  : Available for discovered networks that are not visible under IPAM. A dialog box appears summarizing the task.
- **Show Active Users**: For Microsoft Management only. Displays the *Active Users* dialog box. You can view all the active users on the Active Directory domain for the selected device. For more information, see *Viewing Active Network Users.*

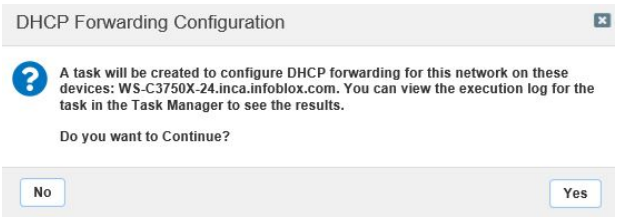
Modifying Networks

Grid Manager enables the user to edit select DHCP configurations, including the following:
IPv4 DHCP Options/IPv6 DHCP Options: DHCP options provide specific configuration and service information to DHCP clients. For more information, see *About IPv4 DHCP Options*.
DHCP Forwarding: Enables routers connecting multiple networks to act as a silent DHCP relay and forward DHCP packets between them. The **DHCP Forwarding** page lists the interfaces on the currently selected network on which DHCP Forwarding is enabled. If more than one device on the selected network also enables DHCP Forwarding, they also appear here. DHCP Forwarding configuration involves simply enabling or disabling the service for a network endpoint on the device. In order for DHCP forwarding to work, you must restart the DHCP service on the Grid member that is serving the network; If you run DHCP service on both LAN1 and LAN2 of the Grid member, then both addresses are written to the device.

1. From the **Data Management** tab, select the **Devices** tab.
2. Click the **Name** link for the device you want to inspect.
3. Click the **Networks** tab.
4. Click the Action icon

   for a network in the table, and choose **Edit**. This feature is enabled only for networks that are managed under IPAM.
5. Click the **DHCP Forwarding** tab.
6. Select the checkbox for any listed instance and do the following if necessary:
    - Click **Configure**. Grid Manager queries you to confirm that DHCP Forwarding are configured on the selected network **(A task will be created to configure DHCP forwarding for this network on these devices: <device_name>. You can view the execution log for the task in the Task Manager to see the results)**.
    - Click **Delete** to remove the selected DHCP Forwarding instance from the network.

DHCP Forwarding confirmations



1. Click **Yes** to confirm the activating or deletion of DHCP forwarding on the selection, or **No** to reject the change.
2. Click **Save & Close**.

Viewing IP Addresses Associated with Discovered Devices

You can view the complete list of discovered IP addresses bound to all interfaces for any device, discovered and managed devices alike.

> **Note**
>
> One useful trick for interfaces is to pick out an interface from the **Interfaces** page that has multiple IPs and open the **IPAddresses** tab; or sort the IP addresses table by its **IPAddress** column, and locate the interface name that bears multiple IPs. Frequently, an interface with multiple addresses can have IPv4 and IPv6 addresses bound to it. Loopbacks are another example.

1. From the **Data Management** tab, select the **Devices** tab. The Devices Home page displays a list of all devices currently found and catalogued by discovery.
2. Click the Action icon

   for a chosen device and choose **Interfaces** from the drop-down menu, or simply click the device name to display the Interfaces list. Click **Devices Home** to return to the main **Devices** page.
3. Click the **IP Addresses** tab. Grid Manager displays all IP addresses associated with the chosen device. Grid Manager displays the following information for each IP address:
   - **IP Address**: The IP address for each discovered interface as managed by NIOS and IPAM. The table supports IPv4 and IPv6 values. Each IP address is a link to the home IPAM page for the interface. If an IP address does appear but is not a link, this indicates the discovered IP is not recognized under IPAM.
   - **VRF Name**: The name of the VRF associated with the interface, if applicable.
   - **Network View**: The name of the network view to which the VRF instance belongs, if applicable. If there is only one network view in the Grid, which is the default view, the **Network View** column is hidden by default.
   - **VRF Description**: The description about the VRF instance, if applicable.
   - **VRF RD**: The route distinguisher associated with the VRF instance, if applicable.
   - **Interface Name**: The name of the interface (usually a switched interface) associated with the discovered device.
   - **MAC Address**: The hardware MAC address associated with the interface.

   - **VLAN Name/VLAN ID**: The data VLAN name and VLAN identifier to which the interface is bound, if applicable. In most cases, you see both the VLAN name and the VLAN ID as two values in the same field. Multiple VLAN entries may be present for an interface or IP Address.Some interfaces may have a large number of associated VLANs. By default, Network Insight does not automatically show all of them, instead providing a **Show all...** link for reference within the table cell. All VLAN ID/VLAN name values appear within the table cell, with a **Hide...** link provided to shorted the list back to original length.
   - **AdminStatus**: Lists whether the interface is administratively Up or administratively Down.
   - **OperationStatus**: The operational status of the interface (operationally Up or operationally Down).

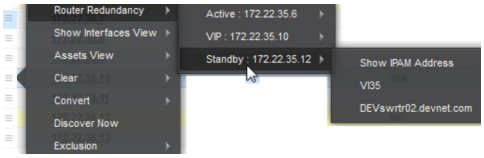
    - **Managed**: Indicates whether or not the IP Address is managed by Grid Manager. If the IP address is unmanaged, you will be able to Convert the IP address to an Object that is managed by Grid Manager.
    - **Site**: This is a predefined extensible attribute. Extensible attributes may also appear in this table.
4. Click the IP Address link for any interface to open the Related Objects page for the chosen port.
   Click the Action icon

   next to an IP address and select one of the following to perform the specified task. Note that some of these actions are not applicable to the IP address.

- **Edit Interface**: Opens the interface general settings page. You can view and modify basic interface settings such as **Admin Status** (on the **General** page), **Data VLAN** and **Voice VLAN** (on the **VLAN** page), and add or modify extensible attributes.
- **Convert**: Depending on the address type and its IPAM status, you may be able to convert the selected IP to a Host Record, A Record, PTR Record or a Fixed Address. Otherwise, Grid Manager shows **This object cannot be converted**. You can also perform the same action by selecting an IP address checkbox and clicking **Convert** from the Toolbar.
- **Device Details**: Provides information about the device to which the selected IP address belongs. The list includes information such as the **IP Address** and **Device Type** for the device, and in the **IPAM Type** field whether the device itself is a managed or unmanaged object in NIOS. It also provides the following status counters for the device:
    - **Total Available Interfaces**: The total number of interfaces associated with the device.
    - **Administrative Up - Operational Up**: The number of ports that are fully up and passing traffic
    - **Administrative Up - Operations Down**: The number of ports that are administratively up, but have some kind of connectivity issues.
    - **Administrative Down - Operational Down**: The number of ports that are administratively taken down.

Viewing Router Redundancy Information

Some discovered devices may support router redundancy. After discovery, some IP addresses are indicated as a VIP (virtual IP) in the device's IP Addresses page with router redundancy. In the **IP List** page, **Router Redundancy** in the Action icon menu lists the IP addresses associated with the VIP. For each IP, there are various menu items as shown in the below figure.
Virtual IPs and discovered redundancy information



- **Active**: lists the active interface in the redundancy pair;
- **VIP**: The Virtual IP for the router redundancy pair;
- **Standby**: The standby IP interface for the router redundancy.

Discovery of all three IP components of the Router Redundancy instance also provides related information for all three IP entities:

- **Show IPAM Address**: opens the IPAM page to the listed IP address;
- **VIP**: Opens the virtual interface in the host device's Interfaces page;
- Device name: The third item lists the device name of the router for each of the three IP address entities comprising the redundancy instance. The currently active router is identified with the **Active** and **VIP** objects; the second **Standby** router is identified with the **Standby** IP address.

Viewing Assets Associated with Discovered Devices

During discovery, Network Insight classifies end hosts and any other devices connected to switchport interfaces as "Assets" directly associated with each discovered interface. On the device level, the Assets page shows all network devices reachable by the selected network device, including switchports supporting end hosts. In practice, most Asset tables show end hosts and devices that populate Ethernet network segments.
The Assets table lists all managed end hosts and application servers detected through discovery and identity resolution by Grid Manager, that are connected to each network infrastructure device. The records listed in this table date from the

Last Seen discovery time stamp of each end host or other device. In many cases, you see neighbor devices to the current device appearing on this page.
To view assets associated with discovered devices:

1. From the **Data Management** tab, select the **Devices** tab. The Devices Home page displays a list of all devices currently found and catalogued by discovery.
2. Click the Action icon

   for a chosen device and choose **Interfaces** from the drop-down menu, or simply click the device name to display the Interfaces list. Click **Devices Home** to return to the main **Devices** page.
3. Click the **Assets** tab. Grid Manager displays all assets associated with the chosen device.
   Note the list of assets at this level may include devices that are trunked to the current device, including end-user host computers or routers and switch-routers neighboring the currently selected device.
   Grid Manager displays the following information for each asset:

- **Name**: The asset name on the network as discovered by Grid Manager. If the name is that for another infrastructure device, you may click on it to see its associated assets.
- **Interface Name**: The name of the interface (usually a switched interface) associated with the discovered device.
- **VRF Name**: The name of the VRF associated with the interface, if applicable.
- **Network View**: The name of the network view to which the VRF instance belongs, if applicable. If there is only one network view in the Grid, which is the default view, the **Network View** column is hidden by default.
- **VRF Description**: The description about the VRF instance, if applicable.
- **VRF RD**: The route distinguisher associated with the VRF instance, if applicable.
- **IP Address**: The IP Address for each discovered asset as managed by NIOS and IPAM. The IP address is a link to the home IPAM page for the interface.
- **Type**: The type of device. Infrastructure devices such as routers and switches may also be categorized as an Asset.
- **Username**: The User Name for the asset, as defined from the host's DHCP lease.
- **Asset MAC Address**: The hardware MAC address associated with the asset.
- **VLAN Name/VLAN ID**: The VLAN identifier from which the asset is reachable.
- **Admin Status**: The administrative status (Up or Down) of the management port that identifies the asset device.
- **Operation Status**: Normally reads **Up** or **Down**. Asset records may appear as **Down** because they are disconnected from the network or being rebooted.
- **Managed**: Indicates whether the asset is managed by NIOS.
- **Reservation**: Indicates whether the interface has a port reservation bound to it.
- **Capabilities**: Describes the capabilities of each interface in the selected device. Hover the mouse over each entry to view the complete listing.
- **Site**: This is a predefined extensible attribute.

Using the Action icon , you can perform the following tasks in the IP Addresses page:

- **Edit IPAM Object**: For managed objects, this opens the editor for the object so you can modify its properties.
- **Edit Interface**: Opens the interface general settings page. You can view and modify basic interface settings such as **Admin Status** (on the General page), **Data VLAN** and **Voice VLAN** (on the VLAN page), and add or modify extensible attributes.
- **Show IPAM IP Address**: Shows discovered data, related objects, and audit history of the selected asset. This option is disabled for devices that have a management IP that is not part of an IPAM network. Discovered data may or may not appear for the asset, depending on the device type.
- **Convert**: Depending on the asset type and its IPAM status, you may be able to convert the selected asset to a Host Record, A Record, PTR Record or a Fixed Address. Otherwise, Grid Manager shows **This object cannot be converted**. You can also perform the same action by selecting an IP address checkbox and clicking **Convert** from the Toolbar.
- **Device Details**: Provides information about the device to which the selected IP address belongs. The list includes information such as the **IP Address** and **Device Type** for the device, and in the **IPAM Type** field whether the device itself is a managed or unmanaged object in NIOS. It also provides the following status counters for the device:
  - **Total Available Interfaces**: The total number of interfaces associated with the device.
  - **Administrative Up - Operational Up**: The number of ports that are fully up and passing traffic
  - **Administrative Up - Operations Down**: The number of ports that are administratively up, but have some kind of connectivity issues.

- **Administrative Down - Operational Down**: The number of ports that are administratively taken down.

Viewing Assets Associated with an Interface

You can narrow down an Asset list to individual interfaces on any managed network device. On the interface level, the **Assets** page shows all devices associated with the chosen interface, including switchports supporting many end hosts. In practice, most Asset tables show end hosts and devices that populate Ethernet network segments.

1. From the **Data Management** tab, select the **Devices** tab.
2. Click the **Name** link for the device you want to inspect.
3. Click the Action icon

   for an interface in the table, and choose **Show Assets**. (Applies only to switched interfaces that do not have an IP address.)

Values listed in the Assets table include the following:

- Name: The asset's name on the network as discovered by Grid Manager. If the Name is that for another infrastructure device, you may click on it to see its associated Assets.
- Interface Name: The name of the interface (typically a switched interface) associated with the asset (by which the asset was discovered).
- IP Address: The IP Address for each discovered end host as managed by IPAM. The IP address is a link to the home IPAM page for the interface.
- MAC Address: The hardware MAC address associated with the asset.
- **VLAN ID/VLAN Name**: The VLAN identifier from which the asset is reachable.
- Operation Status: Normally reads **Up** or **Down**. Asset records may appear as **Down** because they are disconnected from the network or being rebooted.

In the Interfaces page, if you select an interface for a switch that is only connected to a neighboring switch, router, or switch-router, and then choose **Show Assets**, the Assets page displays only the neighboring device that is reachable from the chosen port.

Viewing Components of Discovered and Managed Devices

Network Insight provides a table of hardware components for each discovered/managed network device. Elements listed in the Components table include the following:

- Name: The discovered name of the device component.
- Description: The description string associated with the component. In many cases, this value is the same as the Name field.
- Class: Type of component. Possible values include, but are not limited to, Port, Power Supply, Fan, Module, Stack, RoutingEngine, powerEntryModule, Chassis, and more, based upon the collected SNMP data.
- Serial Number: The discovered vendor serial number for the component.
- Model: Describes the model number or model name of the component, based upon collected SNMP data.

Note

- Note To view information about the device, including its IPAM Type and the operating status of its ports, click the **Action** icon

  for a chosen device and choose **Device Details** in the drop-down menu.

Adding Discovery Device Support

> **Note**
>
> Adding Device Support Bundles, viewing and deleting them requires Superuser permissions.

Infoblox frequently provides support files for additional network devices that may not previously be supported by discovery, and updates to support new operating system versions of existing devices. To add device support updates:

1. From the **Grid** tab, select the **Device Support** tab.
2. Expand the Toolbar and click **Add**.
3. Click **Select** and navigate to the file you want to upload.
4. Select the file, and then click **Upload**.
   The Device Support table shows its installed library of files with the following data points:

- **Name**: The descriptive device name for the device support file.
- **Version**: The version of the currently active device support file.
- **Author**: The developer of the device support file.
- **Type**: The Type column lists two types of Device Support files: the System type indicates a support bundle that is installed with the NIOS/Grid Manager system. The Downloaded type indicates device support bundles that are installed by the administrator.
  System bundles are read-only and cannot be removed or overwritten by administrators.

You may remove custom support bundles that you have installed on the Device Support Page. To do so, click the Action icon ☰ for a chosen device and choose **Delete** from the popup menu.

Excluding IP Addresses from Discovery

> **Note**
>
> You use the IPv4 Network or IPv6 Network editors to exclude IP addresses or ranges of IP addresses from discovery within the specified network. For more information, see *Disabling Discovery for a Network*.

Host records, fixed address and IPv4 reservations can be excluded from discovery. You may also exclude an IP address or a range of IPs within a network from discovery.

> **Note**
>
> You may create a network and choose not to discover it at that time, by disabling both **Enable Immediate Discovery** and **Enable Discovery**. If you disable the **Enable Discovery** checkbox, the network will never be discovered unless you change the setting again at a later time.
> Conversely, you can explicitly exclude specific IPs or IP ranges from discovery. Discovery will never take place on these IPs unless the admin specifically changes their exclusion setting.

Administrators can specify IPv4 and/or IPv6 addresses that must be immediately discovered by the appliance. Some devices may need exclusion because they do not support SNMP, or for other organizational reasons.
Devices matching IP addresses selected for immediate discovery (using the **Discover Now** feature described in *Using Discover Now to Discover an Existing Object*) are given one-time priority over other discovered devices, for data collection and counting toward any device found matching the license limits.
A device specified through an IP address can also be excluded from discovery or management.

Quick Exclusion of IPs from Discovery

You can use the IPAM IP Map or IP List page to quickly exclude IP addresses and selected ranges of IP addresses from discovery. For example, you may have Infoblox appliances or routers that provide the gateway to networks that are already managed by Grid Manager, or devices on which you do not wish to have discovery operations take place.

1. From the **Data Management** tab, select the **IPAM** tab. The IPAM Home page appears.
2. Click on any network or network container in the list. The **IP Map** appears for the selected network.
   Note that you may also use the **List** page for the selected network to exclude IPs or selected ranges of IPs. However, you have to page through or search through the pages comprising the list view to locate the IPs you want to exclude. (If you know the IP address value in the **List** view but it does not appear on the page, enter it in the **Go to** field to search for the IP.) The **IP Map** view allows you to view every IP address in a selected network, such as a /24 prefix.
3. Select one or more IPs in the map. SHIFT+click to select a series of contiguous IPs. CTRL+click to select non-contiguous IPs.
4. Expand the Toolbar and click **Exclusion –> Enable Exclusion**. The selected IP addresses are excluded from any discovery actions.

> ⚠ Note
>
> You can click the Action icon ☰ for any List record and choose **Exclusion–>EnableExclusion**.

To locate an IP to exclude within a network container:

1. From the **Data Management** tab, select the **IPAM** tab. The IPAM Home page appears.
2. Select the network container by clicking it. The IPAM Home page changes to display the List page, showing the list of networks within the container.
3. Click the network that has the IP in its space that you wish to exclude.
4. Select the network IP address from the **List** table. If you know the IP address value but it does not appear on the page, enter it in the **Go to** field to search for the IP.
5. Expand the Toolbar and choose **Exclusion –> Enable Exclusion**.

A parent network container may exclude IPs, and you may add and remove discovery exclusions within network containers. You can drill down to the child networks in the **Net Map** view to perform exclusions on IPs. For example, consider a /16 network container that has a number of smaller /24 child networks within it. Right-clicking on any child network in the network container and choosing **Edit** from the popup menu, opens the editor with its **Discovery Exclusions** tab, where you can perform exclusions within the child network.

Creating a New IPAM Object and Excluding it from Discovery

You can create a new object from the main **Data Management –> IPAM** or **Data Management –> DHCP** pages.

1. From the **Data Management** tab, select the **IPAM** or **DHCP** tab.
   a. For IPAM, the **IPAM** home page appears, listing all networks reachable by IPAM.
   b. For DHCP, the home **Networks** page appears, showing all networks reachable by DHCP.

> ⚠ Note
>
> Note the network lists between IPAM and DHCP will likely differ, because networks can be set to be Disabled from DHCP. IPAM provides a complete list of all networks configured or discovered by Grid Manager.

2. To select a network, do one of the following:

   - On the **IPAM** page, select the network.
   - Click **DHCP–>Networks** and then select the network.

3. On the Toolbar, expand the **Add** drop-down list and then select the object type from the drop-down menu, such as **Host**, **Fixed Address** –>**IPv4**, or another object type.

4. In the second Wizard step, click **NextAvailableIP** to obtain the next available IP address in the chosen network. For more information about obtaining the next available IP address, see *About the Next Available Network or IP*.

> ⚠ Note
>
> For adding a host record, the first step in the Add Host Wizard requires adding an IP address.

5. If the network of the IP address is served by a Grid member, Grid Manager displays the **AssignIPAddressby** section, with its **MACAddress**, **DHCPClientIdentifier** and **DHCPRelayAgent** settings. Select the different options as needed to define a fixed IP Address or another object.
6. Click **Next** to continue to the DHCP Options page in the wizard.

> ⚠ Note
>
> For more information about DHCP Options configuration, see *About the Next Available Network or IP.*

7. If you do not wish to configure DHCP Options for this Fixed IP, click **Next** to go to the following Wizard step.
8. (*Optional*) In the **DeviceInformation** page, select the Device Type and the Device Vendor, or, if you do not wish to configure device settings for the current object, click Next to go to the next Wizard step, for defining discovery settings.

> ⚠ Note
>
> For more information about Device Information settings, see *Creating Port Reservations for IPAM Objects*.

9. Choose from the options on the Step 5 Wizard page:

- Check **Exclude from Network Discovery** to prevent the object from being probed by discovery.
- (Enabled by default) If you want immediate discovery of the current Fixed IP, select the **Enable Immediate Discovery** checkbox.
  You may disable both checkboxes. Doing so does not disable discovery for the current object–discovery is simply performed by Network Insight on its own internal timetable.
- To override SNMP credentials for either SNMPv1/v2 or for SNMPv3 for the current Fixed IP, select the **Override Credentials** checkbox.
  You can enter both a SNMPv1/v2 Read community string and an SNMPv3 credential, or enter only the single type you need. Each can be selected and edited in turn.
  - Select **SNMPv1/v2** and enter the **Read** community string;
    –or–
  - Select **SNMPv3** and enter the device admin account name, and the **Auth Protocol**, **Auth Password**, **Privacy Protocol** and **Privacy Password** values where necessary.
- You can apply a set of CLI Credentials to the specific fixed address object. To override the inherited CLI credentials from the Grid, select the **Override CLI Credentials** checkbox. You can enter the admin user **Name** and **Password** values and, if necessary, an **Enable Password**. The values you enter here are specific only to the current object.

> **Note**
>
> Clicking **Schedule for Later** is a navigational button to allow you to skip quickly to the scheduling step in the Wizard. You can return at any time to complete remaining Wizard steps to finish creating the object. You may click the **Schedule for Later** button at any time in the Wizard process. For more information, see *Scheduling New IPAM/DHCP Objects and Associated Port Configurations*.

10. (*Optional*) Click **Next** to go to the sixth Wizard step, which governs **Reserve Port** and **Configure Port** settings. (For more information, see *Creating Port Reservations for IPAM Objects*.) Click **Next** when finished with settings.
11. If necessary, add or apply any extensible attributes necessary for the new record. Click **Next**.
12. The final Wizard page governs scheduling of the object creation task and the optional port reservation task. Click **Save & Close**.

Excluding IP Addresses in Grid Manager

You may exclude IP addresses from discovery from within a number of different contexts in Grid Manager. Under IPAM, you can exclude in the IP Map and IP List pages. The IP List page provides an Exclude data column that directly shows the exclusion status for all IPs in the selected network. Various objects, such as host records, IPv4 and IPv6 fixed addresses, and IPv4 reservations, may be excluded from discovery.
You may view excluded IP addresses in the IP List page or in the network editor's **Exclusions** tab.

Disabling Discovery for a Network

You go to the DHCP feature under **Data Management** to disable discovery for a network. Disabling discovery for a network differs from discovery blackouts; disabling discovery for a network simply ensures that discovery never takes place on the chosen network.
To disable discovery for an IP network:

1. Select a managed network from one of the following locations:
   a. **Data Management –> IPAM –>** list view
   b. **Data Management –> DHCP –> Networks**
2. Click the Action icon

   next to the network you want (this automatically selects it) and select **Edit** from the menu. The Network editor appears.
3. Click the **Discovery** tab.
4. Child networks inherit their discovery default settings from their parent networks. Click **Override** to change the **Enable Discovery** setting. (The **Discovery Member** setting remains unchanged.)
5. Deselect the **Enable Discovery** checkbox, and then save the configuration.

Discovering Devices and Networks

To start discovery on connected networks, complete the following:

1. Ensure that your appliances are licensed for discovery.
2. Add the needed seed routers to each Probe appliance, as described in *Defining Seed Routers for Probe Members.*
3. Add the necessary SNMPv1/v2 and SNMPv3 credentials at the Grid level and/or Member/Probe level. For information, see *Configuring SNMP1/v2 Credentials for Polling*, *Configuring SNMPv3 Properties*, *Defining Seed Routers for Probe Members*, and *Defining Seed Routers for Probe Members*.
4. If necessary, add CLI Credentials, including device admin username/password tuples and Enable passwords, at the Grid level and/or Member/Probe level, as described in *Configuring CLI Discovery Properties* and *Testing SNMP and CLI Credentials*.
5. If necessary, enable the use of DHCP routers and servers as seeds to increase device discovery, as described in *Configuring SNMP1/v2 Credentials for Polling*.

6. If you have extensive end host Ethernet segments connected to Ethernet switches, enable switch port discovery, as described in *Defining Seed Routers for Probe Members.*

With these settings, the Probe appliances automatically begin discovering network infrastructure devices.
You can elect to immediately discover or schedule discovery of new objects that you create and enable under IPAM or DHCP. Objects that allow immediate discovery include the following:

- **IPv4 Fixed Address** (see *Configuring IPv4 Fixed Addresses* for the complete procedure).
  You can **Enable Immediate Discovery** or **Exclude from Network Discovery** after creating the IPv4 fixed address, and override the SNMP credentials if necessary.
- **IPv6 Fixed Address** (see *Configuring IPv6 Fixed Addresses* for the complete procedure).
  You can **Enable Immediate Discovery** or **Exclude from Network Discovery** after creating the fixed address, and override the SNMP credentials if necessary.
- **IPv4 Reservation** (see *Configuring IPv4 Reservations* for the complete procedure).
  You can **Enable Immediate Discovery** or **Exclude from Network Discovery** after creating the IPv4 reservation, and override the SNMP credentials if necessary.
- **Host** (see *Adding Host Records* for the complete procedure).
  You can **Enable Immediate Discovery** or **Exclude from Network Discovery** after creating the host, and override the SNMP credentials if necessary.
- **IPv4 Network** (see *Configuring IPv4 Networks* for the complete procedure).
  You can **Enable Immediate Discovery** (option is enabled by default) and override inherited discovery **Polling Options** for the new network.
- **IPv6 Network** (see *Configuring IPv6 Networks* for the complete procedure).
  You can **Enable Immediate Discovery** (option is enabled by default) and override inherited discovery **Polling Options** for the new network.
- **IPv4 DHCP Range** (see *Configuring IPv4 Address Ranges* for the complete procedure).
  You can **Enable Immediate Discovery** (option is enabled by default) and override inherited discovery **Polling Options** for the new IPv4 DHCP range.
- **IPv6 DHCP Range** (see *Configuring IPv6 Address Ranges* for the complete procedure).
  You can **Enable Immediate Discovery** (option is enabled by default) and override inherited discovery **Polling Options** for the new IPv6 address range.

During configuration, you can choose to **Exclude from Network Discovery** if you wish to postpone discovery for specific object types.

> ⚠ Note
>
> Individual IP addresses within a network, and specific object types (IPv4 reservation, fixed address, and host), may be excluded from discovery. You must explicitly select **Enable Discovery** for other object types (IPv4 and IPv6 Ranges, IPv4 and IPv6 Networks); you can optionally **Enable Immediate Discovery**.
> If you choose not to perform immediate discovery, but do **Enable Discovery**, the new network or other object is discovered at a normal time determined by Network Insight.

You can manually perform discovery on any object at any time by selecting the object and choosing

Discover Now from the Toolbar. For more information, see *Object*. When you do so, you see a status icon appear in the **Discover Now** data column
for the object under IPAM, in the **Data Management –> DHCP** page and other locations.
By default, Grid discovery settings are the prevailing settings for all newly created objects. You can override basic discovery polling options for networks and DHCP ranges allowing immediate discovery.
In such cases, local settings take priority. Credentials cannot be overridden for networks and DHCP ranges,

Using Discover Now to Discover an Existing Object

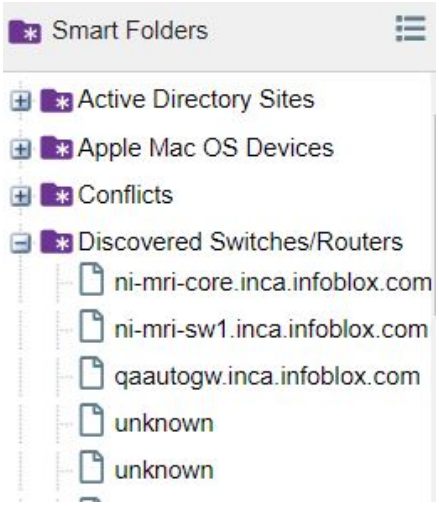
> **Note**
>
> If after you select a a network, object or IP and the **Discover Now** button is not enabled, make sure the network or other object has a discovery Probe member assigned to it.

After you create any supported IPAM object, you may wish to perform discovery on it at a later time. You can simply select the object and discover it.

1. From the **Data Management** tab, select the **IPAM** tab. The IPAM Home page appears.
2. Select the network or other object over which you want to perform discovery.
   Depending on the object type, navigate from the network level to the individual IP table in the **List** page to locate the object for immediate discovery.
3. Expand the Toolbar and click **Discover Now**.
   You can also click the Action icon

   for the network and choose **Discover Now** from the menu.

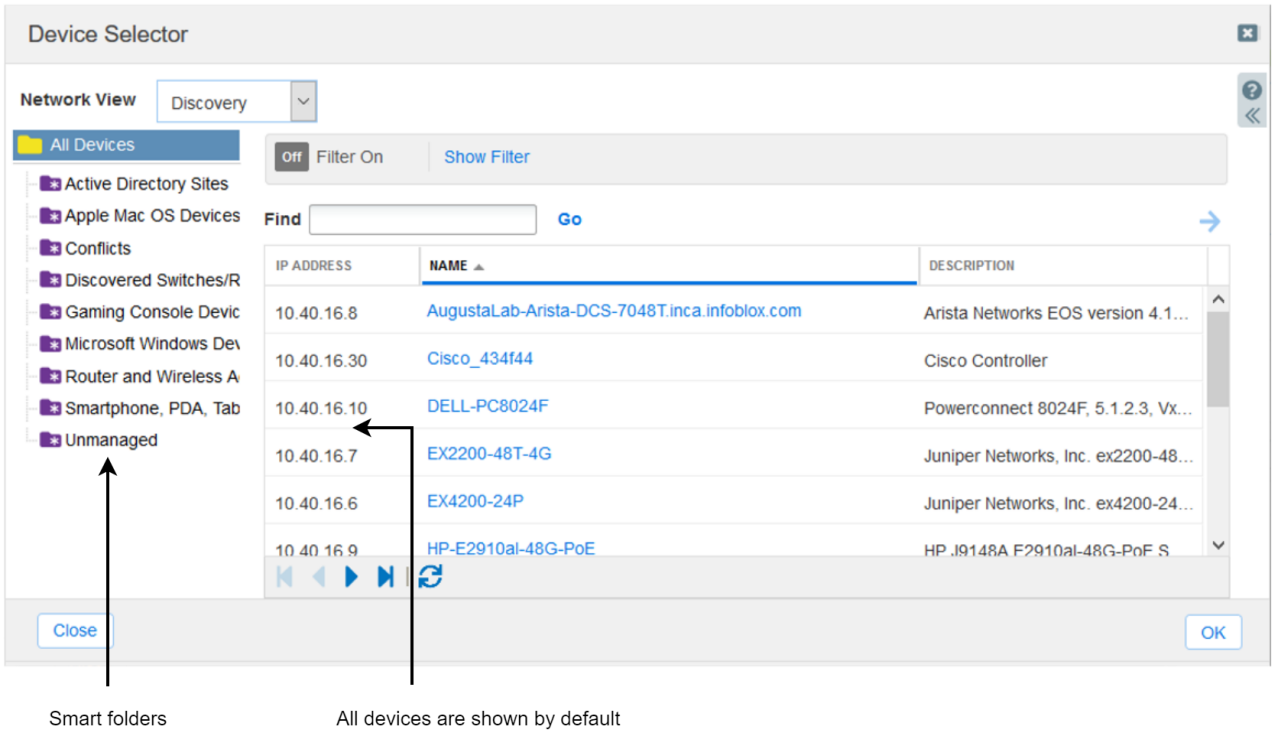
The Probe member associated with the network or other object initiates a discovery procedure. Smart Folders and Discovered Devices



Grid Manager maintains a Smart Folder titled **Discovered Switches/Routers**, under which appears a list of all routers, switches and switch-routers that thus far have been discovered and catalogued through discovery. Clicking a device name opens the device's main page, with **Interfaces**, **Networks**, **IP Addresses**, **Assets** and **Components** panels. For more information, see *Managing Discovered Data*.
Open the Smart Folders category under the Finder menu and click on the **Discovered Switches/Routers** folder. Clicking on a device name opens the device page under **Data Management –> Devices** and shows the **Interfaces** page for the chosen device. For related information, go to *My Smart Folders and Predefined Smart Folders*.

Using the Device Selector

You use a dedicated Device Selector window to choose a discovered device for creating a port reservation with various IPAM objects such as IPv4 reservations, fixed addresses, host records, and provisioning of IPv4 and IPv6 networks on device interfaces; testing SNMP or CLI credentials, and other purposes, as shown in the below figure.
Using the Device Selector Window



The chosen device is discovered and listed in the Devices panel in IPAM, or any other device on the network under the **All Devices** category in the left pane of the device selector.
Clicking a managed device's device name selects the device and brings you back to the originating page. Otherwise, select a device and click **OK** to continue.
If you have a long list of devices even after selecting a smart folder, enter a device name search value or a search expression in the **Find** field and click **Go**.

Tips for Quick Navigation

To locate interface and device information quickly, along with associated IPAM objects that may be associated with elements such as port reservations, you can use Device and Interface terms in Global Search. (For additional information on Global Search, see *Global Search*.)
Smart Folders provide another means of locating items such as IP addresses and IPAM objects of various types. Smart Folders provides additional filters for Device Type, Vendor, Model and Version. In a Smart Folder containing interfaces, you can filter by Admin Status, Operation Status, Trunk Status, VLAN ID or VLAN Name, and Description.
Using Smart Folders, you can also isolate all objects of a certain type by creating a smart folder with settings such as: **Type equals IPv4 Fixed Address**. Title the smart folder appropriately, to make clear what data set it is presenting.

Starting Discovery

To ensure a successful discovery, complete the following:

1. In the Grid, install valid Discovery licenses on the Network Insight supported members that will later become the Consolidator and Probes. For information about the available license types and procedure to obtain and install licenses, see *Managing Licenses*.
2. When you join the discovery members to the Grid, the first member automatically becomes the Consolidator while the others become Probes. If you want to change the roles of these members after they join the Grid, you can re-define their member types, as described in *Defining the Discovery Member Type*. If you have only one

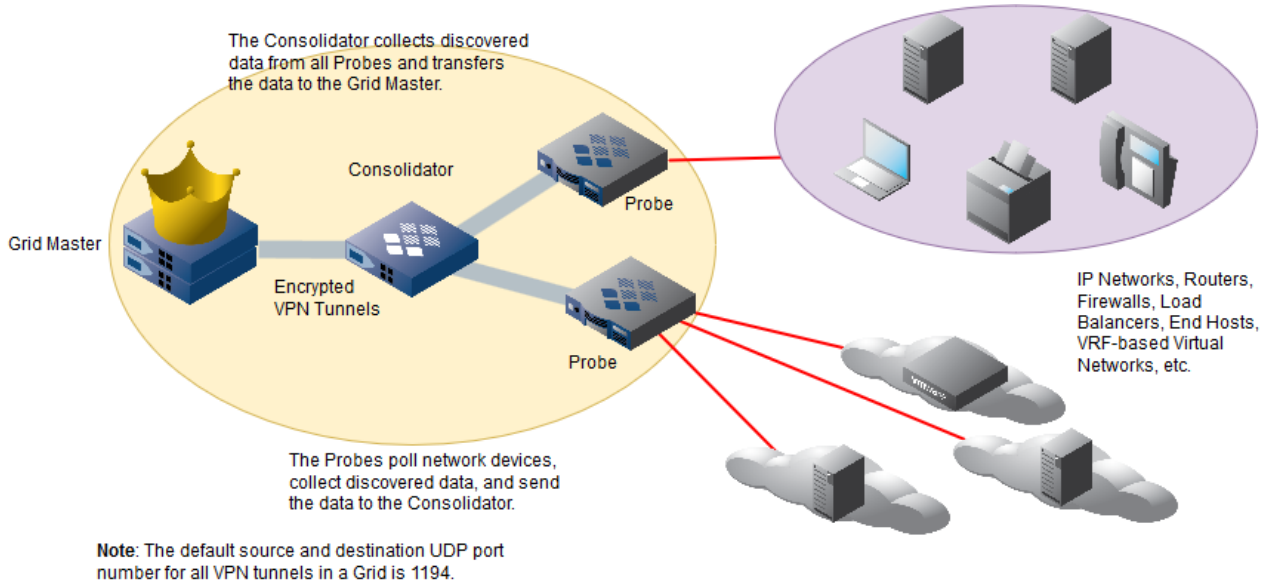
discovery member, it automatically becomes the Consolidator-Probe appliance after it joins the Grid. For more information about the Consolidator and Probes, see *Consolidator and Probes*.

3. Configure applicable admin permissions for managing discovery and discovered data. For more information, see *Administrative Permissions for Discovery*.
4. Define discovery interfaces and map them to corresponding network views. This step is especially important for discovering VRF virtual networks. For more information, see *Mapping Discovery Interfaces to Network Views.*
5. Configure Grid discovery properties such as defining polling settings, configuring SNMP and CLI credentials, and configuring automatic VRF mapping. For more information, see *Configuring Discovery Properties*. Note that you can override the Grid settings at the member and network levels, except for automatic VRF mapping which can be configured only at the Grid level.
6. Optionally, you can configure seed routers and map them to the corresponding network views. You can also use the default gateways for associated DHCP ranges and networks as seed routers for discovery by selecting the **Use DHCP Routers as Seed Routers** in the **General** -> **Advanced** tab of the *Grid Discovery Properties* editor. For more information, see *Defining Seed Routers for Probe Members* and *Defining Advanced Polling Settings for the Grid.*
   Note that you must map each discovery interface, seed, and VRF to its respective network view in order to have a successful discovery for virtual routing instances.
7. Specify a network view, network container, or network to be discovered. For more information, see *Discovering Devices and Networks*.
8. Optionally, define IP address exclusions when you want to exclude certain IPs from a discovery for various reasons. For more information, see *Excluding IP Addresses from Discovery*.
9. Define blackout periods when you do not want the appliance to perform discovery. For information about how to configure blackout periods, see *Defining Blackout Periods*.
10. Start the discovery service on the Consolidator and Probes to begin discovery, as described in *Starting and Stopping the Discovery Service*. The Probe members continue to discover network devices within the defined networks.

Network Insight Architecture

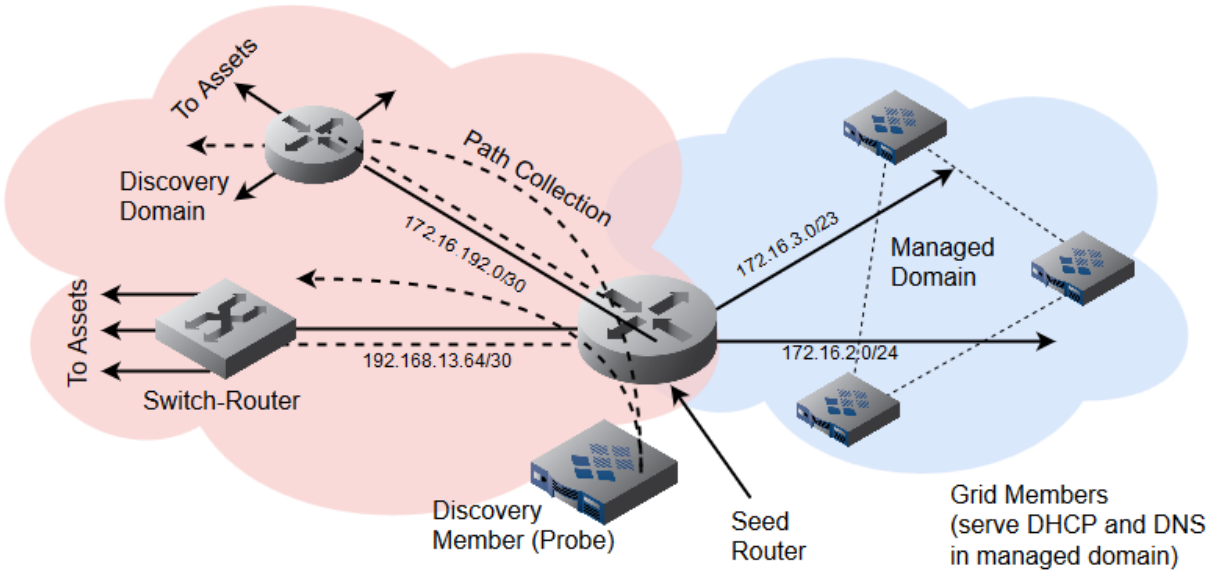
Discovery appliances that only detect devices and collect device data are called Probes, which are members of the Infoblox Grid, separately dedicated to the tasks of polling and discovery of networks and devices. A separate appliance, called the Consolidator, aggregates and organizes all collected device information from the Probes and synchronizes with the Grid Master. For more information, see *Consolidator and Probes*.
You can configure supported appliances as the Consolidator and Probes, as illustrated in the figure Network Insight Appliances Added as Grid members below. The Consolidator aggregates discovered data it collects from Probes and transfers the data to the Grid Master for device management and reporting purposes.
In the Grid, the Grid Master synchronizes data among all Grid members through encrypted VPN tunnels. Communications between the Consolidator and Probes are also through encrypted VPN tunnels. The default source and destination UDP port number for VPN tunnels in a Grid is 1194. You can use the default port number or change it for VPN communications. Note that all the VPN tunnels in the Grid use the same port number you have chosen.

Network Insight Appliances Added as Grid members



Network Insight appliances use SNMP and other protocols to discover and catalogue a diverse assortment of device types, including the following: routers, enterprise switches, firewalls and security appliances, load balancers, enterprise printers, wireless access points, VoIP concentrators, application servers, VRF-based virtual networks, and end hosts. Network Insight provides a tool for administrators to gather key information about networks, including the discovery of routed paths and the host clouds behind enterprise switches, even in organizations where an Infoblox deployment already exists. In the figure Discovery in Action below, an appliance running discovery connects to an enterprise router, and uses its information to determine more about the networks that exist deeper within the unmanaged network, termed the discovery domain in this example.

Discovery in Action



As indicated in the above figure, discovery can trace through multiple hops and perform device discovery at every step, filling out the maps of unmanaged networks for the administrator.

The collection of unmanaged network information extends to the networks of distribution Ethernet switches. Data collection also includes end hosts and application/file servers connected to edge switches in enterprise offices. Discovery uses the term assets to describe these devices. For more information, see *Viewing Assets Associated with Discovered Devices.*

The Probes return discovery data to the Consolidator, which synchronizes device information with the Grid Master. Once

information about discovered networks and devices resides on the Grid Master, you can convert unmanaged networks and devices to managed objects, adding them to the NIOS database. For more information, see *Managing Discovered Data* and *About Automatic Conversion Rules*.
You can also configure the appliance to send SNMP and email notifications when it discovers unmanaged devices and networks. For information about how to enable SNMP and email notifications for discovered unmanaged objects, see *Setting SNMP and Email Notifications*. You can also manage these notifications by configuring the maximum number of unmanaged objects the appliance detects before it sends notifications and how often it notifies about these events. For information about how to configure these parameters, see *Defining Seed Routers for Probe Members*.
You provide one or more routers as seed routers to act as the initial gateways for discovering other networks and their devices in the discovery domain (an example appears in the figure Discovery in Action above). You can also use DHCP routers (e.g., routers serving DHCP leases) as seed routers to aid in faster discovery.
When you create new networks, you can optionally provision them onto devices and perform discovery on them. Once you create the network, discovery can locate, poll and catalogue the network devices comprising the networks. This information is then synchronized with the Grid Master. For more information, see *Discovering Devices and Networks*.

Note

For comprehensive coverage of port control features in Grid Manager, see *Pest Control Features in Network Insight* and its various subsections.

You can also exclude networks and IP addresses from discovery. The basic principle is that some devices do not need to be discovered, perhaps because they are already managed as part of a Grid and hence should not be subjected to discovery; because a device does not support SNMP; or for other organizational reasons. In the figure Discovery in Action above, networks 172.16.2.0/24 and 172.16.3.0/23 are excluded from discovery because they are already fully managed by a Grid. For more information, see *Excluding IP Addresses from Discovery*.
You can define scheduled time periods in which Network Insight does not perform discovery operations in the network. These time periods are called *discovery blackouts*. All protocols associated with discovery (SNMP, CLI through Telnet and SSH, port scanning, fingerprinting and Ping sweeps) can be shut off during discovery blackout periods. This prevents discovery protocols from occupying network bandwidth during periods of peak usage. Network Insight does not communicate with devices in any way during a discovery blackout period. For more information on discovery blackouts, see *Defining Blackout Periods*. Network Insight also provides a second type of blackout period for port configuration tasks, during which no tasks to change device port settings will execute. For more information, see *Defining Port Configuration Blackout Periods*.

Infoblox Network Insight

Mapping Discovery Interfaces to Network Views

Discovery Probe members must have a designated interface or interfaces over which all discovery traffic exchanges take place. You may designate one or multiple discovery interfaces on each Probe member. You can specify the LAN1, LAN2, MGMT, and VLAN ports as the discovery interfaces. These ports must first be defined in the member network settings before they can be used for discovery. Note that when you configure VLANs on Network Insight appliances, the VLANs are used for discovery only. They do not support other core network services. On ND-1405, ND-2205, ND-4000, ND-V1405, and ND-V2205 Network Insight appliances, you can assign multiple VLAN interfaces on the same Probe to different network views.
To discover VRF virtual networks, you must discover their corresponding routes. In order to identify discovered data by routes, you associate each discovery interface with a network view. You must have a network view configured for each discovery interface, and you cannot share the same network view with multiple discovery interfaces on the same Probe member. However, discovery interfaces on different Probe members can share the same network view.
To map discovery interfaces to their respective network views, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Discovery**.
2. In the **Services** tab, select the checkbox of the Probe member you want to configure, and then Click **Edit –> Member Discovery Properties** in the Toolbar.

3. In the *Member Discovery Properties* editor, select the **General** tab and complete the following:
    - **Discovery Interfaces**: Discovery members must have a designated interface or interfaces over which discovery traffic takes place. By default, appliances use the LAN1 port for discovery traffic. You may designate other ports such as the LAN2, MGMT, and VLAN ports as the discovery interfaces. These ports must first be defined in the member network settings before they can be used for discovery. You cannot modify the discovery interface settings while the discovery service is running on the appliance.
      Note that the VLAN interfaces you configured on any Network Insight appliances are used for discovery only. Other services are not supported on these appliances for VLANs. For information about how to define network interfaces on the appliance, see *Configuring Ethernet Ports.*
      The **Discovery Interfaces** table displays all interfaces you have configured on the member. To discover using multiple interfaces, you must associate each interface with an available network view. A single default network view exists in NIOS by default. All networks created or discovered for NIOS management must be part of a network view. If more than one network view exists in the Grid, you can map a network view other than the default view to the interface. This essentially serves to allow one or more discovery members to perform discovery on separate routing domains, because a network view is comprised of a single routing domain with its own networks. If you do not want to use a configured interface as the discovery interface, simply leave the network view empty or unassigned for that interface. When you first set up an interface, no network view is assigned to the interface by default.
      The appliance displays the following for each interface you configure on the Probe member. To modify the network view for an interface, click the **Network View** column and select the network view you want to associate with the corresponding interface.
    - **Interface**: Displays the name of the interface. You cannot modify this field. Discovery supports the LAN1, LAN2, MGMT, and VLAN interfaces. You must first define these interfaces for the member before using them for discovery.
    - **VLAN Tag**: Displays the VLAN tag or ID for the corresponding VLAN interface. This field is left blank for all physical interfaces. You cannot modify this field.
    - **Network View**: Displays the current network view with which the interface is associated. An interface is not associated with any network view and this field is left blank by default, which means the interface is not used as a discovery interface. To modify the network view, click the **Network View** column for the corresponding interface and select the network view you want to reassign to the interface from the drop-down list. The appliance associates an interface with the default network view if you have not configured additional network views.
4. Save the configuration.

