IP List panel of Grid Manager as well as in the **Discovered Data** tab of certain IPAM object editor. When you start synchronization of discovered data from the NetMRI appliance, only the available IP addresses in the network are discovered. The imported data from the NetMRI appliance can only be modified or deleted by the specific synchronization. When you import the discovered data again for the same network and if some of the information in the network is changed, the newly discovered data and the originally discovered data (now old data) co-exist in the database. When you import the data again, the old data is deleted or modified, or the new data is added depending on the information discovered.

For information about NetMRI IP discovery and how to import discovered data from a NetMRI appliance to the NIOS appliance, refer to *Executing NIOS IPAM Sync* in the Infoblox NetMRI documentation.

⚠ Note

- NIOS does not import IPv6 leases that contain prefixes and link-local IPv6 addresses. This data is discarded during an import.
- After an IPAM synchronization, CSV import errors if any are logged in a separate file named discovery_csv_error.log.*xxxxxx* located at /infoblox/var/discovery_csv_error

The appliance can import the following IPv4 and IPv6 data that NetMRI discovers:

- **IP Address**: The discovered IPv4 or IPv6 address.
- **Discovered MAC Address**: The MAC address of the discovered host.
- **Last Discovered**: The date and time the IP address was last discovered.
- **NetBIOS Name**: The name returned in the NetBIOS reply or the name that you manually register for the discovered host.
- **OS**: The operating system of the detected host.
- **First Discovered**: The date and time the IP address was first discovered.
- **Discoverer**: Specifies whether the IP address was discovered by a NetMRI discovery process.
- **Discovered Name**: The name of the network device associated with the discovered IP address.
- **Attached Device Description**: A textual description of the switch that is connected to the end device.
- **Attached Device Address**: The IP address of the switch that is connected to the end device.
- **Attached Device Name**: If a reverse lookup was successful for the IP address associated with this switch, the host name is displayed here.
- **Attached Device Port Description**: A textual description of the switch port that is connected to the end device.
- **Attached Device Port Name**: The name of the switch port or port channel connected to the device. For Cisco devices with virtual port channel configured, this field also displays the list of physical interfaces that form the virtual port channel. For more information, see *IP List Neighbor Information*.
- **Attached Device Port**: The number of the switch port connected to the end device.
- **Attached Device**: Identifies the switch that is connected to the end device.
- **Port Duplex**: The negotiated or operational duplex setting of the switch port connected to the end device.
- **Port Link**: The link status of the switch port connected to the end device. Indicates whether it is connected.
- **Port Speed**: The interface speed, in Mbps, of the switch port.
- **Port Status**: The operational status of the switch port. Indicates whether the port is up or down.
- **VLAN Name**: The name of the VLAN of the switch port.
- **VLAN**: The ID of the VLAN of the switch port.

Infoblox Network Insight

This section provides information about Infoblox Network Insight, which unites network discovery for geographically dispersed networks, infrastructure devices, and network assets with the Infoblox IPAM (IP Address Management) solution. Through discovery, Network Insight provides automated, comprehensive, and accurate data about your network devices and their attributes so you can have better visibility in your network infrastructure, including the virtual network infrastructure, and manage it more efficiently. This section also describes how you can use Network Insight to detect and manage information about network infrastructure devices, how to provision and de-provision networks, and how to manage and provision device ports, including switched Ethernet. It includes the following topics:

- *Managing Discovery*
- *Conflict Resolution in Network Insight*
- *Executing Discovery Diagnostics*
- *Discovering VRF Virtual Networks*
- *Configuring Discovery Properties*
- *Configuring Discovery for SDN and SD-WAN*
- *Consolidator and Probes*
- *Defining the Discovery Member Type*
- *Viewing Discovered Devices and their Properties*
- *Port Control Features in Network Insight*
- *Defining Blackout Periods*
- *Defining Port Configuration Blackout Periods*
- *Creating Port Reservations for IPAM Objects*
- *Editing Interfaces in a Device*
- *Monitoring Device Lifecycle and Vulnerabilities Using Advisor*
- *Viewing Discovery Status*
- *Provisioning and De-Provisioning Networks*
- *Supported Discovery Methods*
- *Starting and Stopping the Discovery Service*
- *Managing Discovered Data*
- *Configuring Automatic VRF Mapping*
- *About Network Insight*

Administrative Permissions for Discovery

You can start a discovery and manage discovered data based on your administrative permissions. For more information, see *About Administrative Permissions*.
Initiating and controlling a discovery requires specific administrative permissions. The following are permission guidelines for initiating and controlling a discovery:

- The **IPAM Discovery Admin** role provides a pre-configured list of permissions by which assigned admin accounts may perform discovery tasks. Administrators with these permissions can initiate and control discovery on any existing network. By default, the **IPAM Discovery Admin** role supports the following permissions:
    - All permissions associated with the Network Discovery feature set (active if you do not have a Network Insight license)
    - Read-Only on all Network Views, network containers, networks and ranges
    - Read-Only on all hosts
    - Read-Only on all Members
    - Read-Write Network Discovery permissions
    - Editing network, network container or range discovery properties: Read-Only for each type. For member assignment, the user also needs additional read-only permission for the assigned member
    - Editing fixed address, host or reservation discovery properties: Read-only for each type
    - Excluding an IP address or an IP Range (from the Network Editor 's **Discovery Exclusions** tab or from the IPAM IP **List** view): read-only permission for the network
    - Defining discovery and port configuration blackouts at the Grid and Network levels
    - **Discover Now** for Network, DHCP Range, IP address or device: Read-Only permission for each.
- If the user does not possess the **Network Discovery** permission, all Network Insight permissions and operations are disabled.
- A **Port Control** permission under the **IPAM Permissions** type allows you to add a Read/Write or Deny permission for a device; a network; a network container; or network view. You can also add a global RW/Deny port control permission for all network views.
    - If the user does not possess the **Port Control** permission, the user cannot provision networks, de-provision networks, perform port reservations or configure interfaces. *All non-Superuser accounts must have the Port Control permission to create port control tasks for any affected objects*.
- Superusers can initiate and control discovery on all networks. Some discovery functions require superuser permissions:

- Grid Discovery properties
- Uploading, Viewing and deletion of device support bundles
- Launching Discovery Diagnostics
- Launching Discovery Status

Similar to Network Discovery, devices and end hosts found through discovery can undergo conversion from unmanaged status to managed status. This entails converting an unmanaged IP address to a host, an A record or AAAA record, a PTR record, or to a fixed address.

- Administrators with read/write permission to a DNS zone or specific record type can convert unmanaged data to a host, fixed address, reservation, A record, or PTR record.
- IPAM Discovery admins can convert unmanaged networks to managed networks and can change discovery settings for networks.
- For unmanaged networks: users may **Delete**, **Convert** (to managed), **Clear Unmanaged Data** and **Clear Discovered Data** if one of the following is true:
  - User has read-write permission for the network
    –or–
  - User has Network Discovery permission plus Read-Only for the network.

After a discovery is complete, the following permission guidelines apply to viewing and managing discovery data:

- Superusers can view and manage all discovered data.
- Administrators with read permission to networks can view all discovery data without editing.
- If a user has read-only permissions for a device's management IP address, the device is visible in the **Data Management –> Devices** tab.

For more information on configuring admin user accounts and working with permissions, see the sections under *Managing Administrators*. For information about discovery permissions, see *Administrative Permissions for Network Insight Tasks*.

About Automatic Conversion Rules

To automate the conversion of IP addresses of discovered entities from "unmanaged" to "managed" in a specific network view, you can configure conversion rules that Network Insight uses to automatically create new DNS records or update existing data for the discovered IP addresses. Network Insight automatically converts newly discovered IP addresses to host records, A and PTR records, or fixed addresses based on your configuration. You can define templates that Network Insight uses to create new records by using supported variables and functions. For information about supported variables, see Supported Variables for Templates below.
Note that corresponding DNS zones in a selected network view must already exist in order for Network Insight to add DNS records during the conversion. Otherwise, Network Insight does not add any DNS records and it logs a message to the syslog.
Network Insight automatically adds DNS records based on the following conditions:

- The corresponding DNS zones must already exist in the NIOS database. Network Insight does not automatically create DNS zones for the records.
- To create a PTR record, the corresponding reverse-mapping zone must exist.
- A DNS zone cannot be associated with more than one DNS view. Network Insight does not create DNS records for zones that are associated with multiple DNS views.
- NIOS adds new DNS records only if the discovered_name for the discovered IP address is available and there is no conflict with information about the associated network view.

On subsequent discovery jobs, if an IP for a VM is removed, the corresponding DNS records are removed accordingly. If the IP for a VM is changed, the IP address in the corresponding DNS record is changed accordingly. If the DNS record name template is changed, all the DNS records are replaced with the DNS records using the new template. All administrative actions for these change are recorded in the audit log. Summary of the changes are logged in the syslog.

> ⚠ **Note**
>
> Network Insight updates only records that are created by the Network Insight process. It does not create or update DNS records that are originally created by other admin users.