Managing Discovery

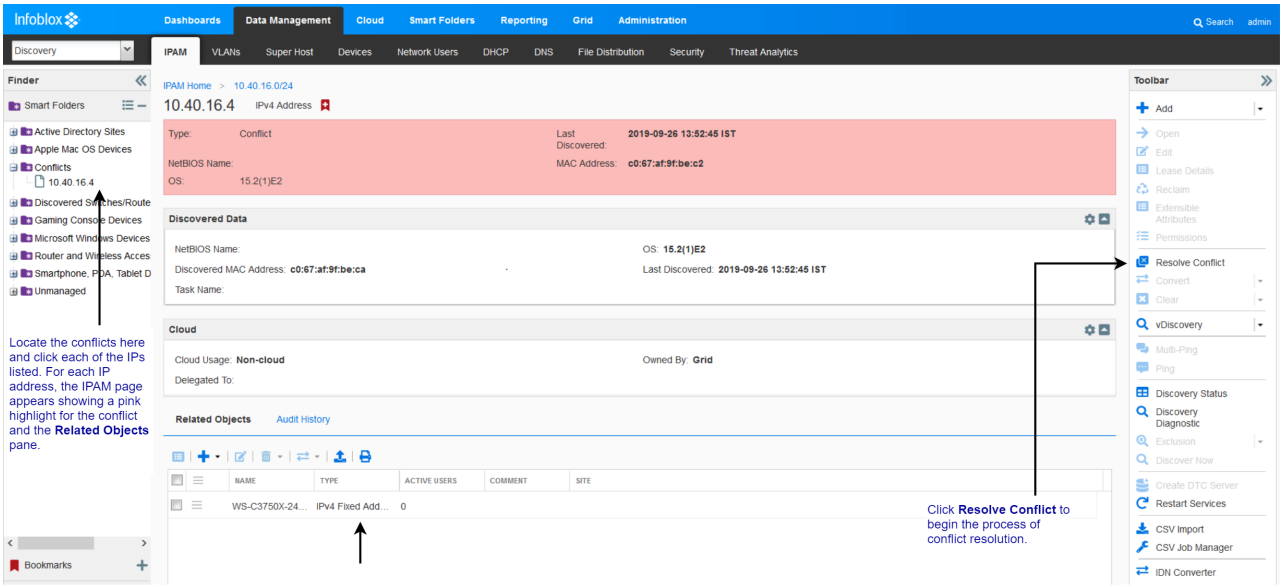
After you start the discovery service, you can do the following to manage the discovery and discovered data:

- Monitor the discovery status, as described in *Viewing Discovery Status*.
- Execute discovery diagnostics to test the connection of a discovery member, as described in *Executing Discovery Diagnostics.*
- Stop discovery on a specific network, as described in *Disabling Discovery for a Network.*
- View a complete list of discovered devices, their associated interfaces, networks, IP addresses, assets, and components. For more information, see *Viewing Discovered Devices and their Properties.*
- Resolve conflicts for discovered data, as described in *Conflict Resolution in Network Insight.*
- Provision and de-provision networks and manage port configurations, as described in *Port Control Features in Network Insight.*

Conflict Resolution in Network Insight

You can sometimes encounter conflicts when defining port reservations for IPAM-managed objects such as Fixed IP addresses or host records. The quickest way to locate any conflicts in Grid Manager is to open the Conflicts Smart Folder as noted in the below figure.

Locating conflicts and beginning their resolution



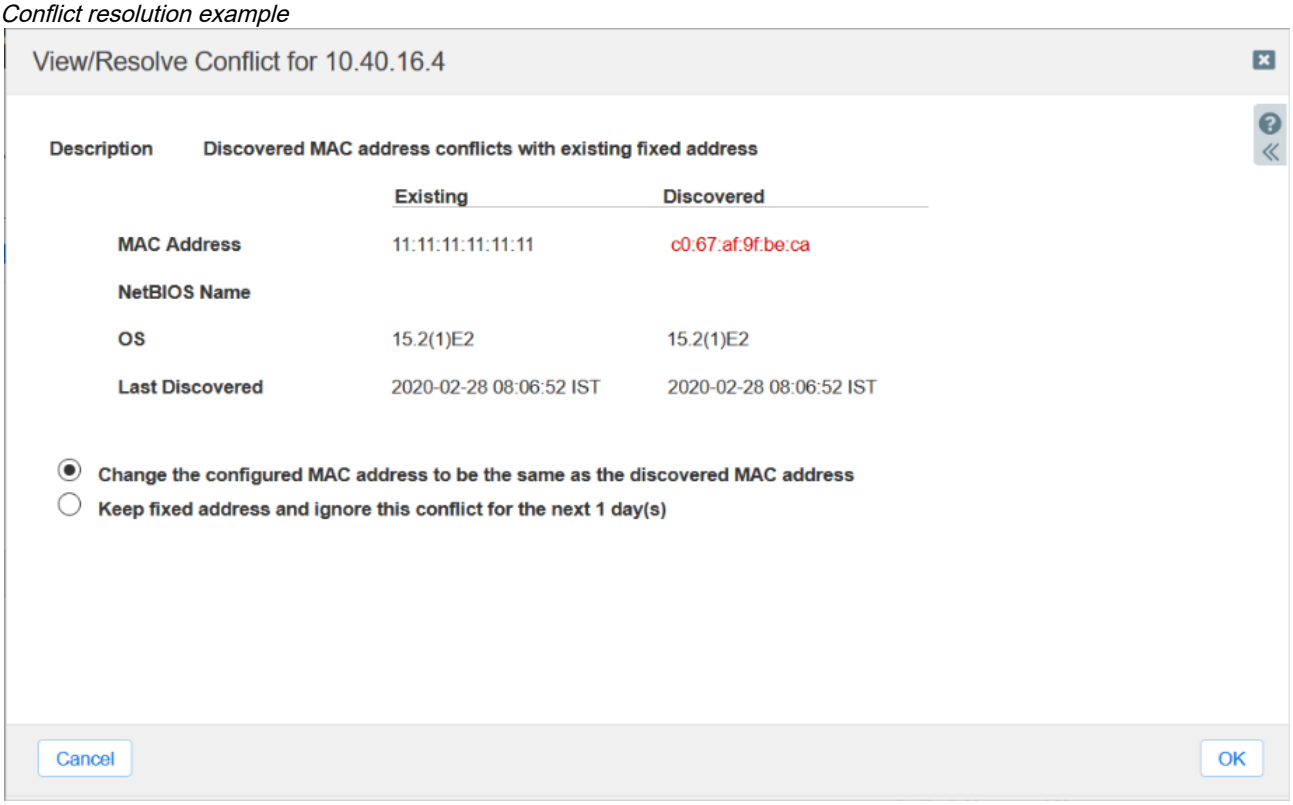
Numerous types of conflicts are possible:

- Device Information conflict
- Port Reservation conflict, including Used Port Reservation conflicts (usually resulting from a request to reserve a port that has already been assigned to another IPAM object)
- Fixed address conflict
- IP Address conflicts
- DHCP Range conflicts (such as: *Discovered address is within an existing DHCP range but does not match an existing lease, fixed address, or exclusion range*)
- MAC Address conflict (such as: *Discovered MAC Address conflicts with existing fixed address*)

> ⚠ Note
>
> When you execute discovery (**Discovery** -> **Discover Now** from the Toolbar), the appliance does not send SNMP trap if it finds any conflicting information between the NIOS data and the discovered data.

The Conflict Resolution wizard automatically recognizes the object associated with the conflict (which is listed in the **Related Objects** pane as noted in the figure Locating conflicts and beginning their resolution above) and ensures that changes you make during resolution are applied correctly to the object. An example appears in the below figure.

Conflict resolution example



Resolving Port Reservation Conflicts

Sometimes, administrators may accidentally request a device port to be reserved for an IP address when the port is already reserved for another object, or try to apply a different port to an object that already has a port reservation. When these cases arise, Grid Manager reports a *conflict*.
To resolve port reservation conflicts:

1. Click the link provided in the **Conflicts** Smart Folder.
2. Expand the Toolbar and click **Resolve Conflict**, as shown in the figure Locating conflicts and beginning their resolution above.
   The Resolve Port Reservation Conflict dialog opens, showing the differences between the reserved and discovered information.
3. Choose from the following options:
   - **Change the reserved port to be the same as the discovered port**.
   - **Keep the configured port reservation and clear the conflict for the next 1 day(s)**.
     Note that in the **Grid Discovery Properties** –> **Advanced** tab, the **Ignore Conflict Duration** setting governs the default time duration to ignore (clear) certain types of conflicts that may occur when defining IPAM objects that are associated with discovered and managed devices, interfaces, or IP addresses. Increments can be defined in **Hours** or **Days**. For more information, see *Defining Seed Routers for Probe Members*.
4. Click **OK** to save changes.
   Note that for other conflict examples, see Resolving Multiple Conflicts below.
   Another category of conflicts involves incorrectly defined device information for the object:

- The reserved Device Type information provided is different from the discovered vendor and device type (Router vs. Switch, for example).
- The defined Device Vendor information does not match with the discovered information.
- A User Port Reservation conflict occurs when an unmanaged IP address attempts to use a port that is already reserved by an IPAM object on a different IP address.

You can choose from the following options:

- **Change configured information to discovered information**.
- **Keep the current device configuration and clear the conflict for the next 1 day(s)**.

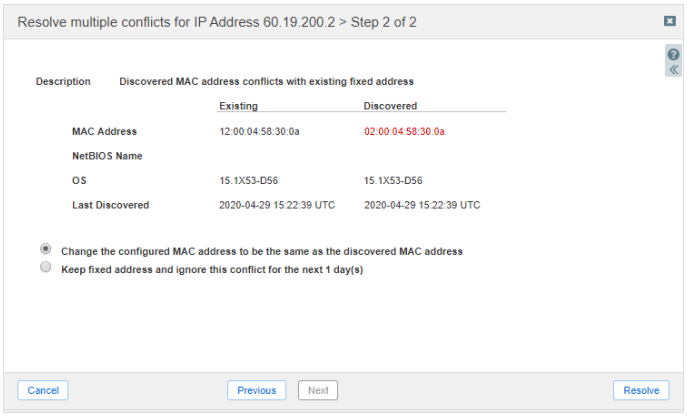
In virtually all cases, replacing the configured information with the discovered information successfully clears the conflict; click **OK** to commit changes or to temporarily clear the conflict.

Resolving Multiple Conflicts

You can define objects for IP addresses, attempt to apply a port reservation, or incorrectly specify a value such as a MAC address or a vendor name, and accidentally cause multiple conflicts after creating the new object.
To resolve multiple conflicts for a particular IP address, use a Resolve Multiple Conflicts wizard:

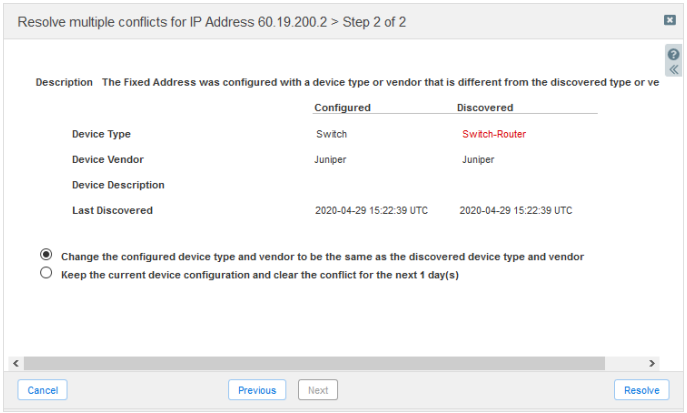
1. To quickly locate any conflicts, open the Smart Folders panel and open the **Conflicts** list.
2. Click the IP address for any entry in the Conflicts list. The IPAM page opens for the selected IP address, with the top panel highlighted in pink to indicate the conflict.
3. Open the vertical toolbar and click **Resolve Conflict**.
4. If multiple issues are involved with the conflict entry, the Resolve Conflicts wizard lists each of them as shown in the below figure.
   Resolution of Multiple Conflicts

5. Select the conflict that you want to resolve first and click Next. For example, consider choosing to resolve the MAC Address conflict as shown in above figure. The second step of the wizard appears, listing the differences between the Existing and Discovered information for the conflict as shown in the figure below.
   Troubleshooting the first selected conflict



a. In this case, the MAC address specified in the last fixed address object configuration, for that object, conflicts with the *discoveredMACaddress* associated with the IP. (You can verify this by checking the **RelatedObjects** tab in the IPAM page for the IP address.) Choose from one out of two options:
   - **Change the configured MAC address to be the same as the discovered MAC address**;
   - Keep fixed address and ignore this conflict for the next 1 day(s).
     In this example, the **Discovered** information for the MAC address associated with the Fixed Address object is one digit off from the **Existing** MAC information, which was entered incorrectly by the administrator. The DIscovered MAC, shown in red, is the correct value and should be used to overwrite the record for the conflict.

6. Select the **Update... with discovered data** option and click **Resolve**.
7. The wizard updates with a return to the first step, in which you select the next conflict to resolve. A banner shows the result of the first resolution.
8. Select the next conflict to resolve and click **Next**. As an example, the below figure shows a device configuration conflict.
   Device Information conflict for an object



9. a. To resolve the conflict, the Configured information must be overwritten with the Discovered information. Choose any of the following:
      - **Change configured device type and vendor to be the same as the discovered device type and vendor**
      - **Keep current device configuration and clear the conflict for the next 1 day(s)**

   Other conflict types have similar options.
10. Select from the above choices and click **Resolve**.
11. Continue through the wizard to resolve the last conflict associated with the IP address.

Note

In the **Polling** tab –> **Advanced** page of the *Grid Discovery Properties* editor, the **Ignore Conflict Duration** setting governs the default time duration to ignore (clear) certain types of conflicts that may occur when defining IPAM objects that are associated with discovered and managed devices, interfaces, or IP addresses. Increments can be defined in **Hours** or **Days**. This setting cannot be modified when resolving conflicts.

Conflict Calculation Between IP Discovered vs DHCP Range and Leases

The Discovery Engine uses several background processes to determine the existence of IPs. Depending on the process the 'timestamp' of discovery (last-discovered date) corresponds to a real date by a direct check (ping, SNMP, CLI), or an indirect check (presence in forwarding tables, or ARP tables).

When the check is indirect the timestamp of an IP is NOT real time as compared to a direct check against the device. It means that this timestamp may not be accurate when the device was associated to this IP, but not really at the time denoted by the timestamp. This will have impact when computing conflict with RANGE and LEASE, as the timestamp may be inaccurately stated at a time the LEASE is already ended.

Principle of Conflicts for DHCP Ranges

A DHCP Range is an object used for DHCP Service, to define which IP can be temporary allocated to a device using LEASE. It is expected that ONLY the device that hold the LEASE is using this IP.

If an IP is discovered on an IP slot of a DHCP Range and there is no corresponding LEASE, then there is a possible DHCP Range conflict (between the IP and the DHCP Range).

If in case the IP discovered is allocated for a LEASE, then we have two use case scenario:

- The LEASE IP has the same MAC than the discovered IP. All good.
- The LEASE IP has a different MAC than the discovered IP. Here a MAC ADDRESS conflict will be seen between the IP discovered and the IP LEASED.

Computation of Conflicts (for RANGE or MAC ADDRESS Conflicts)

The conflicts are computed (raised or cleared) when:

- IP is discovered or re-discovered or has disappeared
- When the DHCP Range is updated (by UI, WAPI, PAPI)
- Any of the NIOS object that can change the slots in the RANGE are updated (Range reservation, Fixed Address, Reservation …) by UI, WAPI or PAPI.

Note
LEASE operations DOES NOT trigger any recomputation of the conflict.

When computing a conflict, the process lookup for the IP discovered and verify this against any DHCP Range that includes the same IP:

- No Range : There will be no conflict with the Range (However, there can be other type of conflict see documentation
- There is a Range, but there is nothing in that IP slot, neither Reservation, Fixed Addresses … or LEASE: this IP is classified to be available for LEASE. If that IP is discovered, it means there is a device that uses that IP without holding the LEASE and a RANGE conflict is raised.
- There is a Range and this IP slot is used by:
    - Reservation or DHCP Reservation: no RANGE conflict.
    - Fixed Address or Host Address: no RANGE conflict. (There can be a MAC Conflict.)
    - LEASE:

- If the lease has currently no activity or never had any activity (eg BACKUP state). A RANGE Conflict is raised because we consider there is no LEASE.
- If the lease includes dates of activity (eg ACTIVE, RENEW, ABANDONED, FREE, …) , the “last-discovered” timestamp of the IP is checked against the dates of activity:
- If the “last-discovered” is BEFORE start of LEASE : we cannot say if there was a conflict or not. A SYSLOG “Maybe conflict - IGNORED” is issued, but no RANGE, neither MAC ADDRESS conflict is raised.
    - If the “last-discovered” is DURING activity of LEASE, it is expected. No RANGE conflict. However if the MAC does not match, a MAC ADDRESS conflict will be raised.
    - If the “last-discovered” is AFTER the activity of the LEASE : a RANGE conflict is raised, as there is no LEASE at time of the timestamp.

⚠ Note
Conflicts based on dates of “last-discovered” timestamp, depends on how the IP was discovered, with timestamps more or less accurate. Then a FALSE POSITIVE conflict can get raised. This condition needs to be manually verified along with the dates, assess the conflict and maybe resolve that conflict manually.
If there is a delay to collect the LEASE from the DHCP Member, a conflict is raised at the time of processing the IP, because the corresponding LEASE was not yet consolidated on GM. This require a manual assessment of the conflict, and needs to be resolved manually.

Executing Discovery Diagnostics

You can execute a discovery diagnostic to help determine why a specific device is presenting difficulties in discovery. For example, a given device may be reachable but show an overall status of **Failed** in the *Discovery Status* dialog. A discovery diagnostic steps through a complete discovery process based on the configuration on the Probe member to which the device is assigned. The diagnostic runs the gamut from fetching SNMP object ID information to ARP table reading and to ICMP pings and traceroutes.

You can do the following in the Discovery Diagnostics dialog:

- View all existing discovery diagnostic tasks that were executed in the last 12 hours.
- Enable or disable SNMP debugging for a device. The SNMP debugging is enabled by default.

Note that you must be a superuser to perform a discovery diagnostic. To execute a discovery diagnostic, complete the following:

1. From the **Data Management** tab, select the **IPAM** tab, and then click **Discovery Diagnostics** from the Toolbar.
2. In the *Discovery Diagnostic* editor, complete the following:
    - **Existing Discovery Diagnostic Task:** Select this option to choose an existing discovery task from the **Task ID** drop-down list. The appliance displays all the discovery diagnostic tasks that were executed in the last 12 hours.
    - **New Discovery Diagnostic Task**: Select this option to initiate a new discovery diagnostic. To start a new discovery diagnostic task, complete the following:
        - **Discovery Member**: Make sure that you select a discovery member for an IP address that does not exist in any network (in the **IPAM** tab) or excluded from discovery. Click **Select** to select a discovery member. You can click **Clear** to remove the discovery member
        - **IP address**: Enter the IPv4 or IPv6 address of the device on which you want to perform the test. The discovery diagnostic runs a full discovery procedure against the specified IP address. Ensure that you select the respective network view in which this IP address resides.
        - **NetworkView**: If you have multiple network views, select the network view in which the IP address resides from the drop-down list. If you have only one network view, which is the default view, the **NetworkView** drop-down list is hidden by default. NIOS conducts a discovery diagnostic for the IP address in the selected network view.
        - **CommunityString**: Specify the community string for the device if the required SNMP credential is not currently configured for the discovery member. It may not be necessary to enter a community string if the device is already discovered by NIOS and is a managed device.
        - **ForceTest**: To force a diagnostic against the device, select **Yes**.

- **Enable SNMP debug**: As a troubleshooting aid, the SNMP debugging option is enabled by default. When you enable this option, the appliance collects all SNMP communications between NetMRI and a device. The SNMP logs are useful for troubleshooting purposes. Clear this checkbox to disable the SNMP debugging for a device.

3. Click **Start** to start the discovery diagnostic. The lower pane displays the complete discovery sequence for the chosen device, and whether or not the discovery is successful. You can click **Stop** at any time to end the diagnostic sequence.

The output log of the diagnostic is displayed in the lower pane, and it shows the attempt for the complete discovery process. You can then do the following:

- You can click **Select All** to select the complete text in the lower pane for copying and pasting to the Clipboard and a text editor. You can also monitor the test messages in this pane.
- Click **Download as text** to download the complete discovery diagnostics in a text file for the selected device. The default name of the downloaded file is discovery_diagnostic_nnn.nnn.nnn.nnn.txt, where nnn.nnn.nnn.nnn is the IP address of the selected device. The **Download as text** button remains disabled until the download is complete.

Viewing the Management State of IPs in Discovered Networks

You can view the management state for any IP address, in any network, that is associated with any discovered device.

1. From the **Data Management** tab, select the **Devices** tab. The Devices Home page displays a list of all devices currently found and catalogued by discovery.
2. Click the Action icon

   for a chosen device and choose **Networks** from the popup menu.
3. Choose a network from the list. Grid Manager switches to the IPAM page view of the selected network. The IPAM Home page displays the IP Map for the chosen network. The page shows information in graphical format, indicating elements such as **Used** Addresses, fixed addresses and IP reservations, **Unmanaged** IPs, **Host Not in DNS/DHCP**, and all other objects or information associated with IP management. The user benefits from this view by immediately seeing which IPs in the network contain devices that remain unmanaged by Grid Manager. These Unmanaged IP values appear in light yellow. Hovering the mouse over any IP address in the graphical table shows the information that has already been determined about the IP address.

> ⚠ Note
>
> An Unmanaged IP cannot be converted to Managed unless the network that contains it, is converted to managed status. For more information, see *Converting Unmanaged Networks under IPAM to Managed Status*.

Discovering VRF Virtual Networks

You can configure Network Insight to discover network devices that are configured or deployed within VRF (Virtual Routing and Forwarding) virtual networks. Using Network Insight to discover virtual networks provides visibility into your entire virtual network infrastructure, which allows you to view and manage overlapping IP addresses, VRF-specific data, and discovered end hosts. Note that a virtual network can consist of one or more physical devices that are configured to route packets using separate and distinct routing processes. Multiple routing tables can coexist on the same physical device or virtual device context, and traffic is exchanged among those devices using multiple routing tables.
Depending on your network topology, there are a few ways you can use Network Insight for VRF network management. To use Network Insight effectively in the network, review the different deployment scenarios and configure Network Insight accordingly, as described in VRF Deployment Guidelines below.
In addition, before you start a discovery for VRF virtual networks, ensure that you have reviewed the guidelines listed in *Special Considerations for Managing VRF Virtual Networks below*.

Special Considerations for Managing VRF Virtual Networks

When you define discovery settings and perform management of VRF virtual networks, consider the following:

- If you limit the context of the SNMP community string in an individual VRF to the context of only that VRF, Network Insight will not be able to determine that the device it has discovered inside that VRF is the same device it has found inside other virtual networks. This may result in extra, un-correlated devices in the network. For information about how to configure SNMP credentials, see *Configuring SNMP1/v2 Credentials for Polling* and *Configuring SNMPv3 Properties*.
- Network Insight will become aware of some devices inside of virtual networks from the route and ARP tables of routers that it manages. Without network connectivity into those virtual networks through a virtual discovery interface, Network Insight cannot discover all the devices or manage them. To create the necessary connectivity, you must configure a Network Insight discovery interface to be part of the VRF.
- Network Insight collects and parses the ARP and routing information from within a VRF context, but this data will not be used for further discovery unless the VRF virtual network is associated with a network view that is mapped on a discovery interface. For more information about how to map network views to discovery interfaces, see *Mapping Discovery Interfaces to Network Views*.
- Global VRFs are labeled as: "default(IOS)" for IOS, "default" for Nexus and "master" for JunOS.
- For discovery and periodic polling on Juniper devices through an interface that is not in the Juniper default VRF (master), the query must use a special "default@credential" format. This setting assumes that users do not have management interfaces in a VRF. Your defined SNMP credentials for VRF-aware Juniper devices must use syntax similar to: "@credential". (Note that when querying VRF-aware Juniper devices via an interface that is in the default VRF, a plain community string can be used without the "@" character.)
- When configuring Network Insight to discover networks that employ route-leaking, discovery ranges for each network view should only be defined to include IP addresses that belong to that network view. In other words, any given Device IP should only fall within the discovery ranges of one network view. If discovery ranges are defined such that a device can be discovered by two different network views, the device may also be discovered via an unexpected network view. For information about how to define discovery ranges, see *Discovering Devices and Networks*.

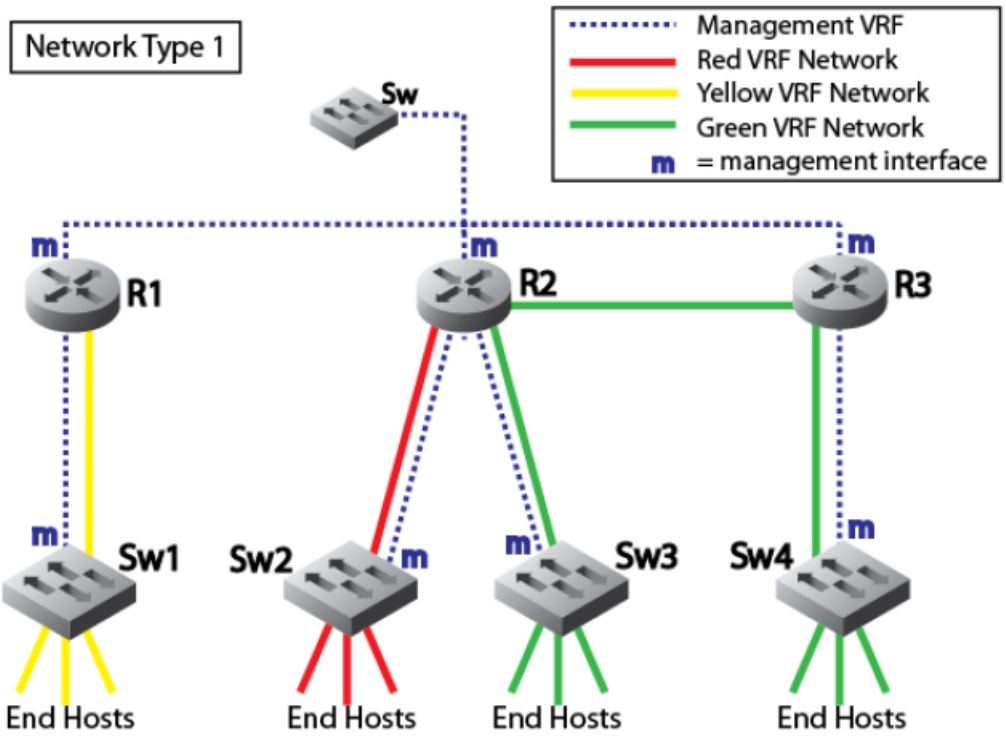
VRF Deployment Guidelines

The topology of your network helps determine how you deploy Network Insight for VRF network management. To use Network Insight effectively in the network, you must possess some knowledge about your network so you can decide how to configure Network Insight to reach all the virtual networks you want to discover and manage. This section describes some common VRF-related network types for which you can deploy Network Insight.
Using the following three network types, all examples in this section help you define the number of network views and discovery interfaces so you can reach all locations in your network.

1. **VRF Network Type 1**: A network with a management VRF and several isolated production VRFs that include VRF-aware devices in the network.
2. **VRF Network Type 2**: A network with a shared service deployment VRF (shared VRF) and several isolated production VRFs that include VRF-aware devices in the network. The production VRFs share routes with the shared VRF, a practice also called route-leaking.
3. **VRF Network Type 3**: A network with several VRF-ignorant devices that reside in different L3 spaces, with no management VRF.

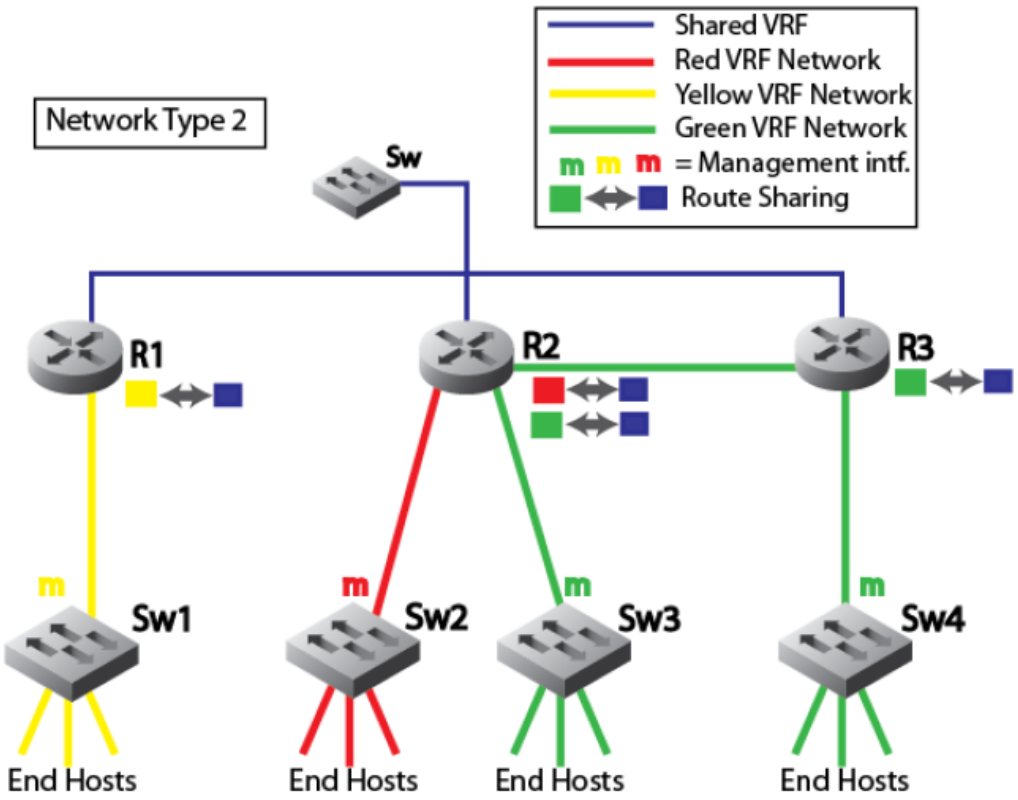
VRF Network Type 1 has the following characteristics:

- A management VRF that reaches all VRF instances throughout the network.
- Isolated production VRFs (all VRFs can route to/from the management VRF but not to one another).
- The management VRF has complete visibility to all VRF instances in the network.



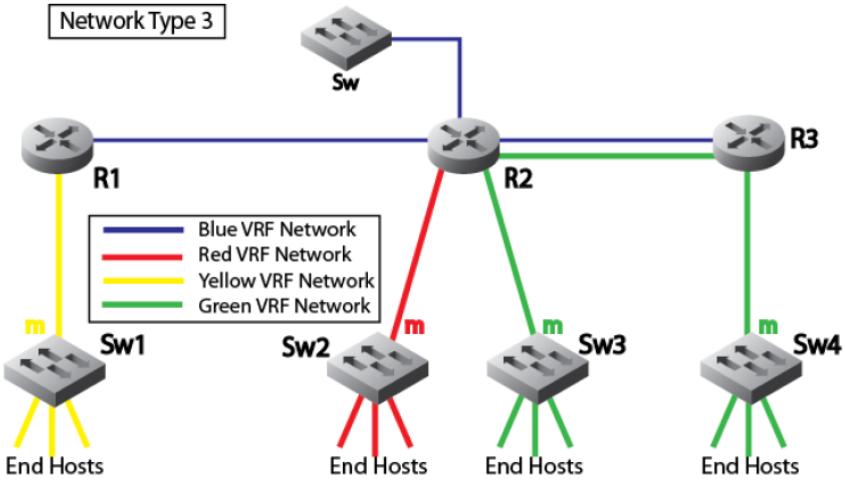
VRF Network Type 2 has the following characteristics:

- Uses a shared services deployment VRF to offer network services to the other production VRFs (shared VRF).
- All VRFs are reachable from the shared VRF, but VRFs cannot reach each other through the shared VRF or between each other.
- The production VRFs (Red, Yellow, Green) share routes with the shared services VRF (Blue).
- The shared VRF has complete visibility to all VRF instances.



VRF Network Type 3 has the following characteristics:

- Devices have management IPs only inside their respective networks.
- The routers in the network are VRF-aware; the switches are VRF-ignorant.



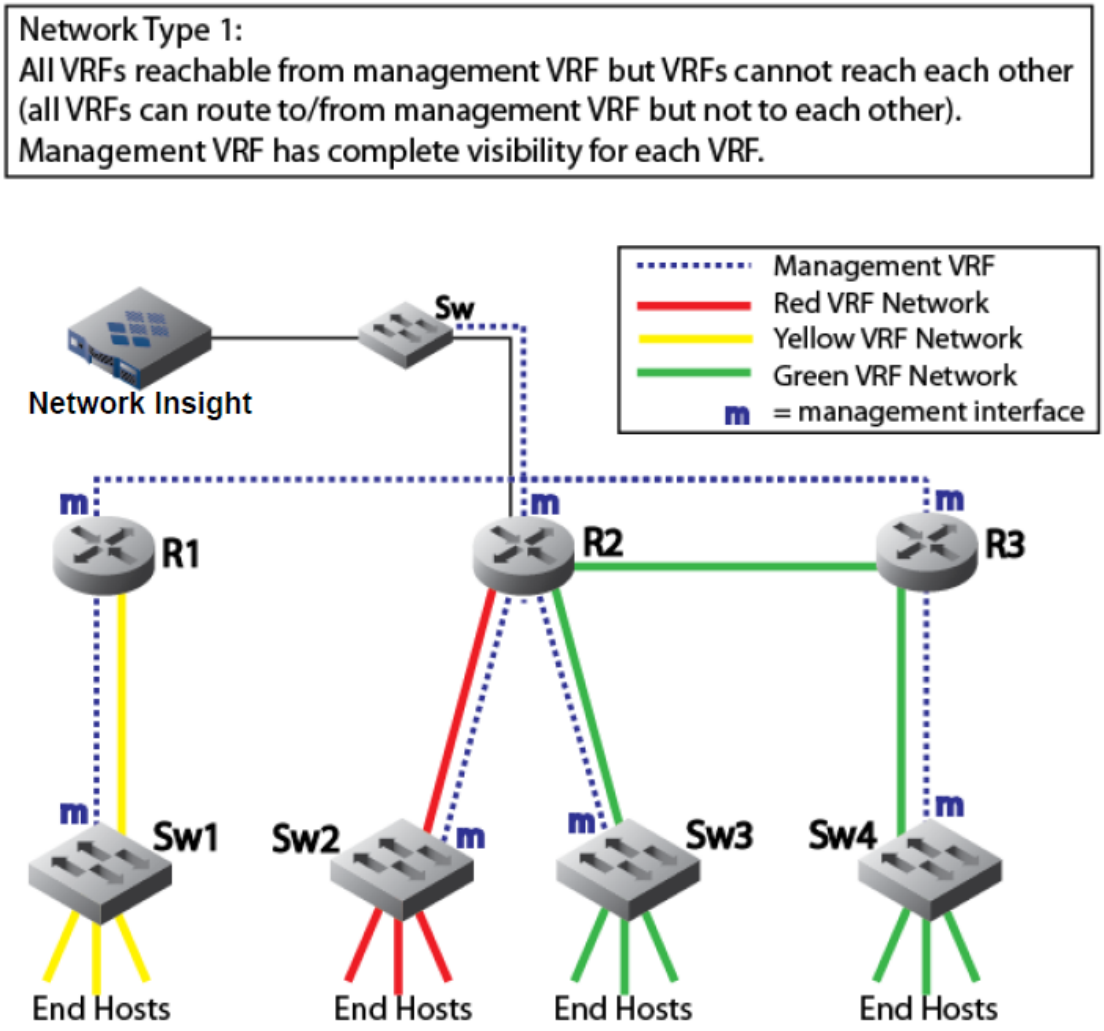
Defining Network Views and Discovery Interfaces

In all three deployment types, you decide whether you want one or multiple network views based on how your network operates, as outlined in the three network types above. You can also consider the following guidelines:

- When all infrastructure devices for the network are reachable through a management VRF or a shared services VRF, and you do not need extended discovery capabilities to discover and/or manage end hosts, you can use a single network view. You also use a single virtual discovery interface to connect to the same 802.1q ID as the management VRF network. You can then discover and analyze all VRF-aware devices on the management VRF.
- If you want your devices end host and downstream device information separated for viewing and reporting, then you will want to use network views for each virtual network. Doing so is helpful for visual purposes, but it is not required.
- If you want ping sweeps, port scanning, fingerprinting and other discovery services into end hosts within each of your VRF networks, you must define multiple network views, one for each of your VRF networks; and each of which requires an associated virtual discovery interface and discovery ranges.

Deploying Network Insight in VRF Network Type 1: All Devices on a Management Network

The following figure shows an example of integrating Network Insight with **Network Type 1**. In this network deployment type, a single virtual discovery interface can manage all VRF instances' identification of ARP entries, because Network Insight needs only one discovery interface into the Management VRF.

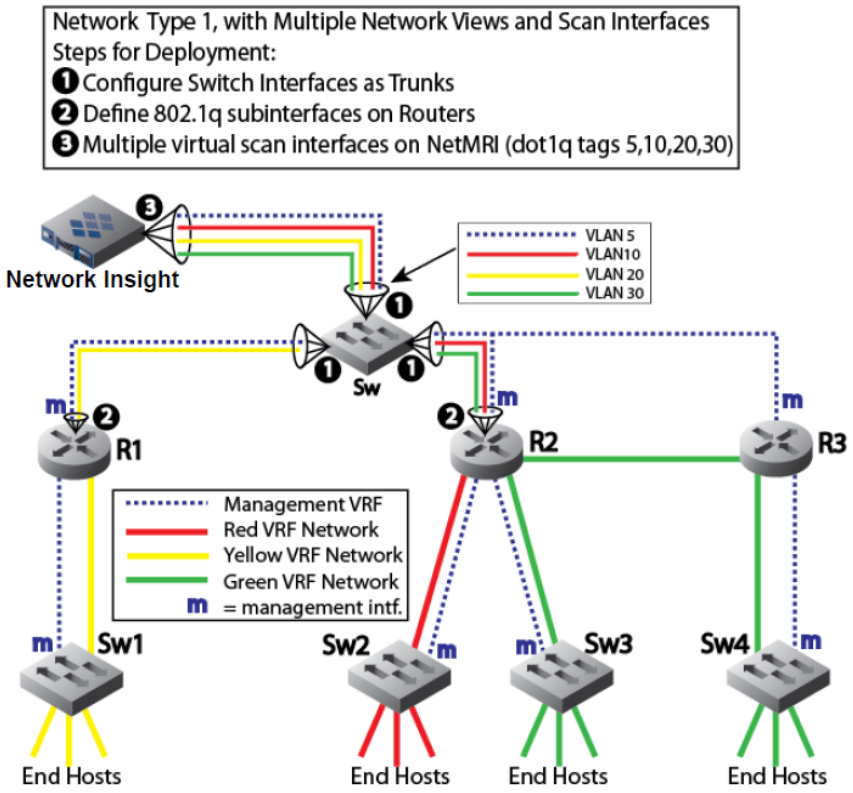


Network Insight
You configure the following for this example:

- **Network View**: Create one network view for the management VRF.
- **Discovery Interface**: Add the active discovery interface to the management VRF and tag it with the corresponding 802.1q VLAN value.
- **Discovery Ranges**: Define IP discovery ranges for the management network.
- All discovered VRFs must be associated with the network view configured for the management VRF.

Deploying Network Insight in VRF Network Type 1: All Devices on a Management Network (Part 2)

The following figure shows the same topology for Network Type 1, but using multiple discovery interfaces and multiple network views.
In this example, the switch must be configured with the trunk port 'facing' Network Insight to forward Network Insight's tagged 802.1q traffic to the appropriate destination networks (VLAN 5, VLAN 10, VLAN 20 and VLAN 30 in this example). The encapsulated sub-interfaces are defined using the correct values on each port; the virtual discovery interfaces on Network Insight match these values.



Network Insight
You configure the following for this example:

- **Network Views**: Create a network view for each network (Management, Red, Yellow, Green).
- **Discovery Interfaces**: Create virtual discovery interfaces for each VRF network.
- **Discovery Ranges**: Define IP discovery ranges for each VRF network.
- The discovered VRF instances must be associated with the network views to which they belong. For more information, see *Viewing Discovered VRFs and Mapping Network Views*.

Deploying Network Insight in VRF Network Type 2: All VRFs Reachable from a Shared Services VRF

This example illustrates the use of a shared service VRF between the distribution routers in the network and how Network Insight integrates into such a topology.
All virtual networks are reachable through a shared VRF, to which Network Insight may connect using a single virtual

discovery interface and reach all other VRFs from the one to which it is connected. Each Router in this topology also shares routes between the VRFs.

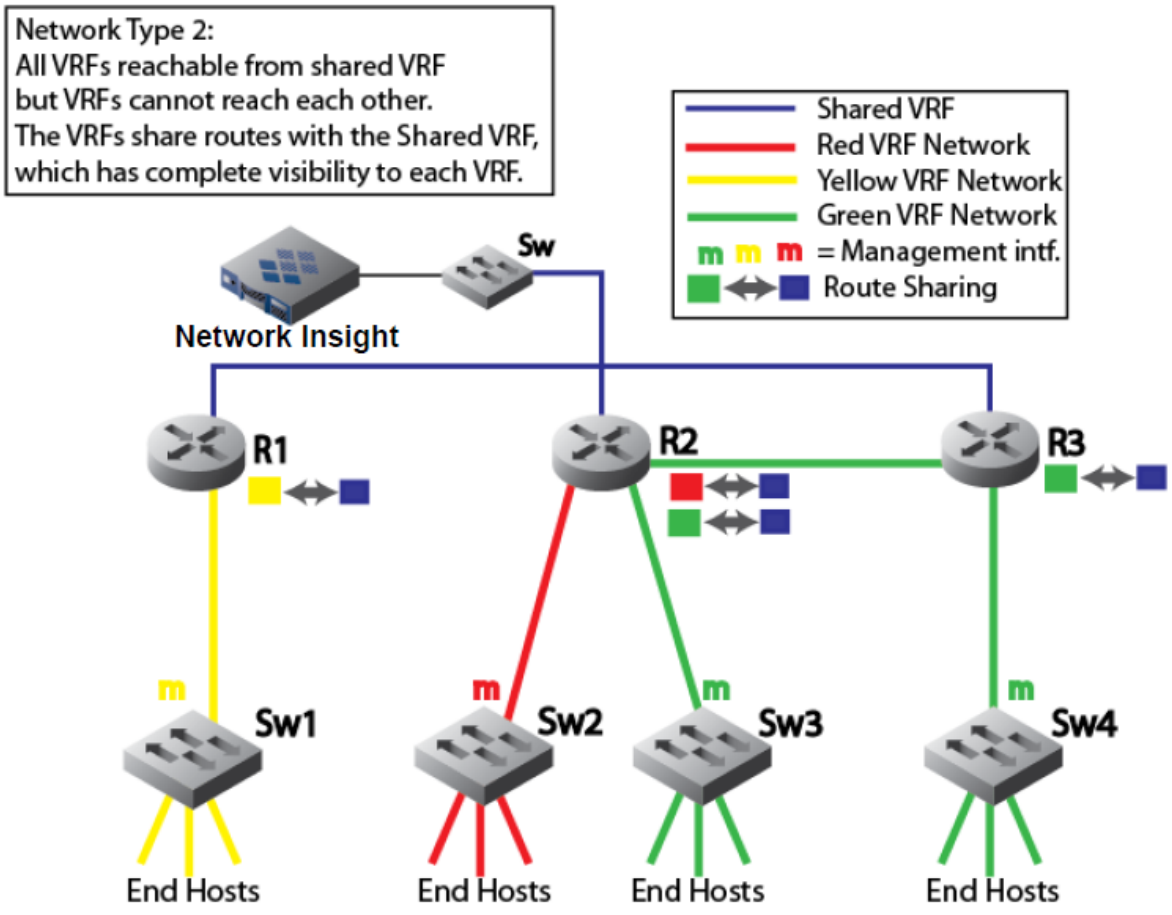
You configure the following for this example:

- **Network View**: Use one network view for the shared VRF.
- **Discovery Interface**: Create a virtual discovery interface on the network view. Use a single virtual discovery interface in Network Insight, and connect through the facing switch to the shared VRF using the tagged 802.1q value. There is a 1:1 ratio between network views and discovery interfaces.
- **Discovery Ranges**: Define IP discovery ranges in the single network view for all VRFs.
- All discovered VRFs must be associated with this network view.

If you want your device end hosts and downstream devices information separated, then use network views for each virtual network. This is helpful for viewing and reporting but it is not required. In this example, only a single network view is applied.

Deploying Network Insight in VRF Network Type 2: All VRFs Reachable from a Shared Services VRF (Part 2)

In this version of the VRF Network Type 2 deployment, you use multiple network views and multiple discovery interfaces in a 1:1 ratio, with the same requirements for trunking and switch VLAN sub interfaces.



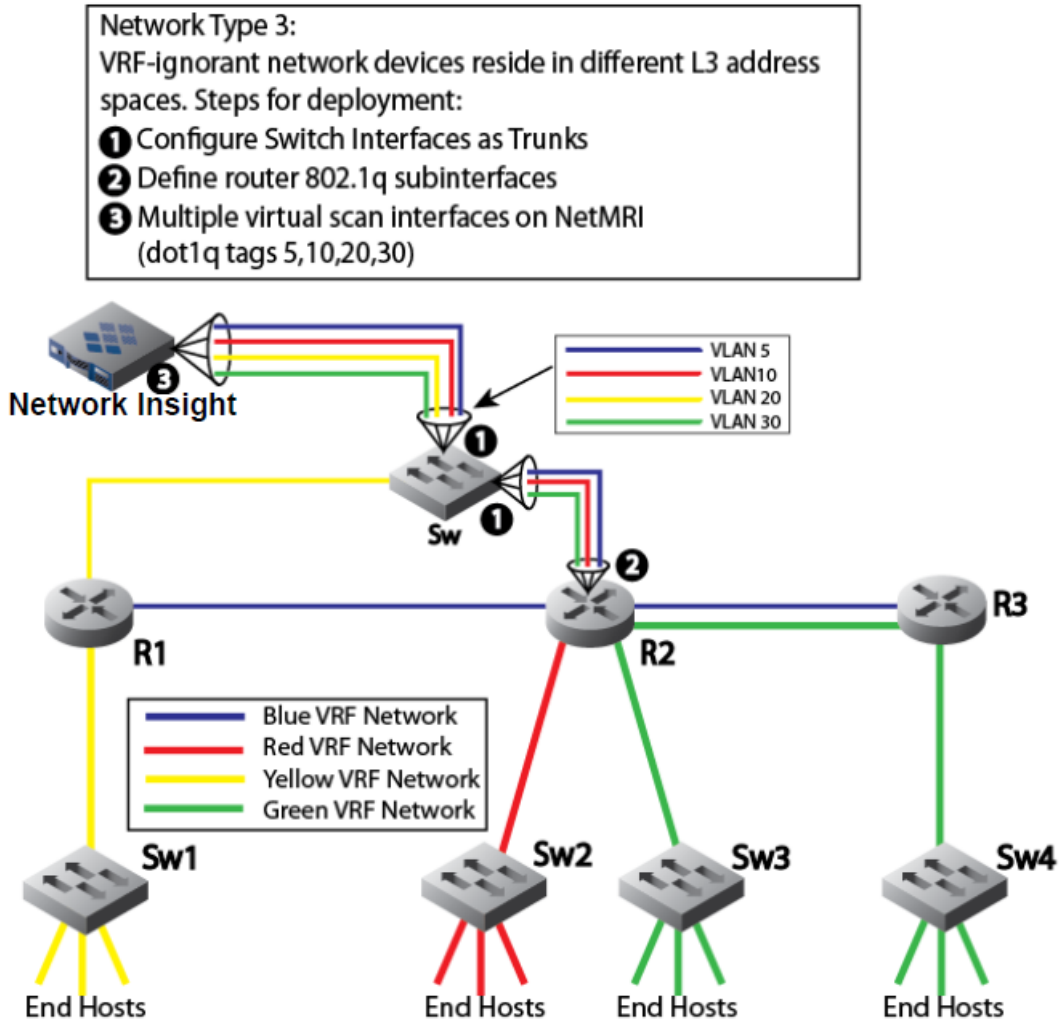
You configure the following for this example:

- **Network Views**: Create a network view for each network (e.g., Management, Red, Yellow, Green).
- **Discovery Interfaces**: Create virtual discovery interfaces for each VRF network.
- **Discovery Ranges**: Define IP discovery ranges in Network Insight for each VRF network.

- The discovered VRF instances must be associated with the network views to which they belong. For more information, see *Viewing Discovered VRFs and Mapping Network Views*.

Deploying Network Insight in VRF Network Type 3: Devices Reside in Disconnected Networks

In the final example, trunking is in use between Network Insight and its facing gateway switch into the managed network. This topology requires the use of multiple network views as all VRF networks are completely separate and cannot be reached through any management virtual network.



You configure the following for this example:

- **Network Views**: Create a network view for each network (e.g., Management, Red, Yellow, Green).
- **Discovery Interfaces**: Create virtual discovery interfaces for each VRF network.
- **Discovery Ranges**: Define IP discovery ranges for each VRF network.
- The discovered VRF instances must be associated with the network views to which they belong. For more information, see *Viewing Discovered VRFs and Mapping Network Views*.

Each of the network views requires a single virtual discovery interface using 802.1q tagging as indicated in the figure. When defining the virtual discovery interfaces, use the 802.1q tag from the network devices. The primary differences are as follows:

- All devices do not have a management IP address in the so-called management VRF.
- The routers are VRF-aware while the switches are not.
- No VRF shares routes between any of the VRFs.