Configuring Automatic Conversion Rules

To add automatic conversion rules:

1. From the **Grid** tab, select the **Grid Manager** tab, and click **Edit –> Grid Discovery Properties** from the Toolbar.
2. Click the **Conversion Policy** tab and complete the following:
   - **Enable the automatic conversion rules defined for newly discovered IP addresses**: Select this checkbox to enable the automatic conversion of unmanaged IP addresses of newly discovered entities to managed objects in a specific network view. This is disabled by default.
   - **Update discovered data for managed objects**: Select this checkbox if you want the appliance to update discovered data for all corresponding NIOS objects (if they exist in NIOS), such as A records, PTR records, host records, and fixed addresses, with the discovered data. If you do not select this checkbox, the appliance updates only the discovered data for unmanaged objects. None of the managed data will be updated. This checkbox is selected by default, but is disabled if you do not enable the automatic conversion feature.

     Click the Add (+) icon and Grid Manager adds a row to the table (this table is enabled only when you enable the automatic conversion feature). Complete the following:
   - **Network View:** From the drop-down list, select the network view in which your conversion rule will take effect. Note that this rule applies only to objects in the selected network view. If you have multiple network views, you must configure a separate policy for each network view.
   - **Template**: Define a naming template that Network Insight uses to automatically create DNS records for the unmanaged IP addresses in the network view. You can use the following syntax: ${**substitution**}, where **substitution** can be a supported variable or function. Note that each IPv6 address substitution is unwrapped into dotted presentation. For information about supported variables and functions, see Supported Variables for Templates below.

     For example, when you enter `${discovered_name}.corpxyz.com` and the discovered_name for the asset is **XYZ**, the DNS name for this IP becomes `XYZ.corpxyz.com`. When you enter `$dev-{ip_address_octet3}.corpxyz.com` and the IP for the asset **is2dba::db8::1**, the DNS name for this IP becomes `dev-3.corpxyz.com`. When you enter `${ip_address[7]}.corpxyz.com` for an IPv6 address and if the IP for the asset is **2001:db8:acad::1**, the DNS name becomes `b.corpxyz.com`.

     You can also use the following functions in the naming template: dashed, reversed, and underscored. For example, when you enter `${dashed(${ip_address})}-corpxyz.com` and the IP is 1.2.3.4, the DNS name becomes

1-2-3-4-corpxyz.com. When you enter **${reversed(${ip_address})}-*corpxyz.com*** and the IP is **1.2.3.4**, the DNS name becomes *4.3.2.1-corpxyz.com*.

- **Conditions**: Enter the matching conditions for the conversion rule. You can use magic variables, supported variables, operators, and functions in the condition. When Network Insight finds IP addresses that match this condition, it will convert the IP addresses into DNS records (Hosts, A/PTR records, or fixed addresses) based on your selected conversion type. For information about supported parameters, see Supported Conversion Parameters below.

  For example, if you want to match IP addresses that do not have an FQDN in the **discovered_name**, you can enter this condition: **${is_fqdn(${discovered_name})} == false AND ${discovered_name} == 'unknown'**. That is, you can use `unknown` as the filter value for IP addresses that do not have FQDN.

  If you want to match devices from the network **192.168.1.0/24** with the name starting with "**Serial0**", you can enter this condition: **${ip_belongs_to("192.168.1.0/24")} == true AND ${discovered_name} like "Serial0"**.

  ConversionType: From the drop-down list, select the DNS record type that you want Network insight to convert the unmanaged IP addresses into. You can convert an unmanaged IP into **Host**, **A/PTR**, or **FixedAddress**. When you select **A/PTR**, Network Insight converts each IP into A and PTR records simultaneously.

  Comment: Enter description about this policy to distinguish it from others. For example, if the policy is used to identify and convert IP addresses with **discovered_name** that does not contain an FQDN, you can enter "No FQDN in discovered_name." as the comment to remind yourself about this conversion rule.

Supported Variables for Templates

The following table list the supported variables and functions that you can use in templates.
Supported Variables

Name	Example	Result	Description
1	`vm${1}-example.com`	vm172-example.com / 192.168.1.1	The first octet (quad for IPv6) of the discovered asset. Alias for "ip_address_octet1".

Name	Example	Result	Description
2	`vm${2}-example.com`	vm41-example.com / 192.168.1.1	The second octet (quad for IPv6) of the discovered asset. Alias for "ip_address_octet2".
3	`vm${3}-example.com`	vm13-example.com / 192.168.1.1	The third octet (quad for IPv6) of the discovered asset. Alias for "ip_address_octet3".
4	`vm${4}-example.com`	vm9-example.com / 192.168.1.1	The fourth octet (quad for IPv6) of the discovered asset. Alias for "ip_address_octet4".
discovered_name	`iface-${discovered_name}.example.org`	iface-example09.example.org / iface-example09	The discovered name of the asset.
ip_address	`${ip_address}.example.org`	1.2.3.4.example.org / 1.2.3.4	The IP address of the discovered asset.
ip_address[index]	`${ip_address[7]}.example.com`	b.example.com / 2001:db8:acad::1	The IP address octet (quad) substitution. Useful for IPv6 addresses. Throws an error if address have less octets (quads) than specified.
ip_address_octet1	`dev-${ip_address_octet1}.example.com`	dev-2.example.com / 2dba::db8::1	The first octet (quad) of the discovered asset.
ip_address_octet2	`dev-${ip_address_octet2}.example.com`	dev-d.example.com / 2dba::db8::1	The second octet (quad) of the discovered asset.
ip_address_octet3	`dev-${ip_address_octet3}.example.com`	dev-b.example.com / 2dba::db8::1	The third octet (quad) of the discovered asset.
ip_address_octet4	`dev-${ip_address_octet4}.example.com`	dev-a.example.com / 2dba::db8::1	The fourth octet (quad) of the discovered asset.