Configuring Discovery Properties

To ensure a successful discovery, complete the following configurations for the Grid and Grid members that are acting as the Consolidator and Probes before you start a discovery:

- Define polling methods and schedule.
- Define advanced polling settings for TCP scanning and Ping sweeps. Also, specify routers and logging options.
- To collect data from SDN and SD-WAN devices, add and configure them as described in Configuring Discovery for SDN and SD-WAN below.
- If you use SNMP or CLI collection as the polling methods, define device credentials for data collection. .
- Assign credentials to device groups.
- Enable and schedule blackout periods for discovery and port configuration. For more information, see *Defining Blackout Periods.*
- Configure automatic network view mapping for unassigned VRFs that have been discovered. For more information, see *Configuring Automatic VRF Mapping*.
- Configure settings to monitor the lifecycle and vulnerabilities of discovered devices. For more information, see Configuring Advisor Properties below.

The following sections describe in detail how to configure discovery for the Grid, Grid members, and networks.

> ⚠ Note
>
> You must be a superuser to configure discovery properties for the Grid.

Defining Basic Polling Settings

Grid polling settings apply to all Probe members and all discovery networks that are assigned to a Probe. You can override the Grid settings at the Probe member and network levels.

To define basic polling settings, complete the following:

1. For the Grid: From the **Grid** tab, select **Grid Manager** > **Discovery** service, and then select **Edit** > **Grid Discovery Properties** from the Toolbar.
   For Probe members: From the **Grid** tab, select **Grid Manager** > **Discovery** service, select a member, and then select **Edit** > **Member Discovery Properties** from the Toolbar.
   For networks: From the **IPAM** tab, click a network name, and then click the Edit icon.
2. In the *Grid Discovery Properties* or *Member Discovery Properties* editor, click **Polling** > **Basic**.
   In the *Network* editor, click **Discovery**.
3. If you want to override the inherited Grid settings for Probe members and networks, click **Override** and define the following settings.
4. **SNMP Collection**: Select this to execute SNMP protocols to discover and collect information such as traceroute/ path collection, vendor and model, SNMP credential collection, routing and ARP tables, switch port data, and VLAN configuration data. If you disable SNMP collection, previously discovered data remains available for viewing.No new data is added and no existing data is removed.
   Some devices may not support SNMP, and some devices may not enable SNMP by default.
   Note When you disable SNMP collection on a network with enabled discovery, Network Insight still attempts to authenticate the SNMP credentials of devices that are newly discovered under this network. All newly discovered devices are automatically bound to a default group with enabled SNMP collection.
5. **CLI Collection**: Select this if you expect to use Network Insight to discover devices that support CLI connectivity through Telnet or SSH, and that you possess admin account information. NIOS can use device admin account logins to query network devices for discovery data collection, including IP configuration, port configuration, routing and forwarding tables, and much more.

Note that for SNMP and CLI Collection methods, configure device polling credentials in the **Credentials** tab of the editor. For more information, see Configuring Device Credentials below.

6. **Port Scanning**: Select this to probe the TCP ports. Ensure that you go to the **Advanced** tab to configure more settings for this option as described in the next section. If you disable Port Scanning, NIOS attempts no port probes other than SNMP on any device.
    - **Profile Device**: If enabled, NIOS attempts to identify the network device based on the response characteristics of its TCP stack, and uses this information to determine the device type. In the absence of SNMP access, the Profile Device function is usually the only way to identify non-network devices. If disabled, devices accessible via SNMP are identified correctly. All other devices are assigned a device type of Unknown. Profile Device is disabled by default for network polling.
7. **Smart IPv4 Subnet Ping Sweep**: Select this to execute Ping sweeps only on subnetworks that are known to exist but no IPs can be found within the subnet, such as through ARP or other means.
8. **Complete Ping Sweep**: Select this to enable brute-force subnet Ping sweeps on IPv4 networks. This method executes Nmap that uses ICMP echo requests, ICMP timestamp requests, and TCP SYN to ports 161, 162, 22, and 23 (for the SNMP, SNMPTRAP, SSH, and TELNET services correspondingly). Subnet ping sweeps are used as a last resort in the discovery process. Perform a subnet ping sweep if NIOS cannot identify any network devices in a given subnet. Subnet ping sweeps should be performed no more than once per day, and will stop on a given subnet once NIOS Discovery locates a network device and is able to collect data from it. Ensure that you configure advanced settings for this option in the **Advanced** tab as described in the next section.
   Note that NIOS does not perform Smart Subnet Ping sweeps on subnets larger than /22. NIOS also does not perform Ping sweeps on IPv6 networks, because of the dramatically greater scale of network addresses in the IPv6 realm. The Complete Ping Sweep differs from the Smart Subnet Ping Sweep in the following ways:
    - The Complete Ping Sweep will run only against the specified range.
    - The sweep will run regardless of the range size.
    - The sweep will run regardless of the number of discovered devices within the specified range.
9. **NetBIOS Scanning**: Select this to enable NIOS to collect the NetBIOS name for endpoint devices in the network. This feature can be enabled only by users with SysAdmin privileges. This feature is globally disabled by default (and also for device groups) to prevent unexpected scanning of the network by a new collector.
10. **Automatic ARP Refresh Before Switch Port Polling**: Select this to enable refreshing of ARP caches on switches and switch-routers in the managed network before NIOS performs polling of switch ports. Enabling this feature applies only to switched Ethernet devices. This feature enables more accurate detection of all endpoint devices on L2 switches. Without ARP refresh, some endpoint devices may not be detected. This feature is globally disabled by default. Individual ARPs can also be set to enable or disable this feature.
11. **Switch Port Data Collection**: Select this to enable the Probe member to poll L2 enterprise switches. You can completely disable switch port polling by deselecting this checkbox. You can also separately schedule polling for switch port data collection as follows:
12. **Periodic Polling**: Define regular polling time periods. Choose a polling interval of 30 or more minutes or 1-24 hours.
13. **Scheduled Polling**: Schedule recurrent polling based on hourly, daily, weekly, or monthly time periods. Choosing this option, click the Calendar icon and a Polling Scheduler appears; click the Edit icon to make scheduling changes. Choose a recurrence pattern of **Once**, **Hourly**, **Daily**, **Weekly,** or **Monthly.** In all cases, you must choose an **Execution Time**.
14. Save the configuration.

Defining Advanced Polling Settings

If you selected any polling settings that involve the TCP scanning and Ping sweeps, configure additional settings for them. Advanced SNMP polling settings consist of choosing the TCP Scan Technique, along with a number of specialized settings for Ping Sweeps and other operations.

To define advanced Grid-wide polling settings for TCP scanning and Ping sweeps, complete the following:

1. For the Grid: From the **Grid** tab -> **Grid Manager** tab -> **Discovery** service, select **Edit** -> **Grid Discovery Properties** from the Toolbar.
   For members: From the **Grid** tab -> **Grid Manager** tab -> **Discovery** service, select **Edit** -> **Member Discovery Properties** from the Toolbar.
   For networks: From the **IPAM** tab, select the *network* checkbox and click the Edit icon.
2. In the *Grid Discovery Properties, Member Discovery Properties, or (IPv4 or IPv6) Network* editor, click **Polling** -> **Advanced** and define the following settings.

3. If you want to override the inherited Grid settings for Probe members and networks, click **Override** and define the following settings.
4. **TCP Scan Technique**: Select the TCP technique you want to use for the discovery. The default is **SYN**. For more information, see *TCP.*
    - **SYN**: Select this to quickly perform scans on thousands of TCP ports per system, never completing connections across any well-known port. SYN packets are sent and the poller waits for a response while continuing to scan other ports. A SYN/ACK response indicates the protocol port is listening while an RST indicates it is not listening. The SYN option presents less impact on the network.
    - **CONNECT**: Select this to scan IPv6 networks. Unlike the SYN option, complete connections are attempted on the scanned system and each successive TCP protocol port being scanned.
5. Specify the TCP ports settings:
    - In the table, select the checkboxes of the TCP ports you want to discover. To select all ports, click the checkbox in the header.
    - To add a new port, click the Add icon.
6. Specify other advanced polling settings:
    - **Purge expired assets data after**: Removes records of discovered assets that are no longer reachable after a specified period of time. The default is set to one day.
    - **Purge expired device data after**: Removes records of discovered network infrastructure devices that are no longer reachable after a specified period of time. The default is set to seven days, a more forgiving value given that devices sometimes require maintenance, upgrades or repairs, or in cases where hosts leave the network on long trips.
    - **ARP Aggregate Limit**: Sets a limit for the number of entries (IP addresses) per MAC address in ARP tables. If there are too many entries associated with a MAC address, this can be treated, for example, as a "honeypot". Therefore, MAC addresses with more entries than the specified limit are ignored and filtered out during data extraction and parsing. The default limit is 30 ARP table entries (IP addresses) per MAC address.
    - **Route Limit**: Limits the size of the routing table that discovery is required to collect from any given device. Some routers can have tables in the hundreds of thousands of entries, and collecting such a large body of data can impose performance problems in the network and in discovery data collection. This setting defaults to 3000, and automatically excludes BGP routes from the collection. Consult Infoblox Technical Support before making changes to this value.
    - **Ping Sweep Timeout (ms)**: Period of time allowed, in milliseconds, before a Ping times out to any given device.
    - **Ping Sweep Attempts**: The number of attempts on each address in a Ping sweep before the sweep continues.
    - **Ping Sweep Frequency**: Defaults to 1, because ping sweep should not be executed more than once a day when the feature is enabled at the grid level or for a given discovery range. This setting affects the **Smart Ping Sweep** and **Complete Ping Sweep** features under *Grid Discovery Properties*.
    - **ARP Cache Refresh**: Defines the time period between ARP refreshes by Network Insight across all switch ports. Before any other switch port polling and discovery operations take place (including any global discovery polling operations initiated by the administrator), another ARP refresh is carried out by the Probe appliance regardless of the time interval. The default is five minutes, because switch forwarding tables are frequently purged from LAN switching devices. The default on Cisco switches is five minutes/ 300 seconds. Network Insight primarily uses ARP Cache refreshes to improve the accuracy of end-device discovery. Without this feature, some endpoints may not be discovered and cataloged.
    - **Ignore Conflict Duration**: Used when resolving conflicts and when choosing the option to Ignore the conflict when resolving it. The length of time during which conflicts is ignored is defined with this settings. Increments can be defined in **Hours** or **Days**.
    - **Number of discovered unmanaged IP addresses per notification**: The maximum number of unmanaged IP addresses that the appliance discovers before it sends SNMP and email notifications, if enabled. The appliance resets the counter after it hits this number and sends notifications. The default is 20.
    - **Interval between notifications for discovered unmanaged IP addresses**: This number determines how often the appliance sends SNMP and email notifications, if enabled, when it discovers the maximum number of unmanaged IP addresses (configured for **Number of discovered unmanaged IP addresses per notification**). This is the time interval between two notifications for discovered unmanaged objects. Select the time unit from the drop-down menu. The default is five minutes.
    - **DNS Lookup Option**: Specify whether you want to perform a reverse DNS lookup from discovered IP addresses. Select one of the following from the drop-down list:

        - **Network Devices**: Select this to resolve network device (switches and routers) IP addresses. This option is selected by default.
        - **Network Devices and End Hosts**: Select this to resolve both network device (switches and routers) and end host IP addresses.
        - **Off**: Select this to turn off reverse DNS lookups for discovered IP addresses.
        - **DNS Lookup Throttle**: This is the value in a percentage that throttles the traffic on the DNS servers. Setting a lower value reduces the number of requests to DNS servers. You can specify a value between 1 and 100. The default value is 100.
    - **Disable discovery for networks not in IPAM**: Disables executing discovery on any infrastructure networks that are not presented in the Infoblox IPAM system; e.g. present and managed in a network view or network container.
    - **Authenticate and poll using SNMPv2c or later only**: For credential discovery and device polling exclusively using SNMPv2c and up, preventing use of SNMPv1, enable this checkbox.
    - **Use DHCP Routers as Seed Routers**: Select this so the Probe members can use the default gateways for associated DHCP ranges and networks as seed routers to more quickly discover and catalog all devices (such as endpoint hosts, printers and other devices). All such default gateways are automatically leveraged by discovery, and no further configuration is necessary unless you wish to exclude a device from usage.
      Use this option carefully and avoid continuous updating of DHCP routers by a third-party component such as Microsoft servers, as it may trigger a discovery service restart when attempting to apply the new configuration.
      Ensure to check for a list of configured DHCP seed routers for any discovery Probe member in the **Seed** tab -> **Advanced** tab of the *Member Discovery Properties* editor.
    - **Log IP Discovery events in Syslog**: Sends a message to the configured Syslog service when an IP address of an active host is discovered.
    - **Log network discovery events in Syslog**: Sends a message to the configured Syslog service when a network discovery process takes place in the Grid.
7. Save the configuration.

Configuring Device Credentials

Credentials apply to devices at the following levels:

- The Grid: Settings apply across the Grid and all Probe appliances licensed for Discovery.
- Discovery Probe appliances: You can use inherited Grid settings or override them.
- Individual devices: You can use inherited Grid or Probe settings or override them with device-specific settings.

You can configure the following types of device polling credentials:

- SNMPv1/v2 Credentials
- SNMPv3 Credentials
- CLI Credentials

Once configured, you can test the credentials.

For more information on configuring device credentials, see the following sections:

- Configuring SNMPv1/v2 Credentials
- Configuring SNMPv3 Credentials
- Configuring CLI Credentials
- Defining CLI Credentials for Objects
- Testing SNMP and CLI Credentials

If any SNMP or CLI credentials become obsolete, you can reset them for all affected devices at once. After that, Network Insight re-guesses the credentials for each device. This does not apply to CLI credentials manually set for specific devices. For more information, see the *reset snmp* and *reset cli* Administrative Shell commands.

You can assign a credential to a credential group that is specific to a particular device group. For more information about credential groups, see Configuring Credential Groups below.

Configuring SNMPv1/v2 Credentials

An SNMPv1/v2 community string is similar to a password in that the discovered device accepts queries only from management systems that send the correct community string. This community string must exactly match the value that is entered in the managed system.

To add an SNMPv1/v2 credential, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Discovery**.
2. For the Grid: Click **Edit** -> **Grid Discovery Properties** in the Toolbar.
   For the Probe member: Select the *member* checkbox, and then click **Edit** -> **Member Discovery Properties** in the Toolbar.
3. Click the **Credentials** tab.
4. To override the inherited Grid settings for a Probe member, click **Override**.
5. Click the Add icon and specify the credential details in the corresponding cells:
   - **Read Community**: Enter a text string that the management system sends together with its queries to the network device during discovery.
   - **Credential Group**: For the Grid, select a group to which you want to assign the credential. For the Probe member, the table displays settings that were configured on the Grid, but only the default credential group is used for the member. You can edit the credentials list making up the default group by clicking **Override**.
   - **Order**: The order for attempting the use of the credential.
   - **Comment**: A text comment about the credential.
6. Optionally, you can test the credentials you added to the list. You can test SNMPv1/v2c and SNMPv3 credentials against any device or any IP address, at the Grid level or from any Probe member or network view. For more information, see Testing SNMP and CLI Credentials below.
7. Click **Save & Close** to save changes.

To find a specific string in the SNMPv1/v2 tab, enter the value in the **Go To** field and then click **Go**.

To remove a community string entry, select the checkbox and click the Delete icon.

To export the entire list of community strings in a table file readable by a spreadsheet program, click the Export icon and choose Export Data in Infoblox CSV Import Format. To export all data in a different format, click the **Export** icon and choose **Export Visible Data**.

Configuring SNMPv3 Credentials

SNMPv3 allows the use of two secret keys for every credential — one for authentication and another for encryption. Network Insight allows flexible application of keys — authentication but no encryption, for example. You define users in one of the three following ways:

- SNMPv3 user with no authentication or privacy credentials.
- SNMPv3 user with authentication but no privacy credentials.
- SNMPv3 user with both authentication and privacy credentials.

To add an SNMPv3 credential, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Discovery**.
2. For the Grid: Click **Edit** > **Grid Discovery Properties** in the Toolbar.
   For the Probe member: Select the *member* checkbox, and then click **Edit** > **Member Discovery Properties** in the Toolbar.
3. Click the **Credentials** tab > **SNMPv3** tab.
4. To override the inherited Grid settings for a Probe member, click **Override**.
5. Click the Add icon and specify the credential details in the corresponding cells:
   - **Name**: The username for the credential.
   - **Auth Protocol**: Select one of the listed authentication protocols.
   - **Auth Password**: The password to use with the authentication protocol.
   - **Privacy Protocol**: Select one of the listed privacy protocols.
   - **Privacy Password**: The password to use with the privacy protocol.

- **Credential Group**: For the Grid, select a group to which you want to assign the credential. For the Probe member, the table displays settings that were configured on the Grid, but only the default credential group is used for the member. You can edit the credentials list making up the default group by clicking **Override**.
- **Order**: The order for attempting the use of the credential.
- **Comment**: A text comment about the credential.

6. Optionally, you can test the credentials you added to the list. You can test SNMPv3 credentials against any device or any IP address, at the Grid level or from any Probe member or network view. For more information, see Testing SNMP and CLI Credentials below.
7. Click **Save & Close** to save changes.

To find a specific SNMPv3 entry, enter the value in the **Go To** field and click **Go**.

To remove an SNMPv3 authentication entry, select the checkbox and click the Delete icon.

To export the entire list of community strings in a table file readable by a spreadsheet program, click the Export icon and choose Export Data in Infoblox CSV Import Format. To export just the subset of data that is visible in the dialog, click the **Export** icon and choose **Export Visible Data**. A **Show Passwords** option allows the secret keys to be visible in the import.

Configuring CLI Credentials

SNMP protocols provide a powerful means of querying devices for broad arrays of information. The CLI discovery feature is required for port control tasks including port configuration and network provisioning and de-provisioning, but is not used for other discovery operations or to otherwise manage devices. By default, Probe appliances inherit their member discovery properties, including CLI credential sets, from the Grid level. Enable passwords are entered in separate records and kept as a separate list in Grid Manager.

For CLI credentials, you define a global set of Admin account/password tuples, as well as Enable passwords, at the Grid level. You can also specify credentials and Enable passwords for individual devices at the member level. Should such a credential not work for a given device, or if command-line access is lost for a device, Network Insight re-guesses credentials from the Grid-level credential list, including vendor defaults if available.

> ⚠ Note
> You can test username/password credentials or an Enable password credential. You can also combine a username/password credential and an Enable password credential as part of the same test.

To add a CLI credential, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Discovery**.
2. For the Grid: Click **Edit** > **Grid Discovery Properties** in the Toolbar.
   For the Probe member: Select a *member* checkbox, and then click **Edit** > **Member Discovery Properties** in the Toolbar.
3. Click the **Credentials** tab > **CLI** tab.
4. To override the inherited Grid settings for a Probe member, click **Override**.
5. Click the Add icon to add a new CLI username/password entry to the list. Select the **Credential Type**, which can be one of two choices.
6. In **Login Credentials**, click the Add icon and specify the credential details in the corresponding cells:
   - **Protocol**: Select **SSH** or **Telnet**. Infoblox recommends the use of SSH.
     - **SSH**: SSH credentials require both a username and a password. The default protocol is SSH.
     - **Telnet**: In Network Insight, Telnet credentials must use both a username and a password. Note that should you choose to use a Telnet-based credential, Network Insight requires both the username and password for the login account. This also applies when you override the CLI credentials on objects such as a fixed address, host, or IPv4 reservation. For more information, see the section Defining CLI Credentials *Settings for Objects* below.
   - **Name**: Username for the CLI login account.
   - **Password**: Login password for the CLI login account.
   - **Credential Group**: For the Grid, select a group to which you want to assign the credential. For the Probe member, the table displays settings that were configured on the Grid, but only the default credential group is used for the member. You can edit the credentials list making up the default group by clicking **Override**.
   - **Comment**: A text comment describing the CLI login account.

- **Order**: By default, Network Insight inserts the new credential record at the bottom of the credentials list, which is reflected by its **Order** value, showing the order used for attempting the use of CLI credentials. Enter a new value in the **Order** field if you want the new credential to be in a position other than the last in order.

7. In **Enable Credentials**, click the Add icon and specify the credential details in the corresponding cells:
   - **Protocol**: SSH or Telnet. Infoblox recommends the use of SSH.
   - **Password**: Enable password for device configuration access.
   - **Credential Group**: For the Grid, select a group to which you want to assign the current credential. For the Probe member, this setting is inherited and cannot be changed.
   - **Comment**: A text comment about the credential.
   - **Order**: By default, Network Insight inserts the new record at the bottom of the list, reflected by its **Order** value, showing the order used for attempting use of the CLI credentials. Enter a new value in the **Order** field if you want the new credential to be in a position other than the last in order.
8. Optionally, you can test the credentials you added to the list. For more information, see Testing SNMP and CLI Credentials below.
9. Click **Save & Close**.

Defining CLI Credentials for Objects

You can define CLI credentials and enable password credentials for individual devices through associated IPAM objects:

- Fixed addresses
- IP reservations
- Hosts

For a quick way to locate all objects of a certain type in the Grid, you may create a smart folder with settings such as **Type** > **Equals** > **IPv4 Fixed Address**. Title the smart folder appropriately.

To define and test the CLI credentials for an IPAM object, complete the following:

1. From the **Data Management** tab, select the **IPAM** tab.
2. In the *IPAM IP List* page or the *IPAM IP Map* page, navigate to the required network and then to the IP associated with the object you want to edit.
   Note for each network, the IP list page provides a **Type** data column showing the IPAM object type that is associated with any IP address. Also, check the **MAC Address** column in the IP List page for information about associated objects.
3. Click the IP address. On the IP address page, click the **Related Objects** tab.
4. Select the checkbox for the object in the Related Objects panel and click **Edit**.
5. In the object editor, click the **Discovery** tab.
6. Click **Override CLI Credentials**.
   By default, CLI credential definitions use SSH at the object level. Select **Allow Telnet** if you want to allow both SSH and Telnet credential usage. Infoblox recommends SSH because of better security.
7. Enter the **Name** and **Password** values and the **Enable Password** value.
8. Click **Test CLI Credentials** to test the CLI discovery credential settings applied to the object.
9. When finished, click **Save & Close**.

Testing SNMP and CLI Credentials

After configuring SNMP and CLI credentials, you can click **Test Credentials** in the SNMP Credentials or CLI Credentials panel to test the credentials. Credential testing ensures that the configured credentials work for as many devices and networks as possible. The procedure in this section applies to both the Grid and the member levels. You can override the Grid settings at the member level.

For CLI credentials, you can test an admin login name and password tuple as well as a following enable credential, if necessary. You can also override CLI credentials and enable credentials for IPAM objects such as fixed addresses, IP reservations, and host objects. You can test any credential set, an enable credential, or both in combination against any device within any network view. Network Insight sets the login sequence to match the command-line standards for the selected device.

To test SNMP credentials or CLI credentials, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Discovery**.
2. For the Grid: Click **Edit** > **Grid Discovery Properties** in the Toolbar.
   For a Probe member: Select a *member* checkbox, and then click **Edit** > **Member Discovery Properties** in the Toolbar.
3. In the **Grid Discovery Properties** or **Member Discovery Properties Editor**, click the **Credentials** tab > **SNMPv1/v2** tab, **SNMPv3** tab, or **CLI** tab.
4. Select the checkbox or checkboxes for the Login credentials and/or Enable credentials (if applicable) you want to test.
   For a Probe member, click **Override**, and then select the credential checkboxes.
5. Click **Test Credentials**.
6. In the **Test SNMP Credentials** or **Test CLI Credentials** dialog box, complete the following:
   - **IP Address**: Select this to test the credential against an IP address of a reachable device in a network (even if it has not been discovered or managed through NIOS) within a specified network view. Enter the IP address in the field. Ensure that you select the respective network view in which this IP address resides.
   - **Network View**: If you have multiple network views, select the network view in which the IP address resides from the drop-down list. If you have only one network view, which is the default view, the **Network View** drop-down list is hidden by default. NIOS conducts credential testing for the IP address in the selected network view.
   - **Device**: Select this to test against a selected device. Click **Select Device** and the *Device Selector* appears. If you have multiple network views, you must first select the network view in which the device resides from the **Network View** drop-down list, located at the upper left-hand corner of the selector. If you have only one network view, which is the default view, the **Network View** drop-down list is hidden by default. You can check the device categories under **All Devices** to locate discovered switches and routers or any unmanaged devices previously detected by discovery under NIOS. You can explore categories including Discovered Switches/Routers, Microsoft Windows Devices (this can include items such as Windows Servers of various types), Router and Wireless Access Point Devices, Unmanaged, and others. By default, all devices previously discovered appear in this selector. If you have a long list of devices, you can enter a device name search value or a search expression in the **Find** field and click **Go**. You can also click **Show Filter** to narrow down your selection by selecting available filters. Click **OK** after you have selected a device and its corresponding network view.
7. Click **Start** to begin testing the credential against the IP address or selected device. The communication and testing processes appear in the lower panel of the editor.

> ⚠ Note
> If the specified IP address is excluded from all discovery ranges, if it is not a part of the selected network view, or if the credential is entered with missing information, a message appears at the top of the editor after clicking **Start**. Otherwise, the test begins and its process and results appear in the lower panel of the editor.

Configuring Credential Groups

You can organize specific credential sets into groups that you can use to guess device credentials by assigning different credential groups to IPAM objects such as networks. For example, when a credential group is assigned to a network, Network Insight runs the guessing process only over credentials of this group for devices in this network.

You can use credential groups for credential guessing on the following levels:

- The Grid
- Probe members
- IPAM networks and network containers
- DHCP networks and DHCP ranges

A default credential group preexists on the Grid. The default credential group is automatically pre-assigned to the Grid, members, and IPAM objects such as networks, network containers, or ranges. You can create custom credential groups and add credentials to them. After that, you assign credential groups to the Grid, Probe members, and IPAM objects.

For more information, see the following sections:

- Creating a Credential Group

- Adding SNMP and CLI Device Credentials to a Credential Group
- Assigning a Credential Group
- Viewing Credential Group Used for Device

Creating a Credential Group

You can create, edit and delete custom credential groups. As for the default credential group, you can rename it, but not delete it.

To create a credential group, complete the following:

1. Go to **Grid** > **Grid Manager** > **Discovery**.
2. In the **Toolbar**, click **Edit** > **Grid Discovery Properties**.
3. Select the **Credential Groups** tab.
4. Click the Add icon.
5. Type a name for the credential group and press **Enter**.
   Note that the **Name** field does not support the Unicode encoding.
6. Click **Save & Close**.

To edit a credential group, click the group name in the table cell and edit as required.

To delete a credential group, select the group and click the Delete icon.

Adding SNMP and CLI Device Credentials to a Credential Group

You populate a credential group with credentials in the Grid Discovery Properties. For Probe members, you can edit the credentials list inside a group for the default credential group only. choose to inherit the Grid credential groups settings or to override them with the default group. If the deafult group contains credentials from both Grid and member and it is assigned to a network, Network Insight uses only member-level credentials.

See the following sections on how to add device credentials of different types to a credential group:

- Configuring SNMPv1/v2 Credentials
- Configuring SNMPv3 Credentials
- Configuring CLI Credentials

Assigning a Credential Group

Probe members, networks and ranges inherit the credential groups assignment from the Grid. You can override this assignment with another credential group for networks and ranges. For members, you cannot assign a credential group as they always use the default group for credential guessing.

Assigning a Credential Group to the Grid

To assign credentials to the Grid, complete the following:

1. Go to **Grid** > **Grid Manager** > **Discovery**.
2. In the **Toolbar**, click **Edit** > **Grid Discovery Properties**.
3. On the **Polling** tab.
4. For **Credential Group**, select the required credential group.
5. Save the configuration.

Assigning a Credential Group to Network or Network Container

To assign credentials to an IPv4/IPv6 network or network container, complete the following:

1. Go to **Data Management** > **IPAM** or **DHCP**.
2. Click the name of an existing network or network container.
3. Click the Edit icon.
4. Click the **Discovery** tab.

5. **Credential Group**: The field displays the selection inherited from the Grid unless you override it. Click **Override** and select the required credential group.
6. Save the configuration.

Assigning a Credential Group to DHCP Network or Range

To assign credentials to a DHCP range, complete the following:

1. Go to **Data Management** > **DHCP**.
2. Click the name of an existing IPv4/IPv6 network.
3. Click the Add or Edit icon > **Range**.
4. Click the **Discovery** tab.
5. **Credential Group**: The field displays the selection inherited from the Grid unless you override it. Click **Override** and select the required credential group.
6. Save the configuration.

Viewing Credential Group Used for Device

To view which credential group was used to guess credentials for a particular device, complete the following:

1. Go to **Data Management** > **IPAM** or **Devices** tab > **Discovery Status**.
2. Hover the mouse over SNMP or CLI credential status of a device.
   A tooltip mentioning the credential group name appears.

Defining Seed Routers for Probe Members

Seed routers can be defined only on Probe appliances. You can define seed routers that NIOS uses in quickly performing network discovery. The definition of seed routers is highly recommended for IPv4 networks and is required for IPv6 networks. For the discovery of any IPv6 networks, you must use seed router values that comprised of at least one well-connected IPv6 router, preferably with routes to all other networks to be managed. In some cases, seed routers may not have the full routing tables or be unable to provide full information for some reason. The general rule of thumb is that more seed routers are better, but the connectivity of seed router(s) also helps determine how many seed routers you need. Avoid having more seed entries than necessary.

You must associate each seed router with a network view so the appliance can properly discover virtual networks when using multiple seed routers.

Note

All NIOS Probe members automatically use their default gateway as a seed router. These gateways are automatically displayed in the table. For effective use of seed routers, you must also provide SNMP credentials to NIOS to allow it to pull the key routing and connectivity information, including the IPv6 routing table and the local Neighbor Discovery Cache, from the device. If you do not define a seed router, it is recommended that you enable discovery for a network or DHCP range.

You can check **Discovery Status** to see whether a seed router is successfully being reached and whether the seed is providing information. By reviewing discovery status for each seed router, you can determine whether Network Insight should be able to discover the network successfully, or if there are possible configuration errors preventing network discovery, without having to wait to see what Network Insight finds. For seed routers, **Reached Status** and **Overall Status** should both read as **Passed**.

To add, view, or delete seed routers for a Probe, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and click **Discovery**.
2. Select the checkbox for any Probe appliance on the Discovery page and click **Edit** > **Member Discovery Properties** from the **Toolbar**.
3. In the **Member Discovery Properties Editor** dialog box, click **Seed**.
4. To add a seed router, do the following:

a. Click the **Add** icon. The Grid Manager adds a row to the table.
b. In the new row, do the following:
    - Click the **Router** field and then enter the IP address for the IPv4 or IPv6 seed router. Note that you can assign a seed IP address to different network views if your deployment has overlapping IP addresses.
    - Click the **Network View** field and then choose the network view you want to assign to the interface. A newly added seed IP does not have any associated network view by default.
    - Click the **Comment** field and then enter information about the seed router.

You can delete a seed router by selecting it and then click the Delete icon. Note that you cannot delete any seed router that is a default gateway.

IPv6 Seed Router Usage

For the discovery of any IPv6 network, you must use seed router values, comprised of at least one well-connected IPv6 router, preferably with routes to all other networks to be managed. In some cases, seed routers may not have the full routing tables or be unable to provide full information for some reason. The general rule of thumb is that more seed routers are better, but the connectivity of seed router(s) also helps determine how many seed routers you need. Avoid having more seed router entries than necessary.

> ⚠ Note
> For effective use of seed routers, provide SNMP credentials to the Probe member to allow it to pull the key routing and connectivity information, including the IPv6 routing table and the local Neighbor Discovery Cache, from the device. For more information, see Defining Seed Routers for Probe Members below.

Configuring Advisor Properties

For information about Advisor, see *Monitoring Device Lifecycle and Vulnerabilities Using Advisor*.

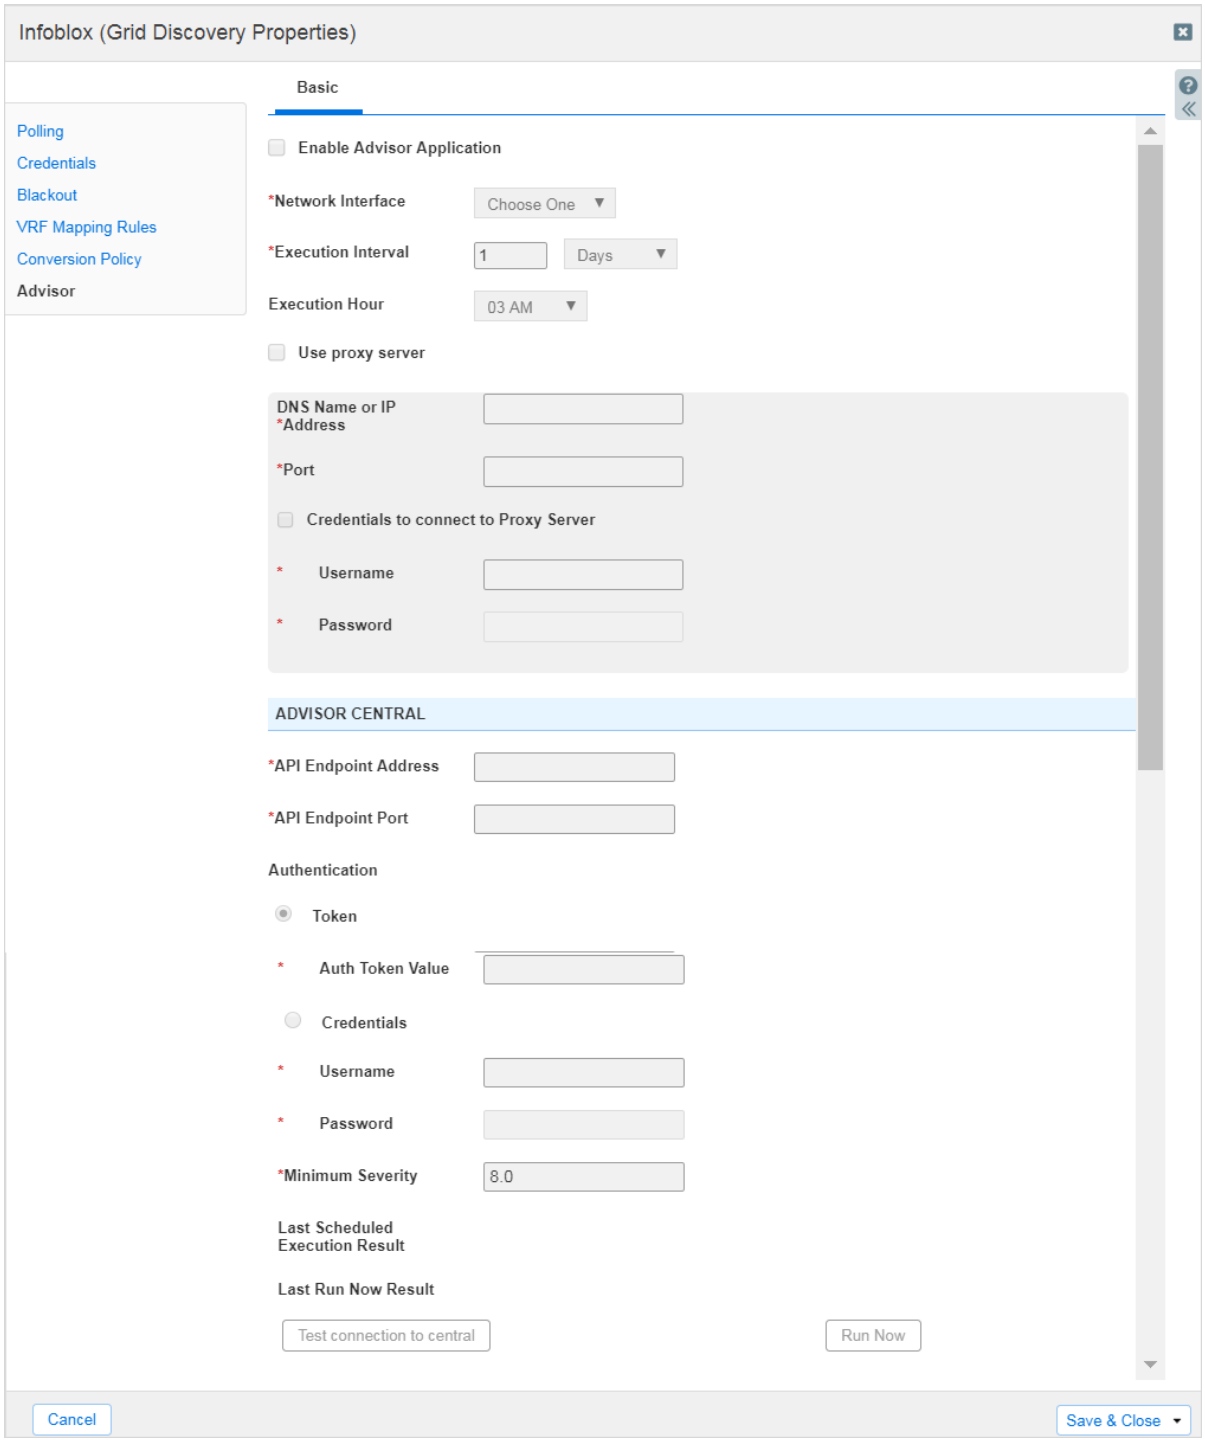
See the following pre-requisites:

- You have purchased the Advisor subscription.
- You have access to the internet, either through one of the Consolidator interfaces or through a proxy server.
- You have a Consolidator with the discovery service working on it.
- You have a local DNS resolver working on the discovery node. For more information, see *Enabling DNS Resolution*.

To configure Advisor properties, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Discovery**.
2. Click **Edit** > **Grid Discovery Properties** in the Toolbar.

3. Click the **Advisor** tab.



4. Select **Enable Advisor Application**.
   Note this checkbox is available if a Consolidator exists in the Grid and the discovery service is working.
5. **Network Interface**: Specify one of the network interfaces of the Consolidator that runs Advisor. This interface is used for the internet connection to obtain the lifecycle and vulnerability data.
6. **Execution Interval**: Specify how often the Advisor service should be executed every N days or weeks.
7. **Execution Hour**: Specify the server hour when the Advisor service should be executed.
   Note the Advisor runs not at the exact hour specified, but at any minute of the specified hour.

8. If you do not want to expose your Grid member directly to the internet, select **Use proxy server**. Ensure that the proxy server has access to the internet.
9. Specify the following information for the proxy server:
    - DNS Name or IP Address
    - Port
    - Credentials to connect to Proxy Server (username and password)
10. Under **Advisor Central**, specify the following data:
    - **API Endpoint Address**: The IP address of the Advisor API endpoint.
    - **API Endpoint Port**: The port of the Advisor API endpoint.
    - **Authentication**: Select **Token** or **Credentials**.
    - If you selected token authentication, specify the authentication token value.
    - If you selected credentials authentication, specify the username and password.
11. In **Minimum Severity**, specify the severity threshold for vulnerabilities data that you want to obtain for your devices. To see possible values, hover the mouse over the field. The popup window displays the following values:
    - **Critical**: 9.0-10.0
    - **High:** 7.0-8.9
    - **Medium:** 4.0-6.9
    - **Low**: 0.1-3.9
    - **None**: 0.0
12. **Last Scheduled Execution Result**: Displays the timestamp of the last successful or unsuccessful scheduled execution result.
13. **Last Run Now Result**: Displays the timestamp of the last successful or unsuccessful immediate execution result.
14. **Test connection to central**: Central refers to the server where the application for Network Insight Advisor is running, that is the Advisor server. NIOS sends a POST query to the Advisor server from Discovery Consolidator, when you click **Test connection to central**. In the API Endpoint Address, the server address is specified. If the query enters the Advisor server successfully and returns a correct response, then OK is displayed else Not OK is displayed.
15. If you want to launch Advisor immediately, click **Run Now**.
16. Save the configuration.

Configuring Discovery for SDN and SD-WAN

Network Insight allows you to collect and manage data from SDN and SD-WAN environments. Currently, you can discover Cisco ACI, Cisco Meraki, Cisco Viptela, and Juniper Mist. For information about adding, configuring, discovering data, and configuring polling settings for these devices, see:

- *Cisco Network Solutions*
    - *Adding and Configuring Cisco ACI Discovery*
    - *Adding and Configuring Cisco Meraki Discovery*
    - *Adding and Configuring Cisco Viptela Discovery*
- *Juniper Mist Network Solutions*
- *Configuring SDN and SD-WAN Polling Properties*

You can add specific SDN and SD-WAN entries in the discovery properties of Probe or Standalone members. You cannot configure these settings on Consolidators. Also, you can configure general SDN and SD-WAN polling properties in the Grid discovery settings.

To view discovery results for SDN and SD-WAN, go to **Data Management** > **Devices**. For information, see *Viewing Discovered Devices and their Properties*.

> ⚠ Note
>
> To ensure successful SDN and SD-WAN discovery, use an admin user account.

Cisco Network Solutions

You can add, configure, and discover data for the following Cisco solutions: Cisco ACI, Cisco Meraki, Cisco Viptela.

Adding and Configuring Cisco ACI Discovery

Enabling the discovery of Cisco ACI devices provides visibility into your Cisco ACI infrastructure. This allows you to view and manage discovered IP addresses of Cisco ACI fabric members such as APIC controllers and fabric switches with their attached end points.

> **Note**
> The **Cisco APIC Configuration** tab in the member discovery properties was renamed to **SDN/SD-WAN**. You can find all previously configured Cisco ACIs in this tab that is described below.

To add and configure a Cisco ACI fabric, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Discovery**.
2. Select a Probe member, and then click **Edit** > **Member Discovery Properties** in the Toolbar.
3. Click the **SDN/SD-WAN** tab.
4. Click the Add icon and select **Cisco ACI**.
5. Complete the following:
   - **Fabric Name**: Specify a short and unique name for the current Cisco ACI configuration.
   - **Addresses**: Enter the hostname or IP address of the Cisco APIC controller. If your fabric includes more than one controller, click the Add icon to add more addresses.
   - **Protocol**: Select **HTTP** or **HTTPS**.
   - **Network View**: Select the network view to identify the corresponding network interface for connectivity with the Cisco ACI. Also, this network view will be assigned to discovered devices from this ACI.
   - **Username**: The login name for the Cisco ACI.
   - **Password**: The login password.
   - **Comment**: Additional information about the Cisco ACI.
   - **Connect using Grid Proxy settings if available**: Select if you want to use the Grid Proxy for connectivity to or from the Cisco ACI. If the Proxy is specified in the Grid properties, then Network Insight uses it. For more information, see *Configuring Proxy Servers*.
6. Click **Test Connection** to check if the fabric is reachable and the provided credentials are correct. The connection test results are also written to syslog.
7. Click **Add**.
8. Click **Save & Close**.

Adding and Configuring Cisco Meraki Discovery

Enabling the discovery of Cisco Meraki provides visibility into your Cisco Meraki SD-WAN elements, for example:

- Wireless access points
- Switches
- Routers
- Cameras
- Phones

Network Insight classifies Meraki cameras and phones as end hosts and other Meraki devices as network devices.

To add and configure Cisco Meraki discovery, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Discovery**.
2. Select a Probe member, and then click **Edit** > **Member Discovery Properties** in the **Toolbar**.
3. Click the **SDN/SD-WAN** tab.
4. Click the Add icon and select **Cisco Meraki**.
5. Complete the following:
   - **Config Name**: Specify a short and unique name for the current Cisco Meraki configuration.

- **Address**: Enter the hostname or IP address of the Cisco Meraki Dashboard API. By default, it is *api.meraki.com*.
- **Protocol**: HTTPS by default.
- **Network Interface**: Select the interface that will be used to access the device.
- **API Key**: An access key is required to use Cisco APIs.
- **Comment**: Additional information about the Cisco Meraki device.
- **Connect using Grid Proxy settings if available**: Select if you want to use the Grid Proxy for connectivity to or from the Cisco Meraki device. If the Proxy is specified in the Grid properties, then Network Insight uses it. For more information, see *Configuring Proxy Servers*.

6. Click **Test Connection** to check if the device is reachable and the provided credentials are correct. The connection test results are also written to the syslog.
7. Click **Add**.
8. Click **Save & Close**.

Adding and Configuring Cisco Viptela Discovery

Enabling the discovery of Cisco Viptela devices provides visibility into your Viptela SDN/SD-WAN infrastructure. You can use Viptela as an on-premises SDN controller or as a cloud solution.

To add and configure Cisco Viptela discovery, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Discovery**.
2. Select a Probe member, and then click **Edit** > **Member Discovery Properties** in the **Toolbar**.
3. Click the **SDN/SD-WAN** tab.
4. Click the Add icon and select **Viptela**.
5. Complete the following:
   - **Config Name**: Specify a short and unique name for the current Viptela configuration.
   - **Address**: Enter the hostname or IP address of the Viptela vManage controller.
   - **On-premise controller**: Check this if your Viptela setup is on-premises.
   - **Protocol**: Select **HTTP** or **HTTPS**.
   - **Network Interface**: Select the interface that will be used to access the device.
   - **Network View**: Select the network view in which the discovered Viptela devices will be shown.
   - **Username**: The login name for the Viptela vManage controller.
   - **Password**: The login password.
   - **Comment**: Additional information about the Viptela vManage controller.
   - **Connect using Grid Proxy settings if available**: Select if you want to use the Grid Proxy for connectivity to or from the Viptela. If the Proxy is specified in the Grid properties, Network Insight uses it.
6. Click **Test Connection** to check if the device is reachable and the provided credentials are correct. The connection test results are also written to syslog.
7. Click **Add**.
8. Click **Save & Close**.

Juniper Mist Network Solutions

Enabling the discovery of Juniper Mist provides visibility into your Juniper Mist SD-WAN elements, for example:

- Wireless access points
- Switches
- Routers
- Firewalls

To add and configure Juniper Mist discovery, do the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Discovery**. The Grid Manager tab will be automatically chosen as the default selection.
2. Under the **Services** tab, select a Probe member. The **Edit** icon becomes active when you select the Probe member.
3. Click the **Edit** icon.
4. Click the **SDN/SD-WAN** tab from the left navigation pane.
5. Click the drop-down next to the Add icon.

6. Select **Juniper Mist**. The **Add Juniper Mist Configuration** page will be displayed.
7. Complete the following:
    - **Config Name**: Specify a short and unique name for the current Juniper Mist configuration.
    - **Address**: Enter the hostname or IP address of the Juniper Mist Dashboard API. By default, it is *api.mist.com*.
    - **Protocol**: This field is populated as **HTTPS** automatically and is not editable.
    - **Network Interface**: Select the interface for accessing the device.
    - **API Key**: An access key required to use Juniper Mist APIs.
    - **Comment**: Additional information about the Juniper Mist device.
    - **Connect using Grid Proxy settings if available**: Select if you want to use the Grid Proxy for connectivity to or from the Juniper Mist device. If the Proxy is specified in the Grid properties, then Network Insight uses it. For more information, see *Configuring Proxy Servers*.
8. Click **Test Connection** to check if the device is reachable and the provided credentials are correct. The connection test results are also logged to syslog.
9. Click **Add**.
10. Click **Save & Close**.

Configuring SDN and SD-WAN Polling Properties

The following devices are supported for SDN and SD-WAN polling settings:

- Cisco ACI
- Cisco Meraki
- Cisco Viptela
- Juniper Mist

On the Grid side, you can enable or disable the SDN and SD-WAN polling, specify end host collection timing, and define network view mapping rules. If SDN and SD-WAN polling is disabled, only traditional network devices are polled. Controlling the polling setting and end host data collection allows you to reduce the load on your system if required.

For the supported devices, you can select between different modes for mapping networks to NIOS network views. This mapping mechanism is required as your defined device infrastructure may have overlapping IP ranges that can be supported under different network views. The mapping rules include:

- Mapping to the predefined SDN network view
- Automatic mapping
- Custom mapping

To configure SDN/SD-WAN polling properties, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Discovery**.
2. From the Toolbar, select **Edit** > **Grid Discovery Properties**.
3. Click the **SDN/SD-WAN** tab.
4. On the **Basic** tab, complete the following:
    - **Enable SDN/SD-WAN polling**: Select to enable or disable SDN and SD-WAN polling.
    - **Default SDN Network View**: The network view that will be assigned to discovered Cisco Meraki devices for which the automatic network view mapping is disabled. You enable or disable automatic mapping in the advanced SDN and SD-WAN polling settings. For more information, see step 5 below.
    - **Detailed End Host Collection Interval**: Select to enable or disable the collection of end hosts (or clients in Cisco Meraki terminology). If enabled, specify one of the following:
        - **Periodic Collection**: Specify the N minutes or hours when the collection should occur.
        - **Scheduled Collection**: Schedule recurrent collection based on hourly, daily, weekly, or monthly time periods. Choosing this option, click the Calendar icon, and a Polling Scheduler appears; click the Edit icon to make scheduling changes. Choose a recurrence pattern of **Once**, **Hourly**, **Daily**, **Weekly,** or **Monthly**; in all cases, you must choose an **Execution Time**.
5. On the **Advanced** tab, complete the following:
    - **Disable SDN/SD-WAN Discovery for networks not in IPAM**: If set, new unmanaged networks discovered on the SDN controller are not created in the Infoblox IPAM.
    - **Network View Mapping**: Select one of the following:
        - **Disable automatic mapping and use predefined SDN Network View**: Select to map the collected SDN/SD-WAN devices to the default SDN network view defined in step 4 above.