Supported Functions

Name	Example	Result	Description
dashed	`${dashed(${ip_address})}-vm.example.com`	1-2-3-4-vm.example.com / 1.2.3.4	Replaces the dot "." and colon ":" symbols with the hyphen symbol "-".
reversed	`${reversed(${ip_address})}-vm.example.com`	4.3.2.1-vm.example.com / 1.2.3.4	Reverts the octets of the IP address. IPv6 address is converted to the dotted representation.
underscored	`${underscored(${ip_address})}-vm.example.com`	1_2_3_4-vm.example.com / 1.2.3.4	Replaces the dot "." and colon ":" symbols with the underscore symbol "_".

Supported Conversion Parameters

The following table list the supported magic variables, variables, operators, and functions that you can use to build the formula for the automatic conversion rules.

Magic Variables for Conversion Rules
Some of the functions or predicates use the following magic variables to calculate the matching results.

Name	Example	Description
ip_address	${ip_address}	The IP address. Used in is_ipv4, is_ipv6 predicates.
mgmt_ip_address	${mgmt_ip_address}	The management IP address. Used in is_interface predicate.

Supported Variables for Conversion Rules
This table lists all the variables you can use in the condition syntax.

Name	Discovered by Network Insight	Description
ip_address	Y	Discovered IP address.
mac_address	Y	Discovered MAC address.
duid	Y	DUID associated with the IPv6 address.
netbios_name	Y	Discovered NetBIOS name.
os	Y	OS guessed by network discovery.
method	Y	The method being used for network discovery: FULL, ICMP, NETBIOS, TCP, or CSV.
network_component_type	Y	The type of network component, such as Switch, Router, and others.
network_component_name	Y	The name of the network component.

Name	Discovered by Network Insight	Description
network_component_description	Y	A descriptive string for the network component
network_component_ip	Y	IP Address of the network component.
network_component_port_number	Y	Port number on the network component on which the IP was discovered.
network_component_port_name	Y	Port name on the network component on which the IP was discovered.
network_component_vendor	Y	Vendor name of the network component to which the device is connected.
network_component_model	Y	Model name of the network component to which the device is connected in the vendor terminology.
network_component_port_id	Y	Interface ID of the connected switch/switch-router.
port_vlan_name	Y	Name of the VLAN on the port on the network component.
port_vlan_description	Y	Description of the VLAN on the port on the network component.
port_vlan_number	Y	Number of the VLAN on the port on the network component.
port_speed	Y	Speed settings on the port on the network component: 10M, 100M, 1G, 10G, 100G, or Unknown.
port_duplex	Y	Duplex settings on the port on the network component.
port_status	Y	Status of the port on the network component.
port_link_status	Y	Link Status of the port on the network component.
port_type	Y	Type of interface on the network component to which the device is connected.
open_ports	Y	List of opened ports on the IP address, represented as: "TCP: 21,22,23 UDP: 137,139". Limited to max total of 1000 ports.
last_discovered_timestamp	Y	The timestamp when this data discovered.
first_discovered_timestamp	Y	The timestamp when this IP was first seen by the discovery station.
discovered_name	Y	Name of the IP as seen by the discovery station.
discoverer	Y	Name of the discoverer or Grid member.
device_vendor	Y	Vendor name of the device.