- **Automatically create network views for unmapped networks**: Select to automatically map collected networks to their network views using Network Insight's internal rules. Network views that do not exist are created automatically. The mapped networks are displayed in the table that is not editable.
- **Enable network view mapping defined below**: This is custom mapping. Select to manually map the collected networks to appropriate network views. To change a network view entry, click it in the table.

6. Click **Save & Close**.

> ⚠ Note
>
> A network name in the mapping table is made up by combining a vendor name and network name. The **Source** column displays the fabric name or config name that you previously defined for the SDN or SD-WAN configuration. The name of a network view is made up by combining a network value with a source value.

Consolidator and Probes

When you first join a discovery member to the Grid, the first discovery member that joins the Grid automatically becomes the Consolidator and all other discovery members become Probes. If you have only one discovery member in the Grid, it becomes the Consolidator-Probe standalone discovery appliance.

Consolidator

The central repository of discovery data for the entire managed network. The Consolidator is a single appliance that contains data about all devices detected through discovery. The Consolidator communicates with the Grid Master as a normal Grid Member and transfers all its data to the Grid Master, as indicated in the figure *Network Insight Appliances Added as Grid members*. The Consolidator compiles information from one or more associated Probe appliances. The Consolidator appliance requires the Discovery license. If you have one or more Probe appliances or virtual appliances, the Consolidator performs no discovery on its own. If you plan to use a single dedicated appliance for discovery, that appliance must be licensed for discovery and be configured as a Consolidator. Note that the Grid Master cannot be licensed as a Consolidator.

Probes

A Probe is a Network Insight appliance or virtual appliance that performs the direct querying, probing and polling of network devices and the initial data collection. Probe appliances also require the Discovery license.
Infoblox recommends using one or more Probe appliances with the Consolidator. Each Probe can override the Grid level discovery credentials with its own discovery credentials.
Data synchronization occurs continuously between the Consolidator and all associated Probe appliances and between the Consolidator and the Grid Master.

> ⚠ Note
>
> You assign each Probe appliance to a single network view, and multiple Probe appliances can share the same network view. You can change network view assignments for Probe appliances at any time. On ND-1405, ND-2205, ND-4000, ND-V1405, and ND-V2205 Network Insight appliances, you can assign multiple VLAN interfaces on the same Probe to different network views.

Consolidator Probe Appliance

You may also choose to operate a Consolidator-Probe appliance as a single discovery system. In this deployment, the appliance operates as both a Consolidator and a Probe, performs all discovery operations, aggregates all databases within it, and synchronizes with the Grid Master.

Standalone discovery appliances cannot be installed in a network that already has existing Probes and a Consolidator. For more information, see *Defining the Discovery Member Type* and *Mapping Discovery Interfaces to Network Views*.

Deployment Guidelines for Consolidator and Probes

When you wish to install and deploy discovery appliances, use the following installation guidelines:

- **Installing a Standalone in the Grid**–Before you designate an appliance as a standalone discovery appliance, no previously installed Probes should be present on the network and joined to the Grid. If you install a new appliance intended as a standalone, in a network that already has one or more Probe instances (perhaps for testing or evaluation purposes), before discovery service is stopped on the Probe instances, the new "standalone" appliance automatically detects the Probe instances and start as a Consolidator appliance, preventing it from acting to probe and detect devices as a standalone appliance. Consolidators cannot be assigned to network views or to discovery in network objects such as IPv4 or IPv6 network containers.
- **Converting a Consolidator to a Standalone**–Also consider the example of a Consolidator appliance operating with one or more instances running as Probes, each with respective Discovery licenses. If you wish to convert the Consolidator to a standalone discovery appliance, stop the discovery service on all associated probes. Then, stop and restart the discovery service on the Consolidator appliance. The appliance is selectable for discovery of network objects, acting as a standalone discovery appliance.
- **Adding new Probe Instances to a Standalone deployment**–Finally, consider the use of a standalone discovery appliance to which you wish to associate a new Probe instance or instances. This process converts a standalone to a Consolidator. After the new Probe instances join the Grid, stop the discovery service on the standalone discovery appliance. Then, start the discovery service on the new Probe or Probes. Next, restart the discovery service on the previously defined standalone appliance. It detects the newly active Probe instances and activate as a Consolidator.
- In all cases, you must maintain proper Discovery licensing.

Defining the Discovery Member Type

Before using Network Insight to discover devices and networks, you must first define the consolidator and probes in your Grid and specify the discovering interfaces on these members.

You choose between the following member types:

- **Probe**: Turns the appliance into a discovery Probe appliance.
- **Consolidator**: Turns the appliance into a discovery Consolidator appliance.
- **Unassigned**: Disables the discovery feature on the appliance.

When you first join discovery members to the Grid, the first discovery member that joins the Grid automatically becomes the Consolidator and all other discovery members become Probes. This is the Grid mode. If you have only one discovery member in the Grid, it becomes a Consolidator-Probe discovery appliance – this is the standalone mode.

On some occasions, you may wish to change an appliance with a Discovery license to a Consolidator or to a Probe, or change a Consolidator to a standalone discovery appliance. To make any of these changes, you must first stop the discovery service on the appliance. For more information, see *Starting and Stopping the Discovery Service*.

To define the discovery member type:

1. From the **Grid** tab, select **Grid Manager** -> **Discovery** to display the list of members running the discovery service.
2. Select the discovery member for which you wish to change the member type.
3. If the discovery service is running on the member, stop it.
4. In the Toolbar, click **Edit** –> **Member Discovery Properties**.
5. In the **General** tab –> **Member Type** field, choose the required member type.

Note that the **Consolidator** and **Unassigned** member types in the Grid mode are disabled if the member has SDN/SD-WAN configurations on it. This is because SDN/SD-WAN configurations can be added to only Probe or standalone member types. In the standalone mode all member types are available for selection.

6. Save the configuration.

To change the interface over which a member sends and receives discovery traffic, see *Mapping Discovery Interfaces to Network Views*.

Viewing Discovered Devices and their Properties

Grid Manager provides a **Devices** page under **Data Management** for a complete list of every device that discovery finds, and lists all unmanaged and managed devices. Here you can explore information about the discovered devices and drill down to specific information about every device. For information, see the next section.

Listed devices can be displayed in one of three states in the **Devices** page:

- Devices that appear with an empty value in the **Managed** column are devices that are discovered, but are not recognized by IPAM, are not part of an IPAM network, and hence cannot be changed to managed status in Grid Manager. These discovered devices cannot be changed to managed status, but you can perform actions such as activating and deactivating ports, executing **DiscoverNow** on the device, view their list of connected networks, and other actions. Avoid changing the state of ports or taking other actions on a discovered device, unless the action is verified by an administrator.
- Device shown in yellow table rows are unmanaged devices, but are recognized by IPAM and can be converted to managed status. Yellow rows appear with a value of **No** in the **Managed** column. You can convert devices in yellow table rows to managed objects under IPAM (host, fixed address, A record or PTR record).
- Devices shown in light grey table rows are managed devices, with a value of **Yes** in the **Managed** column.

> ⚠ Note
>
> For information about managed and unmanaged devices, see *Converting Unmanaged Devices to Managed Devices*. You can also use the "Unmanaged devices and networks" filter in global search to locate all the unmanaged devices and networks discovered through discovery. For more information, see *Using Global Search*.

Also, you can view VRF-based devices and map them to network views from the **Data Management** → **Devices** tab. See Viewing Discovered VRFs and Mapping Network Views below.

Viewing the Complete List of Discovered Devices

The **Data Management** tab **–> Devices** tab provides a complete view of all discovered devices discovered by Network Insight. The list includes routers, switches, firewalls and other security devices, wireless APs, end hosts and servers in end-host networks. Use NIOS standard filtering to narrow down the status table to the devices or values you want to examine.

You can see the following information in the devices table:

- **IP Address**: The detected management IP address (IPv4 or IPv6).
- **Name**: Detected name of the device. Each device name provides a link to the complete body of information associated with the device, arranged in five tabs: **Interfaces**, **Networks**, **IP Addresses**, **Assets** and **Components**. For more information, see the sections under *Accessing Detailed Device Information*.
- **Device Type**: The network device type: **Router**, **Switch-Router**, **Firewall**, **NIOS (Infoblox appliance)**, **vNIOS**, **SDN Controller**, **SDN Element**, **LWAP**, and others.
- **Model**: The model name as detected by the device during discovery.
- **Serial Number**: The serial number of the discovered device.
- **Vendor**: The equipment manufacturer (Cisco, Juniper, Fortinet, F5, and others).
- **Device Version**: The Operating System version for the network device.
- **Chassis S/N**: The chassis serial number of the discovered device.

- **Location**: The physical location of the network device as detected by the device during discovery.
- **Description**: Verbose description of the network device as collected from the device by discovery.
- **Discover Now**: Indicates when the device is undergoing a current discovery process. A "Pending" icon appears in this column to indicate the status.
- **Managed**: Indicates the status of the device in Grid Manager. A blank value in this field indicates the device has been discovered but is not recognized in IPAM; a **No** value indicates the device is recognized by IPAM but is not managed under Grid Manager; and a **Yes** value indicates that the device is fully managed by Grid Manager from use of the **Convert** command and can support related features such as port reservations and IPAM/DHCP object assignments.
- **Active Users**: The number of active users on the Active Directory domain for the selected IP address.

For each listed device, the Action icon provides the following options depending on the device type and its status:

- **Show IPAM IP Address**: Shows the management IP address for the device that has a network in IPAM–the main **IPAM** tab appears, showing details for the IP address. This option is greyed out for devices that have a management IP that is not part of an IPAM network.
- **Edit**: Displays the Device Properties Editor window. Alternatively, you can select the device and click the Edit icon above the devices table. For more information, see Editing Device Properties below.
- **Interfaces**: A direct link to the **Interfaces** page for the chosen device. Unmanaged devices may have managed interfaces that appear in this page, and managed devices may have unmanaged interfaces that appear here. For more information, see *Viewing Interface Information for Discovered Devices*.
- **Discover Now**: Immediately performs discovery on the selected device.
- **Convert**: For devices in unmanaged status (shown in yellow), allows conversion of the device to a managed object in Grid Manager: a host, fixed address, A record or PTR record. For more information, see *Converting Unmanaged Devices to Managed Devices*.
- **IPAM Networks**: A drop-down list of all IPv4/IPv6 IPAM networks currently provisioned on the device. Each network provides a link to the IP Map page for the selected network.
- **Device Details**: A basic list of information about the chosen device, including the IP address by which the device is discovered, operational status, IPAM Type (whether the device is managed or unmanaged), the Device Type and the number of Interfaces.
- Click **Device Support** to verify data collection activities in the following tabs:
    - **Data Collection**: You can view the timestamp at which the most recent collection from various data sources was completed. The sources from which device support information is collected are listed under the Data Source column, and it includes the device's routing table (ipRouteTable), environment monitoring (DeviceEnvMon), and numerous other data sources as applicable to the specific device type. It displays the following information for each discovered device:
        - **Data Source**: The sources from which the device support information was collected.
        - **End Time**: The most recent timestamp of the data collected by the discovery member.
    - **Device Support**: Lists various types of information supported for collection on the current device. You can view the following details for each discovered device:
        - **Function**: Data function that can be collected by Network Insight. The value can be **Device Vendor**, **Device Model**, **Device Version**, **VLANs**, **Forwarding**, **VRFs**, **Inventory**, and **SecurityControl**.
        - **Supported**: Indicates whether this data function is supported for the selected device. The value can be **Yes** or **No**. If it is **No**, Network Insight will not attempt to gather the data. For instance, for a Cisco router, Network Insight does not attempt to gather VLAN information, so a No value will be displayed in the **Supported** column.
        - **Available**: Reflects whether the data has actually been collected. The value can be **Yes** or **No**. A value of **Yes** for **Supported** and **No** for **Available** indicates a discovery misconfiguration or could possibly require an adjustment to the Device Support Bundle (DSB) for that particular device model.
        - **Value**: Displays the value collected for the **Device Vendor**, **Device Model**, and **Device Version** data functions. Displays **Last Collected** time for the **VLANs**, **Forwarding**, **VRFs**, **Inventory**, and **Security Control** data functions.
- **Show Active Users**: Displays the *Active Users* dialog box. You can view all the active users on the Active Directory domain for the selected device. For more information, see *Viewing Active Network Users*.

Click **Discovery Status** in the Toolbar to view the same list of network devices showing the discovery data set. You can sort the table by Name or IP address. Use Grid Manager-standard filtering to display device names, IP addresses or other values in which you are interested.

Editing Device Properties

In the Device Properties Editor, you can change the management IP address and settings for interfaces of the selected device, apply extensible attributes, or apply administrative permissions for Grid Manager admin access to the device.

To edit properties of a device:

1. In the **Data Management** → **Devices** tab, click the Action icon

   for the required device or select the device and click the Edit icon above the table.
2. In the **General** tab, edit the following general device properties:
   - **Name**: The discovered device name, such as SPINE, LEAF, switch1.building2.com, or office1router.
   - **Management IP address**: This IP address is used for the device to be discovered by the discovery member. If the device has more than one IP address that can be used as the management IP, you can manually select the required address from the list of those discovered on the device.
     If more than one network view is used in the discovery, the name of the corresponding network view is displayed next to the IP address.
     Note changing of management IP address may take some time.
   - **Managed**: Indicates whether this device is managed or unmanaged in NIOS.
   - **Device Type**: Indicates the device type: Router, Switch-Router, Firewall, NIOS (Infoblox appliance), vNIOS, SDN Controller, SDN Element, and others.
   - **Description**: Description of the network device as collected from the device by discovery.
   - **Model**: The device model.
   - **Vendor**: The vendor of network device. For example, Cisco, Juniper, Aruba, Dell, Infoblox, or HP.
   - **Device Version**: The OS version of the device.
   - **Location**: Displays the physical location of the device as detected during discovery.
   - **Discover Now**: Displays the status of the Discovery Now operation of the device.
   - **Object Type**: The object type.
3. In the **Interfaces** tab, edit the followng basic port settings:
   - **Admin Status**
   - **Description**
   - **Data VLA**N
   - **Voice VLAN**
4. In the **Extensible Attributes** tab, add any attributes that are necessary for the device.
5. In the **Permissions** tab, edit administrative permissions for the device:
   a. Click the Add icon. Grid Manager displays the Admin Group/Role Selector dialog box.
   b. In the Admin Group/Role Selector dialog box, select the admin group you want to add, and then click the Select icon.
   c. Select the permission for the group.
   d. Select an object to which the permission applies from the drop-down list in the Resources column.
   Note that administrators can access discovered and managed devices in Grid Manager. For tasks such as provisioning networks, adding administrative permissions is advised to ensure that unauthorized changes to device configurations cannot take place. For example, you can use accounts with the Port Control permission to control and manage network provisioning tasks.
6. Click **Verify** where applicable, for example, in the interfaces settings.
7. Click **Save & Close**.

Viewing Discovered VRFs and Mapping Network Views

To view VRF instances (or VRFs) and map corresponding network views, do the following:

1. From the **Data Management** tab, select the **Devices** tab, and then click **VRF Mapping** from the Toolbar.
2. The *VRF Mapping dialog* appears and displays the following:
   - **VRF Name**: The name of the VRF on the hosting device, which typically contains the interface name and its VRF route distinguisher.
   - **Device Name**: The discovered name of the device that is hosting the VRF.
   - **Device IP Address**: The IP address of the managed VRF hosting device.
   - **Network View**: The network view that is associated with the VRF. You can click this field and select a different network view from the drop-down list.

You can do the following in this tab:

- To assign the same network view to multiple VRFs, select the checkboxes of the VRFs, and then click the Edit icon. The *VRF Mapping* dialog displays the **Edit VRF Network View** panel. From the **Network View** drop-down list, select the network view you want to assign to all the selected VRFs, and then click **Save**. If there is only one network view in the Grid, which is the default view, the **Network View** column is hidden by default.
- You can use filters to narrow down the list. You can filter the list based on the VRF name, Device name, Device IP address, and network view. For more information, see *Using Filters*.
- You can sort the data in ascending or descending order by column.

> ⚠ Note
>
> The appliance displays a warning message when there are discovered VRFs that are not mapped to network views. To ensure that discovered VRFs are mapped to network views, you can configure automatic VRF mapping, as described in *Configuring Automatic VRF Mapping*.

Port Control Features in Network Insight

> ⚠ Note
>
> Port control involves two primary operations: *network provisioning/de-provisioning* and *port configurations*. These operations are classified as port control tasks that can be monitored and viewed in the Task Manager (**Administration –> Workflow –> Task Manager**).

Port control enables changes to the interface-level configurations of switches and switch-router devices, and assignment of these resources to network objects defined and created within IPAM.

- Port configurations and network provisioning and de-provisioning use CLI admin credentials, supporting SSH and Telnet. You may test credentials before use, against an IP address or a selected device;
- Port configuration consists of two primary operations: setting admin status for a port, and defining Data VLAN and Voice VLAN assignments (where applicable), along with minor changes such as editing descriptions;
- You can define port configuration blackout periods using the same methods provided for discovery blackouts. These blackout periods also apply to network provisioning and de-provisioning tasks;
- Configuring a port on a device always creates a new port control task that can be viewed and managed in the Task Manager.
- You can separately schedule port control tasks using the same method as for object creation.
- You can edit multiple interfaces at a time.
- You can edit interfaces, inline, from the **Interfaces**, **IP Addresses** and **Assets** pages in Grid Manager. These operations generally consist of setting the interface to be Administratively Up or administratively Down, and VLAN assignments.

Network provisioning includes the following:

- If a user deletes a discovered network from the system, Grid Manager displays the list of *interfaces* on which the network is currently provisioned;
- Network provisioning allows you to provision a network on one interface at a time. The network must be in managed status under IPAM;
- The user can also *de-provision* a network, which removes it from one or more interfaces;
- You can perform network provisioning and de-provisioning tasks on routers and switch-routers.

Devices do not have to be in managed state for some port control operations (setting ports to Admin Up and Admin Down, for example) but some port control operations require it:

- Provisioning a network (through IPAM) onto a port on a managed device;
- De-provisioning a network.

When you create a new object using the wizard, you can configure the port or ports that are associated with the object's port reservation. In this case, two new tasks are created: an object creation task, and a port control task, which can be scheduled separately from the object creation. *The port control task is a separate task that may also require administrator approval*. When you create a new task, an information feedback panel provides a link to the port control task in the Task Manager.
You may also select and reschedule both tasks. For more information, see *Rescheduling Tasks*.

> ⚠ Note
>
> If you edit an object, you can only edit an associated port reservation.

Objects are completed in their configuration by Grid Manager before executing a port configuration.
If, for example, a fixed address object is subject to administrative approval, no port control task takes place for that object until the approval is executed and the object is created. This has implications for scheduling: if you schedule the creation of a new host, IPv4 reservation or fixed address, and wish to schedule a port control task for the same object, the scheduled object creation must take place first, and must complete, before the scheduled port configuration executes.
All port configuration operations can be scheduled and subject to administrator approval. For more information, see *Configuring Approval Workflows*.

About Port Reservations

You can define a device *port reservation* for a defined object such as a host, fixed address or IPv4 reservation, or for an Infoblox Grid Member. Port reservations assign device interfaces to Infoblox-managed objects in Grid Manager. The port reservation is a property of each object, such as a fixed address or host record, that you create. After discovering and cataloguing infrastructure devices, Grid Manager compiles the lists of interfaces and separately tracks available switch ports on each device. When you attempt to reserve a switch port, Grid Manager provides the complete list of *available* switch ports on the device, automatically preventing possible conflicts over port usage.
Characteristics of port reservations include the following:

- Device Ports can be reserved to Grid Manager objects under IPAM and DHCP;
  - The user can choose to immediately create the new object (IPv4 reservation, IPv4/IPv6 fixed address or host, or a Grid member), and to also immediately assign a device port to the object. In such cases, the object is created and the port is reserved for the object;
  - An object can be scheduled for creation at a later time, and its port assignment scheduled for the same time, or for a different date and time, in the future;
  - A port reservation does not guarantee that the switch interface is in fact available for the assignment.
- You can create port reservations for multiple objects at a time;
- Interface tables show the objects to which they are bound, in a special **Reservation** column;
- When you delete an IPAM object such as a fixed address, its associated port reservation is automatically deleted.

Once a switch port or other device port is reserved, Network Insight prevents future tasks from trying to use the same port for another reservation.
Device switchports and router interfaces, and other interface types may be assigned to the following types of objects:

- Grid members (including HA Pairs). For more information, see the following sections *Defining Port Reservations for an Infoblox Grid Member* and *Defining Port Reservations for an HA Pair.*
- Hosts. For more information about defining hosts with included port configuration, see *Adding Host Records*.
- IPv4 reservations. For more information, see *Adding IPv4 Reservations*.
- Fixed addresses (IPv4 and IPv6). For more information, see *Adding IPv4 Fixed Addresses* and *Adding IPv6 Fixed Addresses.*
- IP networks (IPv4 and IPv6). For more information, see *Adding IPv4 Networks* and *Adding IPv6 Networks*

Devices involved in these operations must be under managed status in Grid Manager. For more information, see *Converting Unmanaged Devices to Managed Devices*.

Defining Blackout Periods

> **Note**
>
> You can separately define blackout periods for discovery, and for port configuration. This section describes how to use the blackout feature for discovery. For more information on blackouts for port configuration tasks, consult the section *Defining Port Configuration Blackout Periods*.

Discovery protocols can occupy significant resources within the network when discovery is taking place. While you can schedule any discovery or port control task for any single time period or recurring time period, you can also establish time periods when Network Insight does not talk to devices or networks for discovery.
You can define blackout settings at two levels in Grid Manager:

- Under Grid Discovery Properties, applying across the entire Grid;
  - All networks managed by the Grid inherit discovery blackout settings by default;
- For individual networks under IPAM and under DHCP.
  - A network must be Managed before you can edit its discovery blackout settings.
  - Under IPAM, you can define discovery blackout settings for Network Containers and for networks (for DHCP, you can also set blackouts for DHCP Ranges);
  - If a network is in Managed state, it can be edited under IPAM or under DHCP for discovery settings and discovery blackout settings.

Discovery tasks may already be running when a blackout period takes effect. Current tasks are not interrupted and will complete within their time. Network Insight does not activate new discovery tasks during the blackout period, however.

Defining Blackout Periods for the Grid

This procedure also covers defining port configuration blackout periods for the Grid. To define blackouts for the Grid:

1. From the **Grid** tab, select the **Grid Manager** tab, and click **Edit –> Grid Discovery Properties**.
   If you do not select an appliance from the list, the **Grid Discovery Properties** option remains enabled.
2. Expand the Toolbar and click **Edit –> Grid Discovery Properties**.
3. Click the **Blackout** tab.
4. Select the **Enable Discovery Blackout** checkbox and click the Scheduling icon to open a separate scheduling window. The Blackout Scheduler dialog opens.
   a. Select how often you want to execute the blackout period. You can select **Once**, **Daily**, **Weekly**, or **Monthly**.
   b. If you select **Once**, enter the day in the date picker and select a month from the drop-down list.
      - Enter a time in the hh:mm:ssAM/PM format. You can also select a time from the drop-down list.
      - Choose the **Time Zone**.
      - Specify the **Duration**: 1 or more Minutes, Hours or Days.
   c. If you select **Daily**, click either **Every Day** or **Every Week day**.
      - Enter a time in the hh:mm:ssAM/PM format. You can also select a time from the drop-down list.
      - Choose the **Time Zone**.
      - Specify the **Duration**: 1 or more Minutes, Hours or Days.
   d. If you select **Weekly**, complete the following:
      - Under **Schedule every week on**:, select the checkbox for any day of the week.
      - Enter a time in the hh:mm:ssAM/PM format. You can choose a time from the drop-down list.
      - Choose the **Time Zone**.
      - Specify the **Duration**: 1 or more Minutes, Hours or Days.
   e. If you select **Monthly**, complete the following:
   - **Schedule the day of the month**: A discovery blackout can be executed monthly on a specific day, or instances can be executed more than one month apart on a specific day, in the **Day every month(s)** field.
   - Enter a time in the hh:mm:ssAM/PM format. You can choose a time from the drop-down list.
   - Choose the **Time Zone**.
   - Specify the **Duration**: 1 or more Minutes, Hours or Days.

5. If necessary, select the **Enable Port Configuration Blackout** checkbox and click the Scheduling icon to open the scheduling window. For more information, see *Defining Port Configuration Blackout Periods*.
6. Follow Steps 5a–5e to schedule the port configuration blackout for the Infoblox Grid.
   –or–
   Select the **Use Discovery Blackout Schedule** checkbox to apply the discovery blackout schedule to port configurations.
7. When you have finished configuring schedules for blackout periods, click **Save & Close**.

When a scheduled Grid-level blackout period goes into effect, no operations related to discovery take place for the specified time period across the Infoblox Grid. Any discovery tasks already in progress will run to completion but no new ones will start.

Defining Blackout Periods for Networks

Network Insight offers considerable flexibility in how you apply blackout periods. You may choose to have discovery allowed for most managed networks but elect to have a discovery blackout for selected networks that are traffic- or latency-sensitive.
You can define extended time periods and regularly scheduled times when discovery and/or port configuration tasks is not in progress on a specific IPAM network or within a network container. By default, the network inherits its discovery blackout settings from the Grid level. Editing a network under IPAM or DHCP, blackout settings apply only to the specified network. You also specify the scheduled time when the blackout period begins and the duration of the blackout period. As noted, a network must be in managed status before editing discovery or blackout features. To define a discovery blackout for a network under IPAM or DHCP:

1. Select a managed network from one of the following locations:
   a. **Data Management –> IPAM –>** list view
      –or–
   b. **Data Management –> DHCP –> Networks**
2. Click the Action icon

   next to the network you want (this automatically selects it) and select **Edit** from the menu. The Edit Network dialog appears.
3. Click the **Discovery Blackout** tab.
4. Click **Override** to change blackout settings for the chosen network.
5. Select the **Enable Discovery Blackout** checkbox and click the Scheduling icon to open a separate scheduling window. (Because the settings are inherited, **Enable Discovery Blackout** may or may not already be enabled.) The Blackout Scheduler dialog opens.
   a. Select how often you want to execute the blackout period. You can select **Once**, **Daily**, **Weekly**, or **Monthly**.
   b. If you select **Once**, enter the day in the date picker and select a month from the drop-down list.
      i. Enter a time in the hh:mm:ss AM/PM format. You can also select a time from the drop-down list.
      ii. Choose the **TimeZone**.
      iii. Specify the **Duration**: 1 or more Minutes, Hours or Days.
   c. If you select **Daily**, click either **Every Day** or **Every Weekday**.
      i. Enter a time in the hh:mm:ss AM/PM format. You can also select a time from the drop-down list
      ii. Choose the **TimeZone**.
      iii. Specify the **Duration**: 1 or more Minutes, Hours or Days.
   d. If you select **Weekly**, complete the following:
      i. Under **Schedule every week on**: Select the checkbox for any day of the week.
      i. Enter a time in the hh:mm:ss AM/PM format. You can choose a time from the drop-down list.
      i. Choose the **TimeZone**.
      i. Specify the **Duration**: 1 or more Minutes, Hours or Days.
   e. If! you select **Monthly**, complete the following:
      - **Schedule the day of the month**: A discovery blackout can be executed monthly on a specific day, or instances can be executed more than one month apart on a specific day, in the **Day every month(s)** field.
      - Enter a time in the hh:mm:ss AM/PM format. You can choose a time from the drop-down list.
      - Choose the **Time Zone**.
      - Specify the **Duration**: 1 or more Minutes, Hours or Days.

6. If necessary, select the **Enable Port Configuration Blackout** checkbox and click the Scheduling icon to open the scheduling window. For information, see *Defining Port Configuration Blackout Periods*.
7. Follow Steps 5a–5e to schedule the port configuration blackout for the chosen network.
   –or–
   Select the **Use Discovery Blackout Schedule** checkbox to apply the discovery blackout schedule defined for the network.
8. When you have finished configuring schedules for blackout periods for the network, click **Save & Close**.

When a scheduled blackout goes into effect, no operations related to discovery and/or port configuration take place for the specified time period on the selected network. Any related operations in progress will run to completion but no new ones will start.

Defining Port Configuration Blackout Periods

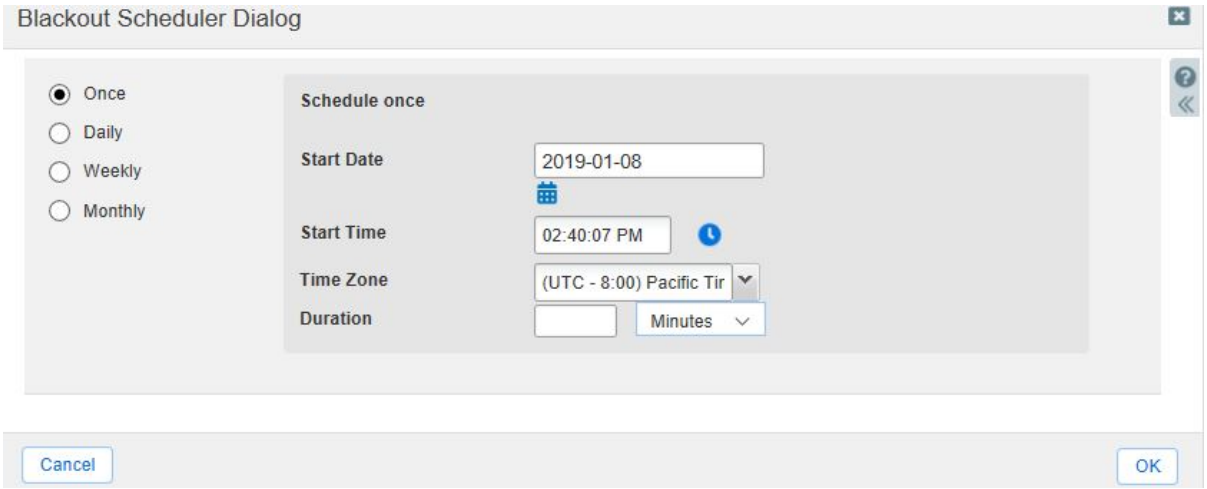
Similar to discovery blackout periods, you can define port configuration blackout periods for managed networks under IPAM and DHCP. You specify the scheduled time when the blackout period begins, and the duration of the blackout period.
By default, networks inherit their blackout settings from the Grid level. For port configuration blackout settings in a network, the network must be under managed status in IPAM.

Defining Port Configuration Blackouts for the Grid

Port configuration blackout settings apply globally across the entire Infoblox Grid unless overridden by members or for specific networks.

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Expand the Toolbar and click **Edit –> Grid Discovery Properties**.
3. Click the **Blackout** tab.
4. Click the **Enable Port Configuration Blackout** checkbox.
   a. Select the **Use Discovery Blackout Schedule** checkbox to apply the same blackout schedule to port configurations that is applied locally to discovery blackouts. (For more information on discovery blackouts, see *Defining Blackout Periods*.)
      –or–
   b. Click the Schedule icon below. The Blackout Scheduler dialog opens.

Scheduling a Port Configuration Blackout



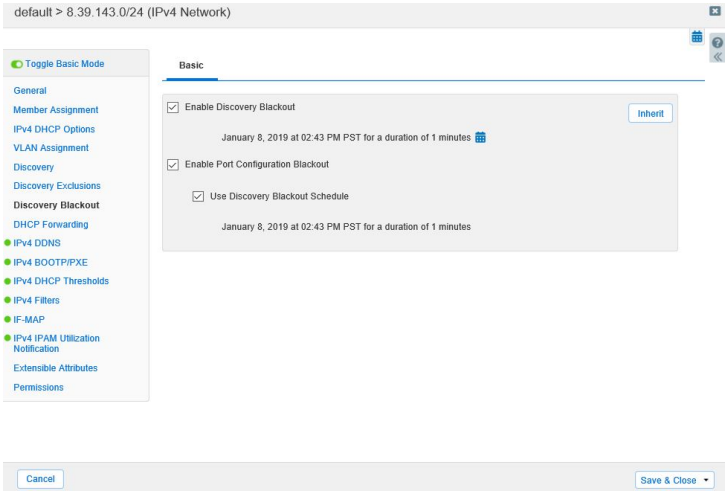
Defining Port Configuration Blackouts for Networks

By default, networks inherit their blackout settings from the Grid level. You can override these with local settings for the network or for a network container, for both IPAM and DHCP. To change port configuration blackout settings for an IPAM or DHCP network or network container:

1. Select a managed network or network container from one of the following locations:
   a. **Data Management –> IPAM –>** list view
   –or–
   b. **Data Management –> DHCP –> Networks**
2. Click the Action icon

   for a chosen network and choose **Edit** from the popup menu.
   - Under IPAM, the network must be in managed status (a value of **Yes** appears in the **Managed** field, and the table row is highlighted in white).
   - Under DHCP, all networks appearing on this page may be selected for this purpose.
3. Click the **Discovery Blackout** tab. The editor page appears as shown in the below figure.

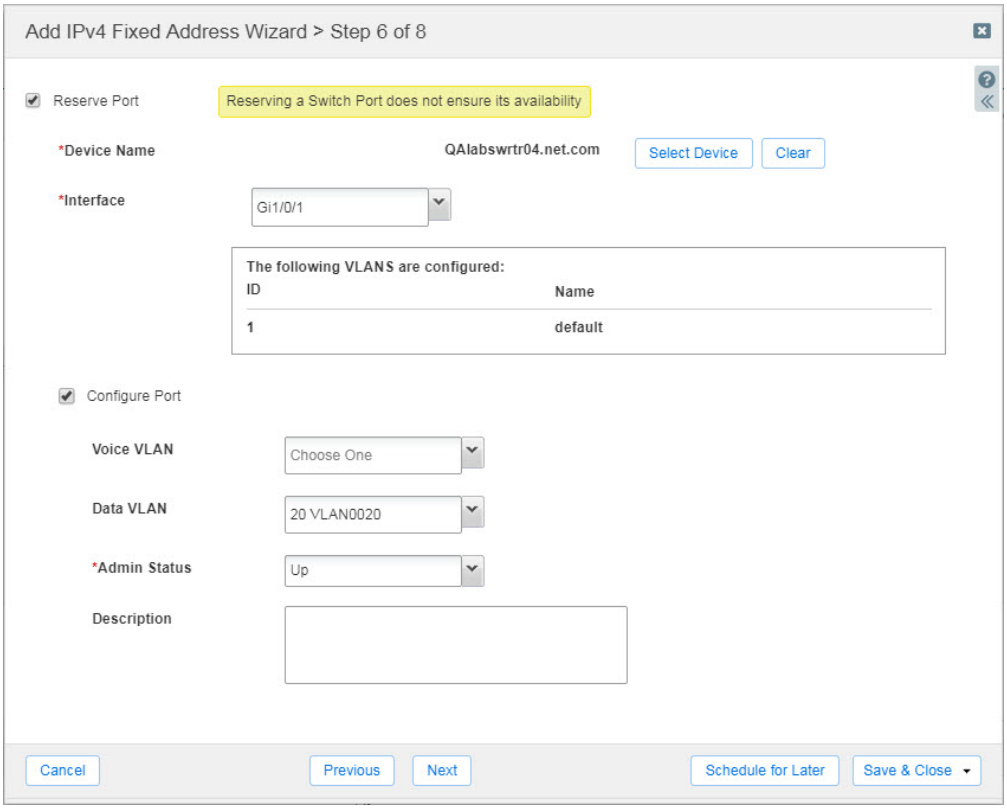
   The Discovery Blackout tab with enabled Port Configuration Blackouts



Creating Port Reservations for IPAM Objects

A port reservation instructs Network Insight to reserve ports on discovered and managed devices, for exclusive use by Grid members and by IPAM objects such as hosts or fixed addresses. Network Insight ensures that doing so does not interfere with existing device and port configurations and active networks, because port reservations automatically apply only to ports that are discovered to be available on network devices. Network Insight prevents a user from reserving the same port for more than one object. Should a port reservation somehow conflict with another more recent port reservation, Network Insight automatically reports a conflict and enables you to respond to the issue (for more information on this topic, see *Resolving Port Reservation Conflicts*).

When you create new IPAM objects, you can create the new objects and define port reservation settings at that time, or create the new object without any port-related settings and edit them later, after the object is established in Grid Manager. The Add IPv4 Reservation Wizard, Add Fixed Address Wizard, Add Host Wizard and Add Grid Member Wizards all support the full set of port configuration settings, as shown in the below figure.
Defining Port Reservations during Object Creation



Making a port reservation does not guarantee that the port is in fact available on the requested device. All interfaces appearing in the Interface list are ports that are otherwise known to Network Insight as Operationally Down during its last discovery task, and that are not already reserved by a port reservation.

1. Begin by checking the Reserve Port checkbox.
   Note that optionally, you can completely skip port reservation and port configuration by clicking **Next**.
2. Click the Device Name button to choose the device for which the port reservation is associated. You should know the identity of the device to which the Infoblox appliance is connected before taking this step.
3. After choosing the device, choose the Interface with which the reservation is bound. The drop-down list shows only interfaces that are most recently found to be available by Network Insight during the last discovery cycle. This list does not include any ports that are Administratively Up and Operationally Up and are otherwise already assigned to other networks or objects.
   - The Wizard page also shows a list of any VLANs that are currently configured in the chosen device. This Wizard page does not allow the definition of new VLANs for port configuration–only the assignment of an existing VLAN in the device for port configuration.
4. Select the Configure Port checkbox to define specific port control settings for the port reservation.
   Note that if you do not take this action when you create the object, you cannot perform the configuration later while editing the object.
5. If the chosen device supports them, choose the Voice VLAN and/or the Data VLAN settings you may need for the port assignment. You do not create new VLAN values in this step; you can select from VLANs that are provisioned on the currently chosen device. All VLANs configured on the device and discovered by Network Insight during its most recent discovery polling cycle appear in the drop-down lists.
6. Set the Admin Status to Up if you need to activate the port in the current task. Though the port reservation is associated only with the current object, any port configuration creates a new Port Control task under Task Manager.
7. Enter a description for the port assignment. Infoblox recommends doing so to help other technicians to recognize the port assignment event.
8. When finished, click **Save & Close** or select other tabs to change settings for the object.
   Note once a switch port or other device port is reserved, Network Insight prevents further port reservations from using the same port for another reservation.
   See the following sections for examples on how to create IPAM objects with port reservations:

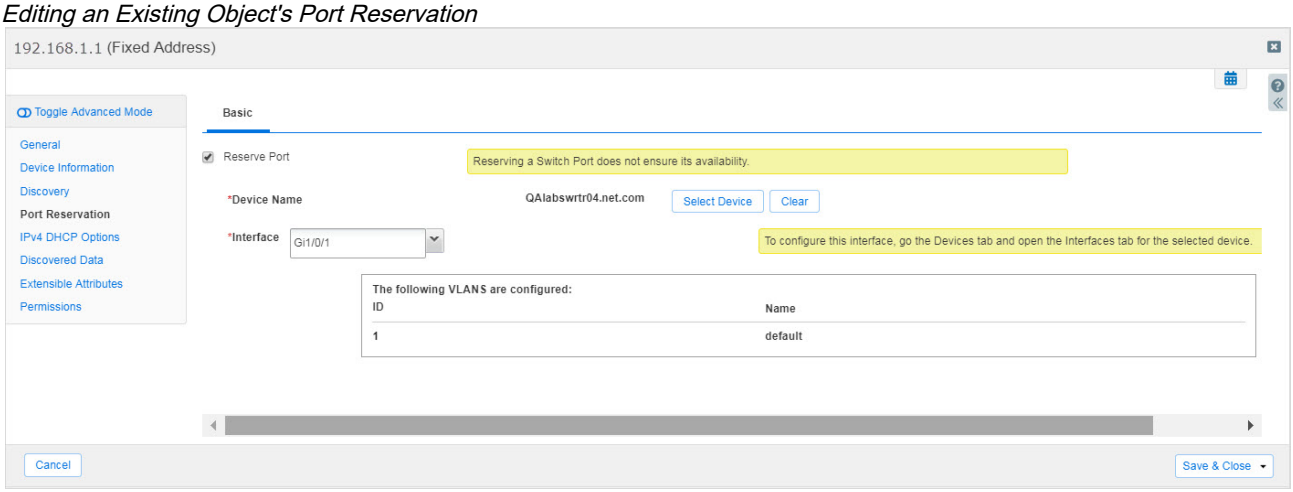
- *Adding Host Records*
- *Configuring IPv4 Networks*
- *Configuring IPv4 Fixed Addresses*
- *Configuring IPv4 Reservations*
- *Configuring IPv6 Networks*
- *Configuring an IPv6-only Grid*
- *Adding Grid Members*
- See Defining Port Reservations for an Infoblox Grid Member below

Editing Port Reservation Settings for IPAM Objects

As previously noted, you can create IPAM objects such as hosts or fixed addresses without device information and port reservation settings, and edit them later after the object is established in the Grid Manager. You can change port reservations in any object to new settings. Limitations exist when editing existing objects.

The **Port Reservation** editing page settings uniformly apply to Grid members, IPv4 reservations, hosts, and fixed address objects. Note that you cannot change port configurations when editing objects, as shown in the below figure.

Editing an Existing Object's Port Reservation



Unlike creating an object, editing an existing object's port reservation does not permit configuring the selected port. (You can edit the port from the device's **Interfaces** page, including inline editing.) Physical interfaces with an Operational Status of Down appear in the **Interface** drop-down list. Ports that are already active, that are reserved through a port reservation, or that are administratively Up/Operationally Up do not appear in the **Interface** drop-down list.

For object editing, you can select interfaces but you cannot edit their settings, such as setting the **Admin Status** to **Up** or choosing the **Data VLAN** or **Voice VLAN**.

Port reservation editable settings are as follows:

- **Reserve Port**–Enables the port reservation task for the new object;
- **Device Name**–Shows the name of the chosen devices, which must be selected by clicking Select Device and using the Device Selector window (for information, see *Using the Device Selector*);
- **Interface**–Drop-down menu listing for all interfaces on the selected device.
  The Following VLANs Are Configured–A read-only panel that shows the VLANs, if any, that are configured on the currently selected **Interface** setting.

Port configuration and VLAN settings cannot be performed when editing objects–you are limited to selecting a different port (from the same device or from a different device) to be bound to the current object.

Defining Port Reservations for an Infoblox Grid Member

> **Note**
>
> Editing Grid members does not allow for port configuration when you create or change a port reservation. For Grid member editing, you can select interfaces but you cannot edit them, such as setting the **Admin Status** to **Up** or choosing the **Data VLAN** or **Voice VLAN**. This section applies only to creating and defining port reservations and configurations for new Grid members. For the complete Grid member creation procedure, see *Adding Grid Members*.

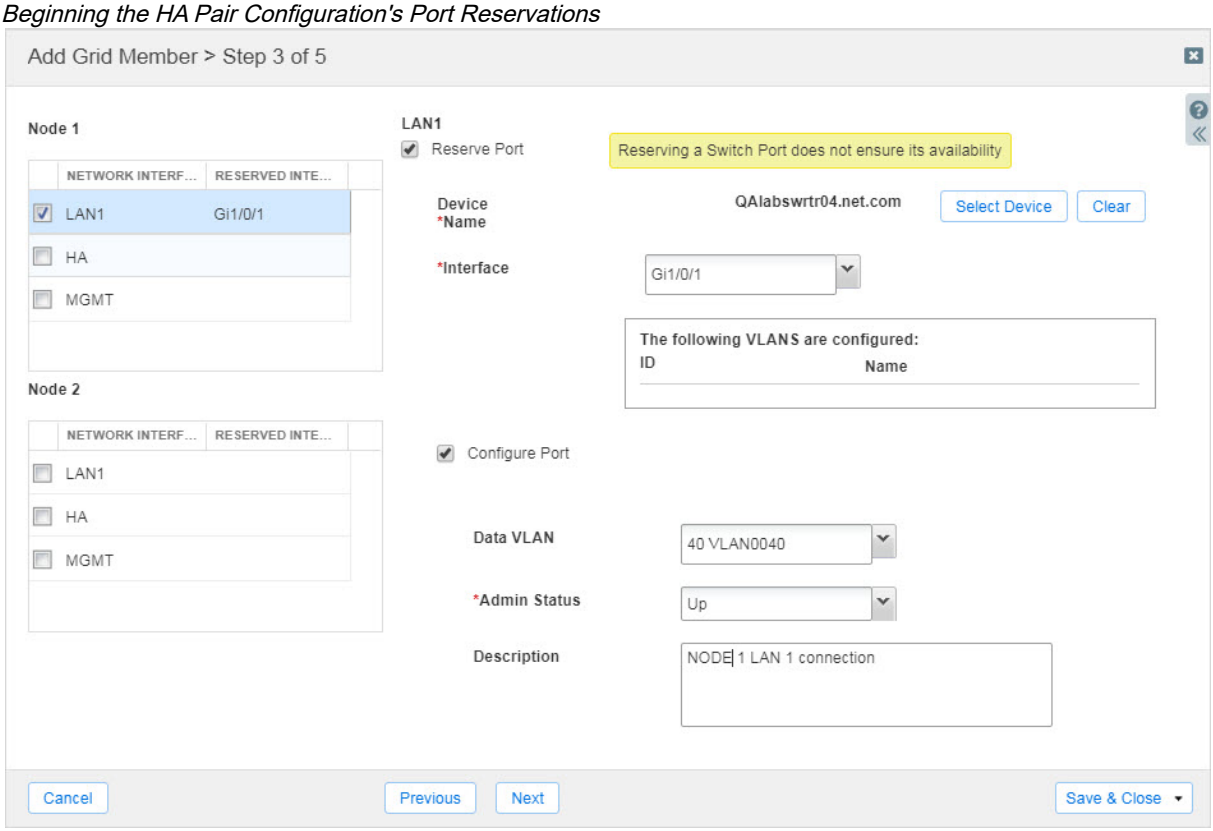
You can configure port reservations for a Grid member, including HA members, in the Add Grid Member wizard. All interfaces on a member (LAN1, LAN2, HA and MGMT) may have independently defined port reservations. For Grid members, port reservations are not subject to scheduling and workflow approval, and Grid Manager executes them immediately.

Defining Port Reservations for an HA Pair

The process of defining port reservations and port configurations for a Grid member allows these settings to be defined during the creation of the new member. (You can also edit them afterwards.) Before performing this procedure, consult the sections *Planning for an HA Pair* , *About HA Failover* and *Adding an HA Member* for more details.

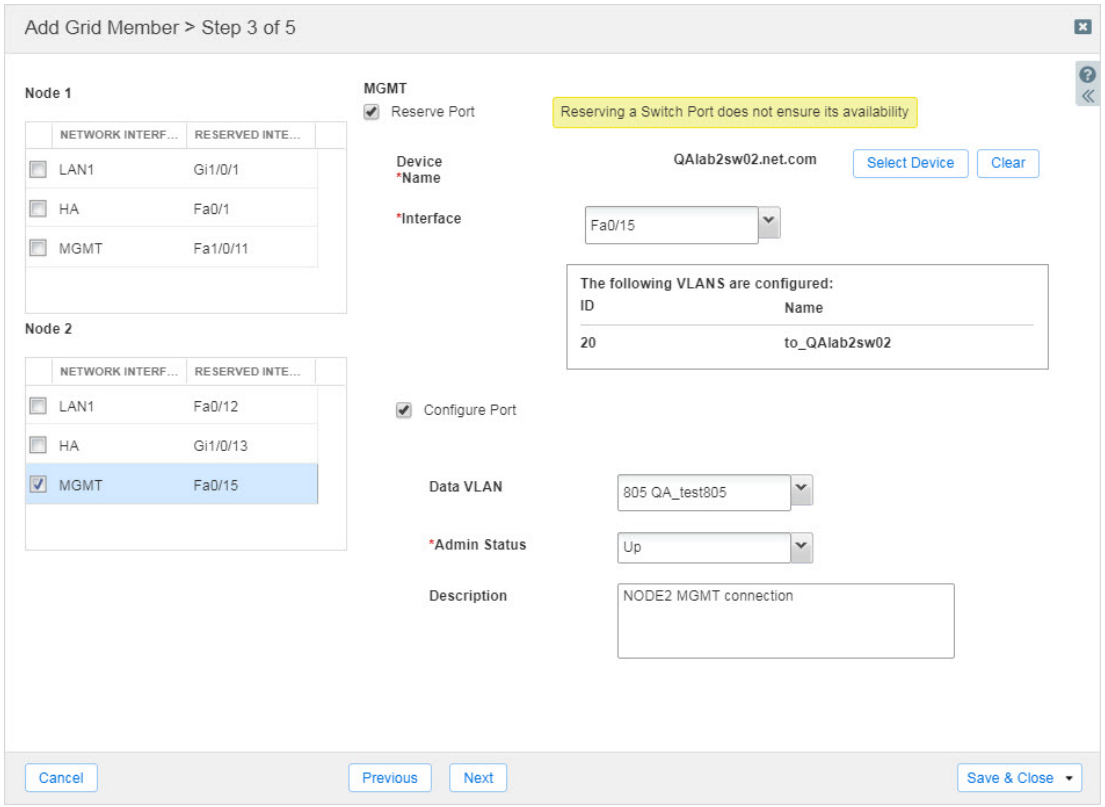
1. Go to **Grid –>Grid Manager** and choose **Add –> Grid Member** from the vertical toolbar. Define your new HA Pair's settings and click **Next**.
2. In the second Add Grid Member Wizard step (Step 2 of 5), click the **High Availability Pair** option and enter the required **Virtual Router ID** value.
3. As with a normal HA pair configuration, enter the IP information about the following interfaces: VIP, Node 1 HA and LAN1 ports, Node 2 HA and LAN1 ports. The VIP address and the IP addresses for all the ports must be in the same subnet. Follow the guidelines provided in the section *Adding an HA Member.*
4. Ensure all settings are correct and click **Next**.
5. The following step in the Add Grid Member Wizard presents a workflow that must be performed three times for each appliance–once for each of the three interfaces (LAN1, HA andMGMT) participating in the HA pair. (LAN2 may be configured by editing the Grid member afterwards.)