Name	Discovered by Network Insight	Description
vswitch_segment_type	N/A	Type of network segment on which the current virtual machine/vport is connected.
vswitch_tep_ip	N/A	IP address of the virtual tunnel endpoint (VTEP) in the virtual switch.
vswitch_tep_port_group	N/A	Port group of the virtual tunnel endpoint (VTEP) in the virtual switch.
vswitch_tep_vlan	N/A	VLAN of the virtual tunnel endpoint (VTEP) in the virtual switch.
vswitch_tep_dhcp_server	N/A	DHCP server of the virtual tunnel endpoint (VTEP) in the virtual switch.
vswitch_tep_multicast	N/A	Multicast address of the virtual tunnel endpoint (VTEP) in the virtual switch.
vmhost_ip_address	N/A	IP address of the physical node on which the virtual machine is hosted.
vmhost_name	N/A	Name of the physical node on which the virtual machine is hosted.
vmhost_mac_address	N/A	MAC address of the physical node on which the virtual machine is hosted.
vmhost_subnet_cidr	N/A	CIDR subnet of the physical node on which the virtual machine is hosted.
vmhost_nic_names	N/A	List of all physical port names used by the virtual switch on the physical node on which the virtual machine is hosted. Represented as: eth1,eth2,eth3.
vmi_tenant_id	N/A	ID of the tenant to which the virtual machine belongs.
cmp_type	N/A	If the IP is coming from a Cloud environment, the Cloud Management Platform type.
vmi_ip_type	N/A	Discovered IP address type.
vmi_ip_type	N/A	Discovered IP address type.
vmi_private_address	N/A	Private IP address of the virtual machine.
vmi_is_public_address	N/A	Indicates whether the IP address is a public address.
cisco_ise_ssid	N/A	Service Set Identifier.
cisco_ise_security_group	N/A	Name of the security group created in Cisco ISE.
cisco_ise_quarantine_status	N/A	Quarantine status for the IPAddress as coming from Cisco ISE: NONE or QUARANTINE
cisco_ise_endpoint_profile	N/A	Endpoint profile in Cisco ISE.

Name	Discovered by Network Insight	Description
device_type	Y	Type of the device in the vendor terminology.
device_model	Y	Model name of the device in the vendor terminology.
mgmt_ip_address	Y	Management IP address of the device if the device has more than one IP.
device_port_name	Y	System name of the interface with which the IP associates.
device_port_type	Y	Hardware type of the interface with which the IP associates.
is_end_host	Y	Whether this object is an end host or an infrastructure device for the purpose of discovery.
iprg_id	Y	Port Redundant Group ID of this device interface.
iprg_no	Y	Port Redundant Group no of this device interface.
iprg_type	Y	Type of Port Redundant Group
iprg_state	Y	State of this IP address in the group.
vmi_name	N/A	Name of the virtual machine.
vmi_id	N/A	ID of the virtual machine.
vlan_port_group	N/A	Port group to which the virtual machine belongs.
vswitch_name	N/A	Name of the virtual switch.
vswitch_id	N/A	ID of the virtual switch.
vswitch_type	N/A	Type of the virtual switch: standard or distributed: Unknown, Standard, or Distributed
vswitch_ipv6_enabled	N/A	Indicates whether the virtual switch has IPV6 enabled: true or false
vport_name	N/A	Name of the network adapter on the virtual switch connected with the virtual machine.
vport_mac_address	N/A	MAC address of the network adapter on the virtual switch to which the virtual machine is connected.
vport_link_status	N/A	Link status of the network adapter on the virtual switch to which the virtual machine is connected.

Name	Discovered by Network Insight	Description
vport_conf_speed	N/A	Configured speed of the network adapter on the virtual switch to which the virtual machine is connected. Unit is Kib.
vport_conf_mode	N/A	Configured mode of the network adapter on the virtual switch to which the virtual machine is connected: Unknown, Full-duplex, or Half-duplex
vport_speed	N/A	Actual speed of the network adapter on the virtual switch to which the virtual machine is connected. Unit is Kib.

Supported Operators for Conversion Rules

Operators always result in boolean value: true or false. Therefore, you can use them only in logical expressions.

Name	Left Value (lvalue)	Right Value (rvalue)	Example	Description
LIKE	variable	string (regular expression in extended format)	`${discovered_name} like "[vV]m-[0-9]+.devnet.org"`	Evaluates as true if the lvaluevariable matches the given regular expression rvalue; otherwise false
==	variable	string	`${ip_address} == "167.45.13.29"`	Evaluates to true if the lvalue variable equals to rvalue string literal, false otherwise
!=	variable	string	`${mac_address} != "00:50:56:00:00:01"`	Evaluates to true if the lvalue variable is not equal to rvalue string literal, false otherwise

Supported Functions or Predicates for Conversion Rules

Predicates accept either none or one argument. Depending on the predicate, it could accept both variables and strings or only one of them. The predicate can be compared only to boolean value: true or false.

Name	Argument Type	Example	Description
is_interface	N/A	`${is_interface} == true`	Check discovered data in an interface. It validates the mgmt_ip_address variable.
is_ipv4	N/A	`${is_ipv4} == true`	Check to see if the variable ip_address is an IPv4 address.
is_ipv6	N/A	`${is_ipv6} == false`	Check to see if the variable ip_address is an IPv6 address.
is_belongs_to	string	`${ip_belongs_to("10.0.0.0/8")} == false`	Check to see if the ip_address variable belongs to the given IPv4 or IPv6 network range.

Name	Argument Type	Example	Description
is_fqdn	variable	`${is_fqdn($ {discovered_name})} == true`	Check to see if the given variable is an FQDN.