Beginning the HA Pair Configuration's Port Reservations



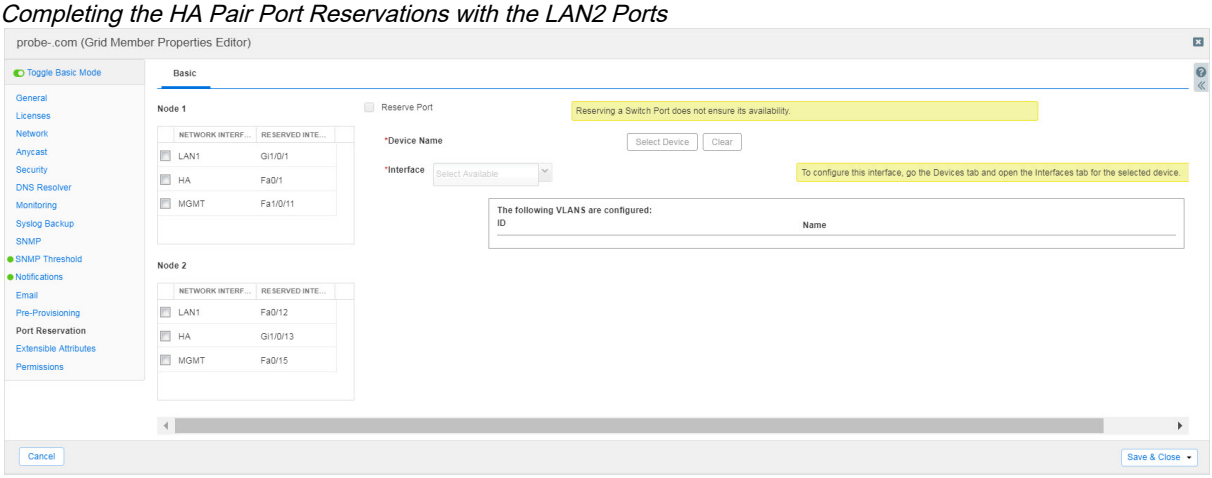
6. Begin by clicking the checkbox for the **Node** 1 **-> LAN1** appliance port. (You do not perform port reservation for the VIP port).
    a. Select the **Reserve Port** checkbox. The **Node1-> LAN1** port listing changes to read **Pending**.
    b. Click **Select Device** to choose the device (switch or switch-router) that is Node 1 of the HA Pair. For information, see *Using the Device Selector*.
    c. After selecting the device, click **OK**.
    d. Choose the device port for Node 1's LAN1 port by choosing it from the **Interface** menu.
    The panel **The Following VLANs are configured** refreshes to show any VLANs that are currently provisioned on the selected port.
    e. (*This step is optional.*) Select the **ConfigurePort** checkbox.
    f. (This step is optional.) If the **Data VLAN** setting is enabled, select the **VLAN** from the **Data VLAN** menu.
    g. (This step is optional.) Choose an **AdminStatus** of **Up**.
    h. (This step is optional.) Enter a **Description**.
    i. For the **Node 1 –> HA** port, follow steps 6a through 6h for that appliance port. Ensure you select the same switch and **Data VLAN** settings.
    j. For the **Node 1 –> MGMT** port, follow steps 6a through 6h for that appliance port. Ensure you select the same switch and **Data VLAN** settings.
7. For the second appliance Node 2, follow steps 6a through 6j above.
8. Click **Next** when finished with the Reserve Port and optional Configure Port settings for all interfaces. The result appears similar to the example shown in the below figure.

Port Reservations for an HA Pair



9. In the final step of the Add Grid Member Wizard, *if you have defined* port configuration, a final wizard step shows that the port configuration (which is a Port Control task) executes Now, without allowing a scheduling of the task. *Port reservation for the HA Pair is not scheduled* and also takes effect automatically as a part of the new Grid member configuration. (Grid Manager creates the Grid member immediately after you click **Save & Close**.)
10. After you click **Save & Close** to create the new HA pair Grid member, thus closing the Add Grid Member wizard, opening the editor for the HA member and clicking the **Port Reservations** tab displays the LAN2 port along with the previous port settings:

Completing the HA Pair Port Reservations with the LAN2 Ports



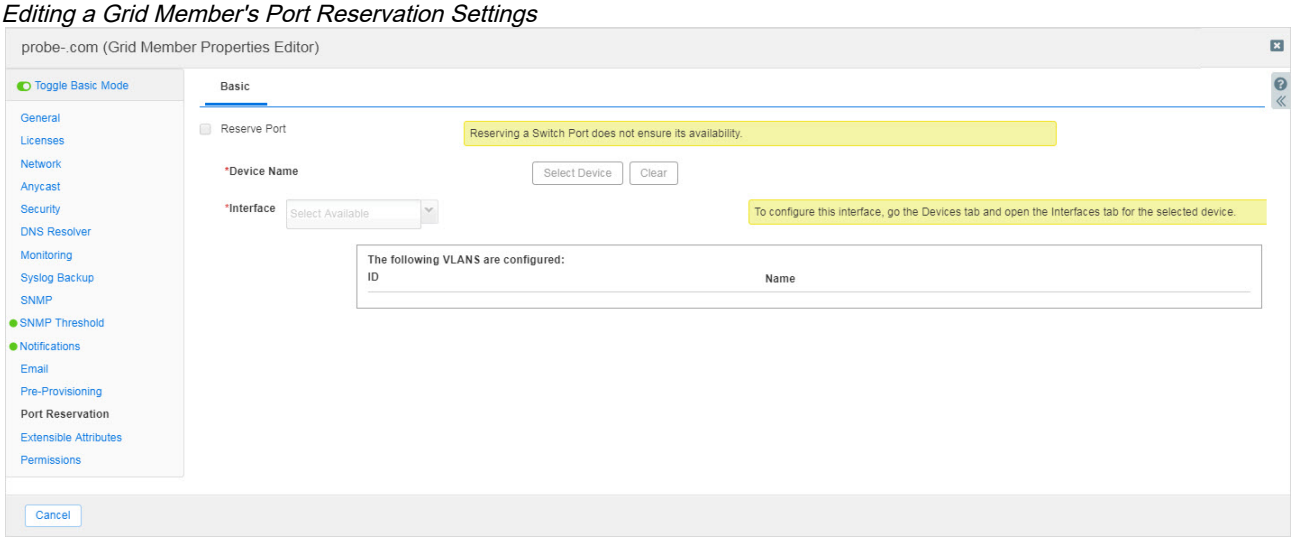
11. Select the LAN2 port for each node and follow steps 6a through 6h above. If VLANs are provisioned on the selected port, you can also select them.
12. Click **Save & Close**.

Editing Port Reservation Settings for an Infoblox Grid Member

Editing an existing Grid member's port reservation does not permit configuring the currently selected port. You can select ports from any device to change the port reservation. For any selected device, ports with an Operational Status of Down appear in the **Interface** list.

For editing Grid member settings, you can select interfaces but you cannot configure them; setting the **Admin Status** to **Up** or choosing the **Data VLAN** and changing the **Description** are not allowed when editing a Grid member.

Editing a Grid Member's Port Reservation Settings



You can edit any appliance's port reservation settings:

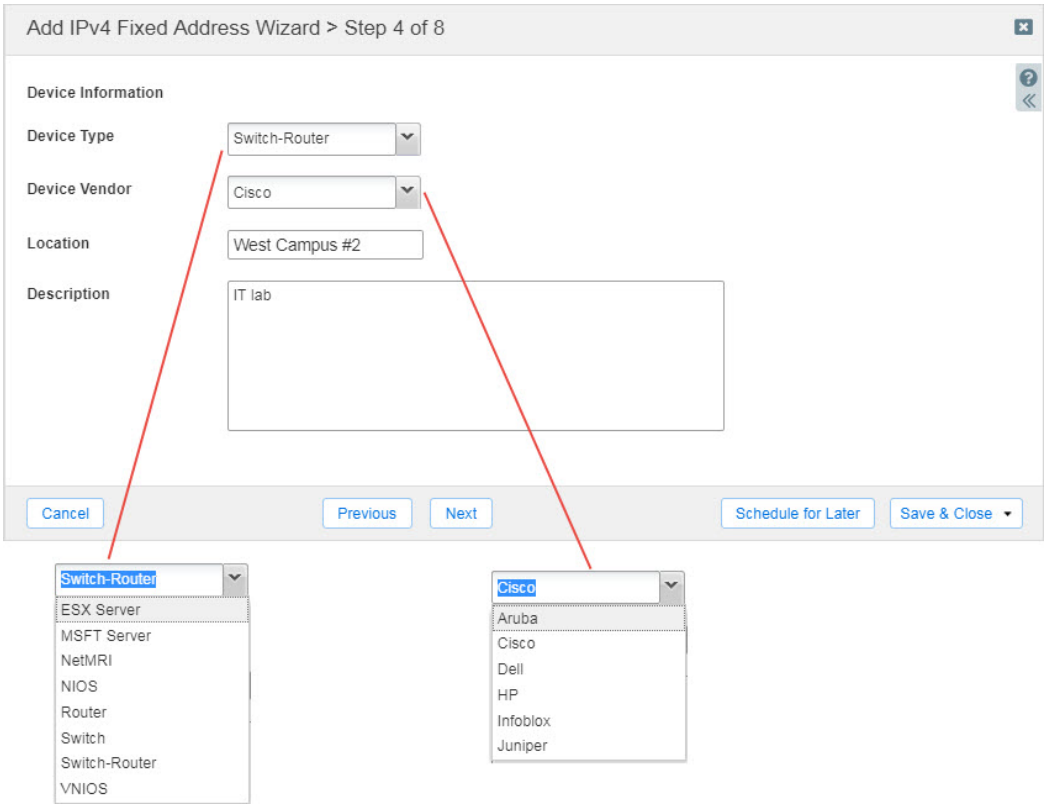
1. Go to **Grid –> Grid Manager** and select the checkbox for the Grid member you wish to edit. Click **Edit** from the vertical toolbar.
2. Click the **Port Reservation** tab.
3. Select the **Reserve Port** checkbox. The **Node1->LAN1** port listing changes to read **Pending**.
4. Click **Select Device** to choose the device. (For information, see *Using the Device Selector*.)
5. After selecting the device, click **OK**.
6. Choose the device interface from the **Interface** menu. Click **Save&Close** when finished.

On HA pairs the process is quite similar except that you may edit up to the full complement of interfaces used for each appliance in the HA pair. The Grid Member Properties Editor supports all ports for each appliance in the HA Pair.

> ⚠ Note
> When editing Grid members and HA Grid members, Grid Manager does not allow changes to VLAN settings, Admin Status or port description in the editor. You can change these values in the **Interfaces** table by double-clicking the table row for the interface you want to edit.

Defining Device Information

During the process of configuring a port reservation for an IPAM object, you can define device information settings as descriptive information for IPAM objects, as seen in the below figure.
Device Information Settings for IPAM Objects in the Wizard



Note: If you define Device Information and Device Vendor settings for a port reservation, which are optional, and choose to discover the object to which the port reservation is associated, you may see a conflict if discovery of the object finds that the device for the port reservation is a different type or different vendor. For example, if the specified information states that the device is a switch, and the discovered device is a router, Network Insight reports a conflict. Another example: you declare the vendor to be Aruba, and the discovered value is Cisco. For information on resolving such conflicts, see *Resolving Port Reservation Conflicts*.

The **Device Type** menu provides the following settings:

- **ESX Server**–identifies the object as a VMware ESX host.
- **MSFT Server**–identifies the object as a Microsoft Hyper-V host.
- **Net MRI**–NetMRI appliance from Infoblox;
- **NIOS**–Infoblox appliance;
- **Router**–Provides routed connections, including VLANs;
- **Switch**–provides L2 switched connections only;
- **Switch-Router**–Provides L2/L3 switched connectivity, including VLANs;
- **VNIOS**–Infoblox virtual appliance.

The **Device Vendor** menu provides the following device vendor choices:

- Cisco
- Juniper
- Infoblox
- Aruba
- Dell
- HP

IPAM object wizards allow definition of the settings when you create the object, or you can define the settings later.

Editing Interfaces in a Device

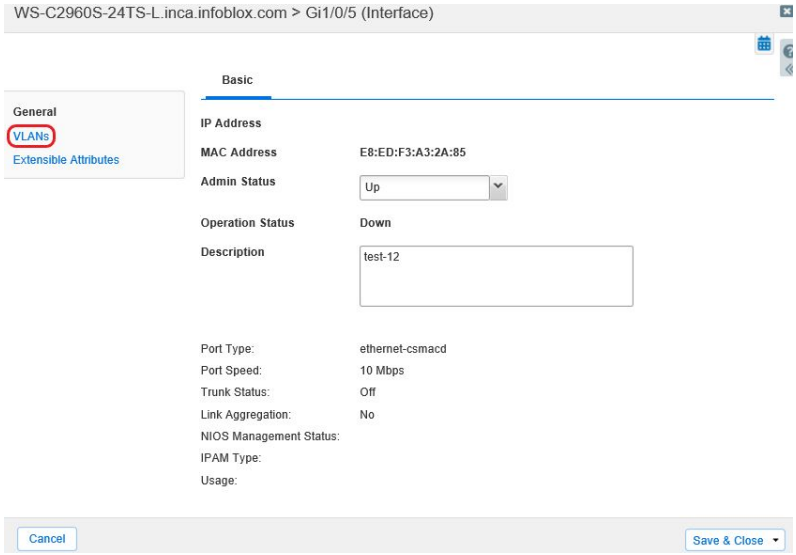
> **Note**
>
> Voice VLAN settings are applicable only for Cisco devices.

To speed port configuration workflows, you can select one interface or multiple interfaces for a device to change the admin status, description and VLAN settings. For example, this feature is handy if you want multiple interfaces to participate in the same data VLAN. There are two ways to approach this feature: directly from the **Devices** page, or by selecting a device on the **Devices** page, opening its **Interfaces** page and selecting ports from there.
Editing interfaces is done from the main **Data Management –> Devices** page.

1. From the **Data Management** tab, select the **Devices** tab.
2. Click the Action icon

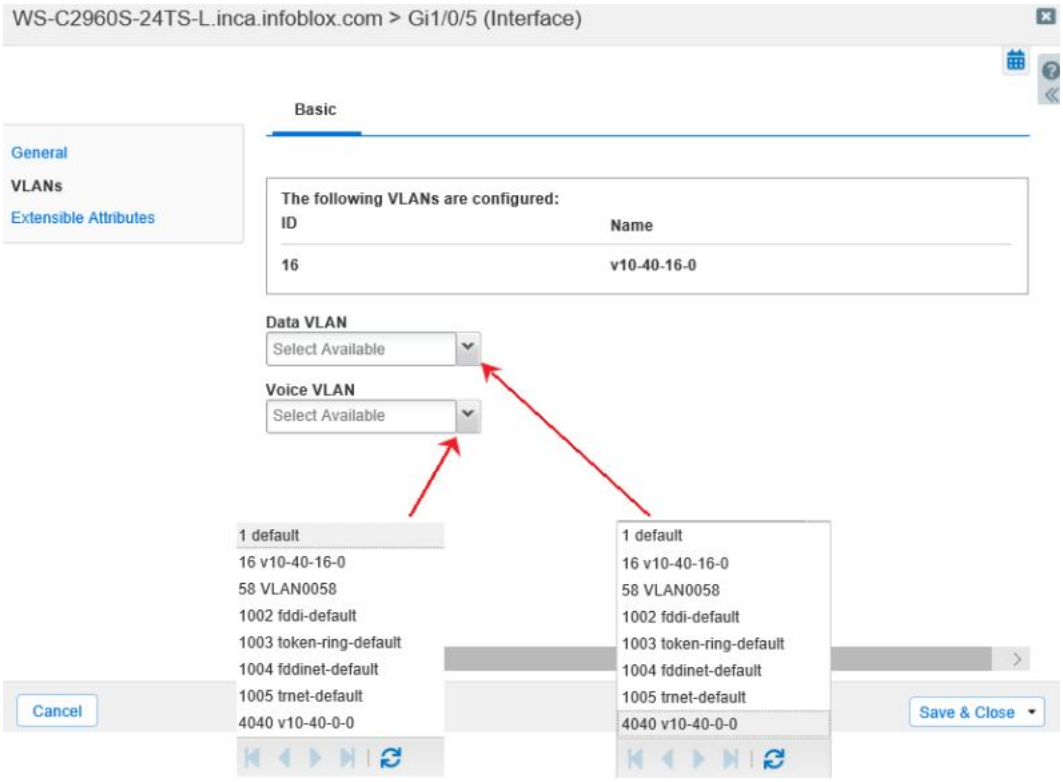
   for a chosen device and choose **Interfaces** from the popup menu.
3. Select the checkbox for a specific interface, click the Action icon

   for the interface and choose **Edit**. The interface editor appears as shown in the figure below.
   Interface Editor, with editable Admin Status and Description settings



4. The editable settings are **Admin Status** (**Up** or **Down**) and **Description** (click inside the field to edit). In some cases, owing to device permissions, the device type or other device settings, you may not be able to edit these values for the selected interface.
5. To edit VLANs for the chosen interface, click the **VLAN** tab. The following figure shows an example. VLAN editing also is subject to permission limitations based on the device, and on the device type.

Editing VLANs



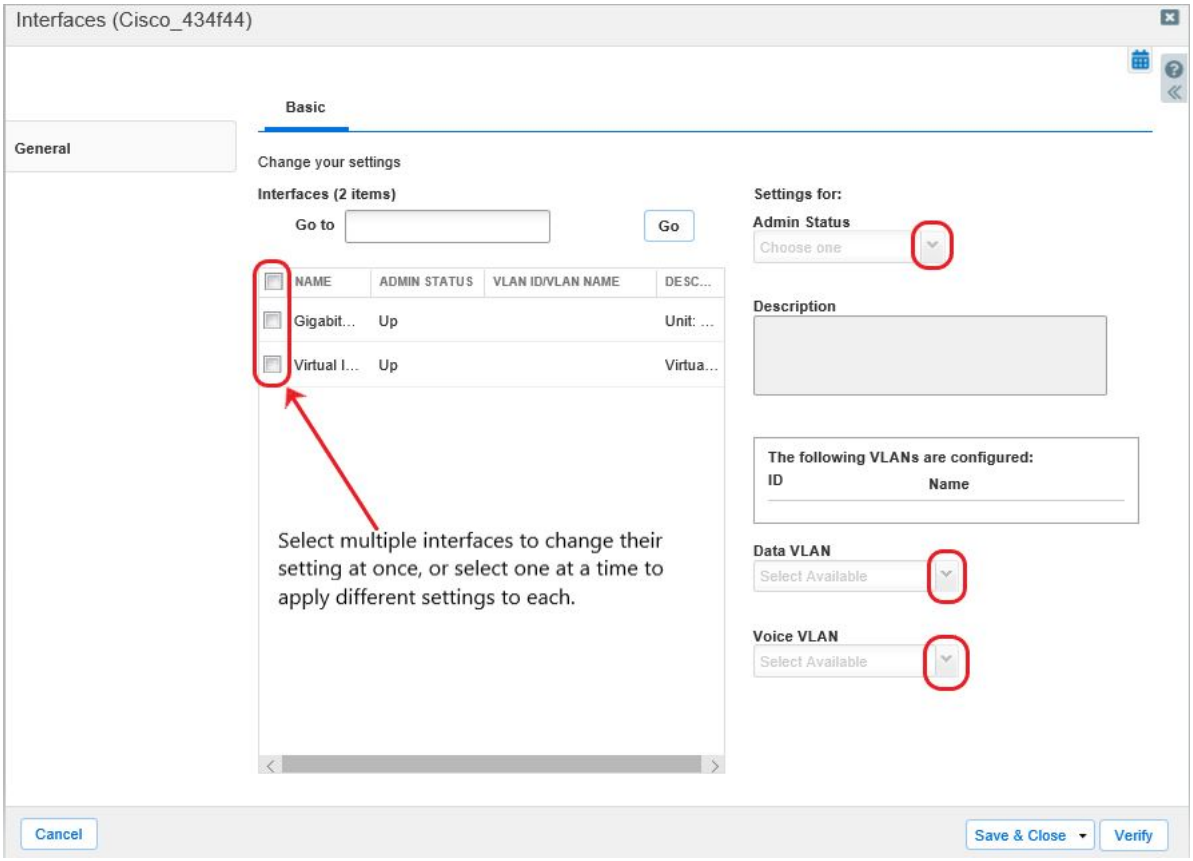
6. Choose a data VLAN to assign to the port from the **Data VLAN** drop-down menu.
7. If supported, choose a voice VLAN (Cisco only) from the **Voice VLAN** drop-down menu.
8. Click the **Extensible Attributes** tab to add any attributes that are necessary for the interface.
9. Click **Save & Close** to close the interface editor.

Editing Multiple Interfaces

To edit multiple interfaces for a device:

1. From the **Data Management** tab, select the **Devices** tab.
2. Click the Action icon

   for a chosen device and choose **Interfaces** from the popup menu.
3. Select the checkboxes for each interface that you want to edit.
4. Expand the Toolbar and click **Edit**. The Interfaces editor appears as shown in the figure below.
   Editing Multiple Interfaces



You can select one or more interfaces for configuration, define their settings in the dialog, and then select other interfaces and define different settings for them.

> ⚠ Note
>
> Once you change **Admin Status**, **Data VLAN** or **Voice VLAN** settings for any selected port, no automatic eversion exists to the original settings from the same editing session. You must cancel out of the Interfaces editor to reject any changes and begin with a new editing session from the **Interfaces** page. Use the **Verify** button to verify your changes.

5. Select the checkboxes for one or more ports and define the Port Configuration settings for the following:
   - **Admin Status**: Select Up or Down from the menu, depending on the current state of the port(s);
   - **Description**: Provide a brief description of the port configuration or other information;
   - **DataVLAN**: (Hidden if editing a VLAN is not supported) Drop-down list of all data VLANs actively configured in the current device. One of the values can be chosen for the currently select interface(s);
   - **VoiceVLAN**: (Hidden if editing a voice VLAN is not supported) Drop-down list of all voice VLANs actively configured in the current device. One of the values can be chosen for the currently select interface(s).
6. After making configuration changes to all ports, click **Verify** to check over your changes:

Verifying port configuration changes

7. Click **OK**. The changes are not committed by doing so.
8. If the port configuration changes are correct, click **Save & Close** or click the Scheduling icon at the top of the editor.

To schedule this task, click the Schedule icon at the top of the editor. In the *ScheduleChange* panel, click **Later**, and then specify a date, time, and time zone. The Schedule icon is green when there is a pending scheduled task. You can reschedule the task if you have the applicable permissions.

When you complete the configuration, all port configurations in the session are combined into a single task by Grid Manager.

Editing Multiple Interfaces from the Devices Page

The **Data Management –> Devices** page allows you to immediately set the Admin Status, descriptions and VLAN settings for any selection of ports on a single device.

1. Click the Action icon

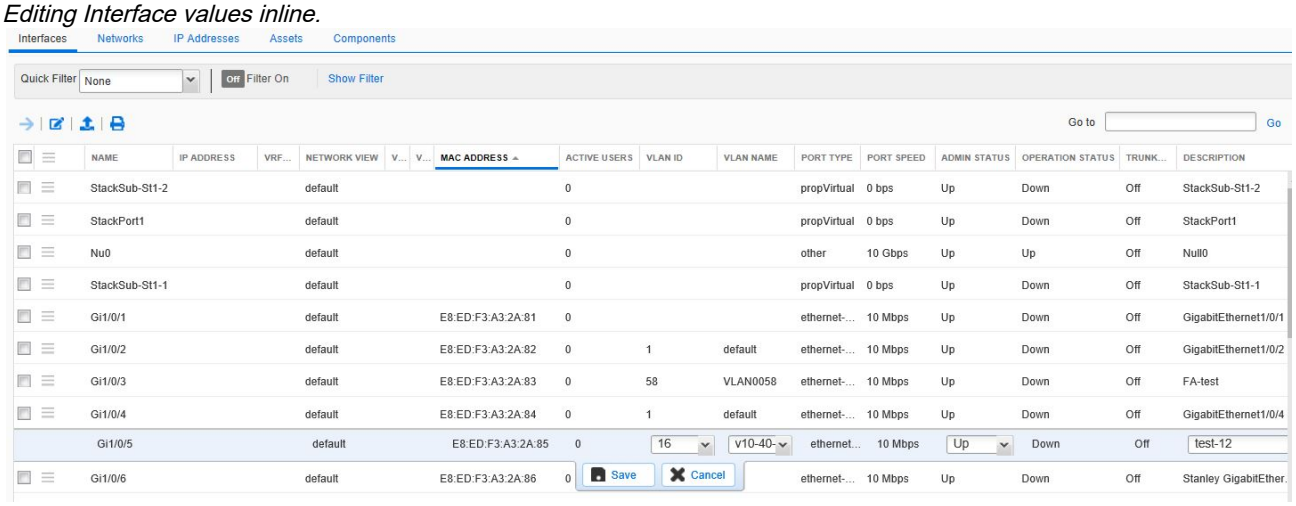
   for a chosen device and choose **Edit** from the popup menu. The **Interfaces** page appears for the device editor.
2. Select the checkboxes for one or more ports and define the Port Configuration settings for the following:
   a. **Admin Status**: Select Up or Down from the menu, depending on the current state of the port(s);
   b. **Description**: Provide a brief description of the port configuration or other information;
   c. **Data VLAN**: (Hidden if editing a VLAN is not supported) Drop-down list of all data VLANs actively configured in the current device. One of the values can be chosen for the currently select interface(s);
   d. **Voice VLAN**: (Hidden if editing a voice VLAN is not supported) Drop-down list of all voice VLANs actively configured in the current device. One of the values can be chosen for the currently select interface(s).
3. After making configuration changes to all ports, click **Verify** to check over your changes.
4. Click **OK**. The changes are not committed by doing so.
5. If the port configuration changes are correct, click **Save & Close** or click the Scheduling icon at the top of the editor. To schedule this task, click the Schedule icon at the top of the editor. In the *Schedule Change* panel, click **Later**, and then specify a date, time, and time zone. The Schedule icon is green when there is a pending scheduled task. You can reschedule the task if you have the applicable permissions.

When you complete the configuration, Network Insight combines all port configurations in the session into a single task.

Inline Interface Editing

You can directly edit a device's interface listings in the Interfaces page. Double-click any table row and the fields that you can edit for the row, which consist of the VLAN ID, Admin Status and **Description** fields for each interface, open in an inline editing selection field.
Fields are editable as applicable to device types. If you are editing an interface on a L2 switch, for example, the **VLAN ID** field does not appear.

Editing Interface values inline.



Double-clicking a table row opens the editable fields for the selected record.
If editable fields are not present in the table display, you cannot change their values in the **Interfaces** page.
After making inline changes, click **Save** on the selected row to commit them. To prevent using any changes, click **Cancel**. This also de-selects the row.

> **Note**
>
> When you make inline changes to an interface, a new task is created under Grid Manager, which you can view in the Task Manager page (for more information, see *Viewing Tasks*). A status icon appears next to the interface element you have changed, indicating the status of the new task and providing a link to the Task Manager page. New tasks appear with a status icon of Pending (||). When the new task completes, the icon changes to a green checkmark.

Monitoring Device Lifecycle and Vulnerabilities Using Advisor

Advisor is a subscription-based service that assists you in monitoring and maintaining network and security infrastructure based on released Common Vulnerabilities and Exposures (CVEs) and vendor product lifecycle announcements. It allows you to monitor the following equipment lifecycle and vulnerability data for the devices discovered by Network Insight:

- CVE Bulletin Count: The count of CVEs that affect the device.
- CVE Bulletin List: The names of manufacturer's CVEs that affect the device.
- End of Sale Date: The date announced by the manufacturer when the device cannot be ordered.
- End of Support Date: The date announced by the manufacturer when the device is no longer eligible for support.
- EOL Bulletin URL: The URL pointing to the manufacturer's announcement.
- EOL Status: The End of Life status of the device, e.g. Current, End of Sale, and End of Support.

You can execute Advisor at any time or configure it to run at specific intervals and time. For information, see *Configuring Advisor Properties*. In addition, you can use the "Device Advisor" report and *dashboard* and Advisor filters in Smart Folders.

You can view lifecycle and vulnerability data in the **Devices** tab. If not present, add the Advisor-related columns to the table. To do so, click a column header, click the down arrow, select **Columns** -> **Edit Columns**, and then select the Advisor-related columns. You can also view this data in the properties of any discovered device as described in the next section.

Also see Advisor Vendor Support Matrix below.

Viewing Advisor Data

To see lifecycle and vulnerability data for an individual device:

1. In the Grid Manager, select **Data Management** → **Devices**.
2. Select a device in the table and click **Edit**.
3. In the **Device Properties** editor, select **Extensible Attributes**. The **Value** column displays the lifecycle and vulnerability data, if detected for the device.

> **Note**
>
> Unlike regular extensible attributes that you can create to track NIOS objects, Grid Manager creates the Advisor extensible attributes automatically to obtain and display device lifecycle and vulnerability data.

Advisor Vendor Support Matrix

The following table lists vendors that support Advisor. It includes supported announcement types and the NIOS version when they were added or updated.

Vendor	Vulnerabilities	Lifecycle
8.4		
Cisco	Yes	Yes
8.4.4		
Arista	Yes	Yes
Blue Coat	Yes	Yes
Checkpoint	Yes	No
Infoblox	Yes	Yes
Juniper	Yes	Yes
Palo Alto Networks	Yes	Yes
8.6		
Aruba	Yes	Yes

Vendor	Vulnerabilities	Lifecycle
Avaya/Nortel	Yes	Yes
Brocade	Yes	Yes
Checkpoint (API updated)	Yes	Yes
Netscreen (same API as Juniper)	Yes	Yes

Viewing Discovery Status

> **Note**
>
> Opening Discovery Status for viewing requires Superuser permissions under Grid Manager.

You can view the complete discovery status of all devices or of selected devices.

To isolate devices for evaluation, use filtering to reduce the list. Click **Use Filter** at the top of the table and choose **IP Address**, **Name,** or **Overall Status** as the filter.

To view the discovery status, complete the following:

1. From the **Data Management** tab, select the **IPAM** or **Devices** tab.
2. In the Toolbar, click **Discovery Status**. The Discovery Status table is displayed.

The Discovery Status table lists detailed information about network devices and end hosts discovered through all methods, including SNMP, ICMP ping sweeps, and other processes. It includes:

- **IP Address**: the IPv4 or IPv6 address of the discovered device. You can filter the table by this value.
- **Name**: The name of the discovered device as reported through SNMP. You can filter the table by this value.
- **Type**: The discovered device type. Examples include **Router**, **NIOS**, **Switch-Router**, **Firewall**, **Load Balancer**, **LWAP**, and numerous others.
- **Overall Status**: Indicates the overall success or failure of the discovery task on the device. Hover the mouse over the device to see more detailed information about the discovery status, including the timestamp of the last discovery event, confirmation of detection ("Device Exists"), and the means of detection, which are usually methods such as SNMP, reading the ARP table or location through a Seed router. You can filter the table by this value.
- **Reached Status**: Indicates the reachability of the discovered device. Typically, devices are reported **Passed** for **Reached Status** if they are reachable through SNMP, a path trace through ICMP, or UDP-based path tracing for an IPv6 address.
  You may see a **Reached Status** of **Passed** and still receive an **Overall Status** of **Failed**. This often occurs because either the CLI credentials or SNMP credentials provided for discovering the device do not work, or another problem occurs in some part of the discovery process.
- **SNMP Collection Enabled**: Indicates whether the managed device allows SNMP as a management protocol. This value shows **Yes** or **No**. You do not see any SNMP collection status updates if this value shows No.
- **SNMP Credential Status**: Indicates whether the correct SNMP credential is used by discovery. Usually shows simple **Passed** or **Failed** status. Passing the mouse over the Failed status reading for this column shows the location in the SNMP data collection where information gathering failed. The typical message for a failure of this type shows Failure to Authenticate, which simply means that the correct SNMP credentials have not been provided for either SNMPv1, SNMPv2c, or SNMPv3 as required and defined for the device's discovery configuration. The tooltip also displays the name of the credential group that was used to guess credentials for the device.
  If **SNMP Credential Status** shows Failed, you do not see a value under **SNMP Collection Status**, because that is

dependent on successful credential authentication. Should you succeed in SNMP Credential Authentication for a device, this value shows **Passed**.

- **SNMP Collection Status**: Indicates whether managed device information has been successfully collected from the device. If the current device shows an **SNMP Credential Status** of Failed, this field remains blank. Should you succeed in SNMP Credential Authentication, **SNMP Collection Status** may or may not show a Passed outcome. If the final outcome is successful, passing the mouse over the table value shows the SNMP data set that was successfully collected from the device. When the **SNMP Collection Status** is set to **Passed**, it indicates that the credentials provided in *Member Discovery Properties* for discovering the device are correct and discovery has been completed successfully on the device. For more information, see *Defining the Discovery Member Type*.
- **CLI Credential Status**: Reports the basic success state of CLI credential usage for device discovery. When you see a Failed status in this column, hover the mouse over the table value. Details related to failed CLI credentials normally relate to "Failed to Authenticate" events. (For more information, see the following subsection Analyzing Discovery Status.) If you define device discovery requirements to use both SNMP and CLI, and you receive complete SNMP discovery information but fail to authenticate for CLI, the **Overall Status** for the device remains as **Failed**. The tooltip also displays the name of the credential group that was used to guess credentials for the device.
- **CLI Collection Enabled**: indicates the CLI collection configuration state for the discovered or managed device. Possible values are **Yes** (CLI collection is enabled) or **No** (CLI collection is disabled for the device).
- **Fingerprint Status**: Shows the status of discovery of the device's OS through fingerprinting.
- **Last Update**: Timestamp showing the conclusion of the last data update for the current device.
- **First Seen**: Timestamp showing the initial discovery event.
- **Last Seen**: The date and time when the device was last successfully polled by discovery.
- **Last Action**: The last action performed by discovery upon the device after the discovery took place. Hover the mouse over this field to obtain details.

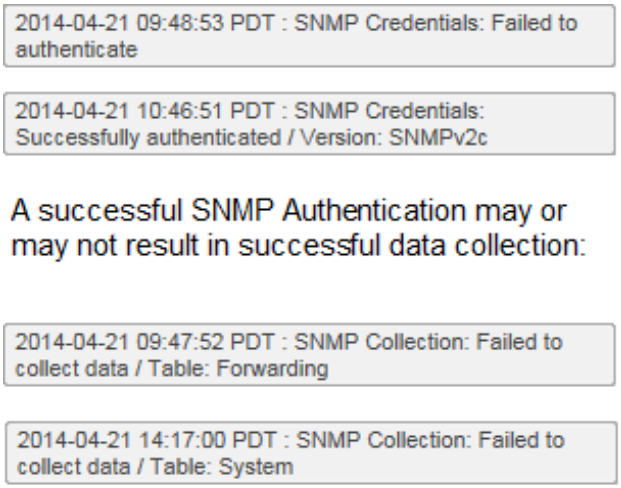
Visible columns can be changed in the Discovery Status window. At the top of any column header, click the down arrow tool, and choose **Columns** –> **Edit Columns**.

Analyzing Discovery Status

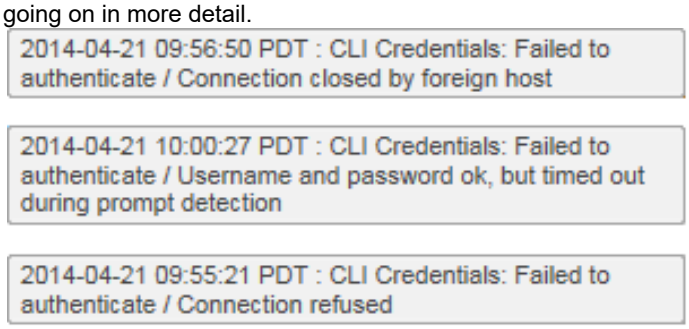
When you see the Failed status for a device under **Overall Status**, the problem usually relates to issues in discovery data collection. When **Overall Status** shows a value of **Passed**, it indicates that everything has passed for the device. If the value is Failed, it indicates that one or more elements of the device have failed discovery. Your discovery settings have a great deal to do with what you see in the respective Status columns. You key on the Overall Status result and read columns to the right to narrow down possible causes. To start, you typically see three basic discovery credential configurations for network devices:

- SNMP credentials and no CLI credentials;
- SNMP credentials and CLI credentials;
- No SNMP credentials, CLI credentials only.

Begin by considering SNMP-only device discovery configurations. In the table, **Overall Status** shows only a simple Failed message with no detail. Go to the next data column, which is **Reached Status**. If the device proves reachable, this value shows Passed, indicating that discovery can successfully reach and query the device. If **Reached Status** shows Failed, this is the first and most fundamental problem, that the device cannot be Pinged or contacted in any way across the network.
As an example, assume a **Reached Status** value of Passed. If the device is reachable, discovery can successfully attempt SNMP or CLI communication to the device. Beginning with SNMP, and assuming that SNMP collection is enabled, select the **SNMP Credential Status** counter. If it shows Failed, that normally indicates a Failure to Authenticate, which can be shown as a tooltip by hovering the mouse over the table field:



A successful authentication also shows which protocol was used for SNMP authentication; SNMPv1, SNMPv2c or SNMPv3. This does not guarantee successful data collection through SNMP, however.
The **SNMP Collection Status** counter shows possible Passed and Failed values. Hovering the mouse over a Failed value in this column shows a tooltip reporting the set of data that discovery could not collect through SNMP. When discovery encounters an error during collection of a specific data set (Forwarding table, or System identification data, for example), data collection stops and issues an error message and an SNMP trap, which is reported and also appears in the tooltip. If **SNMP Collection Status** shows a value of Passed, and discovery does not use CLI data collection on the device, discovery has successfully completed on the device.
The **CLI Credential Status** counter also reports either Passed or Failed results, and uses tooltips to tell the user what is going on in more detail.



CLI credentials failure messages are straightforward and can be tested by verifying login tuples or Enable passwords from the credential sets defined in discovery configuration.
If you receive a **CLI Credential Status** value of Passed, the correct command-line admin login information is specified in the discovery configuration.
For more information about checking and diagnosing discovery behavior for devices listed in the status table, see the following topic *Executing Discovery Diagnostics*.

Provisioning and De-Provisioning Networks

You may provision networks and remove or de-provision networks from individual devices. You can also provision networks when creating a network in IPAM (for more information, see *Adding IPv4 and IPv6 Network Containers and Networks*). Network provisioning and de-provisioning comprises the second type of port control tasks under Network Insight. Provisioning a network involves creating a new network and adding it to the list of networks in IPAM, and also involves changes to device configuration.

> **Note**
>
> If a port control task requires administrative approval, and it is not approved before its scheduled execution, the task appears as unsuccessful in Task Manager.

Provisioning networks also allows for provisioning VLANs. If devices do not support VLANs, options for provisioning VLANs do not appear for those devices and their associated interfaces.

If a network is already provisioned for an interface, regardless of its status under Grid Manager, you cannot provision another network upon it.

Only available interfaces that support network provisioning are shown in Grid Manager for provisioning tasks. The horizontal toolbar also provides related functions:

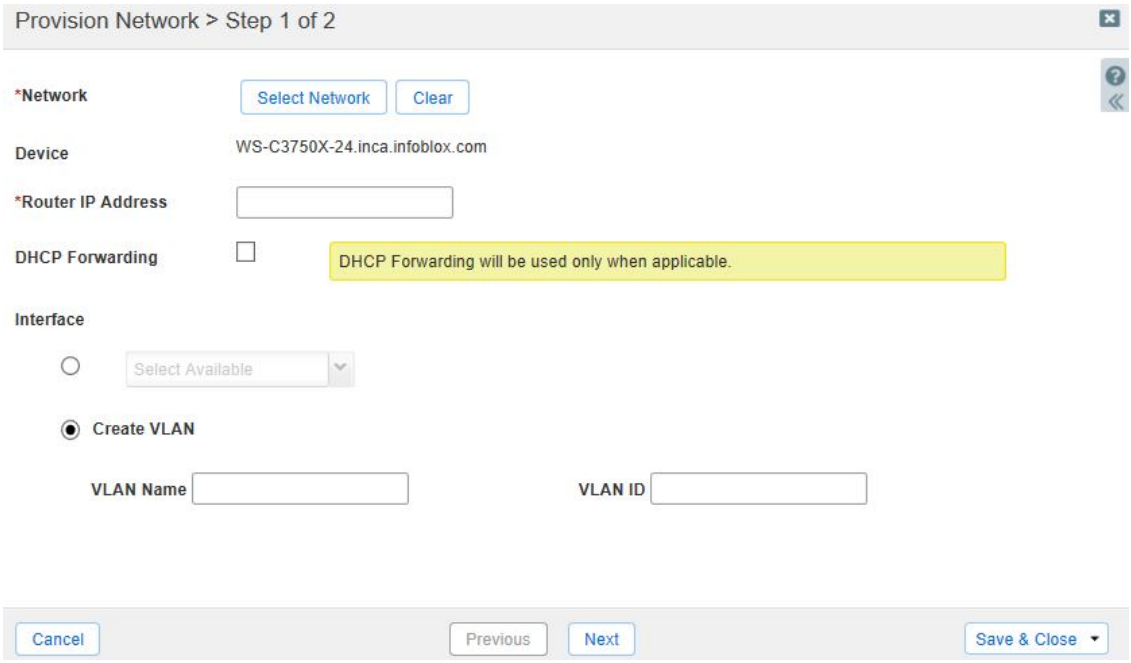
Provision Network : Available for discovered devices and for managed devices, this icon opens the **Provision Network** feature, allowing you to provision an existing IPAM network onto the selected device by selecting a device interface or assigning a VLAN. Grid Manager creates a new Port Control task, and you can choose the interface on which the network is provisioned, along with VLAN configuration and other settings.

De-provision Network : Available for networks that are managed under IPAM, for de-provisioning on devices that are managed under IPAM on the **Data Management –> Devices** page. A dialog box appears summarizing the task you are instructing Grid Manager to perform. This action changes the configuration of the device.

To provision IPAM networks onto a device:

1. From the **Data Management** tab, select the **Devices** tab.
2. Click the **Next Page** and **Last Page** icons to locate the device whose interfaces you want to provision.
3. Click the Name of the device. The Devices page displays the five tabs of information associated with the device.
4. Click the **Networks** tab.
5. The Networks page lists all discovered networks (highlighted in grey), unmanaged networks (highlighted in yellow), and any managed networks (highlighted in white, showing **Yes** in the **Managed** column) present on the selected device.
6. Open the vertical toolbar and click **Provision Network**. The Provision network wizard appears.
7. Click **Select Network** to choose the network the you want to provision. If only one managed network is available on the device, that network value is populated after clicking the button.
   If more than one managed network is available under IPAM, the Network Selector dialog opens, listing all networks managed under IPAM.
8. Choose the network to provision onto the device and click **OK**.
9. Enter the **Router IP Address**. This required field may be pre-populated with the DHCP router IP address if the device already has a DHCP configuration. If not, enter the gateway router IP address for the current device.
10. If necessary, check the **DHCP Forwarding** checkbox. Check this checkbox to enable DHCP forwarding for the newly provisioned network. If a DHCP failover is already present, the IP addresses from that failover are used for DHCP forwarding information.
11. For choosing the Interface, you can choose one out of two options:
    a. **Interface** drop down list: If you are provisioning the network directly onto an interface, select it from this list. Only interfaces that are available for provisioning on the chosen device appears on this list; interfaces that are already active in a network do not appear;
       –or–
    b. For a switch-router, select **Create VLAN**, and specify the **VLAN Name** and its new **VLAN ID**. Ensure that the VLAN ID is not one that is already provisioned on the device.

       Provisioning a VLAN on a Switch-Router



12. Click **Next** to go to the second step in the Provision Network wizard, in which you define whether to provision the configuration now or to schedule it.
13. To immediately provision the new network on the chosen device, select **Now**.
    a. You can choose to have Grid Manager create the network at a later time. To do so, select Later. Choose a **Selected** time by entering or selecting a **Start Date** (click the calendar icon to choose a calendar date) and a **Start Time**, and choose a **Time Zone**.
14. Click **Save & Close** when finished.

De-Provisioning Networks

> **Note**
>
> De-provisioning a network changes the device configuration. As such, a separate task is created for the action under Task Manager. However, you cannot schedule the de-provisioning of a network–once you confirm the de-provisioning action in Grid Manager, the action takes place. Each managed and unmanaged device under Grid Manager provides a Permissions page (**DataManagement–>Devices–>** Select Device **–>** click **Edit–>Permissions** tab). By default, no admin group or Role is assigned to managed devices. Infoblox recommends using caution when assigning rights to users that may be able to access devices and change device configurations.

De-provisioning networks is a relatively straightforward task that can be performed for any selected network, whether it is a non-NIOS network (a network that cannot be configured in IPAM), an unmanaged network, or a managed network.

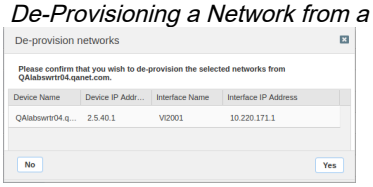
> **Note**
>
> If the network is also managed under IPAM, de-provisioning the network from a device does not delete the network from IPAM.

If you are deleting a network from the main IPAM page, any devices that have endpoints provisioned on that network are also de-provisioned for that network.

> **Note**
>
> A network may not be de-provisioned until after you set the interface for the network on the device(s), to **Down** in **Admin Status**.

1. From the **Data Management** tab, select the **Devices** tab.
2. Click the **Next Page** and **Last Page** icons to locate the device through which you want to locate the interfaces to convert.
3. Click the Name of the device. The Devices page displays the five tabs of information associated with the device.
4. Click the **Networks** tab for the chosen device. The Network page lists all discovered networks (highlighted in grey), unmanaged networks (highlighted in yellow), and managed networks (highlighted in white) present on the selected device.
5. Click the **Next Page** and **Last Page** icons to locate the network that you wish to de-provision.
6. Click the Action icon

   next to the network you want (this automatically selects it) and select **De-Provision Network**. The dialog box appears, listing the device name, the device's IP address, the interface to which the network is currently bound, and the network's endpoint IP address on the current device.
   De-Provisioning a Network from a Device



7. Click **Yes** to confirm the de-provisioning action.

> **Note**
>
> Ensure that the de-provisioning of the network has administrative approval.

You can also select multiple network entries from the list on the same device and de-provision all of them in a single step. Exercise caution when performing such actions.

De-Provisioning Networks by Deleting Networks in IPAM

> **Note**
>
> Deleting a network under IPAM creates a new Object Change task in Task Manager. You can check the **Administration–>Workflow–>TaskManager** page to view its status.

You can simply delete a managed or unmanaged network in IPAM to de-provision it. Doing so opens a Delete Confirmation dialog. IPAM also automatically prompts you to verify that you are deleting the network from all devices that have interfaces connecting to the network, subject to verification and permissions.

By default, when you delete the network, all devices that connect to the network, *that are also managed by IPAM*, are part of the new de-provisioning port control task created by Grid Manager. If you do not want the network de-provisioned from all devices, clear the **De-provision network from all interfaces** checkbox or simply cancel out from the Delete Confirmation dialog.

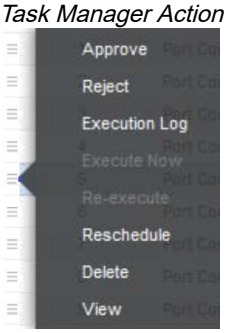
Troubleshooting Port Control Tasks

Issues can occur when attempting to define port configurations on devices. When you define port configurations through Network Insight, you are defining a *port control task* that can be viewed, investigated, and run again when necessary.

You do so by using the Task Manager (**Administration –> Workflow –> Task Manager**) and looking for tasks that show a **Type** of **Port Control**. Each Port Control task provides an Execution Log and the ability to re-run a task that has failed for any reason.

The Task Manager page provides an Action icon column with a series of menu options for features related to Grid Manager tasks to manage task execution, scheduling and approval. Menu choices change based upon the context and the current state of tasks in the table; features available in the Action menu include the following:

Task Manager Action menu



- **Approve**: Enables admins to approve a pending job.
- **Reject**: Enables admins to reject a pending job, immediately cancelling it.
- **Execution Log**: Opens a completed task's execution log window. the Execution Log lists the complete communications sequence sent to a device to perform a port control task.
- **Execute Now**: Force a selected pending task to execute immediately.
- **Re-Execute**: Allows you to re-run the selected task. Combined with the Execution Log, this process can aid in troubleshooting a failed port control task.
- **Reschedule**: Opens the Reschedule window for the selected task. To immediately execute this task, click **Now**. Or, in the *Reschedule* panel, click **Later**, and then specify a date, time, and time zone. You can reschedule the task if you have the applicable permissions. Click **Save** to commit the changes.
- **Delete**: Deletes the pending task.
- **View**: Opens the Task Viewer to the currently selected task. For related information, see *Using the Task Viewer to View Job Logs and Approve Jobs*.

The Execution Log allows you to see task behavior when it executes. You can check the configuration directly on the device and re-run the job if it has failed, by selecting **Re-execute** from the Action menu on the Task Manager page.

Supported Discovery Methods

When you perform a discovery, you can choose any or all of the following discovery methods:

- SNMPv1/v2c device polling as described in SNMP below.
- SNMPv3 device polling as described in SNMP below.
- CLI device querying as described in CLI below.
- ICMP Ping Sweep and Smart Subnet Ping Sweep as described in ICMP below.
- TCP as described in TCP below.
- NetBIOS as described in NetBIOS below.

These methods actively scan predefined networks and probe IP addresses. The appliance listens for responses from the IP addresses as proof of activity. The IP discovery scans through the specified network ranges and probes IP addresses (except for the network, broadcast, and multicast address types) in each network, including the /31 and /32 subnets. Note that addresses in the /31 and /32 subnets can be used only as source addresses for point-to-point links and loopbacks. In these cases, no broadcast or network addresses exist in the /31 and /32 subnets, and the appliance can discover source addresses in these subnets.

SNMP

> **Note**
>
> Infoblox does not recommend using vendor default SNMP credentials on network devices. Should you need to use vendor defaults for a given device type, you enter those values in the list of SNMP credentials on the Grid Master.

Network Insight supports discovery of devices and networks through SNMPv1/v2c and through SNMPv3 protocols. Discovery acquires information from standard SNMP MIB object IDs (OIDs) to correctly identify and catalogue devices. You enter or import lists of SNMP credentials with which the appliances query devices on the network to perform discovery.

SNMPv1 and SNMPv2c protocols are combined into a set termed **SNMPv1/v2** for discovery. SNMPv1/v2 discovery requires standard read community strings to be stored on the Grid Master.
Accounts using SNMPv3 use a standard suite of authentication and security protocols. If Network Insight uses SNMPv3 to collect data from devices supporting the protocol, you can define specific user credentials with combinations of authentication and protocol support, and the unique keys for each protocol. Network Insight also supports multiple entries for the same username string, enabling checking of similar SNMPv3 credentials that use different authentication and security protocols.
Some devices found by discovery may not have known SNMP credentials or credentials that are entered into the sets of SNMP credentials defined for discovery.

> **Note**
>
> SNMP Credentials from the Grid or from the Member credential list are always tried in the specified order unless a credential is associated with a host, fixed address or reservation being discovered.

CLI

> **Note**
>
> CLI is optional for discovery but is required for all Port Control operations. Discovery can perform CLI data collection to collect information for specific device types. SNMP is required for all device discovery.

Network Insight enables the use of dynamically created and closed Telnet and SSH command-line sessions to log in, query, and configure ports using each device's command-line syntax. Network Insight does so without requiring extensive configuration from the user. You need to provide known admin account login information and any Enable passwords for devices in the networks to be discovered. CLI credentials are required for port reservation and port configuration operations under Grid Manager. You enter CLI credentials under Grid Discovery Properties (**Grid –> Grid Manager –>** click **Edit –> Grid Discovery Properties**) to be inherited by discovery Probe members, and as necessary for each discovery Probe member. You can also override them for individual IPAM objects (fixed addresses, hosts and IPv4 reservations) and test the CLI credentials against devices for correctness. For more information, see *Testing SNMP and CLI Credentials*.

ICMP

Discovery uses different variations of Ping traces to perform higher-performance, brute-force device discovery. ICMP is the last resort when devices do not support SNMP management protocols or an SNMP credential is lacking.
The ICMP Smart Ping Sweep option enables brute-force subnet Ping sweeps on IPv4 networks. Subnet ping sweeps are used as a last resort in the discovery process. A subnet ping sweep is performed if Network Insight is unable to identify any network devices in a given subnet. Subnet ping sweeps are performed no more that once per day, and will end the

ping sweep on a given subnet once Network Insight discovers a network device and is able to collect data from it. You can configure the timeout value (**Ping Sweep Timeout**) and the number of attempts (**Ping Sweep Attempts**).

> ⚠ Note
>
> Smart subnet ping sweeps are not performed on subnets larger than /22. Ping sweeps of any kind do not apply on IPv6 networks because of the greater scale of network addresses in the IPv6 realm.

Complete Ping Sweep differs from the Smart Subnet ping sweep in the following ways:

- The discovery ping sweep runs only against the specified range.
- The sweep runs regardless of the range size.
- The sweep runs regardless of the number of discovered devices within the specified range.

Discovery also performs automatic Ping traceroutes when needed for path collection. Path collections run without user intervention or configuration.

TCP

TCP scanning probes each active host on a list of TCP ports using TCP SYN packets. This method detects all active hosts that generate SYN ACK responses to at least one TCP SYN. The discovery can determine the OS on a host by analyzing how the host reacts to the requests on opened and closed ports. It then uses the TCP fingerprints to guess the OS. To obtain a TCP fingerprint, IP discovery provides two scanning techniques, SYN and CONNECT.
When you use the SYN technique, the discovery sends a TCP SYN packet to establish a connection on a TCP port. If the port is open, the host replies with a SYN ACK response. The discovery does not close the port connection.
The CONNECT technique is a three-way TCP handshake. The discovery starts with the same process as the SYN technique by sending the TCP SYN packet. A response containing a RST flag indicates that the port is closed. If the host replies with a SYN ACK response, discovery sends a RST packet to close the connection. If there is no reply, the port is considered filtered. TCP scanning is a deliberate and accurate discovery method, enabling detection of all active hosts on a network provided that there are no firewalls blocking TCP packet exchanges.
You can choose the TCP ports and the TCP scanning technique in the *Grid Discovery Properties* editor. This method returns the following information for each detected host:

- **IP address**: The IP address of the host.
- **MAC address**: The discovery returns the MAC address only if the Probe member running the discovery is on the same discovered network.
- **OS**: This is set to the highest probable OS reported in the response.

To use the TCP discovery method, the TCP port and a specific set of ports between the Probe member and the discovered networks must be unfiltered. The default set of ports is defined by the factory settings.

TCP Port Scanning

By enabling port scanning, Network Insight probes the list of TCP ports enabled in the Advanced tab, to determine whether they are open. You can control some settings for port scanning behavior, including the choice of a TCP scanning technique.

- Profile Device: If enabled, Network Insight attempts to identify the network device based on the response characteristics of its TCP stack, and uses this information to determine the device type. In the absence of SNMP access, the Profile Device function is usually the only way to identify devices that do not support SNMP. If you disable Profile Device, devices accessible via SNMP are still correctly identified; all other devices are assigned a device type of **Unknown**. **Profile Device** is disabled by default for discovery polling.

The Profile Device option uses the editable list of TCP protocol ports from the **Grid Discovery Properties –> Polling –> Advanced** tab as its profile, and polls each of the ports enabled in that list, using the configured timeout value and the number of polling attempts for each port.
For more information, see *Defining Seed Routers for Probe Members*.
Should you disable Port Scanning, discovery attempts no port probes other than SNMP on any device.

NetBIOS

The NetBIOS method queries IP addresses for an existing NetBIOS service. This method detects active hosts by sending NetBIOS queries and listening for NetBIOS replies. It is a fast discovery that focuses on Microsoft hosts or non-Microsoft hosts that run NetBIOS services.
NetBIOS discovery returns the following information for each detected host:

- IP address: The IP address of the host.
- NetBIOS name: This value is set to the name returned in the NetBIOS reply.

To use the NetBIOS discovery method, ports 137 (UDP/TCP) and 139 (UDP/TCP) between the Grid member performing the discovery and the target networks must be unfiltered.
The following table summarizes the supported discovery methods:

Discovery Type	Returned Data	Guideline	Mechanism
Smart IPv4 Subnet Ping Sweep	• IP address • MAC address	Apply on known subnetworks on which no devices are readily found. Limited to networks of /22 and smaller.	ICMP echo request and reply.
Complete Ping Sweep	• IP address • MAC address	Last resort for discovery. Use ICMP for a rough and fast discovery. Enables path tracing.	ICMP echo request and reply, ICMP traceroute.
NetBIOS	• IP address • NetBIOS name	Use NetBIOS for discovering Microsoft networks or non-Microsoft networks that run some NetBIOS services	NetBIOS query and reply.
TCP	• IP address • MAC address • OS	Use TCP for an accurate but slow discovery	TCP SYN packet and SYN ACK packet.
Port Scanning/ Profile Device	• Open and Closed TCP ports • IP Address	Disabled by default, use for non-SNMP devices.	Scans specified list of TCP ports, using TCP SYN packet.

Discovery Type	Returned Data	Guideline	Mechanism
SNMPv1/v2 SNMPv3	• Open and Closed TCP ports • IP Address • System Description • System Up Time • Routing Neighbors • Routing and Forwarding Tables • ARP tables • SNMP credentials	Most important protocols for discovery. Ensure you have the SNMP credentials necessary for probing devices using SNMP.	Queries and collects system OIDs such as SysDescr and sysUpTime.
CLI (Device Command-Line by Telnet or SSH)	• Similar data set to SNMP • May be used instead of, or in combination with, SNMP	Requires correctly defined admin login tuples and Enable passwords where needed for device types. You may test credentials against devices and assign CLI credentials to individual objects, overriding Grid-level and Network-level credential settings.	Uses standard device-language scripts and configured Telnet or SSH connection settings to collect discovery data.

Discovery Type	Returned Data	Guideline	Mechanism
vDiscovery	• IP address • MAC address • OS • Discovered name • Virtual entity type • Virtual entity name • Virtual cluster • Virtual datacenter • Virtual switch • Virtual host • Virtual host adapter	Add the VMware vSphere servers on which you want to perform the vDiscovery. For information about how execute a vDiscovery, see *Configuring vDiscovery Jobs*.	The appliance communicates with the vSphere servers to collect discovery data on virtual machine instances.

Starting and Stopping the Discovery Service

> **Note**
>
> The discovery service can only be started on Grid members that are configured as the Consolidator or Probe (i.e. the Grid members with valid Discovery installed).

Each discovery member requires separate **Discovery** licenses, and must have a running discovery service. Consider the following before starting or stopping the discovery service:

- The Grid Master does not run the discovery service.
- Appliances running a Discovery license and the discovery service do not support HA pairs.
- Discovery Probe appliances appear as Grid members in Grid Manager.
- All appliances running discovery must have the Discovery license installed before starting the service.
- Appliances running discovery do not run core network services such as DNS and DHCP. Discovery appliances may also run the NTP service.
- If you expect to run a single appliance in the Grid for discovery, the appliance is designated as a Consolidator, and also performs Probe discovery operations.
- When you add a new Grid member with a Discovery license, the appliance is set automatically to the following:
  - A Consolidator, if no other discovery member exists in the Grid.
  - A Probe, when at least one discovery appliance exists in the Grid

> **Note**
>
> When a member joins the Grid and applies a Discovery license for the first time, the admin user needs to log off and log in again to Grid Manager to see the discovery-enabled functionality.

For information about discovery configuration at the service level, see *Configuring Discovery Properties*.

Starting the Discovery Service

To start the discovery service on a licensed Consolidator or Probe appliance:

1. From the **Grid** tab, select the **Grid Manager** tab, and click the **Services** tab.
2. Click the **Discovery** icon to display the list of members running the discovery service.
3. Select the discovery member or members for which you wish to start the service.
4. Expand the Toolbar and click **Start**.
   The appliance asks you to verify that you want to proceed with starting the service for the selected member.
5. Click **Yes**.

Stopping the Discovery Service

To stop the discovery service on the Consolidator or Probe appliance:

1. From the **Grid** tab, select the **Grid Manager** tab, and click the **Services** tab.
2. Click the **Discovery** icon to display the list of members running the discovery service.
3. Select the discovery member or members for which you wish to stop the service.
4. Expand the Toolbar and click **Stop**.
   The appliance asks you to verify that you want to proceed with stopping the service for the selected member.
5. Click **Yes**.

Managing Discovered Data

After a discovery, key information is collected and displayed in the following tabs: **Data Management** tab -> **Devices** -> **Interfaces**, **Networks**, **IP Addresses**, and **Assets** tabs of Grid Manager. You can view information about each discovered entity in one of these tabs. For more information, see *Viewing Discovered Devices and their Properties*.
A discovered entity is considered "unmanaged" if it is discovered in a network for which no information is being stored in the NIOS database. You are not able to configure unmanaged objects in NIOS. Depending on the nature of the discovered entity, you may convert certain unmanaged entities into managed objects so you can manage them through Grid Manager. When an entity is in the managed state, you can configure settings such as applying permissions to it, limiting who can modify the configurations and deployments, and when those changes can be applied. You cannot do so with unmanaged objects.
Grid Manager allows you to convert certain unmanaged devices, interfaces, networks, and assets to the following IPAM object types:

- Host record, as described in *About Host Records*.
- A and PTR records, as described in *Managing A Records* and in *Managing PTR Records.*
- Fixed IPv4 Address, as described in *Configuring IPv4 Fixed Addresses.*
- Fixed IPv6 Address, *Configuring IPv6 Fixed Addresses*.

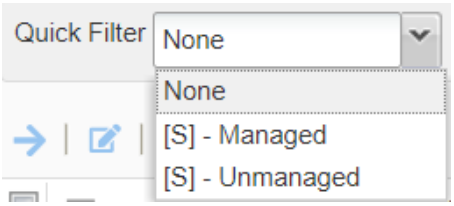
When converting unmanaged entities to managed objects in NIOS, you can choose to convert them one at a time or as a group. To convert a single entity, just select a specific entity and perform the conversion. To convert multiple entities to the same IPAM object type, you can select the entities you want to manage and then perform a bulk conversion. You can also perform an automatic conversion for unmanaged entities in a network view by configuring conversion rules at the Grid level. For information about how to create conversion rules, see *Configuring Automatic Conversion Rules*.

> **Note**
>
> In a bulk conversion, if one or more of the selected entities are not eligible for conversion because they do not have a discovered name (FQDN) or due to other reasons, Grid Manager displays a warning message indicating only eligible entities are displayed in the conversion wizard and qualified for conversion. Those that cannot be converted are ignored and will remain in unmanaged state.

For more information about how to convert unmanaged entities to managed objects, see the following sections:

- For unmanaged devices, see Converting Unmanaged Devices to Managed Devices below.
- For unmanaged interfaces, see Converting Unmanaged Interfaces to Managed Status below.
- For unmanaged networks from the **Data Management** -> **Devices** -> **Networks** tab, see Converting Unmanaged Networks to Managed Status below.
- For unmanaged networks from the **IPAM** or **DHCP** tab, see Converting Unmanaged Networks under IPAM to Managed Status below.
- For unmanaged IP Addresses, see *Converting Unmanaged IP Addresses to Managed Status below.*
- For unmanaged assets, see Converting Unmanaged Assets to Managed Status below.
- For automatic conversions using global conversion rules, see *About Automatic Conversion Rules*.

Converting Unmanaged Devices to Managed Devices



> **Note**
>
> For convenience, the home **DataManagement–>Devices** page provides a quick filter to list only managed devices. In the Devices page, all devices highlighted in yellow indicate a device that is unmanaged.

Device discovery allows you to define a fully managed state for any discovered routers, switches, firewalls, end hosts, and other network infrastructure devices. The process differs from converting an unmanaged network, because you can bind a discovered device to a fixed address, a PTR Record, a host record or an IPv4 reservation. Doing so offers the following benefits:

- **Host Record** – Infoblox hosts are data objects that contain DNS, DHCP, and IPAM data of the assigned addresses. Host objects allow you to assign multiple IPv4 and IPv6 addresses to a host. When you create a host record, you are specifying the name-to-address and address-to-name mappings for the IP address that you assign to the host. The Infoblox DNS server then uses this data to respond to DNS queries for the host. This establishes the identity of any infrastructure device or asset on the network. For more information, see *About Host Records.*
- **A Record** – An A (address) record is a DNS resource record that maps a domain name to an IP address. A records essentially tell DNS that a host exists inside a domain, as part of a forward-mapping zone. All traffic to a domain or subdomain is directed to the IP address specified by the A record. The DNS zone must exist in the Grid Manager before attempting to assign A records to devices. For more information about A records, see *Managing A Records.*
- **PTR Record** – Maps a device IP address to a host name in a reverse-mapping zone. The zone must already be defined before assigning the new PTR record object. For more information about PTR records, see *Managing PTR Records*.
- **Fixed Address** – A fixed address represents a persistent link between an IP address and one of the following: MAC address, Client identifier, or Circuit ID/remote ID in the DHCP relay agent option (option 82). Most applications in the current context are for a MAC address. You can configure fixed addresses for network devices,

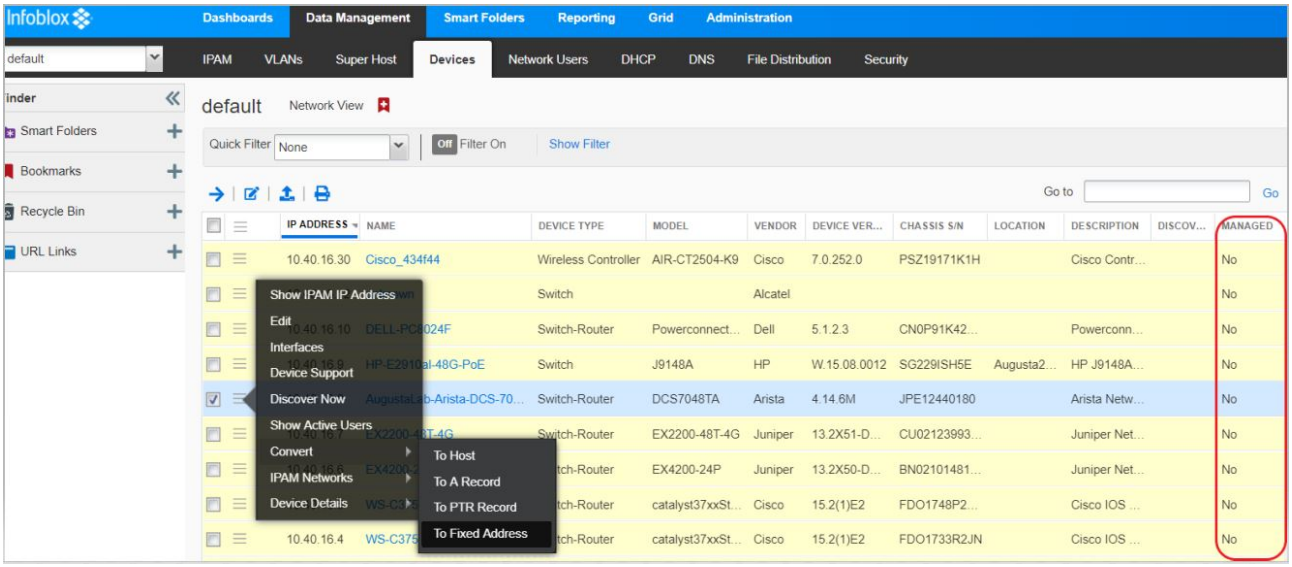
such as routers and printers, that do not frequently move from network to network. By creating fixed addresses for network devices, clients can reliably reach them by their domain names. Some network devices, such as web or FTP servers, can benefit from having fixed addresses for this reason. For more information about these object types, see *Configuring IPv4 Fixed Addresses* and *Configuring IPv6 Fixed Addresses*.

Each object type has its own characteristics that you may apply to specific types of discovered devices. For many infrastructure devices such as routers, or Assets such as servers, a fixed address is a likely choice.
Begin by examining the **Data Management –> Devices** page. The **Managed** column, as shown in in the following figure, can list one of three possible states for all discovered devices:

- Blank value–indicates that the device is not known to IPAM, because insufficient information is available to identify and catalog the device at the present time;
- **No**–Shows that the device in the Devices table is not managed under IPAM or Grid Manager, but enough information is collected and the device can be converted to the Managed state.
- **Yes**–The device in the table is a managed object with an IPAM object type (host, A record, PTR record or fixed address).

An Action icon (shown as a gear in each row for the table) provides the quickest access to the **Convert** feature for unmanaged devices, as shown in the following figure. You can also click **Convert** in the Toolbar to select the object type.

Unmanaged Devices That May be Converted to IPAM objects



To convert unmanaged devices to managed objects:

1. From the **Data Management** tab, select the **Devices** tab.
2. Click the **Next Page** and **Last Page** icons to locate the device you want to convert.
3. To convert a single device : Click the Action icon

   next to the device you want to convert (this automatically selects it), and then select **Convert –> To Host**, **To A Record**, **To PTR Record**, or **To Fixed Address** from the menu.
   To convert multiple devices (bulk conversion): Select the checkboxes of the devices you want to convert to the same IPAM object type. From the Toolbar, select **Convert -> To Host**, **To A & PTR Record**, or **To Fixed Address** from the menu.
4. For a single device: The respective object editor appears based on the conversion type you have selected. For example, if you select **To Host**, the *Host* editor appears. In the editor, define the required **General** settings for the new object. You can also define other settings you need from any of the tabs in the editor. For details about how to configure these settings, refer to the online Help in Grid Manager or see the appropriate sections in this guide.
   For bulk conversion: The respective bulk conversion wizard (such as the *Convert Unmanaged IP Addresses to Host Record* wizard) appears based on the conversion type you have selected.
   Note that the Network Insight creates the names of the new managed objects using the Discovered Name (FQDN) for the entities being converted. In the wizard, Grid Manager displays the IP addresses of the selected

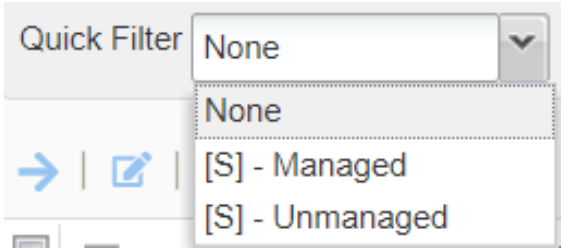
devices that are eligible for conversion in the **Selected IP Addresses** table. Entities that are not eligible for conversion will not be converted and will not appear in this table.
Based on the selected conversion type, complete the following to start a bulk conversion:

a. **To Host**: You can select **Enable in DNS** and/or **Enable in DHCP** so the appliance can serve DNS and/or DHCP for the selected IP addresses in the host record. When you enable DNS, you must select a DNS zone for all entities that do not have an FQDN.
b. **To A & PTR Record**: Network Insight converts the selected entities to A & PTR records simultaneously. You must select a DNS zone for all entities that do not have an FQDN.
c. **To Fixed Address**: Network Insight automatically converts all selected IP addresses to fixed addresses in a bulk conversion. As with host record and A/PTR record conversions, entities without a Discovered Name are not eligible for conversions to fixed addresses.

5. In all bulk conversions, you can define extensible attributes for the selected IP addresses. After you configure the necessary settings, you can convert the discovered entities immediately or schedule the conversion by selecting **Later** and entering the date and time.
6. Click **Save & Close** to make the conversion. You can return to the managed object at any time to make further configuration changes.

In the **Managed** column for all converted entities, Grid Manager displays **Yes** to indicate their managed status. You can now manage these IPAM objects through Grid Manager.

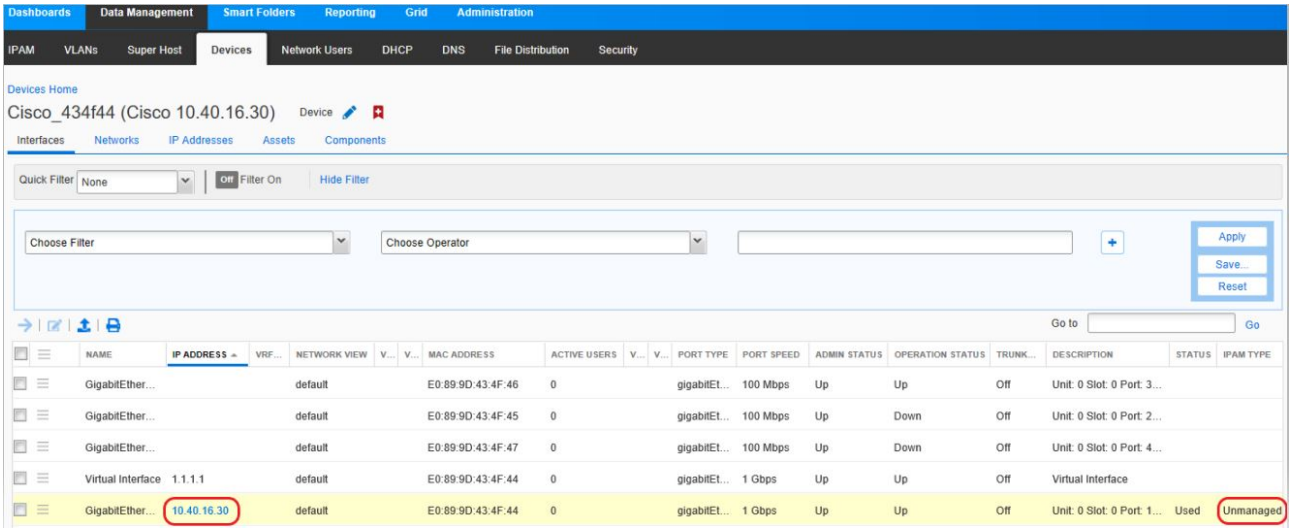
Converting Unmanaged Interfaces to Managed Status



> **Note**
>
> For convenience, a device Interfaces panel provides a quick filter to list only managed interfaces for the device. When a device is converted to managed status, interfaces in the device may remain in unmanaged state. If the interface has an IP address that is recognized under IPAM, it may be converted to managed state.

Interfaces that appear in the Interfaces table for a device may be converted to managed status, under specific circumstances. If an interface is bound to an IP address that is present in an IPAM network (for example, a leaf network inside a network container under IPAM), that interface can be converted to managed status.
For any device, any interface with a hotlink to IPAM may be converted. Examples are shown in the following figure.

Device Interfaces Available for Conversion



In the figure above, two interfaces provide a link to their respective IPAM interface pages, and show an **IPAM Type** of **Unmanaged**. These ports may be converted to IPAM objects and managed under Grid Manager.

1. From the **Data Management** tab, select the **Devices** tab.
2. Click the **Next Page** and **Last Page** icons to locate the device through which you want to locate the interfaces to convert.
3. Click the **Name** link of the device.
4. Click the **Interfaces** tab for the chosen device. This tab lists all ports discovered on the device.
5. To convert a single interface: Click the Action icon

   next to the interface you want to convert (this automatically selects it), and then select **Convert –> To Host**, **To A Record**, **To PTR Record**, or **To Fixed Address** from the menu.
   To convert multiple interfaces (bulk conversion): Select the checkboxes of the interfaces you want to convert. From the Toolbar, select **Convert -> To Host**, **To A & PTR Record**, or **To Fixed Address** from the menu.
6. For a single interface: The respective object editor appears based on the conversion type you have selected. For example, if you select **To Host**, the *Host* editor appears. In the editor, define the required **General** settings for the new object. You can also define other settings you need from any of the tabs in the editor. For details about how to configure these settings, refer to the online Help in Grid Manager or see the appropriate chapters in this guide.
   For bulk conversion: The respective bulk conversion wizard (such as the *Convert Unmanaged IP Addresses to Host Record* wizard) appears based on the conversion type you have selected.
   Note that the Network Insight creates the names of the new managed objects using the Discovered Name (FQDN) for the entities being converted. In the wizard, Grid Manager displays the IP addresses of the selected devices that are eligible for conversion in the **Selected IP Addresses** table. Entities that are not eligible for conversion will not be converted and will not appear in this table.
   Based on the selected conversion type, complete the following to start a bulk conversion:
   a. **To Host**: You can select **Enable in DNS** and/or **Enable in DHCP** so the appliance can serve DNS and/or DHCP for the selected IP addresses in the host record. When you enable DNS for the record, you must select a DNS zone for all entities that do not have an FQDN.
   b. **To A & PTR Record**: Network Insight converts the selected entities to A & PTR records simultaneously. You must select a DNS zone for all entities that do not have an FQDN.
   c. **To Fixed Address**: Network Insight automatically converts all selected IP addresses to fixed addresses in a bulk conversion. As with host record and A/PTR record conversions, entities without a Discovered Name FQDN are not eligible for conversions to fixed addresses.
7. In all bulk conversions, you can define extensible attributes for the selected IP addresses. After you have configured the necessary settings, you can convert the discovered entities immediately or schedule the conversion by selecting **Later** and entering the date and time.

7. Click **Save & Close** to make the conversion. The interface is associated with the new IPAM object.
   In the **IPAM Type** column for all converted entities, Grid Manager displays **Managed** to indicate their managed status. You can now manage these IPAM objects through Grid Manager.

Converting Unmanaged Networks to Managed Status

On the **Data Management –> Devices** page, click a device name, and then open the **Networks** tab. You see the following types of networks based on their managed or unmanaged status:

- Unmanaged: These networks are displayed in yellow rows with the value of **No** in the Managed column. Shows that the network is not managed under IPAM/Grid Manager, but enough information is catalogued so that the network can be converted to managed status. You can provision these networks onto devices.
- Managed: These networks are displayed in white rows with the value of **Yes** in the Managed column. These networks are currently managed under IPAM, converted to an IPAM network. You can provision and de-provision managed networks.
- The so called "non-NIOS networks": These networks are displayed in grey rows with a blank value in the Managed column. Indicates that the network is discovered but available information is insufficient to identify and catalog the network in IPAM at the present time. This can be due to the following reasons:
    - The admin or operation status of the corresponding interface is "down". That is, the interface is either disconnected physically or disabled by administrator.
    - The prefix length for the network is /32 (ipv4) or /128 (ipv6). Network Insight treats this as a route to a specific device rather than a subnet, therefore it does not create such network in IPAM.
    - The route for this interface is configured incorrectly.
    - The route is learned from a remote source via BGP, OSPF and so on (i.e., indirect next hop), or come from a static route using the netmgmt protocol. Network Insight creates networks in IPAM for only direct and local routes from routing tables.
    - The network is within a VRF and the VRF is not mapped to a network view. VRF mapping is required in this case for the network to appear in IPAM. Some time after the VRF is mapped, the network turns from non-NIOS to unmanaged, or managed if the network is already present in IPAM.

Unmanaged networks listed under discovered devices present the same conversion features as networks listed under IPAM (see the following section Converting Unmanaged Networks under IPAM to Managed Status below).

Converting a network in the device context is the same as converting it at the top IPAM level. You cannot apply services or IPAM objects to IP addresses in unmanaged networks until the networks are converted to managed status. Many operations cannot be carried out on unmanaged networks, including editing, splitting, resizing, permissions changes and many other tasks.

1. From the **Data Management** tab, select the **Devices** tab.
2. Click the **Next Page** and **Last Page** icons to locate the device through which you want to locate the assets to convert.
3. Click the device name.
4. Click the **Networks** tab.
5. To convert a single network: Click the Action icon

   next to the network you want to convert to the Managed state (this automatically selects it), and then select **Convert** from the menu.
   To convert multiple networks (bulk conversion): Select the checkboxes of the networks you want to convert to the Managed state. From the Toolbar, select **Convert** from the menu.
6. The *Network* editor appears. In the editor, define the required **General** settings for the network. You can also define other settings you need from any of the tabs in the editor. For details about how to configure these settings, refer to the online Help in Grid Manager.
   Note Networks inherit discovery setting from their parent networks. Discovery will be disabled for networks that do not have a parent network.

1. If necessary, select the **Disable for DHCP** checkbox. When you convert a network to managed status, Grid Manager uses the discovered Router IP for the network to automatically populate the Router IP value in DHCP configurations for the selected network. Selecting this option disallows the converted network from being usable under DHCP.
2. If necessary, click the **Discovery** tab and click **Enable Discovery** to start discovery on the network after it is converted to Managed state. You can also elect not to discover the network, by leaving the checkbox clear.
    - Click **Select Member** to choose the Probe member through which the network may be discovered.
    - If necessary, click **Override** under **Polling Options**, and modify the device discovery polling options for the network. You can also specify **Discovery Exclusions** or a **Discovery Blackout** period.

- A number of associated DNS and DHCP services are also available for configuration for the new IPAM network, including DHCP Forwarding, IPv4 DDNS settings, and an array of other DDI service settings for the network. None of these configurations are required in order for the network to be in Managed state, but may be required for other purposes.

7. Click **Save & Close** to make the conversion.
   In the **Managed** column in the **Networks** tab, Grid Manager displays **Yes** for all converted entities to indicate their Managed status. You can now manage the networks through Grid Manager.

Converting Unmanaged Networks under IPAM to Managed Status

> **Note**
>
> When you convert a network to managed status, Grid Manager uses the discovered Router IP for the network to automatically populate the Router IP value in DHCP configurations for the selected network. Conversion for DHCP is optional; you can choose to **DisableforDHCP** when you convert the network.

The IPAM tab lists all discovered networks as unmanaged, highlighted in yellow. Administrators cannot apply services or IPAM objects to IP addresses in unmanaged networks until the networks are converted to managed status. You can explore unmanaged networks through the IP Map and IP List views, but many operations cannot be carried out on unmanaged networks, including editing, splitting, resizing, permissions changes and other tasks.

> **Note**
>
> Unmanaged IP addresses that are part of an unmanaged network cannot be independently converted to a managed IP address.

Unmanaged networks can be converted at the IPAM main page and at the device level under **Data Management –> Devices**, selecting a device and opening the **Networks** page.
Under IPAM, the **Managed** column for the Network tables can show one of two possible states for all discovered IPAM networks:

- **No**–Shows that the network is not managed under IPAM/Grid Manager, but enough information is catalogued that the device can be converted to Managed state. This state is required before a network can be converted to managed status.
- **Yes**–The network shown in the table is now Managed under IPAM, converted to an IPAM network.

You can discover the network again after it is converted, or keep discovery disabled and execute it at another time, or impose blackout periods that limit the time windows under which discovery can execute on the network. Other management benefits include the ability to enable Infoblox services to the network;

1. From the **Data Management** tab, select the **IPAM** tab.
2. To convert a single network: Click the Action icon

   next to the network you want to convert to the Managed state (this automatically selects it), and then select **Convert** from the menu.
   To convert multiple networks (bulk conversion): Select the checkboxes of the networks you want to convert to the Managed state. From the Toolbar, select **Convert** from the menu.
   You do not need to take further action other than **Save & Close** to set the network as Managed.
3. If necessary, you can select the converted network and do the following in the *Network* editor:
4. Select the **Disable for DHCP** checkbox to disallow the converted network from being usable under DHCP.
   - If necessary, click the **Discovery** tab and click **Enable Discovery** to start discovery on the network immediately after it is converted to Managed state. You can also elect not to discover the network, by leaving the checkbox clear.
   - Click **Select Member** to choose the Probe member through which the network may be discovered.
   - If necessary, click **Override** under **Polling Options**, and modify the device discovery polling options for the network. You can also specify **Discovery Exclusions**, port control settings, or a **Discovery Blackout** period.

- A number of associated DNS and DHCP services are also available for configuration for the new IPAM network, including DHCP Forwarding, IPv4 DDNS settings, and an array of other DDI service settings for the network. None of these configurations are required in order for the network to be in Managed state, but may be required for other purposes.

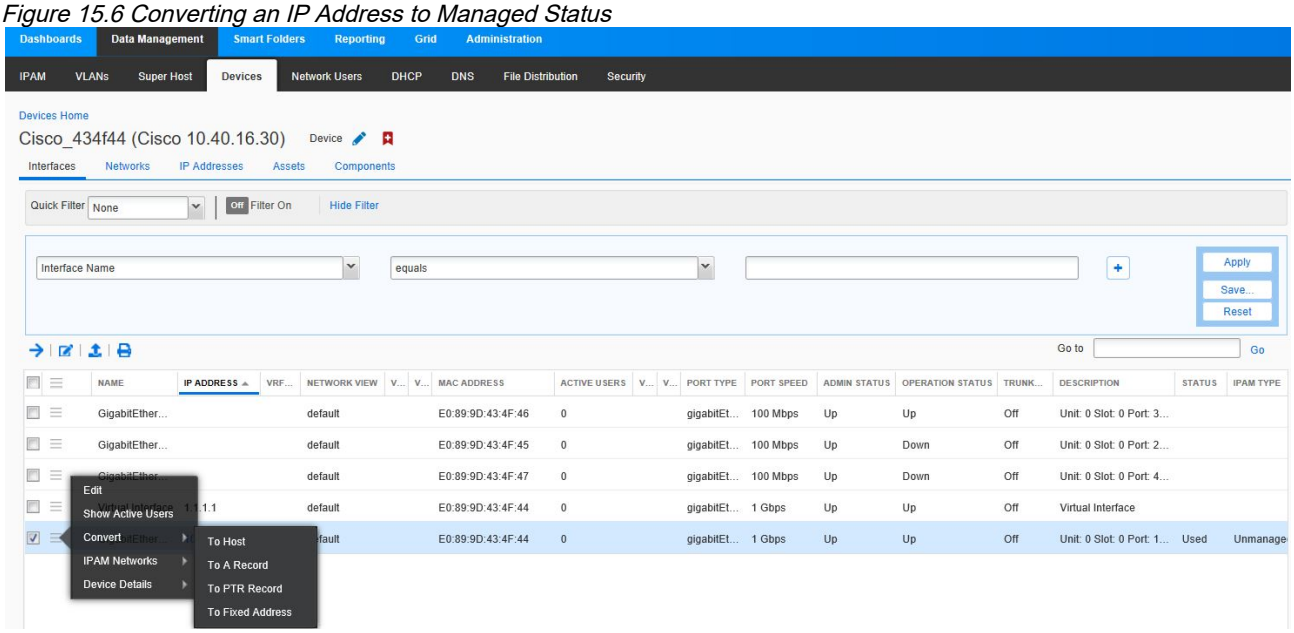
5. The IPAM main page shows **Yes** as the value for the network under the **Managed** column. The network is now under management of IPAM and can participate in Infoblox services.

> **Note**
>
> Most conversion operations for networks and individual IP addresses are managed under IPAM and are described in the section *Managing IPv4 and IPv6 Addresses*.

Converting Unmanaged IP Addresses to Managed Status

The principle for converting an IP address to managed status is the same for IP addresses as for interfaces. If an IP address is unmanaged but is present in IPAM, the IP can be converted to managed status.

Figure 15.6 Converting an IP Address to Managed Status



1. From the **Data Management** tab, select the **Devices** tab.
2. Click the **Next Page** and **Last Page** icons to locate the device through which you want to locate the IP address to convert.
3. Click the Name of the device.
4. Click the **IP Addresses** tab for the chosen device. The IP address page lists all ports discovered on the selected device.
5. To convert a single IP address : Click the Action icon

   next to the IP address you want to convert (this automatically selects it), and then select **Convert–>To Host**, **To A Record**, **To PTR Record**, or **To Fixed Address** from the menu.
   To convert multiple IP addresses (bulk conversion): Select the checkboxes of the IP addresses you want to convert. From the Toolbar, select **Convert->To Host**, **To A & PTR Record**, or **To Fixed Address** from the menu.
6. For a single IP address: The respective object editor appears based on the conversion type you have selected. For example, if you select **ToHost**, the *Host* editor appears. In the editor, define the required **General** settings for the new object. You can also define other settings you need from any of the tabs in the editor. For details about how to configure these settings, refer to the online Help in Grid Manager or see the appropriate chapters in this guide.
   For bulk conversion: The respective bulk conversion wizard (such as the

Convert Unmanaged IP Addresses to Host Record wizard) appears based on the conversion type you have selected.
Note Network Insight creates the names of the new managed objects using the Discovered Name (FQDN) for the entities being converted. In the wizard, Grid Manager displays the IP addresses of the selected devices that are eligible for conversion in the **Selected IP Addresses** table. Entities that are not eligible for conversion will not be converted and will not appear in this table.
Based on the selected conversion type, complete the following to start a bulk conversion:

a. **To Host**: You can select **Enable in DNS** and/or **Enable in DHCP** so the appliance can serve DNS and/or DHCP for the selected IP addresses in the host record. When you enable DNS for the record, you must select a DNS zone for all entities that do not have an FQDN.
b. **ToA&PTRRecord**: Network Insight converts the selected entities to A & PTR records simultaneously. You must select a DNS zone for all entities that do not have an FQDN.
c. **ToFixedAddress**: Network Insight automatically converts all selected IP addresses to fixed addresses in a bulk conversion. As with host record and A/PTR record conversions, entities without a Discovered Name FQDN are not eligible for conversions to fixed addresses.
In all bulk conversions, you can define extensible attributes for the selected IP addresses. After you have configured the necessary settings, you can convert the discovered entities immediately or schedule the conversion by selecting **Later** and entering the date and time.
Click **Save&Close** to make the conversion. You can return to the managed object at any time to make further configuration changes.

7. In the **Managed** column for all converted entities, Grid Manager displays **Yes** to indicate the Managed status. The selected IP addresses are associated with the newly converted IPAM objects. You can now manage these IPAM objects through Grid Manager.

Converting Unmanaged Assets to Managed Status

1. From the **Data Management** tab, select the **Devices** tab.
2. Click the **Next Page** and **Last Page** icons to locate the device through which you want to locate the assets to convert.
3. Click the Name of the device.
4. Click the **Assets** tab for the chosen device. The Assets page lists all network devices that have been detected through connections to the current device. If the device is a switch, you may see a list of end hosts and network servers in the list, along with any other network infrastructure devices that are neighboring the current device.
5. To convert a single asset: Click the Action icon

   next to the asset you want to convert (this automatically selects it), and then select **Convert –> To Host**, **To A Record**, **To PTR Record**, or **To Fixed Address** from the menu.
   To convert multiple assets (bulk conversion): Select the checkboxes of the assets you want to convert. From the Toolbar, select **Convert -> To Host**, **To A & PTR Record**, or **To Fixed Address** from the menu.
6. For a single asset: The respective object editor appears based on the conversion type you have selected. For example, if you select **To Host**, the *Host* editor appears. In the editor, define the required **General** settings for the new object. You can also define other settings you need from any of the tabs in the editor. For details about how to configure these settings, refer to the online Help in Grid Manager or see the appropriate chapters in this guide.
   For bulk conversion: The respective bulk conversion wizard (such as the *Convert Unmanaged IP Addresses to Host Record* wizard) appears based on the conversion type you have selected.
   Note Network Insight creates the names of the new managed objects using the Discovered Name (FQDN) for the entities being converted. In the wizard, Grid Manager displays the IP addresses of the selected devices that are eligible for conversion in the **Selected IP Addresses** table. Entities that are not eligible for conversion will not be converted and will not appear in this table.
   Based on the selected conversion type, complete the following to start a bulk conversion:
   a. **To Host**: You can select **Enable in DNS** and/or **Enable in DHCP** so the appliance can serve DNS and/or DHCP for the selected IP addresses in the host record. When you enable DNS for the record, you must select a DNS zone for all entities that do not have an FQDN.
   b. **To A & PTR Record**: Network Insight converts the selected entities to A & PTR records simultaneously. You must select a DNS zone for all entities that do not have an FQDN.
   c. **To Fixed Address**: Network Insight automatically converts all selected assets to fixed addresses in a bulk conversion. As with host record and A/PTR record conversions, entities without a Discovered Name FQDN are not eligible for conversions to fixed addresses.

In all bulk conversions, you can define extensible attributes for the selected assets. After you have configured the necessary settings, you can convert the discovered entities immediately or schedule the conversion for a later date by selecting **Later** and entering the date and time.

7. Click **Save & Close** to make the conversion. You can return to the managed object at any time to make further configuration changes.

In the **Managed** column for all converted entities, Grid Manager displays **Yes** to indicate the managed status. The selected assets are associated with the newly converted IPAM objects. You can now manage these IPAM objects through Grid Manager.

Configuring Automatic VRF Mapping

You can configure Network Insight to automatically assign network views to VRFs by defining mapping rules that match unassigned VRFs—VRFs that do not have associated network views. You can also disable the automatic VRF mapping and manually assign network views to discovered VRFs, as described in *Viewing Discovered VRFs and Mapping Network Views.*

When you enable automatic VRF mapping, you can add VRF mapping rules that Network Insight uses to map network views to VRFs that do not already have an assigned network view. When you configure mapping rules, you can define criteria using regular expressions and place the rules in specific order to define their priorities. Network Insight matches the rule criteria to the discovered VRF names, starting with the first rule in the VRF Mapping Rules table. You also have a choice to map an unassigned VRF to the network view from which one of the interfaces the VRF is reached, if none of the mapping rules match the VRF name.

To configure automatic VRF mapping and mapping rules for unassigned VRFs, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click the **Discovery** service.
2. Click **Edit** -> **Grid Discovery** Properties from the Toolbar.
3. In the *Grid Discovery Properties* editor, select the **VRF Mapping Rules** tab, and then complete the following:
   - **Enable the automatic VRF mapping rules defined below for unassigned VRFs**: Select this to enable automatic VRF mapping so you can define mapping rules that Network Insight uses to map network views to unassigned VRFs that match the criteria of the rules.
   - **Enable the automatic VRF mapping rules and system mapping extensions**: Select this to enable the VRF Mapping Rules table so you can define mapping rules that Network Insight uses to map network views to unassigned VRFs that match the criteria of the rules; and in cases where none of the rules match a VRF name, Network Insight maps the VRF to the network view from which one of the interfaces the unassigned VRF is reached.
   - **Disable automatic VRF mapping and only use manually defined VRF mapping**: Select this to disable the VRF Mapping Rules table. When you select this, Network Insight does not perform any evaluation of the VRF mapping rules. You can manually assign or unassign network views to the discovered VRFs, as described in *Viewing Discovered VRFs and Mapping Network Views.*

When you enable automatic VRF mapping, you can add mapping rules to the VRF Mapping Rules table, as follows:

1. Click the Add icon, and the appliance adds a row to the table.
2. In the table, click each of the following fields and enter the values accordingly:
   - **Network View**: The network view that you want to use for all matching VRFs. You can click this field and select a network view from the drop-down list that displays all the configured network views, including the default network view.
   - **Order**: The order and priority in which Network Insight evaluates the mapping rules. Each time you add a new rule, the appliance automatically appends the rule to the end of the list and assigns the next incremental number to the rule. To reorder the list, you can select a rule and use the up and down arrows next to the table to move the rules to its desired position so you can set the priority for the rule evaluation. Network Insight evaluates the rules based on the order, starting with 1 as the highest priority.
   - **Criteria**: The criteria that Network Insight uses to match the VRF name of an unassigned VRF. You can use POSIX regular expressions to define the mapping criteria. The appliance validates the rule when you save the configuration, and it returns an error message if the criteria is invalid.
   - **Comment**: Enter a comment about the VRF mapping rule. Click the Add icon again to define another mapping rule.
3. Save the configuration.

> **Note**
>
> All the VRF mapping rules that are currently configured for the Grid are displayed in the VRF Mapping Rules table.

You can also do the following in the **VRF Mapping Rules** tab:

- Select a specific rule and click the Delete icon to remove it from the table.
- Use the up and down arrows next to the rules table to reorder the rules.
- Use the **Go to** function to search for a specific mapping rule. With the autocomplete feature, you can just enter the first few characters of a network view in the **Go to** field and select the network view from the possible matches.

About Network Insight

Infoblox Network Insight provides discovery features for detecting and managing devices in your network infrastructure. You can use discovery to collect device data and manage it through Grid Manager. For more information about device management, see *Managing Discovered Data*.

You can view the operating state of all discovered network infrastructure devices and newly discovered IP networks, including but not limited to routers, wireless routers and access points, firewalls, load balancers, Ethernet L2/L3 switches, end hosts and other devices in end host networks, end host networks, VRF (Virtual Routing and Forwarding) virtual networks, single and multipoint VPNs, SDN and SD-WAN devices, and much more. Network Insight makes it easy to manage and secure your enterprise network by detecting all interfaces for every discovered device and providing specific information about them. For information about discovering VRF virtual networks, see *Discovering VRF Virtual Networks*.

The Infoblox IPAM feature set also provides control mechanisms by including and excluding networks and IP addresses for discovery. You can schedule and define when discovery takes place on any network, and define blackout periods during which no discovery tasks occur. Infoblox IPAM and DHCP functions also extend network control to assigning of discovered switch and router interfaces to IPAM objects such as IP networks, IP reservations, and host records. The assignments are called *port reservations* and are part of a feature set called *port control*, managed through Grid Manager. For more information, see *Port Control Features in Network Insight*.