Accessing Detailed Device Information

Clicking on any device's name in the **Name** column, you open a set of tabs revealing information about the selected device:

- The **Interfaces** tab (see Viewing Interface Information for Discovered Devices below)
- The **Networks** tab (see Viewing Networks Associated with Discovered Devices below)
- The **IP Addresses** tab (see Viewing IP Addresses Associated with Discovered Devices)
- The **Assets** tab (see Viewing Assets Associated with Discovered Devices below)
- The **Components** tab (see Viewing Components of Discovered and Managed Devices below)

Viewing Interface Information for Discovered Devices

This panel lists all discovered interfaces associated with the selected device. Interfaces are detected whether they are loopbacks, unnumbered, or numbered with one or more IP addresses. Interfaces may be listed for either managed or unmanaged devices.

1. From the **Data Management** tab, select the **Devices** tab. The Devices Home page displays a list of all devices currently found and catalogued by discovery.
2. Click the **Action** icon

   for a chosen device and choose **Interfaces** from the drop-down menu, or simply click the device name to display the Interfaces list. Click **Devices Home** to return to the main **Devices** page.
   This panel displays the following information for each interface. Note that some data may appear for some device types and not for others.

- **Name**: The name of the interface (usually a switched interface) associated with the discovered device.
- **Reservation**: Indicates whether the port has been reserved by NIOS as part of a Port Control operation.
- **IP Address**: Detected IPv4 or IPv6 address of the interface.
- **VRF Name**: The name of the VRF associated with the interface, if applicable.
- **Network View**: The name of the network view to which the VRF instance belongs, if applicable. If there is only one network view in the Grid, which is the default view, the **Network View** column is hidden by default.
- **VRF Description**: The description about the VRF instance, if applicable.
- **VRF RD**: The route distinguisher associated with the VRF instance, if applicable.
- **MAC Address**: The hardware address associated with the interface.
- **Description**: Port description associated with the interface, such as **ge-0/0/5** or **FastEthernet0/13**.
- **VLAN ID/VLAN Name**: The data VLAN identifier and VLAN name that is bound to the interface, if applicable.
- **Port Speed**: Interface speed, in Mbps.
- **Port Type**: Type of interface as detected by NIOS Discovery. Examples include **ethernet-csmacd**, **propPointToPoint Serial**, **l2vlan**, **tunnel**, and others.
- **Admin Status**: Shows whether the interface is administratively Up or administratively Down.
- **Operating Status**: Shows whether the interface is operationally Up or operationally Down.
- **Trunk Status**: Where applicable, shows the trunking status of the interface.
- **Link Aggregation**: Shows if the interface is part of a Link Aggregation Group, also known as port channel.
- **Aggregated Interface**: Shows the port channel name, if the interface is part of a port channel or virtual port channel.
- **vPC Peer**: This field is applicable to Cisco devices with virtual port channel. It shows the name of the second aggregated interface of the port channel. The aggregated interface and vPC peer values are identical as aggregated interfaces on a vPC device must have identical names. Clicking the link in the **vPC Peer** column

takes you to the **Interfaces** tab of the device to which the peer interface belongs. Also see *IP List Neighbor Information* for vPC data displayed in the **Attached Device Port Name** field for an end device.

- **Status**: Shows whether the interface is Used or Unused.
- **IPAM Type**: The object type that is associated with the IP address for the interface. Possible values can be Lease, IPv4 DHCP Range or Fixed Address.
- **Usage**: Indicates whether NIOS has configured the IP address for DNS or DHCP.
- **Managed**: Shows whether the interface is managed under IPAM, by being associated with a managed IPAM object such as a Fixed Address. Check the IPAM Type field for related information.
- **Reservation**: Indicates whether the interface has a port reservation bound to it. For information, see *Creating Port Reservations for IPAM Objects*.
- **Capabilities**: Describes the capabilities of each interface in the selected device. Hover the mouse over each entry to view the complete listing. For information, see Determining Interface Capabilities below.
- **Site**: This is a predefined extensible attribute.

You can also click the Action icon next to an interface name and select one of the following to perform the specified task:

- **Edit**: This option is enabled if the network is in managed state. This opens the network editor.
- **Show Assets**: This option is only available for switched Ethernet interfaces with no IP Address. This opens the Assets page for the selected device, and shows a list of end host devices or neighboring linked to the interface. Network Insight filters the asset list for the device by the interface name.
- **Show Multiple IP Addresses**: Opens the IP Addresses page specifically for the interface, listing all IPv4 and IPv6 addresses associated with the interface. This option appears only if the interface has IP addresses.
- **Convert**: Convert a network in the unmanaged state to be managed under IPAM and (optionally) DHCP. Unlike devices and interfaces, you do not assign objects such as fixed addresses or PTR records to a managed network. Conversion enables a network to be fully manageable under IPAM and DHCP. For more information, see *Converting Unmanaged Networks to Managed Status*.
- **IPAM Networks**: Choosing this option lists all IPAM networks associated with the current interface.
- **Device Details**: A basic list of information about the chosen device, including the IP address by which the device is discovered, operational status, IPAM Type (whether the device is Managed or Unmanaged), the Device Type and the number of Interfaces.