Infoblox provides a few reports in which you can view trending information about the device groups, types of devices, and device IP addresses for the devices that are discovered by Network Insight. For information about these reports, see *Status Dashboard*.

Deployment of Network Insight discovery requires a separate Discovery license and one or more NIOS appliances dedicated to discovery tasks.

Network Insight performs discovery in the following ways:

- Through specification of seed routers, which inform discovery of the various networks that should be examined and catalogued.
- Through discovery of the various Object types you can create under IPAM and DHCP, including IPv4 and IPv6 Networks, Host Records, IPv4 reservations, DHCP ranges, and IPv4/IPv6 fixed addresses.
- An enhanced VM discovery allowing both scheduled VM discovery and immediate discovery of VMs.

Supported Appliances for Network Insight

Network Insight is supported on the following physical appliances: ND-805, ND-1405, ND-2205, and ND-4005; and the following virtual appliances: ND-805, ND-V1405, and ND-V2205. All appliances that perform discovery require a Discovery license. Appliances with this license only perform discovery tasks and do not perform core DNS or DHCP functions.

Configuring Super Hosts

A super host is a collection of resource records or fixed addresses that are related. It can contain resource records or fixed addresses that belong to a single network device, such as a router or a switch, or an application server. With super host, you can configure and manage multiple interfaces, IP addresses, and DNS and DHCP records that are associated with the same physical or virtual device. A super host gives you the flexibility to group related objects into a single entity and manage them at one place.

A super host can contain the following record types:

- DNS records - A, AAAA, PTR, and host addresses
- DHCP records - IPv4 or IPv6 fixed addresses.

Note that a super host object and a network view or a DNS view are independent of each other. A super host is an aggregation of NIOS objects that can belong to multiple networks or DNS views, but are related to a single network device. The audit log records all changes to a super host object including addition, modification, deletion, and association or disassociation of resource records.

You can group super host objects in smart folders according to their attributes. For example, you can create a smart folder that contains all records in a specific super host. For more information, see *Smart Folders*. Use Capacity Report to view the total capacity utilization of super host objects. For more information, see *Using the Capacity Report*.

Note

Users must have valid permissions to delete or disable a super host. A resource record can only belong to one super host and cannot be a part of multiple super hosts. You can associate any number of records with a super host.

Limitations of Super Host

- You can associate extensible attributes with a super host, but it does not support inheritance.
- You cannot associate DNS records that are auto-created with a super host.
- Infoblox has limited control over the resource records, from a zone or a network, which is associated with a super host. This can cause inconsistent behaviors when you enable or disable the resource record from the parent zone or network.

Administrative Permissions for Super Hosts

Superusers and limited-access users with read/write permission to **All Super Hosts** and corresponding objects can manage super hosts and their associated resource records. By default, the Super Host Admin role supports read/write permission on super hosts.

To define permissions for super hosts:

1. **For an admin group**: From the **Administration** tab, select the **Administrators** tab -> **Permissions** tab -> *admin_group* in the Groups table, and then click the Add icon -> **Global Permissions** from the Create New Permission area or select Add -> **Global Permissions** from the Toolbar. For more information, see *About Administrative Permissions*.
2. **For an admin role**: From the **Administration** tab, select the **Administrators** tab -> **Permissions** tab -> *admin_role* in the Roles table, and then click Add icon -> **Global Permissions** from the Create New Permission area or select Add -> **Global Permissions** from the Toolbar. For more information, see *About Admin Roles*.
3. Complete the following in the *Manage Global Permissions* dialog box:
    - **Permission Type**: Select **Super Host Permissions** from the drop-down list.
    - In the table, select **Read/Write, Read-Only**, or **Deny** for All Super Hosts.

4. Click **Save & Close**.

You can also define object level permissions for a super host. For more information, see *Defining Object Permissions*.

Adding Super Hosts

To add a super host, complete the following:

1. From the **Data Management** tab, select the **Super Host** tab, and then click the Add icon.
2. In the *Add Super Host* wizard, enter the following details:
    - **Name**: Enter a name for the super host.
    - **Comment**: Enter additional information about the super host.
    - **Disabled**: Select this checkbox if you want to disable the super host at this time. Clear the checkbox to enable it. When you disable a super host, the DNS and DHCP records that are associated with it are disabled, but still associated with the super host.
3. Click **Next** to associate DNS or DHCP records with the super host. Click the arrow next to the Add icon and select Add DNS and Host Records or Add DHCP Records. Note that you must have valid DNS and DHCP permissions to add resource records and fixed addresses.
4. The records that you associate with the super host are listed. To delete a specific record, select the respective checkbox and click the Delete icon.
5. Click **Next** to define extensible attributes. For information, see *Managing Extensible Attributes*.
6. Click **Save & Close**.

Adding DNS and Host Records

In the *Select Record* dialog box, complete the following to select and associate DNS or host records:

- **Network View**: Select a network view from the drop-down list. This is displayed only if you have configured multiple network views.
- **DNS View**: Select a DNS view from the drop-down list.
- **Zone**: Select a zone from the drop-down list. You must select a zone before you start searching for records. Click **Apply** to apply your settings or **Reset** to reset the settings. Optionally, click the + icon to add another filter rule. To delete an additional filter rule, click the - icon.
- **Find**: Specify the name of the resource record and click **Go** to search for a specific record.
- **Host Record:** Select the checkbox to search for a host record.
- **A Record:** Select the checkbox to search for an A record.
- **AAAA Record:** Select the checkbox to search for an AAAA record.
- **PTR Record**: Select the checkbox to search for a PTR record.
- Click the right arrow to navigate to the search results in the next page.

The appliance displays the following details:

- **Name**: Displays the name of the resource record.
- **IP address**: Displays the IP address of the resource record.
- **Type**: Displays the type of the resource record.
- **Comment**: Displays additional comments about the resource record.
- **Site**: Displays the values that were entered for this pre-defined attribute.
- Click on a row and click **OK** to associate the resource record with the super host, or click **Close** to cancel. To select and associate multiple records, use Shift+click and Ctrl+click.

You can edit a resource record that is associated with a super host. For more information, see *Copying and Modifying Host Records*.

Adding DHCP Records

In the *DHCP Objects Selector* dialog box, complete the following to select and associate a DHCP record:

- **Network View**: Select a network view from the drop-down list. This is displayed only if you have configured multiple network views.
- **Network**: Select a network from the drop-down list. You must select a zone before you start searching for records. Click **Apply** to apply your settings or **Reset** to reset the settings. Optionally, click the + icon to add another filter rule. To delete an additional filter rule, click the - icon.
- **Find**: Specify the fixed address and click **Go** to search for a specific record.
- Click the right arrow to navigate to the search results in the next page.

The appliance displays the following details:

- **IP address**: Displays the IP address of the resource record.
- **Name**: Displays the respective IPv4/IPv6 fixed address or host address.
- **Type**: Displays the type of the resource record.
- **Comment**: Displays additional comments about the fixed address.
- Click on the row and click **OK** to associate the resource record with the super host, or click **Close** to cancel. To select and associate multiple records, use Shift+click and Ctrl+click.

When you search for DHCP records, a host record with multiple host addresses will display all the associated host addresses in the *DHCP Objects Selector* dialog box. When you select multiple hosts, the NIOS appliance considers the records as duplicate. Infoblox recommends that you delete the duplicate records before you save them.

You can edit an IPv4/IPv6 fixed address that is associated with a super host. For more information about modifying IPv4 and IPv6 fixed addresses, see *Configuring IPv4 Networks* and *Configuring IPv6 Fixed Addresses* respectively.

Viewing Super Hosts

The super host Home panel lists all the super hosts that are configured in the Grid. You can provision new super hosts objects and manage them. To view the configured super hosts, navigate to the **Data Management** tab → **Super Host** tab. Grid Manager displays the following information in the super hosts Home panel:

- **Name**: The name of the super host.
- **Comment**: The information you entered about the super host.
- **Disabled**: Indicates whether the super host is disabled.

You can also do the following in this panel:

- Using the Action icon

  , you can modify or delete a super host.
- View associated records. For more information, see Viewing Resource Records Associated with a Super Host below.
- Sort the data in **ascending** or **descending** order by column. For information about customizing tables in Grid Manager, see *Customizing Tables*.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches. For more information, see *Using the Go To Function*.
- Create a quick filter to save frequently used filter criteria. For more information, see *Using Quick Filters*.
- Use **Global Search** to search for a specific super host. For information, see *Using Global Search*.

Viewing Resource Records Associated with a Super Host

You can view the resource records that are associated with a super host by navigating to the **Data Management** tab → **Super Host** tab, click the respective super host. For each super host object, the panel displays the following by default:

- **Name**: The name of the associated DNS or DHCP resource record.
- **Parent**: The name of the super host object in which the record resides.
- **Type:** The record type. When you search for an unspecified record type, all the associated records are displayed.
- **Data**: Value of a resource record. For example, IP address of an A record.
- **Comment**: Comments that were entered for the resource record.
- **Disabled**: Indicates if the associated DNS/DHCP resource record is disabled.

- **Network View**: The network view associated with the resource record.
- **DNS View**: The DNS view to which the zones belong.
- **Creation Timestamp**: The time at which the DNS resource record was created.

You can also do the following in this panel:

- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches. For more information, see *Using the Go To Function*.
- Create a quick filter to save frequently used filter criteria. For more information, see *Using Quick Filters*.
- Click the right arrow to return to the parent object:
  - DNS records, such as A/AAAA/PTR records, and host addresses return to the respective parent zone.
  - DHCP records, such as IPv4 and IPv6 fixed addresses, return to the respective parent network.
- Click the Print icon to print the list of associated resource records.

Modifying Super Hosts

You can select supported DNS or DHCP records and associate or dissociate them from a super host. Infoblox allows you to update the name, comment, and enable or disable the respective super host. To modify a super host:

1. From the **Data Management** tab, select the **Super Host** tab.
2. Select a super host that you want to modify and click the Edit icon, or click the Action icon

   next to the respective super host and select **Edit** from the menu.
3. The *Super Host* editor provides the following tabs from which you can modify data:
   - **General** tab: Modify certain general properties. For more information, see Adding Super Hosts above.
   - **Extensible Attributes** tab: Add or modify values of extensible attributes. For information, see *Managing Extensible Attributes*.
   - **Permissions** tab: Modify the administrative permissions. For more information, see About Administrative Permissions for Super Hosts above.
4. Click **Save & Close**.

Deleting Super Hosts

When you delete a super host, you have an option to delete only the respective super host or delete the associated records also. The deleted super hosts and associated records are moved to the Recycle Bin, from which you can restore or permanently delete them. For information about the Recycle Bin, see *Using the Recycle Bin*.

To delete a super host:

1. From the **Data Management** tab, select the **Super Host** tab.
2. Select a super host that you want to delete and click the Delete icon, or click the Action icon

   next to the respective super host and select **Delete** from the menu.
3. The appliance displays the *Delete Confirmation* dialog box to confirm that you want to delete a super host. You can choose to delete the records that are associated with the super host by selecting the **Delete associated records with the Superhost** checkbox. You cannot delete associated records if you do not have write permissions on those objects. When you restore this super host from the Recycle Bin, the associated resource records are also restored.
   If you do not select the **Delete associated records with the Superhost** checkbox while deleting a super host, the associated records will not be deleted. When you restore the deleted super host, only the respective super host is restored and you must associate the resource records manually.

DNS

This section describes how to configure the Grid to provide DNS services. It includes the following topics:

- *Infoblox DNS Service*

- *Configuring DNS Services*
- *DNS Views*
- *Configuring DNS Zones*
- *Configuring DNS Resource Records*
- *Configuring DDNS Updates*
- *Configuring DNSSEC*
- *Managing DNS Traffic Control*
- *Configuring IP Routing Options*

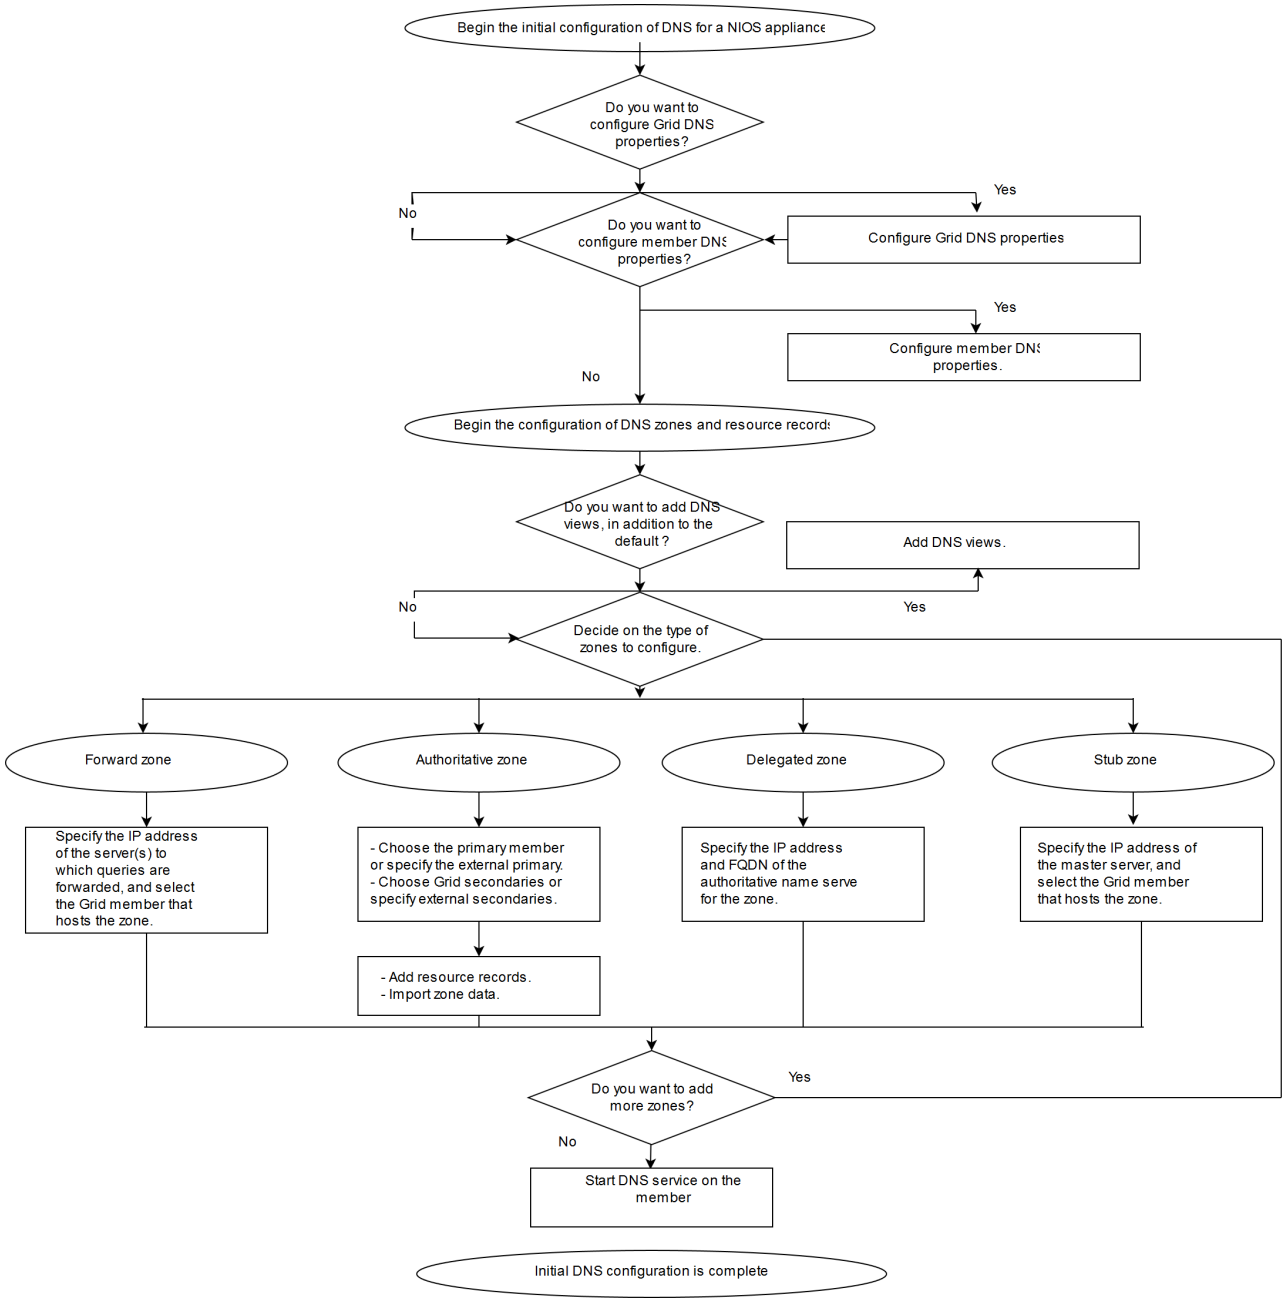
Infoblox DNS Service

The NIOS appliance uses a standard, BIND-based DNS protocol engine. It interoperates with any other name server that complies with the DNS RFCs. This section provides an overview of the DNS configuration tasks. It includes the following topics:

- *Configuring DNS Overview*
- *Inheriting DNS Properties*
- *Understanding DNS for IPv6*

Configuring DNS Overview

An overview of the DNS configuration process is outlined in the following diagram, illustrating the required steps for preparing a NIOS appliance for use:



DNS Configuration Checklist

The following checklist includes the major steps for configuring DNS:

DNS Configuration Checklist

Step	For more information
Decide if you want to configure DNS properties for the Grid and for individual members	*Infoblox DNS Service*
Decide if you want to create a new DNS view, in addition to the default DNS view	*DNS Views*

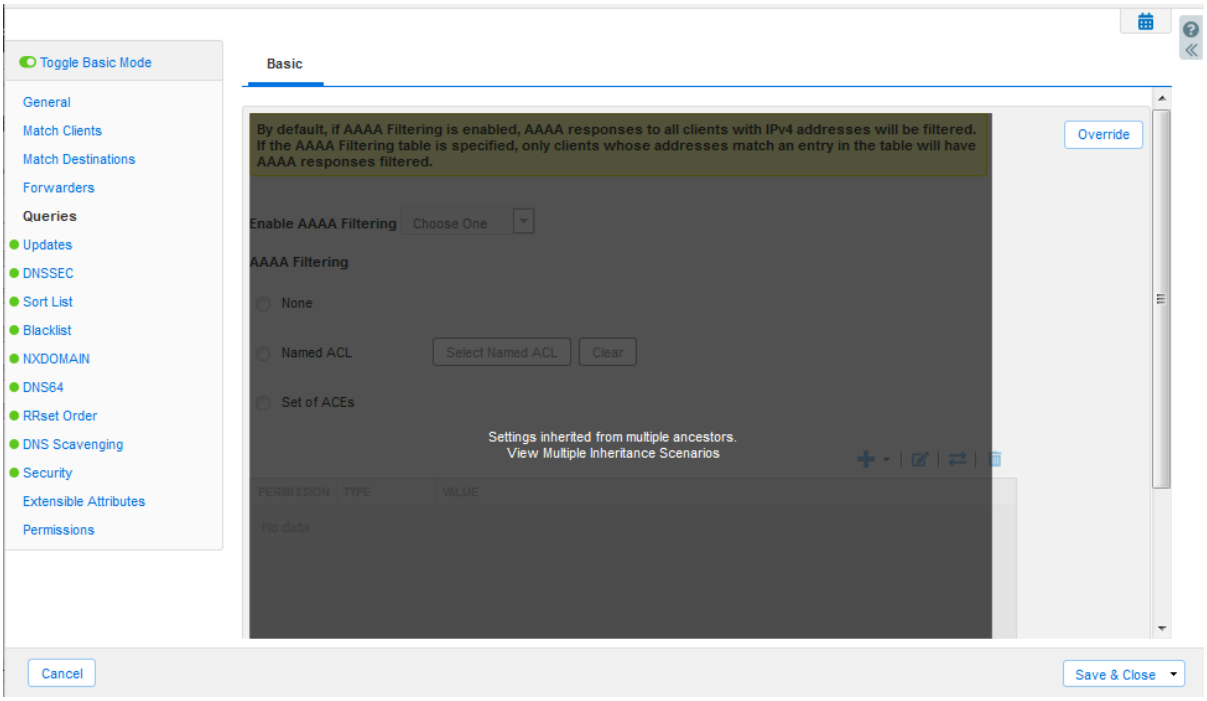
Step	For more information
Decide which type of DNS zone you want to configure	*Configuring DNS Zones*
Add hosts and resource records	*Configuring DNS Cache Acceleration*
Import zone data	*Importing Zone Data*
Enable DNS service on the member	*Starting and Stopping the Discovery Service*

Inheriting DNS Properties

You can configure DNS properties at the Grid, member, zone, and resource records level. The NIOS appliance applies the properties hierarchically, with the Grid at the top of the hierarchy. Grid settings apply to all members in the Grid, unless you override them at the member, zone, or resource record level. When you set DNS properties for a particular member, these properties override the Grid properties and apply to all zones served by that member. When you set properties for a specific zone, they override the member properties and apply to the resource records in the zone. You can also override the zone properties and set properties for specific resource records.
When you configure DNS properties that contain inherited values, the appliance displays the information based on the inheritance sources. There may be times when an object can inherit properties from different sources with different settings. The following table summarizes what the appliance can display:

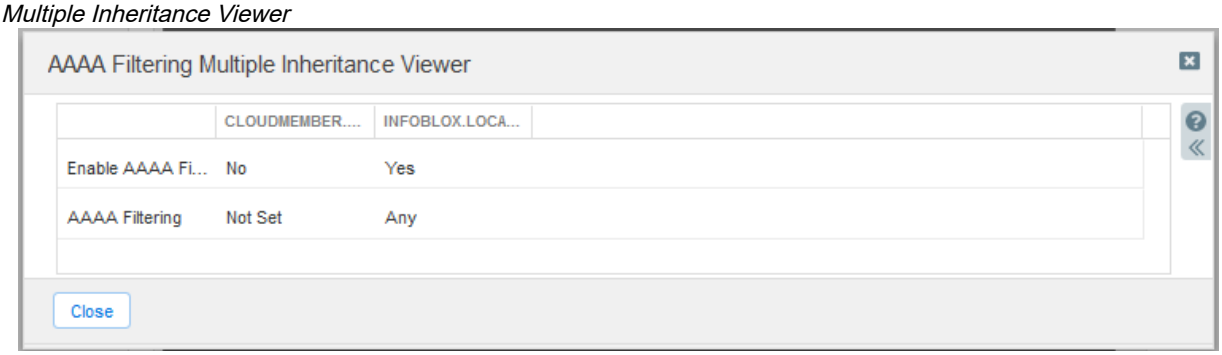
When you see...	it means...
Inherited From *<object>*	the DNS property has a definite value from an inheritance source.
Inherited From Upper Level	the appliance cannot yet determine the inherited value or inheritance source for the DNS property.
Inherited From Multiple	the DNS property has the same value that it inherits from multiple sources.
Settings Inherited from Multiple Ancestors, View Multiple Inheritance Scenarios	the DNS property has different values that it inherits from multiple sources, and you can view the values and their corresponding sources by clicking the **View Multiple Inheritance Scenarios** link.

Based on the information provided, you can then decide whether to override or keep the inherited values. You must have read/write permissions to the DNS resources to override inherited values. You can only view inherited values and paths if you have at least read-only permissions.
In the example in the below figure, the DNS zone is served by members with different query settings.
DNS Zone with Different Inherited Settings



The Multiple Inheritance Viewer indicates that the two servers have different query ACLs, as shown in Multiple Inheritance Viewer figure below. You can then view the Query properties of each member and edit them, or override the setting and specify values that apply to the zone only.

Multiple Inheritance Viewer



Overriding DNS Properties

DNS properties configured at the Grid level apply to the entire Grid. You can choose to keep the inherited properties or override them when you configure the properties for a member, zone, or resource record.

To override an inherited value:

1. In a wizard or editor, click **Override** next to a property to enable the configuration. The **Override** button changes to **Inherit**.
2. Enter a new value to override the inherited value.

Understanding DNS for IPv6

You can configure NIOS appliances to provide DNS services over IPv4 (Internet Protocol version 4) and IPv6 (Internet Protocol version 6) networks. You can configure the Grid member as IPv6, or dual-mode name server. Dual-mode name server is capable of sending and receiving IPv4 and IPv6 queries and responses. It can serve DNS data in response to both IPv4 and IPv6 queries. The appliance supports authoritative forward-mapping zones containing AAAA records mapping host names to IPv6 addresses, as well as authoritative reverse-mapping zones with PTR records mapping IPv6 addresses to host names.

Configuring a Grid containing an IPv4 primary server and IPv6 secondary servers is not supported. You must enable

IPv6 on both the primary and secondary servers within the Grid to enable them to communicate with each other. Infoblox highly recommends that you enable IPv6 on your Grid appliances before configuring IPv6 authoritative zones. The NIOS appliance supports IPv6 configuration on multiple interfaces, such as LAN1,LAN2, MGMT, anycast (OSPF and BGP), and loopback interfaces. Infoblox integrates IPv6 address management into many of the same places where IPv4 addresses are entered. Data validation occurs on all IP address fields and automatic validation is done to ensure proper entry of either an IPv4 address or an IPv6 address.
The NIOS appliance supports the following DNS functions for IPv6:

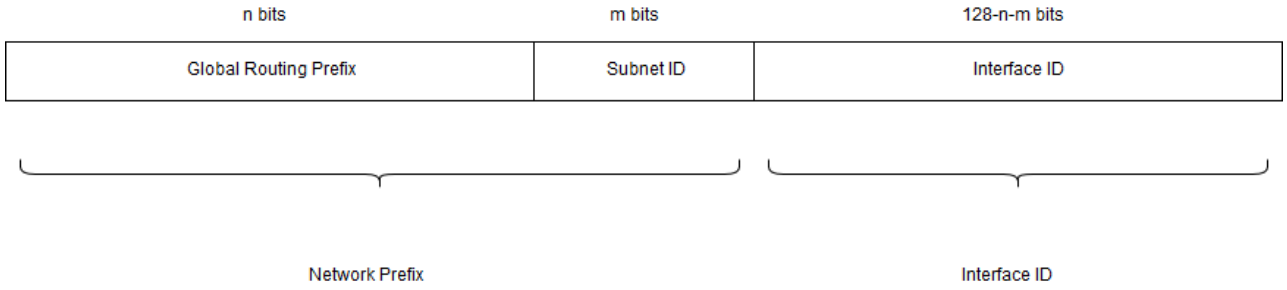
- AAAA records—You can import, serve queries, display, add, delete, and modify AAAA records on the appliance. An AAAA record is equivalent to an IPv4 A record, relying upon a forward-mapping zone to map a hostname to an IPv6 address. A single forward-mapping zone can map names to both IPv4 and IPv6 addresses. The appliance autogenerates AAAA records for any of its interfaces that have IPv6 addresses.
- Hosts—You can configure IPv4 and IPv6 addresses for hosts. For information, see *Adding Host Records*.
- ip6.arpa— A specific domain for IPv6 is used for DNS reverse lookups called ip6.arpa. This domain maps an IPv6 address to a hostname. When you specify an IPv6 network, the appliance automatically creates the appropriate zone under ip6.arpa.
- PTR records—Import, serve queries, display, add, delete, and modify PTR records within an ip6.arpa reverse zone. The PTR record returns a domain name corresponding to an IPv6 address contained in the ip6.arpa zone. The appliance does not autogenerate PTR records; the user must configure PTR records manually.
- DDNS—The appliance supports AAAA and PTR records for DDNS (Dynamic DNS).

For more information about DNS for IPv6, see RFC 3596, *DNS Extensions to Support IP Version 6*.

Address Structures

IPv4 uses a 32-bit, 4-octet (each octet separated by decimals) addressing structure to designate sources and destinations within a network. Since there are 32 bits that make up the address, IPv4 can support up to 4 billion unique addresses.
An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight groups of four hexadecimal digits separated by colons (example: 12ab:0000:0000:0123:4567:89ab:0000:cdef). Since there are 128 bits that make up the address, IPv6 can support up to 3.4x10**38** unique addresses. The increase in the number of unique IPv6 addresses is one of the biggest advantages of an IPv6 implementation.

IPv6 Address Structure



The IPv6 address structure consists of the following:

- Global Routing Prefix—Global routing prefix is a (typically hierarchically-structured) value assigned to a site.
- Subnet ID—Subnet ID is an identifier of a link within the site.
- Interface ID—Interface Identifier. This portion of the address identifies the interface on the subnet. This is equivalent to the host identifier for IPv4 addresses.

When you enter an IPv6 address, you can use double colons to compress a contiguous sequence of zeros. You can also omit any leading zeros in a four-hexadecimal group. For example, the complete IPv6 address 2006:0000:0000:0123:4567:89ab:0000:cdef can be shortened to 2006::123:4567:89ab:0:cdef. Note that if there are multiple noncontiguous groups of zeros, the double colon can only be used for one group to avoid ambiguity. The NIOS appliance displays an IPv6 address in its shortened form, regardless of its form when it was entered.

Configuring IPv6 on a Grid Member

You can configure a Grid member in either IPv6 or dual mode (IPv4 and IPv6) to support IPv6 connections. A dual mode Grid member supports both IPv4 and IPv6 connections by configuring an IPv6 address on the member, in addition to the standard IPv4 address.
When you enable IPv6 on a member, you can manually enter the IPv6 gateway address or enable the member to automatically acquire the address from router advertisements. Routers periodically send router advertisements that contain link-layer addresses and configuration parameters. A NIOS appliance that supports IPv6 can listen for router advertisements and obtain the default gateway IP address and link MTU (maximum transmission unit). The link MTU is the maximum packet size, in octets, that can be conveyed in one transmission unit over a link. Thus you can set parameters on a router once and automatically propagate it to all attached hosts.
To configure the member to support IPv6:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.
2. Expand the Toolbar and click **Add** -> **Add Grid Member**.
3. In the *Add Grid Member* wizard, enter the following and click **Next**:
    - **Member Type**: Specify the appliance type of the Grid member. If the member is an Infoblox appliance, select **Infoblox**, which is the default. If the member is a NIOS virtual appliance, select **Virtual NIOS**.
    - **Host Name:** Type the FQDN (fully qualified domain name) of the appliance that you are adding to the Grid.
    - **Time Zone:** If the Grid member is in a different time zone from the Grid, click **Override** and select a time zone.
    - **Comment:** Type a comment that provides some useful information about the appliance, such as its location.
    - **Master Candidate:** Select this option to designate this appliance as a Master Candidate. For supported vNIOS appliances, see *Supported vNIOS Appliance Models and Specifications*. Note that the Grid Master Candidate must use the same communication protocol as the Grid Master.
4. Enter the following information about the member that you are adding to the Grid and click **Next**:
    - **Type of Network Connectivity:** Select **IPv6** to configure an IPv6 Grid member or select **IPv4 and IPv6** to configure a dual mode Grid member.
    - Select **Standalone Member** to configure a single member or select **High Availability Pair** to configure an HA member.
      For an HA member, enter the **Virtual Router ID** number and if the HA member is configured in dual mode, select **IPv6** in the **Send HA and Grid Communication Over** field.
    - **Required Ports and Addresses:** This table lists the network interfaces based on the type of network connectivity of the Grid member.
      For IPv6 Grid member, specify the network information for LAN1(IPv6) interface. For a dual mode Grid member, specify the network information for both LAN1(IPv4) and LAN1(IPv6) interfaces.
      For IPv6 HA member, specify the network information for VIP (IPv6), Node1 LAN1(IPv6), and Node2 LAN1(IPv6) ports. For a dual mode HA member, specify the network information for the following interfaces: VIP (IPv4), Node1 LAN1(IPv4), Node2 LAN1(IPv4), VIP (IPv6), Node1 LAN1(IPv6), and Node2 LAN1(IPv6).
      Enter correct information for the following by clicking the field:
        - **Interface**: Displays the name of the interface. You cannot modify this.
        - **Address:** You can enter IPv4 or IPv6 address depending on the type of interface. An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight 16-bit groups of hexadecimal digits separated by colons (example: 2001:db8:0000:0123:4567:89ab:0000:cdef or 2001:db8::123:4567:89ab:0:cdef).
        - **Subnet Mask (IPv4) or Prefix Length (IPv6):** Enter an appropriate subnet mask for IPv4 address and prefix length for IPv6 address. The prefix length ranges from 2 to 127.
        - **Gateway:** Type the default gateway for the interface. For IPv6 interface, you can also type **Automatic** to enable the appliance to acquire the IPv6 address of the default gateway and the link MTU from router advertisements.
        - **VLAN Tag**: For a VLAN, enter the VLAN tag or ID. You can enter a number from 1 to 4094. Ensure that you configure the corresponding switch accordingly.
        - **Port Settings:** From the drop-down list, choose the connection speed that you want the port to use. You can also choose the duplex setting. Choose **Full** for concurrent bidirectional data transmission or **Half** for data transmission in one direction at a time. Select **Automatic** to instruct the NIOS appliance to negotiate the optimum port connection type (full or half duplex) and speed with the

connecting switch automatically. This is the default setting. You cannot configure port settings for vNIOS appliances.

- **DSCP Value**: Displays the Grid DSCP value, if configured. To modify, click **Override** and enter the DSCP value. You can enter a value from 0 to 63. For information about DSCP, see *Implementing Quality of Service Using DSCP*.

5. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring DNS for IPv6 Addressing

Configuring the appliance to manage DNS services for IPv6 connections is similar to configuring DNS services for IPv4 connections. For simplicity, the IPv6 procedures are located in the same location as the corresponding procedures for IPv4 in this chapter. In most cases, the key difference within the procedure involves selecting an IPv6 mapping zone instead of an IPv4 mapping zone. You can configure the following tasks:
IPv6 DNS Configuration Checklist

Step	For more information
Create primary or secondary name servers and specify an IPv6 root server.	• *Configuring Authoritative Zones* • *Specifying a Primary Server* • *Specifying Secondary Servers* • *Creating a Root Zone*
Configure the IPv6 zones.	• *Creating an Authoritative Forward-Mapping Zone* • *Creating an Authoritative Reverse-Mapping Zone*
Configure IPv6 resource records	• *Managing AAAA Records* • *Managing PTR Records*

Configuring DNS Services

This chapter provides general information about DNS service properties and includes the following topics:

- *Configuring DNS Service Properties*
- *Clearing DNS Cache*
- *Viewing DNS Cache Entries*
- *Using Forwarders*
- *Controlling DNS Queries*
- *Enabling Recursive Queries*
- *Controlling AAAA Records for IPv4 Clients*
- *About NXDOMAIN Redirection*
- *Configuring DNS over TLS and DNS over HTTPS Services*
- *Detecting and Mitigating DNS DDoS Attacks*
- *Automated Mitigation of Phantom Domain Attacks*
- *Detecting NXDOMAIN Attacks*
- *Mitigating Possible NXDOMAIN Attacks*
- *Support for RRL (Response Rate Limiting)*
- *Blacklists*
- *Configuring Blacklists*
- *About Root Name Servers*
- *About Sort Lists*

- *Configuring a DNS Blackhole List*
- *Specifying Hostname Policies*
- *About DNS64*
- *DNS Record Scavenging*
- *Monitoring DNS Queries*
- *Configuring DNS Traffic Control Properties*

Configuring DNS Service Properties

You can configure general DNS service properties and change some default values. The DNS service is disabled by default. To enable the member to provide DNS service, you must start the DNS service. For information about how to start and stop the DNS service, see *Starting and Stopping the DNS Service*. The following topics describe the DNS service properties that you can configure:

- *Configuring DNS Access Control*
- *Specifying Time To Live Settings*
- *Configuring Hostname and Server ID Options*
- *Enabling and Disabling DNS Health Check Monitor*
- *Adding an Email Address to the SOA Record*
- *Notifying External Secondary Servers*
- *Enabling the Configuration of RRset Orders*
- *Specifying Port Settings for DNS*
- *Using Extension Mechanisms for DNS (EDNS0)*
- *Deleting PTR Records associated with A or AAAA Records*
- *Specifying Minimal Responses*
- *Starting and Stopping the DNS Service*

Configuring DNS Access Control

You can add ACEs (access control entries) or use a named ACL (access control list) to determine which hosts can perform specific DNS tasks. For information about how to define a named ACL, see *Defining Named ACLs*. When you add ACEs or a named ACL to Grid DNS properties, the configuration overrides member and object access control for DNS zone transfers, dynamic DNS updates, DNS queries and recursive queries, blackhole lists, and AAAA filtering. For a full list of operations that support access control, see *Operations that Support Access Control*.

To configure DNS access control:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
2. In the *Grid DNS Properties* editor, click **Toggle Advanced Mode**, and select one of the following tabs for specific DNS tasks:
   - **Updates** tab**:** Define ACEs or a named ACL to control Grid level dynamic DNS updates, as described in *Enabling DNS Servers to Accept DDNS Updates.*
   - **Queries** tab**:** Define ACEs or a named ACL to control Grid level DNS queries, recursive queries, and AAAA filtering, as described in *Controlling DNS Queries, Enabling Recursive Queries* and *Controlling AAAA Records for IPv4 Clients.*
   - **Zone Transfers** tab**:** Define ACEs or a named ACL to control Grid level DNS zone transfers, as described in *Enabling Zone Transfers* .This does not apply to zone transfers for Microsoft servers. For information about Microsoft servers, see *Setting Zone Properties.*
   - **Blackhole** tab**:** Configure ACEs or a named ACL to define IP addresses and networks that you do not want to include during the DNS resolution process, as described in *Configuring a DNS Blackhole List*.
   - **DNS64 tab**: Configure ACEs or a named ACL for clients to which the appliance sends synthesized AAAA records DNS64 groups, as described in *Setting DNS64 Group Properties.*
3. Save the configuration.

You can override the Grid settings at the member and object levels.

Specifying Time To Live Settings

You can specify TTL (time to live) settings for Infoblox host records and resource records. TTL is the time that a name server is allowed to cache data. After the TTL expires, the name server is required to update the data. Setting a high TTL reduces network traffic, but also renders your cached data less current. Conversely, setting a low TTL renders more current cached data, but also increases the traffic on your network.
You can specify global TTL settings at the Grid level, for individual zones, or resource records. When you configure TTL settings for auto-generated records, the following conditions apply:

- NS records that are auto-generated for delegated name servers use TTL settings from their delegated zones.
- Auto-generated glue A and AAAA records use TTL settings from a delegated zone if the name of the name server is below the delegation point and does not belong to an authoritative child zone.
- All other auto-generated NS, A, and AAAA records continue to use TTL settings from their parent zones.
- Auto-generated PTR records do not inherit TTL settings from delegated zones. They use TTL settings from their parent zones.

When you have an RRSET (resource record set) that contains different TTL settings for each record, Grid Manager displays the actual TTL values for these records. However, in DNS responses, the appliance takes the least of the values and returns that as the TTL setting for all resource records in the RRset.
For recursive DNS severs, you can specify the maximum cache TTL value that establishes the time limit for the name server to cache positive responses. You can also specify the maximum negative cache TTL value that specifies the time limit for the name server to cache negative responses. For information about how to configure these settings, see Specifying Max Cache TTL and Max Negative Cache TTL Settings below.

Specifying TTL Settings for a Grid

To specify global TTL settings for resource records hosted by Grid members:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
2. In the **Basic** tab of the **General** section of the *Grid DNS Properties* editor, modify the following values as necessary:
    - **Refresh:** This interval tells secondary servers how often to send a message to the primary server for a zone to check that their data is current, and retrieve fresh data if it is not. The default is three hours. Ensure that you set the refresh interval to a value above 300 seconds; setting the refresh interval to below 300 seconds may not work as expected.
    - **Retry:** This interval tells secondary servers how long to wait before attempting to recontact the primary server after a connection failure between the two occurs. The default is one hour.
    - **Expire:** If the secondary fails to contact the primary for the specified interval, the secondary stops giving out answers about the zone because the zone data is too old to be useful. The default is 4 weeks.
    - **Default TTL:** Specifies how long name servers can cache the data. The default is eight hours.
    - **Negative-caching TTL (Time to Live):** Specifies how long name servers can cache negative responses, such as NXDOMAIN responses. The default is 15 minutes.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Specifying TTL Settings for a Zone

To specify TTL settings for host and resource records in a zone:

1. From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab-> *dns_view* -> *zone* checkbox -> Edit icon.
2. In the *Authoritative Zone* editor, click **Settings**.
3. Click **Override** and complete the fields as described in the preceding section, Specifying TTL Settings for a Grid.

Specifying the TTL of a Host or Resource Record

To specify the TTL setting for an Infoblox host or resource record:

1. From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab -> *dns_view* -> *zone* -> *resource_record*.
2. The **TTL** tab of the resource record editor displays the TTL setting the resource record inherited from the Grid or zone. Click **Override** and enter a value. The setting is in hours by default. You can change it to seconds, minutes, days or weeks.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Specifying TTL Settings for a Lame Server

Servers that are marked as authoritative, but do not respond as authoritative servers are called lame servers. You can specify the number of seconds to cache a lame delegation or lame server indication through the Lame TTL option. Lame TTL usually indicates the amount of time your name server remembers information about the remote name server that is not authoritative for a zone, which is delegated to it.
A domain or sub-domain that is delegated to a server that is not authoritative for the domain is called lame delegation. It indicates that a zone file does not exist for the domain on the server.
The lame time-to-live cache value can be defined at the Grid DNS, Member DNS, or DNS view level. To specify the Lame TTL cache value for a lame delegation or lame server:

1. **Grid:** From the **Grid** tab -> **Grid Manager** tab, select the **DNS** tab, click the **Services** tab -> *member* checkbox, expand the **Toolbar** and click **Edit** -> **Grid DNS Properties**. In the *Grid DNS Properties* editor, select the **General** tab -> click the **Advanced** tab (or click **Toggle Advanced Mode**).
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> *Edit* icon. In the *Member DNS Properties* editor, select the **General** tab -> click the **Advanced** tab (or click **Toggle Advanced Mode**).
   DNS View: From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *dns_view* checkbox -> *Edit* icon. In the *DNS View* editor, select the **General** tab -> click the **Advanced** tab (or click **Toggle Advanced Mode**).
2. In the *Grid DNS Properties*, *Member DNS Properties*, or the *DNS View* editor, select the **General** tab -> click the **Advanced** tab (or click **Toggle Advanced Mode**) and then complete the following:
   Lame TTL: Specify the duration of time to cache a lame delegation or lame server. The default value is 600 seconds (ten minutes) and the maximum value is 1800 seconds (thirty minutes). The appliance displays a warning message when you specify a value equal to 0 (zero). The appliance displays an error message when you specify a value greater than 1800 seconds.
   The **Lame TTL** cache value is inherited from the Grid by the member and DNS view levels and this field is disabled, by default. To override the **Lame TTL** cache value, click **Override**. You can override the value at the member and DNS view levels. To retain the same **Lame TTL** value as the Grid, click **Inherit** at the member and DNS view level.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Specifying Max Cache TTL and Max Negative Cache TTL Settings

You can specify the maximum duration of time for which your name server caches positive responses using the Max Cache TTL settings. The Max Cache TTL indicates the time limit for which the name server retains records in the cache. When the Max Cache TTL for a record expires, the name server deletes the record from the cache.
You can also specify the maximum duration of time for which your name server caches negative responses through the Max Negative Cache TTL settings. The Max Negative Cache TTL sets the time limit for which the name server retains negative responses (NXDOMAIN/NXRRSET responses) in the cache. The name server deletes a negative response from the cache when the Max Negative Cache TTL period for the entry expires.
You can define the Max Cache TTL value and the Max Negative Cache TTL value at the Grid DNS, Member DNS, and DNS view levels.
To specify the Max Cache TTL and the Max Negative Cache TTL:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the **Toolbar** and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   DNS View: From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab -> *dns_view* checkbox -> Edit icon.
2. In the *Grid DNS Properties*, *Member DNS Properties*, or the *DNS View* editor, click **Toggle Advanced Mode** if the editor is in the basic mode.
3. Click the **Advanced** subtab of the **General** tab and then complete the following:

- **Max Cache TTL**: Specify the maximum duration of time for which the name server caches positive responses. Select the time period in minutes, hours, or days from the drop-down list. The default value is one week (7 days), and the maximum value is 49710 days, 1193046 hours, or 71582788 minutes. The appliance displays an error message when you enter a value greater than the maximum value. Note that setting the Max Cache TTL value to 0 (zero) will disable the name server from caching any data, and it is not recommended.
- **Max Negative Cache TTL**: Specify the maximum duration of time for which the name server caches negative responses. Select the time period in minutes, hours, or days from the drop-down list. The default value is three hours, and the maximum value is 7 days, 168 hours, or 10080 minutes. The appliance displays an error message when you enter a value greater than the maximum value. Note that setting the Max Negative Cache TTL value to 0 (zero) will disable the name server from caching negative responses, and it is not recommended.
  The Max Cache TTL value and the Max Negative Cache TTL value are inherited from the Grid at the member and DNS view levels. To override the inherited values, click **Override** and specify the new value. To retain the Grid values, click **Inherit**.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring Hostname and Server ID Options

When you configure DNS anycast, multiple DNS name servers share a single IP address. To identify which DNS name server is answering queries, you can configure the hostname and server ID options so the appliance returns the hostname of the DNS name server that is currently answering queries. By default, the hostname and server ID options are disabled on the NIOS appliance. You can configure the hostname bind directive and server-id directive options at the Grid level and override them at the member level. The appliance returns the hostname of the DNS name server that is currently answering queries when a client queries for the hostname.bind or the id.server with record type as TXT and class CHAOS, as follows:

```
 dig @<IP> hostname.bind txt CH
dig @<IP> id.server txt CH
```

To secure the identity of the internet-facing DNS servers, you can configure the hostname and server ID options for specific Grid members that are internet-facing to return a user defined value instead of the real hostname. Alternatively, you can disable the hostname and server ID options at the Grid level and configure them only for those members that are not internet-facing.
To configure the hostname and server ID options:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, and then select **Grid DNS Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Grid DNS Properties* or the *Member DNS Properties* editor, click **Toggle Advanced Mode** if the editor is in the basic mode.
3. Click the **Advanced** subtab of the **General** tab and then complete the following:
   - **Hostname bind directive**: Select either **Hostname** or **None** from the drop-down list. The default is **None**. If you select **Hostname**, the appliance returns the hostname of the DNS name server that is currently answering queries. Selecting **None** disables the Hostname bind directive option.
     In the *Member DNS Properties* editor, you can also select **User defined** and specify any hostname of your choice. The appliance returns the specified hostname instead of the real hostname of the DNS name server that is currently answering queries.
     To override an inherited setting from the Grid, click **Override**. To retain the same setting as the Grid, click **Inherit**.
   - **Server-id directive**: Select either **Hostname** or **None** from the drop-down list. The default is **None**. If you select **Hostname**, the appliance returns the hostname of the DNS name server that is currently answering queries, when a client queries to identify the server ID of the name server that is answering queries. Selecting **None** disables the Server-id directive option.
     In the *Member DNS Properties* editor, you can also select **User defined** and specify a value of your choice. The appliance returns the specified value when a client queries to identify the server ID of the DNS name server that is answering queries.

To override an inherited setting from the Grid, click **Override**. To retain the same setting as the Grid, click **Inherit**.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Enabling and Disabling DNS Health Check Monitor

You can enable the DNS health check monitor to monitor whether the DNS server is responding to client requests. When you enable this feature, the appliance sends a query to the DNS server and waits for the response until the specified timeout duration. If the appliance is unable to receive a response from the DNS server after the specified number of retries, the appliance sends SNMP traps and email notifications about the failure. The appliance performs the DNS health check periodically based on the specified time interval.

> **Warning**
>
> *The DNS Health Check monitor might not work properly if DNS blackhole feature is enabled or if any named ACL is blocking the query sent to loopback interface.*

To enable or disable the DNS health check monitor:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, and then select **Grid DNS Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Grid DNS Properties* or the *Member DNS Properties* editor, click **Toggle Advanced Mode** if the editor is in the basic mode.
3. Click the **Advanced** subtab of the **General** tab and then complete the following:
   - **Enable DNS Health Check**: This checkbox is deselected by default, meaning the DNS health check monitor is disabled. Select this checkbox to enable the DNS health check monitor and specify the following:
     - **Interval**: Enter the time interval in seconds. The interval value is measured from the end of the previous monitoring cycle. The default is 30 seconds. You can enter a value between 10 and 21600 seconds.
     - **Timeout**: Enter the timeout value in seconds. This is the time the appliance waits for a response to the query. The default is 3 seconds. You can enter a value between 1 and 10 seconds.
     - **Retries**: Enter the number of times the appliance tries to send the query after a failed attempt. The default is 3. You can enter a value between 1 and 10.
4. Save the configuration.

Adding an Email Address to the SOA Record

If the primary name server of a zone is a Grid member, you can add an administrator email address to the SOA record to help admins determine who to contact about this zone.