You can also do the following:

- Modify some of the data in the table. Double click a row, and either modify the data in the field or select an item from a drop-down list. Click **Save** to save the changes or click **Cancel** to exit. Note that some fields are read only. You can modify the following fields in this table: **VLAN ID/VLAN Name**, **Admin Status** and **Description**.
- Sort the data in ascending or descending order by column.
- Select an interface checkbox and click the Edit icon to manage device properties.
- Click the Export icon to export the list of discovered devices to a .csv file.
- Click the Print icon to print the list of discovered devices.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of a device name in the **Go to** field and select the device from the possible matches.
- Create a quick filter to save frequently used filter criteria.

Determining Interface Capabilities

One key piece of information that Network Insight compiles from discovery involves an assessment of interface *capabilities*. The Interfaces table provides a hidden column titled **Capabilities** with a description of the relevant capabilities of each interface in the discovered device.

1. From the **Data Management** tab, select the **Devices** tab. The Devices Home page displays a list of all devices currently found and catalogued by discovery.
2. Click the Action icon

   for a chosen device and choose **Interfaces** from the popup menu.
3. Click the right end of a column header and choose **Columns –> Edit Columns** from the drop-down menu.
4. Select the **Capabilities** checkbox and click **Apply**.

The text listing for the Capabilities field may be too long to display in the Interfaces table. Hover the mouse over any table row to display the complete entry for the **Capabilities** field:

Capabilities information for the selected interface

USAGE	MANAGED	RESERVATION	CAPABILITIES
			Provision IPv4 Network = No: Device type (Wireless Controller) not supported for network provisioning,..
			Provision IPv4 Network = No: Device type (Wireless Controller) not supported for network provisioning,..
			Provision IPv4 Network = No: Device type (Wireless Controller) not supported for network provisioning,..
			Provision IPv4 Network = No: Device type (Wireless Controller) not supported for network provisioning,..
	No		Provision IPv4 Network = No: Device type (Wireless Controller) not supported for network provisioning,..

Critical values in the Capabilities field include the following:

- Provision IPv4 Network – Yes or No
- Provision IPv6 Network – Yes or No
- De-Provision IPv4 Network – Yes or No
- De-Provision IPv6 Network – Yes or No
- Interface has no IP Address – Appears only if no IP address is defined for the interface
- Edit Data VLAN – Yes or No
- Edit Voice VLAN – Yes or No
- Edit Admin Status – Yes or No
- Edit Description – Yes or No

The values you see in this field provide notification when you are unable to set certain values for any interface. When discovery queries devices for their device type, OS version support and other factors, Network Insight compiles the information into table formats that help you to determine issues or exceptions in the network.
For example, loopback interfaces are "always up" and hence do not support an Admin Status configuration and show **Edit Admin Status = No**. If an interface does not have an IP address, it cannot be de-provisioned and hence shows a **De-provision Network = No**. That same device may not support IP addresses or VLANs because it is only a L2 Ethernet switch, and shows **Edit VLAN = No** and **Provision IPv4 Network = No**, among others.
If a device shows a **Provision IPv4 Network = Yes** and **Provision IPv6 Network = No**, it indicates that the device supports only IPv4, perhaps due to OS software version.
Other cases may involve the following reasons:

- **Edit Admin Status = No**:
  - Device not supported
  - Vendor not supported
  - Model not supported
  - Port does not support Admin settings (Loopback, Virtual)
- **Edit VLAN = No**:
  - Device not supported
  - Device type not supported for VLAN assignment (Router, L2 switch)
  - Vendor not supported
  - model not supported
- **Edit Voice VLAN = No**:
  - Device not supported
  - Vendor not supported (Cisco is the only supported device type)
  - Device not licensed
  - Model not supported
- **Provision IPv4 Network=No/Provision IPv6 Network=No**:
  - Device not supported
  - Vendor not supported for network provisioning
- **De-Provision IPv4 Network=No/De-Provision IPv6 Network=No**:
  - Device not supported
  - Vendor not supported for network provisioning
  - Device type not supported for network provisioning (Router)
- **Edit Description=No**
  - Device not supported

- Vendor not supported
- Model not supported

Viewing Networks Associated with Discovered Devices

To view all discovered networks associated with the selected device, complete the following:

1. From the **Data Management** tab, select the **Devices** tab. The Devices Home page displays a list of all devices currently found and catalogued by discovery.
2. Click the device name.
3. Click the **Networks** tab.
   Grid Manager displays all networks to which the chosen device connects. You see the following types of networks based on their managed or unmanaged status:

- Unmanaged: These networks are displayed in yellow rows with the value of **No** in the Managed column. Shows that the network is not managed under IPAM, but enough network information is catalogued so that the network can be converted to managed status. You can provision these networks onto devices.
- Managed: These networks are displayed in white rows with the value of **Yes** in the Managed column. These networks are currently managed under IPAM, converted to an IPAM network. You can provision and de-provision managed networks.
- The so called "non-NIOS networks": These networks are displayed in grey rows with a blank value in the Managed column. Indicates that the network is discovered but available network information is not sufficient to identify and catalog the network in IPAM at the present time. If you encounter such networks and you want them to appear in IPAM, do the following:
  - Check the admin or operation status of the corresponding interface. It should not be disconnected physically or disabled by administrator.
  - Ensure that the prefix length for the network is other than /32 (ipv4) or /128 (ipv6). Network Insight treats named prefixes as a route to a specific device rather than a subnet, therefore it does not create such network in IPAM.
  - Ensure that the route for this interface is configured correctly.
  - Check that the route is a direct or local one based on the routing table and is not learned from a remote source via BGP, OSPF and so on (i.e., indirect next hop), nor comes from a static route using the netmgmt protocol.
  - If the network is within a VRF, ensure that the VRF is mapped to the correct network view. VRF mapping is required in this case for the network to appear in IPAM. After the VRF is correctly mapped, the network turns from non-NIOS to unmanaged, or managed if the network is already present in IPAM.

Grid Manager displays the following information for each network found on the selected device, if applicable:

- **Network**: The network IPv4 or IPv6 address.
- **VRF Name**: The name of the VRF associated with the interface, if applicable.
- **Network View**: The name of the network view to which the VRF instance belongs, if applicable. If there is only one network view in the Grid, which is the default view, the **Network View** column is hidden by default.
- **VRF Description**: The description about the VRF instance, if applicable.
- **VRF RD**: The route distinguisher associated with the VRF instance, if applicable.
- **Comment**: Any information entered by admins about the network.
- **Managed**: Shows values of Yes or No for managed status.

Using the Action icon ☰, you can perform the following tasks in the Networks page:

- **Show IPAM Network**: Opens the IPAM IP MAP that illustrates the IP states for all IPs in the network.
- **De-provision Network**: Available for managed networks that are provisioned and active on a device. Allows you to de-provision (delete) the selected IPAM network from all devices connected to the selected network.
  See *Provisioning and De-Provisioning Networks*.
- **Edit**: Opens the network editor for the selected network. This option is enabled if the network is in managed status.
- **Delete**: Select **Delete** to delete the network now or select **Schedule Deletion** to schedule the deletion at a later time. Note that the deletion function allows you to de-provision the actual network from the device. By default, when you choose **Delete** or **Scheduled Delete**, the network is de-provisioned from all interfaces listed in the panel. Exercise caution when using this feature!
- **Extensible Attributes**: Provides access to the extensible attribute settings for the selected network.

- **Permissions**: Provides access to admin permissions settings for the selected network. This option is enabled if the network is in managed status.
- **Convert**: Converts unmanaged network to a managed network in NIOS. All discovered networks on each device are automatically listed as **Unmanaged** after a discovery. This means that the discovered network, though visible, does not have its identities resolved by NIOS, nor are its IP address managed through IPAM or leased through DHCP. After converting the unmanaged network to managed status, Grid Manager uses the discovered router IP address to populate the same value under subsequent DHCP configurations for the network. You can also select an unmanaged network and convert it to managed status by clicking **Convert** from the Toolbar.
- **Device Details**: Provides information about the device to which the selected network belongs. The list includes information such as the **IP Address** and **Device Type** for the device, and in the **IPAM Type** field whether the device itself is a managed or unmanaged object in NIOS. It also provides the following status counters for the device:
    - **Administrative Up - Operational Up**: The number of ports that are fully up and passing traffic
    - **Administrative Up - Operations Down**: The number of ports that are administratively up, but have some kind of connectivity issues.
    - **Administrative Down - Operational Down**: The number of ports that are administratively taken down.

The horizontal navigation bar and the Toolbar also provide the following functions:

- **Provision Network**

  : Available for managed networks and for unmanaged networks that are recognized by IPAM. For information, see *Provisioning and De-Provisioning Networks*. Clicking this icon opens the Provision Network feature, allowing you to provision the network onto the actual device by selecting a device interface, and enabling DHCP Forwarding and/or assigning a VLAN. Grid Manager creates a new port control task under Task Manager, and you can choose the interface on which the network is provisioned, along with VLAN configuration and other settings.
- **De-Provision Network**