Adding an Email Address for SOA Records in the Grid

If all zones hosted by the Grid members have the same administrator, you can add the email address once for the Grid. The appliance then adds the email address to the RNAME field of the SOA records of the zones.
To add an email address to the SOA records at the Grid level:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
2. In the **General** -> **Basic** tab of the *Grid DNS Properties* editor, enter the email address in the **E-mail Address (for SOA RNAME field)** field.
   Note the appliance does not support IDN for the **E-mail Address (for SOA RNAME field)** field at the Grid level. You can add an email address containing IDN for the SOA records at the zone level.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Adding an Email Address for the Zone SOA Record

To add an email address to the SOA record of a zone:

1. From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab-> *dns_view* -> *zone* checkbox -> Edit icon.
2. In the *Authoritative Zone* editor, click **Settings**.
3. Click **Override** beside the **Email address (for SOA RNAME field)** field and enter the email address of the zone administrator.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

> ⚠ Note
> The appliance supports IDN for the host name of the **Email address (for SOA RNAME field)** field. For example, you can create *admin@инфоблокс.рф* but not админ@инфоблокс.рф.com.

Notifying External Secondary Servers

Grid members can use database replication to maintain up-to-date zone data sets, so the secondary servers in the Grid can keep their zone data synchronized even if the primary server fails. Any external secondary servers can fall out of sync, however, if they rely only on the primary server to send notify messages when there is new zone data. Therefore all authoritative name servers in a Grid (all primary and secondary servers) send notify messages to external secondary servers by default. This ensures that an external secondary name server receives notify messages when its primary server is a secondary name server in a Grid. However, it also increases the number of notify messages.
Infoblox recommends that you do not configure a large number of external secondary servers in stealth mode. To ensure that these secondary servers receive notifications about zone updates, you can allow zone transfers for these IP addresses and then enable the appliance to add them to the also-notify statement. For information about how to configure this feature, see *Configuring Zone Transfers*.
To specify whether secondary name servers in the Grid are to send notify messages to external secondary name servers:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
2. In the *Grid DNS Properties* editor, click **Toggle Advanced Mode**.
3. When the additional tabs appear, click the **Advanced** subtab of the **General** tab.
4. Complete the following:
   - **Enable Grid secondaries to notify external secondaries:** This option is enabled by default.
   - Notify Delay: Specify the number of seconds that the Grid secondary servers delays sending notification messages to the external secondaries. The default is five seconds.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

For the external secondary servers to accept notify messages from the secondary name servers in the Grid and then request zone transfers from them, you must configure the external secondary servers to use the Grid secondary servers as the source of the zone transfers. This ensures that the external secondary servers continue to receive notify messages, even if the primary server is unavailable.

Enabling the Configuration of RRset Orders

You can use the Infoblox GUI to configure the order that the appliance uses to return the A and AAAA records associated with an Infoblox host. This feature is useful when you want the appliance to return the A and AAAA records of a host in a specific order. For example, if you want the management address to appear first on a list of IP addresses associated with a network device, you can configure the order of the IP addresses so the management address is always returned first on the list when you look up the name of the device. For information about using the Infoblox API to configure RRset order (resource record order) of a host, refer to the *Infoblox API Documentation*.
To specify an RRset order of a host record, you must first enable the feature at the Grid level. When you enable this feature and there are multiple IP addresses associated with the host record, you can specify one of the following RRset orders through the *Host Record* wizard and editor:

- **Fixed**: The A and AAAA records of the host are returned in the order that you specify in the IPv4 and IPv6 address tables.
- **Random**: The A and AAAA records of the host are returned in a random order.
- **Cyclic**: The A and AAAA records are returned in a round robin pattern.

For information about specifying RRset order of a host record, see *Adding Host Records*.
Note that when you configure an order type for the IP addresses associated with a host record, the order type applies to both the A and AAAA records of the host. It does not apply to any non-host A or AAAA records that may have the same owner name as the host record. By default, the appliance returns resource records in a cyclic or round robin order. The return order of non-authoritative data retrieved from a recursion is not affected by the host RRset order, and that remains cyclic.
When you enable the RRset order for hosts at the Grid level, you may not be able to maintain the same DNS responses on a recursive server if it exists in the Grid. You can preserve the original cached DNS responses by configuring a fixed RRset order on the recursive server so it can return A and AAAA records associated with domain names in the original order they were received. For information about configuring the RRset order for the cached DNS responses, see Preserving the RRset Order for Cached DNS Responses below..
To enable the configuration of RRset order for a host record:

1. From the **Data Management** tab -> **DNS** tab, expand the Toolbar, and then click **Grid DNS Properties.**
2. In the *Grid DNS Properties* editor, click **Toggle Advanced Mode**.
3. When the additional tabs appear, click the **Advanced** subtab of the **General** tab.
4. Complete the following:
    - **Enable setting RRset order for hosts with multiple addresses:** Select this checkbox to enable the configuration of RRset order for a host record. After you enable this feature, you can configure the RRset order in the *Host Record* wizard or editor. For information, see *Adding Host Records*.
    - Preserve host RRset order for Grid secondaries that use DNS zone transfers: This is enabled only when you have enabled the setting of RRset order for host records. When you select this checkbox, the RRset order that you configure for a host record applies to the resource records of the Grid secondaries that are in the DNS transfer mode.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Preserving the RRset Order for Cached DNS Responses

By default, when a client queries a domain name, the DNS caching appliance returns the A and AAAA records of the domain name in the cyclic order. However, this default behavior can be overridden if you have enabled and configured (at the Grid level) fixed RRset order for hosts that have multiple addresses. When you override the default behavior and preserve the fixed RRset order for cached DNS responses, the DNS caching appliance returns A and AAAA records associated with domain names in the order they were received from an upstream server. You can preserve the RRset order for the cached DNS responses and specify the fixed RRset order for A, AAAA, or both A and AAAA records at the Grid level and override at the member and DNS view levels. Note that configuring fixed RRset order for specific FQDNs might slightly affect the performance of the DNS caching appliance.
To preserve the fixed RRset order for cached DNS responses at the Grid, member, or DNS view level:

1. **Grid**: From the **Data Management** tab -> **DNS** tab, expand the Toolbar, and then click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   DNS View: From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *dns_view* checkbox -> Edit icon.
2. In the editor, select the **RRset Order** tab -> click the **Basic** tab, and then complete the following:
    - **Enable fixed RRset order for following FQDNs:** Select this checkbox to preserve the configuration of RRset order for cached DNS responses.
    - In the FQDN table, specify the list of FQDN entries for which you want to preserve the RRset order. Note that you can configure a maximum of 25 FQDNs for the specified RRset order.
      You can click the Add icon and complete the following to add a new entry to the list:
        - **FQDN:** Enter the fully qualified domain name with which the A or AAAA record is associated.
        - **Record Type:** Select the record type from the drop-down list. You can select **A**, **AAAA**, or **Both A and AAAA**.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Specifying Port Settings for DNS

When requesting zone transfers from the primary server, some secondary DNS servers use the source port number (the primary server used to send the notify message) as the destination port number in the zone transfer request. If the primary server uses a random source port number when sending the notify message—that the secondary server then uses as the destination port number when requesting a zone transfer—zone transfers can fail if there is an intervening firewall blocking traffic to the destination port number.
Specifying a source port number for recursive queries ensures that a firewall allows the response. If you do not specify a source port number, the NIOS appliance sends these messages from a random port number. You can also specify a source for the DNS Traffic Control health check.
When performing recursive queries, the NIOS appliance uses a random source port number above 1024 by default. The queried server responds using the source port number in the query as the destination port number in its response. If there is an intervening firewall that does not perform stateful inspection and blocks incoming traffic to the destination port number, the recursive query fails.
You can specify a source port number for notify messages to ensure the firewall allows the zone transfer request from the secondary server to the primary server. If you do not specify a source port number, the NIOS appliance sends messages from a random port number above 1024.
You can limit If you have configured anycast and non-anycast IP addresses on the loopback interface, you must enable the appliance to provide DNS services on them. You can also configure the appliance to listen for DNS queries on a specific IP address that you configure on the loopback interface, by separating the source port for DNS queries from the port for notify messages and zone transfer requests. For information about the loopback interface and anycast addressing, see *Configuring IP Addresses on the Loopback Interface*.
You can specify the source address settings for a Grid member and for DNS views assigned to a Grid member. Note that you can specify the source address settings for only specific DNS views that contain zones that are assigned to a Grid member. The static source port values for DNS views are inherited from the Member DNS properties.

Specifying Source Ports

To specify port numbers and settings for queries, notify messages and zone transfer requests for a Grid member or DNS view assigned to a Grid member:

1. **Member**: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   DNS view: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Member DNS Properties* editor, click **General** -> **Basic** tab.
3. You can change the port settings as follows:
   - **Listen on these additional IP addresses**: Click the Add icon to add an anycast or non-anycast address you configure on the loopback or VLAN interface. You must add all IP addresses you configure on the loopback or VLAN interface so the appliance can provide DNS services on them. Adding source ports for listening supports both IPv4 and IPv6 interfaces. For information about adding IP addresses on the loopback interface, see *Configuring IP Addresses on the Loopback Interface*.
     Enter correct information for the following by clicking the field in the row:
     - **Address**: Type the IPv4 or IPv6 address depending on the type of interface.
     - **Interface**: The Interface column displays the name of the interface.
     - **VLAN Tag**: For a VLAN, enter the VLAN tag or ID. You can enter a number from 1 to 4094. Ensure that you configure the corresponding switch accordingly.
   - **Send queries from**: If you want to improve the DNS service performance, you can separate the DNS queries from the notify messages and zone transfer requests. Select a value from the drop-down list to select an interface name: **VIP**, **MGMT**, **LAN2**, **Any interface**, **IP**.
     - **IP Address**: This is displayed only when you select **IP** from the drop-down list. Specify the IP address of the source.
   - **Send notify messages and zone transfer requests from**: From the drop-down list, select the source port of the notify messages and zone transfer requests that the Grid member sends. Select a value from the drop-down list to select an interface name: **VIP**, **MGMT**, **LAN2**, **Any interface**, **IP**. You can select IP addresses on the loopback or non-primary VLAN interface.

- **IP Address**: This is displayed only when you select **IP** from the drop-down list. Specify the IP address of the source.
  Note:
  - **IP** is displayed only if you have additional IP addresses such as the loopback address or VLANs configured.
  - If you select IP addresses on the loopback or non-primary VLAN interface, then you must add these IP addresses in the **Listen on these additional IP addresses** table.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

If you have enabled secondary name servers in the Grid to send notify messages to external secondary name servers, you can specify the delay time for sending the notify messages. For information about enabling Grid secondary servers to send notification messages to the external secondaries, see *Notifying External Secondary Servers*.

To specify the delay time for the Grid secondary servers to send notify messages to the external secondaries:

1. **Member**: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   DNS view: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the editor, click **Toggle Advanced Mode**.
3. **Member**: When the additional tabs appear, click the **Advanced** subtab of the **General** tab.
   DNS view: When the additional tabs appear, click the **Advanced** subtab of the **DNS Views** tab.
4. Complete the following:
   - **Notify Delay**: Specify the number of seconds that the Grid secondary servers delays sending notification messages to the external secondaries. You can enter a value between 5 and 86400 seconds. The default is five seconds.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Specifying Static Source Ports

To specify static source ports for a Grid and Grid member:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   DNS View: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the editor, click **Toggle Advanced Mode**.
3. **Member**: When the additional tabs appear, click the **Advanced** subtab of the **General** tab. **DNS View**: When the additional tabs appear, click the **Advanced** subtab of the **DNS Views** tab. To override an inherited property, click **Override** next to it and complete the appropriate fields.
4. Complete the following:
   - **Set static source UDP port for queries (not recommended)**: This is disabled by default. To override the value that has been inherited from the Grid, click **Override**. Select this checkbox to enable it and enter the UDP port number. You can enter a value between 1 and 63999. To retain the same value as the Grid, click Inherit.
   - **Set static source UDP port for notify messages**: This is disabled by default. To override the value that has been inherited from the Grid, click **Override**. Select this checkbox to specify a source port for notify messages to ensure that the firewall allows the zone transfer request from the secondary server to the primary server. You can enter a value between 1 and 63999. If you do not specify a source port, the appliance sends messages from a random port with a number above 1024. To retain the same value as the Grid, click Inherit.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Using Extension Mechanisms for DNS (EDNS0)

The NIOS appliance supports EDNS0 (Extension Mechanisms for DNS), which allows DNS clients to expand and advertise up to 4096 bytes of UDP packets for certain DNS parameters. EDNS0 facilitates the transfer of UDP packets beyond the original restricted packet size of 512 bytes. As defined in RFC 6891, EDNS0 provides extended UDP packet size that supports additional DNS functionality, such as DNSSEC. When EDNS0 is supported, the DNS client adds

information to the additional data section of a DNS request in the form of an OPT pseudo-RR (resource record). An OPT RR does not contain actual DNS data and its contents pertain to the UDP transport layer message only. An OPT RR is not cached, forwarded, or stored. For more information about EDNS0, refer to RFC 6891 Extension Mechanisms for DNS (EDNS0).
By default, EDNS0 is enabled on the NIOS appliance and all outgoing recursive queries are set to have a maximum UDP packet size of 1220 bytes. The EDNS0 UDP packet size (EDNS0 buffer size) is configurable and can be set from a minimum of 512 bytes to a maximum of 4096 bytes. Typically, when the appliance receives a DNS request that contains an OPT RR, it assumes the DNS client supports EDNS0 and thus scales its response accordingly. When the appliance is used as a forwarder or a resolver for recursive queries and communicates with a client that does not support EDNS0, the appliance sends three queries starting with one that contains EDNS0 and DNSSEC support messages and is set to a maximum UDP packet size of 4096 bytes. When the first query fails, the appliance sends another query that contains only the EDNS0 support message. If the second attempt fails too, the appliance sends a third query that indicates a standard 512-byte query. Note that when EDNS0 is not used, DNS packets may be sent over TCP. For DNS service to function properly at this stage, ensure that you configure your firewall accordingly.

The following information demonstrates how the appliance responds when EDNS0 is enabled by default and the end server does not support EDNS0:

```
 Packet 0954: 08:19:38.925 – query for www.google.com from Infoblox to
forwarder (with EDNS0 support by setting the Extended Label Type to '01' and
DNSSEC OK bit to '1')
 Packet 1138: 08:19:47.927 – query for www.google.com from Infoblox to
forwarder (with EDNS0 support by setting the Extended Label Type to '01' and
DNSSEC OK bit to '0')
 Packet 1504: 08:19:58.929 – query for www.google.com from Infoblox to
forwarder (without EDNS0 and DNSSEC support by sending a standard 512-byte
query)
 Packet 1505: 08:19:30:960 – query response for www.google.com from
forwarder to Infoblox
```

Configuring the EDNS0 Buffer Size and UDP Buffer Size

When the size of a DNS message that is transferred over UDP exceeds the maximum transmission unit, IP packets get fragmented and reassembled. IP fragmentation is considered fragile as it makes certain attacks on DNS possible. NIOS allows you to configure the EDNS0 buffer size and UDP buffer size attributes to control the data packet size allowed in DNS responses so that the data is transferred without fragmentation.

- The UDP buffer size is used by authoritative DNS servers when data is transferred between DNS server and DNS client to ensure that DNS messages they send are not larger than the configured buffer size.
- The EDNS0 buffer size is used by recursive DNS servers when data is transferred between DNS servers to ensure that DNS messages they send are not larger than the configured buffer size.

> ⚠ Note
> The UDP buffer size and EDNS0 buffer size attributes are available only for BIND resolvers and not for unbound resolvers.

You can configure the EDNS0 buffer size and the UDP buffer size are configurable for a Grid, member, standalone system, and a DNS view. To configure the EDNS0 buffer size and UDP buffer size, complete the following steps:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab, and then click the **Members** tab -> *member* checkbox -> Edit icon.

To override an inherited property, click **Override** next to it and complete the appropriate fields.
Standalone system: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **System DNS Properties**.
DNS view: From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *dns_view* checkbox -> Edit icon. Note that if there is only one DNS view, for example, the predefined default view, then you can just click the Edit icon beside it.
To override an inherited property, click **Override** next to it and complete the appropriate fields.

2. In the *Grid DNS Properties, Member DNS Properties, System DNS Properties*, or *DNS View* editor, click **Toggle Advanced Mode** if the editor is in basic mode.
3. Click the **General** tab -> **Advanced** tab, and complete the following:
    a. **EDNS0 Buffer Size**: Specify the maximum packet size to be allowed in DNS query responses when transferring DNS messages between DNS servers. The default buffer size is 1220 bytes. The minimum buffer size that you can set is 512 bytes and the maximum is 4096 bytes.
    Infoblox recommends that you configure the **EDNS0 Buffer Size** value in the range of 512 to 1220 bytes. DNS responses that exceed 1220 bytes can get fragmented and may result in unexpected behavior when resolving queries.
    Note that if you want DNS query responses to use the configured EDNS0 buffer size in servers that support EDNS0, then ensure that you do not disable EDNS0.
    b. **UDP Buffer Size**: Specify the maximum packet size to be allowed in DNS query responses when transferring DNS messages from DNS servers to DNS clients. The default buffer size is 1220 bytes. The minimum buffer size that you can set is 512 bytes and the maximum is 4096 bytes.
    Infoblox recommends that you configure the **UDP Buffer Size** value in the range of 512 to 1220 bytes. DNS responses that exceed 1220 bytes can get fragmented and may result in unexpected behavior when resolving queries.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Disabling EDNS0

To ensure that end servers that do not support EDNS0 can respond to recursive queries from the NIOS appliance and to improve DNS performance, you can disable EDNS0 for the Grid and override the Grid settings for individual members. Note that you cannot configure the maximum UDP packet size, which is set for 4096 bytes by default. When you disable EDNS0, the appliance does not include OPT RRs for all outgoing recursive DNS queries. Thus remote end servers that do not support EDNS0 can still respond to the queries. This feature is useful when your NIOS appliance is used as a forwarder or a resolver for recursive queries, and the end servers in the configuration do not support EDNS0.

> Warning
> *When you disable EDNS0, all outgoing DNSSEC queries to zones within trusted anchors will fail even if DNSSEC validation is enabled. This is due to the restriction of the UDP packet length when you disable EDNS0. For more information about DNSEC, see Configuring DNSSEC.*

To disable EDNS0:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click the **General** tab -> **Advanced** tab, and complete the following:
    - **Disable EDNS0**: This checkbox is deselected and EDNS0 is enabled by default. To override the value inherited from the Grid, click **Override**. To retain the same value as the Grid, click **Inherit**. Select this checkbox to disable EDNS0. When you disable EDNS0, the appliance does not include OPT RRs for all outgoing recursive DNS queries and all outgoing DNSSEC queries to zones within trusted anchors will fail even if DNSSEC validation is enabled.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Deleting PTR Records associated with A or AAAA Records

You can configure the appliance to confirm whether to delete a PTR record when its corresponding A or AAAA record is being deleted. This feature is valid only if you have configured the appliance to automatically generate a PTR record when you create an A or AAAA record. For information about adding an A or AAAA record, see *Adding A Records* and *Adding AAAA Records*. When you delete a resource record, the appliance moves it to the Recycle Bin, if enabled. You can later restore it if needed. Note that this option is disabled by default for all new installations.
To enable this option:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
2. In the *Grid DNS Properties*, click the **General** tab -> **Advanced** tab, and complete the following:
    - **Enable PTR record removal for A/AAAA records**: This checkbox is deselected by default. When you select this checkbox, the appliance displays the *Delete Confirmation* dialog box to confirm that you want to delete a PTR record associated with the A or AAAA record that is being deleted. For information about deleting an A or AAAA record, see *Modifying, Disabling, and Deleting Host and Resource Records.*
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Specifying Minimal Responses

A NIOS appliance returns a minimal amount of data in response to a query, by default. It includes records in the authority and additional data sections of its response only when required, such as in negative responses. This feature speeds up the DNS services provided by the appliance.
To disable returning minimal responses:

1. From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Member DNS Configuration* editor, click **General** -> **Basic** tab.
3. Clear the Return minimal responses checkbox.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Starting and Stopping the DNS Service

The DNS service is disabled by default. After you complete the DNS configuration, you can start DNS service on a member. You can also disable the DNS service on any Grid member. Be aware that disabling the DNS service on a member removes the NS records from it. If you later re-enable DNS service for this member, the NS records are then restored.
To start DNS service on a member:

1. From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> click the Edit icon.
2. In the *Member DNS Properties* editor, click **General** -> **Basic** tab, and do the following:
    - **LAN1**: Select **IPv4** to start the DNS service using IPv4 or select **IPv6** to start the DNS service using IPv6. Note that for a dual mode member, **IPv4** will be selected by default.
3. Save the configuration.
4. Expand the Toolbar and click **Start**.
5. In the *Start Member DNS Service* dialog box, click **Yes**.
   Grid Manager starts the DNS service on the selected member.

You can stop DNS service on a member by selecting the member checkbox and click **Stop** from the Toolbar.

Clearing DNS Cache

The NIOS appliance allows you to clear certain information from the DNS cache. You can do the following:

- Clearing DNS Cache
- Clearing Cache for DNS Views
- Clearing Domains and Subdomains from DNS Cache

Clearing DNS Cache

You can clear all the entries that are saved in the DNS cache. When you clear DNS cache on the NIOS appliance, entire BIND recursive cache is cleared.
To clear DNS cache:

1. From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox.
2. Expand the Toolbar, click **Clear** -> **Clear DNS Cache**.
3. Click **Yes** in the confirmation dialog box to clear DNS cache.

Clearing Cache for DNS Views

You can configure the NIOS appliance to clear cache of a specific DNS view. This feature clears cache entries of a specific DNS view that is associated with the selected member.
To clear cache of a DNS view:

1. From the **Data Management** tab, select the **DNS** tab -> click the **Members** tab.
2. Expand the Toolbar, click **Clear** -> **Clear View's Cache**.
3. Specify the following in the *Clear View's Cache* dialog box:
    - **Member:** Click **Select Member** to select a member. If there are multiple members, the *Member Selector* dialog box is displayed, from which you can select a member. Click the required member name in the dialog box. You can also click **Clear** to clear the displayed member and select a new one.
    - **DNS View:** Select a **DNS View** from the drop-down list. This list box appears only when there are multiple DNS views in the network view.
    - Click **Clear Cache** to clear the cache entries of the corresponding DNS View.

> **Note**
>
> The entire name server recursive cache is cleared, if you do not specify a DNS view when you clear cache using **Clear View's Cache** and **Clear Domain Name** features on the NIOS appliance.

Clearing Domains and Subdomains from DNS Cache

You can clear a specific domain and its subdomains from the DNS cache. When you clear a domain from the DNS cache, it is also removed from the BIND recursive cache.
To clear a specific domain and its subdomains:

1. From the **Data Management** tab, select the **DNS** tab -> click the **Members** tab.
2. Expand the Toolbar, click **Clear** -> **Clear Domain Name**.
3. Specify the following in the *Clear Domain Name from Cache* dialog box:
    - **Domain Name:** Enter a domain name you want to delete.
    - **Clear entire domain (including subdomains):** Select the checkbox to clear the specified domain and its subdomains from the DNS cache. For example, if you enter corpxyz.com in the **Domain Name** field, then selecting this checkbox clears the entire domain including its subdomains such as www.corpxyz.com, corpxyz.com, x.corpxyz.com, etc. This checkbox is deselected by default.
    - **Member:** Click **Select Member** to select a member. If there are multiple members, the *Member Selector* dialog box is displayed, from which you can select a member. Click the required member name in the dialog box. You can also click **Clear** to clear the displayed member and select a new one.
    - **DNS View:** Select a **DNS View** from the drop-down list. This list box appears only when there are multiple DNS views in the network view.
    - Click **Clear Domain Name** to clear the domain name from the cache.

Viewing DNS Cache Entries

The NIOS appliance allows you to view certain information that is stored in the DNS cache. You can do the following:

- View DNS configuration
- View DNS cache details
- View statistics

Viewing DNS Configuration

The NIOS appliance enables you to view DNS configuration details. You can view the configuration details by using a browser. To view DNS configuration:

1. From the **Data Management** tab, select the **DNS** tab -> click the **Members** tab.
2. Expand the Toolbar, click **View** -> **View Configuration**.

Sample Output

```
include "/infoblox/var/named_conf/tsig.key";
options {

key DHCP_UPDATER3; };
```

Corresponding Dashboards and Settings

- The `infoblox-top-query-log-interval 60` setting logs the DNS top queries with an interval of 60 seconds.
- The `infoblox-top-query-name 500` setting captures the DNS top query domain names with the limit of 500.
- The `infoblox-top-query-client 500` setting corresponds to the *DNS Domain Queried by Client* dashboard. For more information about the dashboard, see *Predefined Dashboards*.
- The `infoblox-top-query-rpz` and `infoblox-top-query-rpz-items-per-client` settings are RPZ-specific settings. They correspond to the **Top N Limit** and **Total RPZ Entries per Client** fields under *Grid Reporting Properties* > **DNS** > **DNS RPZ Rule Hit Configuration**. For more information, see *Grid Reporting Properties*.
- You can also choose the number of filter options to display by using the Top N . The default is 10. For more information, see *About Dashboards*.

Viewing DNS Cache Details

You can view data stored in cache for the DNS views that are configured in the NIOS appliance. You can view the details through a browser.
To view cache details:

1. From the **Data Management** tab, select the **DNS** tab -> click the **Members** tab.
2. Expand the Toolbar, click **View** -> **View Cache**.

Sample Output

```
;; Start view _default
;;; Cache dump of view '_default' (cache _default)
;$DATE 20121018180555
; authanswer  a.test.com .23876IN A4.4.4.4
;; Address database dump
;; Dump complete
```

Viewing Statistics

The View Statistics feature enables you to view DNS Statistics of a Grid member. You can view statistics through a browser.
To view statistics:

1. From the **Data Management** tab, select the **DNS** tab -> click the **Members** tab.
2. Expand the Toolbar, click **View** -> **View Cache**.

You can view statistics in the *DNS Statistics for Member* dialog box.

Using Forwarders

A forwarder is essentially a name server to which all other name servers first send queries that they cannot resolve locally. The forwarder then sends these queries to DNS servers that are external to the network, avoiding the need for the other name servers in your network to send queries off-site. A forwarder eventually builds up a cache of information, which it uses to resolve queries. This reduces Internet traffic over the network and decreases the response time to DNS clients. This is useful in organizations that need to minimize off-site traffic, such as a remote office with a slow connection to a company's network.

You can select any Grid member to function as a forwarder. You must configure your firewall to allow that Grid member to communicate with external DNS servers. You can also configure NIOS to send queries to one or more forwarders. You can define a list of forwarders for the entire Grid, for each Grid member, or for each DNS view.

If your network configuration includes Infoblox BloxOne Threat Defense, you can configure NIOS Grid members (physical or virtual appliance) to forward recursive queries to BloxOne Threat Defense. For more information about BloxOne Threat Defense, see *BloxOne Threat Defense*. For information about how to configure NIOS members as DNS forwarding proxies, see Forwarding Recursive Queries to BloxOne Threat Defense below.

Selecting Forwarders

When there is more than one forwarder in the Grid, the NIOS resolver uses a smoothed metric derived from RTT (Round Trip Time) to select the name server to send queries to. RTT is the length of time between when a query was sent and when its response was received.

Specifying Forwarders

To configure forwarders for a Grid, member, or DNS view, complete the following:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon.
   DNS View: From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *dns_view* checkbox -> Edit icon.
   Note that if there is only one DNS view— for example, the predefined default view—you can just click the Edit icon beside it.
   To override an inherited property, select **Override** next to it and complete the appropriate fields.

2. Click the **Forwarders** tab.
3. Click the Add icon.
4. Enter an IP address in the text field. The field supports entry for both IPv4 and IPv6 values.
    a. To remove a forwarder, select the IP address from the Forwarders list, and then click the Delete icon.
    b. To move a forwarder up or down on the list, select it and click the **Up** or **Down** arrow.
5. To use only forwarders on your network (and not root servers), select the **Use Forwarders Only** checkbox.
6. Select the **Add client IP, MAC addresses, and DNS View name to outgoing recursive queries** checkbox to include the client IP address, MAC address, and DNS view name of the client from which the DNS query was initiated, to outgoing recursive queries. For information on recursive queries, see *Enabling Recursive Queries*. Selecting this option includes EDNS0 custom options.
7. Select the **Copy client IP, MAC addresses, and DNS View name to outgoing recursive queries** checkbox to copy and validate the client IP address, MAC address, DNS view name from incoming queries to outgoing queries. If this checkbox is selected and:
    - Only one custom option is present, the IP address or MAC address or DNS view name is copied to the outgoing query without adding the missing option. An incoming query can contain only one IP address or MAC address or DNS view name.
    - No custom option is present, if the **Add client IP, MAC addresses, and DNS View name to outgoing recursive queries** checkbox is selected, valid IP address, MAC address, and DNS view name EDNS0 options are copied from incoming queries to outgoing recursive queries without any change. If the **Add client IP, MAC addresses, and DNS View name to outgoing recursive queries** checkbox is not selected, no options are added to outgoing recursive queries.
      For more information about EDNS0 options, see *Configuring DNS Traffic Control Properties* and *Using Extension Mechanisms for DNS (EDNS0)*.
8. Save the configuration and click **Restart** if it appears at the top of the screen.

> **Note**
>
> Infoblox recommends that you do not include client IP addresses and MAC addresses in queries directed to non-Infoblox DNS servers and that you include the addresses in only those queries directed at Infoblox DNS servers.

Forwarder Limitations

- Forwarding zones (also known as conditional forwarders) do not support the **Add client IP, MAC addresses, and DNS View name to outgoing recursive queries** and the **Copy client IP, MAC addresses, and DNS View name to outgoing recursive queries** checkboxes.
- Only BIND-based DNS servers support these options. Unbound-based DNS servers do not support these options.

Forwarding Recursive Queries to BloxOne Threat Defense

To forward recursive queries to BloxOne Threat Defense, you must first register each NIOS member in your Grid as a DNS forwarding proxy through the Cloud Services Portal. When you register a Grid member, the DNS forwarding proxy software is installed on the member. The DNS forwarding proxy embeds the client IP addresses in the DNS queries before forwarding them to BloxOne Threat Defense. The communications are encrypted and client visibility is maintained. Once you set up a DNS forwarding proxy on a Grid member, all recursive queries for that member are forwarded to a local DNS forwarding proxy by the NIOS DNS service. It also caches responses to speed up DNS resolution for future queries. For information about configuring DNS forwarding proxies, see *On-Prem Host Management*.

Make sure that port 443 is open against its respective domain for DNS forwarding proxy to work between NIOS and BloxOne Threat Defense.

Guidelines When Enabling Recursive Query Forwarding on a Grid Member

Note the following when you enable recursive query forwarding on a Grid member:

- Make sure that you enable recursion on the member that you wish to use as a forwarding proxy to BloxOne Threat Defense. For information about how to enable recursion on a Grid member, see *Enabling Recursive Queries*.
- DNS forwarding proxy does not work on systems configured in the IPv6-only mode.
- DNS forwarding proxy is not supported on the IB-100, IB-810, IB-820, IB-V810, and IB-V820 appliances. Infoblox recommends that you do not configure DNS forwarding proxy on these appliances.
- DNS forwarding proxy is not supported on any appliance that is running on a memory lower than 4 GB.
- Grid Manager ignores global forwarders and all recursive queries are send to BloxOne Threat Defense.
- Unbound is not supported on a Grid member when it uses Bind to send recursive queries to BloxOne Threat Defense. For information about Unbound, refer to the *Infoblox DNS Cache Acceleration Application* Guide.
- There might be a significant performance impact on your appliance and network during the DNS forwarding proxy installation process depending on the network connectivity between NIOS and BloxOne Threat Defense. Every node will have to install the DNS forwarding proxy before serving DNS recursive queries, which includes the HA nodes.
- When you enable DNS forwarding to BloxOne Threat Defense, the QPS (query per second) throughout might vary, depending on your appliance models and the cache hit ratios. You might see a bigger performance impact when the cache hit ratio is lower.
- DNS forwarding proxy does not work with DNSSEC in case a request was redirected by BloxOne Threat Defense. If you are running DNS forwarding proxy on NIOS, you must disable DNSSEC validation. Even if you disable DNSSEC validation, validation still takes place through BloxOne Threat Defense. To enable DNS forwarding proxy to work with DNSSEC in case a request was redirected by BloxOne Threat Defense, see Enabling DNS Forwarding Proxy to Work with DNSSEC below.
- To bypass recursive query forwarding to BloxOne Threat Defense, you must disable the DNS forwarding proxy service.
- By adding the join token you obtained from the Cloud Services Portal, and specifying the IP address of the Cloud Services Portal in the **CSP Resolver** field, you can establish connectivity between NIOS and Cloud Services Portal. Thereafter, you can enable the NIOS Grid Connector service in the Cloud Services Portal. This capability provides you with a single interface for viewing comprehensive network data such as global IP space, subnets, IP addresses, and DHCP lease data for your BloxOne Cloud infrastructure and NIOS. For more information, see *Configuring NIOS Grid Connector* in the BloxOne Threat Defense documentation.

Enabling a Grid Member to Forward Recursive Queries to BloxOne Threat Defense

To enable a Grid member to forward recursive queries to BloxOne Threat Defense, complete the following:

1. Log in to the Cloud Services Portal at *csp.infoblox.com*.
2. Create a join token by following the instructions in the *Managing Join Tokens for On-Prem Hosts* section of the BloxOne Threat Defense documentation. In an HA environment, two on-prem hosts are created. You must ensure that the configurations for both these on-prem hosts are the same for the HA nodes to work seamlessly.
3. Log in to Grid Manager.
4. On the **Grid** tab, click the **Grid Manager** tab -> **Grid Properties** -> **Edit**.
5. In *Grid Properties Editor*, click the **CSP Config** tab and complete the following:
    - **Join Token:** Configure the join token that you created in the Cloud Services Portal in step 2. However, if the field is empty, the cloud connection is not to be terminated.
    - **CSP Resolver:** Displays the IP address of the local DNS resolver. This IP address or DNS is used to resolve Infoblox domains when the DNS Forwarding Proxy service starts. You must configure at least one external resolver that will be used to resolve all required domains. If you do not enter an IP address, 52.119.40.100 is taken as the default.
    - **HTTP proxy**: Enter the URL of the proxy server in the http://<*IP*|*host*>:<*port*> format. When you update the HTTP proxy, the NIOS on-prem agent updates it to the other on-prem containers by restarting the containers at a specific interval which can cause a maximum delay of 15 minutes.
6. Click **Save & Close**.
7. **Member**: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox -> Edit icon.
8. In the *Grid Member Properties Editor*, click the **CSP Config** tab, and then complete the following. To override an inherited property, click **Override** next to it and enter the value for the appropriate fields if you do not want to inherit the values from the Grid. Once you override, the settings are applicable only at the member level.
    a. **Join Token**: Displays the join token value that is inherited from the Grid. However, if the field is empty, the cloud connection is not to be terminated.

b. **CSP Resolver**: Displays the Cloud Services Portal resolver value that is inherited from the Grid.
c. **HTTP Proxy**: Displays the URL that is inherited from the Grid.
d. **Standalone:** Select this option when the member is standalone.
    i. **Access Key**: You cannot edit the value of this field; you can only clear it. However, clearing the access key value does not terminate the cloud connection.
e. **HA Enabled:** Select this option when the member is an HA.
    i. **Access Key**: You cannot edit the value of this field; you can only clear it. In case of a NIOS upgrade, the access keys are the same for both the active and passive nodes.

9. Click **Save & Close**.
10. On the **Grid** tab, select the **Grid Manager** tab -> **DFP** tab -> *member* checkbox -> Edit icon.
11. In *Member DFP Properties* editor, select the **Fallback to the default resolution process if BloxOne Threat Defense Cloud does not respond** checkbox to forward recursive queries to the local root name servers in case BloxOne Threat Defense fails or if BloxOne Threat Defense fails to resolve recursive queries. For newly configured DNS forwarding proxies in NIOS, Infoblox recommends that you keep this option selected until you have verified that the NIOS proxies are functioning properly. In the Cloud Services Portal, go to **Manage** -> **On-Prem Hosts** to ensure that the statuses for the NIOS proxies that you have registered are active.

⚠ Note

- If you have upgraded to NIOS 8.5.x with DNS forwarding proxy enabled on any node, Infoblox recommends that you do not remove the on-prem hosts from the Cloud Services Portal. This is because NIOS preserves the access key during the upgrade and the NIOS Grid member connects to the Cloud Services Portal using the same access key.
- You must create a join token to authenticate a virtual DNS forwarding proxy for establishing a connection to the cloud. For more information on creating a join token, see the *Managing Join Tokens for On-Prem Hosts* section in the BloxOne Threat Defense documentation.
- If you have upgraded NIOS, the value of the **Access Key** field is the same as the API key that is displayed in the Cloud Services Portal.

Enabling DNS Forwarding Proxy to Work with DNSSEC

DNS forwarding proxy does not work with DNSSEC in case a request was redirected by BloxOne Threat Defense. To enable DNS forwarding proxy to work with DNSSEC, perform the following steps:

1. Enable DNS Forwarding Proxy on NIOS by clicking **Manage** -> **On-Prem Hosts** in the Cloud Services Portal.
2. On Grid Manager, Disable the **Fall back to the default resolution process if BloxOne Threat Defense Cloud does not respond** option.
3. Enable DNSSEC validation as described in *Enabling DNSSEC Validation*.
4. Remove trust anchors if any. To configure trust anchors, see *Enabling DNSSEC Validation*.

Controlling DNS Queries

By default, the NIOS appliance responds to DNS queries from any IP address. You can create a list of queriers to which the appliance is allowed to respond; restricting it to specific networks, IP addresses, and remote servers that present specified TSIG (transaction signature) keys. When using TSIG keys, it is important that the appliances and servers involved with the authentication procedure use NTP (Network Time Protocol) for their time settings (see *Using NTP for Time Settings*).
In addition, you can also configure the appliance to respond to recursive queries. A recursive query requires the appliance to return requested DNS data, or locate the data through queries to other servers. Recursion is disabled by default. If you enable this feature, you can also create a list of allowed recursive queries. For information about allowing recursion, refer to *Enabling Recursive Queries*.
You can create a list of allowed queriers for the Grid and for individual Grid members.

Specifying Queries

To configure a list of allowed queriers for the Grid or for a member:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click **Toggle Advanced Mode**, select the **Queries** tab.
3. In the Allow queries from section, select one of the following:
   - **Any**: Select this if you do not want to configure access control for DNS queries. The appliance allows queries from all clients. This is selected by default.
   - **Named ACL:** Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this, the appliance allows clients that have the **Allow** permission to send and receive DNS queries. You can click **Clear** to remove the selected named ACL.
   - **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows:
     - **IPv4 Address** and **IPv6 Address:** Select this to add an IPv4 address or IPv6 address. Click the **Value** field and enter the IP address of the remote querier. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
     - **IPv4 Network:** In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address:** Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
       - **Permission:** Select **Allow** or **Deny** from the drop-down list.
     - **IPv6 Network:** In the **Add IPv6 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address:** Enter an IPv6 network address and select the netmask from the drop-down list.
       - **Permission:** Select **Allow** or **Deny** from the drop-down list.
     - **TSIG Key:** In the **Add TSIG Key** panel, complete the following, and then click **Add** to add the TSIG key to the list:
       - **Key name:** Enter a meaningful name for the key, such as a zone name or the name of the remote name server. This name must match the name of the same TSIG key on other name servers.
       - **Key Algorithm:** Select either **HMAC-MD5** or **HMAC-SHA256.**
       - **Key Data:** To use an existing TSIG key, type or paste the key in the **Key Data** field. Alternatively, you can select the key algorithm, select the key length from the **Generate Key Data** drop down list, and then click **Generate Key Data** to create a new key.
     - **Any Address/Network:** Select to allow or deny queries from any IP addresses.
     After you have added access control entries, you can do the following:
       - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
       - Reorder the list of ACEs using the up and down arrows next to the table.
       - Select an ACE and click the Edit icon to modify the entry.
       - Select an ACE or multiple ACEs and click the Delete icon to delete the entries.
4. Save the configuration.

Enabling Recursive Queries

You can enable the appliance to respond to recursive queries and create a list of allowed networks, IP addresses, and remote servers that present specified TSIG (transaction signature) keys. When using TSIG keys, it is important that the appliances and servers involved with the authentication procedure use NTP (Network Time Protocol) for their time settings (see *Using NTP for Time Settings*).
A recursive query requires the appliance to return requested DNS data, or locate the data through queries to other

servers. When a NIOS appliance receives a query for DNS data it does not have and you have enabled recursive queries, it first sends a query to any specified forwarders. If a forwarder does not respond (and you have disabled the **Use Forwarders Only** option in the **Forwarders** tab of the *Member DNS Properties* editor), the appliance sends a non-recursive query to specified internal root servers. If no internal root servers are configured, the appliance sends a non-recursive query to the Internet root servers. For information on specifying root name servers, see *About Root Name Servers.*

You can enable recursion for a Grid, individual Grid members, and DNS views. For information about enabling recursion in a DNS view, see *Configuring DNS Views*. If you do not enable recursion, the appliance denies recursive queries from all clients.

Enabling Recursion

To enable recursion and create a list of recursive queriers:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click **Toggle Advanced Mode**, select the **Queries** tab.
3. Click **Allow recursion**, and then in the *Allow recursive queries from* section, select one of the following:
   - **Any**: Select this if you want to configure access control for recursive queries. When you select **Any**, the appliance allows recursive queries from all clients. This is selected by default.
   - **Named ACL:** Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this, the appliance allows clients that have the **Allow** permission to send and receive recursive DNS queries. You can click **Clear** to remove the selected named ACL.
   - **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows.
     - **IPv4 Address** and **IPv6 Address:** Select this to add an IPv4 address or IPv6 address. Click the **Value** field and enter the IP address of the remote querier. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
     - **IPv4 Network:** In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address:** Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
       - **Permission:** Select **Allow** or **Deny** from the drop-down list.
     - **IPv6 Network:** In the **Add IPv6 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address:** Enter an IPv6 network address and select the netmask from the drop-down list.
       - **Permission:** Select **Allow** or **Deny** from the drop-down list.
     - **TSIG Key:** In the **Add TSIG Key** panel, complete the following, and then click **Add** to add the TSIG key to the list:
       - **Key name:** Enter a meaningful name for the key, such as a zone name or the name of the remote name server. This name must match the name of the same TSIG key on other name servers.
       - **Key Algorithm:** Select either **HMAC-MD5** or **HMAC-SHA256.**
       - **Key Data:** To use an existing TSIG key, type or paste the key in the **Key Data** field. Alternatively, you can select the key algorithm, select the key length from the **Generate Key Data** drop down list, and then click **Generate Key Data** to create a new key.
     - **Any Address/Network:** Select to allow or deny queries from any IP addresses.

     After you have added access control entries, you can do the following:
       - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box.

The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
- Reorder the list of ACEs using the up and down arrows next to the table.
- Select an ACE and click the Edit icon to modify the entry.
- Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.

4. Save the configuration.

Configuring Resolver Queries Timeout

You can configure the amount of time that a recursive query will wait for a response before timing out. The default timeout behavior is to wait for 30 seconds before timing out.
To configure the resolver queries timeout value:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click **Toggle Advanced Mode**, select the **Queries** tab and complete the following:
   - **Resolver queries timeout**: Specify the maximum time allowed for a recursive query to wait for a response before timing out. You can enter either 0 or a value between 10 and 30 seconds. Setting the timeout value to 0 returns to the default timeout behavior, which is to wait for 30 seconds before timing out.
3. Save the configuration.

Restricting Recursive Client Queries

By default, the appliance can serve up to 1,000 outstanding recursive client queries. You can change this default value according to your business needs. After you configure the recursive client queries limit, you can enable the appliance to send SNMP traps for recursive queries. Enabling SNMP traps for recursive clients can help you identify possible flood attacks on the DNS recursive server. The appliance sends SNMP traps when the number of recursive client queries exceeds the configured thresholds. For information about how to set the threshold and reset values, see *Defining Thresholds for Traps*.

1. From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Member DNS Properties* editor, click **Toggle Advanced Mode**.
3. When the additional tabs appear, click the **Advanced** subtab of the **Queries** tab.
4. Select the **Limit number of recursive clients to** option and enter a number. By default, the appliance is allowed to serve up to 1000 concurrent clients that send recursive queries. You can change this default according to your business needs from between 0 to 40000.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Enabling Recursive Resolution Using EDNS Client Subnet (ECS) Option

The EDNS Client Subnet (ECS) option is a DNS extension you use to optimize recursive resolution for query sources that are not topologically close to the recursive resolvers. When you enable ECS for recursive resolution, the appliance includes subnet information of the host that originates a DNS query. Thus, your recursive resolver can perform geotargeting by passing the subnet information to authoritative servers so that the response will be more optimized for the end clients. For example, when you enable ECS and/or ECS forwarding on your recursive resolver, CDNs (Content Delivery Networks) can deliver content faster and more efficiently to the end user by providing information about the end user's subnet to the authoritative DNS server operated by the CDNs.
You can enable the NIOS appliance to handle recursive queries using ECS option and enable ECS forwarding support at the Grid level. You can then add whitelisted zone names that are subject to ECS recursion and specify the source prefix length for IPv4 and IPv6 addresses. Make sure you enter only apex zones. Example: foo.com, corpxyz.com, etc. The whitelisted zone name indicates the zone to which ECS tagged queries must be sent.
Note the following while adding whitelisted zone names:

- ECS options are sent only when the name being queried and the apex of the zone being queried both match ECS zones. For example, if the zone "foo.com" contains a subdomain "www.foo.com", then you must configure

"foo.com" as ECS zone and not "www.foo.com". The latter configuration might result in no ECS queries being sent, because the apex zone, "foo.com" does not match with "www.foo.com".
- Queries for subdomains of the specified zone name, with prefix lengths greater than the specified prefix length is not applicable for the subdomains of the specified zone name. For example, if you specify "foo.com" with IPv4 prefix length 20, then IPv4queries with prefix length greater than 20 is not applicable for the subdomains of "foo.com".
- You can exclude certain subdomains by adding a leading exclamation mark (!) to the subdomain name. Example: ! foo.example.org, ! test.foo.com, etc.

Guidelines for Using ECS and ECS Forwarding

The following are the guidelines for using ECS and ECS forwarding:

- When recursive ECS is enabled, the appliance applies ECS handling for queries that meet both of the following criteria:
    - If the source prefix length is not set to zero.
    - If the query name matches one of the listed whitelisted zone names.
- If you enable ECS forwarding, all queries that contain a valid ECS option will be forwarded to the authoritative server.
- Queries with the source prefix length set to zero will be forwarded unchanged, regardless of whether ECS forwarding is enabled or disabled.
- When recursive ECS and ECS forwarding are enabled, then response to queries that contain a valid ECS option with a non-zero source prefix length will contain an ECS option.
- When recursive ECS is enabled and ECS forwarding is disabled, and if the original query contains a valid ECS option with a non-zero source prefix length, then the resolver returns a REFUSED response.

To enable recursive ECS and configure DNS resolver parameters, complete the following:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
2. In the *Grid DNS Properties* editor, click the **Advanced** subtab of the **Queries** tab and complete the following:
    - **Enable Recursive ECS**: Select this checkbox to enable recursive resolution using ECS. This is disabled by default. If recursive ECS is enabled, the appliance applies ECS handling for queries that meet both of the following criteria:
        - If the source prefix length is not set to zero.
        - If the query zone name is listed in the whitelisted domains.
    - **Enable ECS Forwarding**: Select this checkbox to enable ECS forwarding. If you enable ECS forwarding, all queries containing a valid ECS option will be forwarded to the authoritative server.
      Note: Queries with the source prefix length set to zero will be forwarded unchanged, regardless of whether ECS forwarding is enabled or disabled.
    - **Query Zone Permissions**: Click the Add icon to add a list of query zone names that are subject to ECS recursion and the corresponding permission. Grid Manager adds a row to the table. Complete the following:
        - **Zone Name**: Enter the zone name.
        - **Permission**: Select **Allow** or **Deny** from the drop-down list.
    - **IPv4SourcePrefix**: Specify the IPv4 source prefix length. You can enter a value between 1 and 24. The default value is 24.
    - **IPv6SourcePrefix**: Specify the IPv6 source prefix length. You can enter a value between 1 and 56. The default value is 56.

Enabling DNS Fault Tolerant Caching

When an authoritative DNS server experiences an outage, all web sites served by the DNS server become inaccessible. Enabling the DNS fault tolerant caching option allows users to access the web sites served by the DNS server despite the DNS server outage. When you enable the DNS fault tolerant caching option, DNS records are retained in the recursive cache even after they expire. Whenever recursive query times out or returns a SERVFAIL response, the appliance returns the cached response to the client instead of the SERVFAIL response.

When you enable DNS fault tolerant cache, you can also specify the TTL (time-to-live) and timeout settings for the expired records. TTL specifies the time duration for which the expired record is retained in the recursive cache. Setting a high TTL might cause the client to use incorrect data for a longer duration. Conversely, setting a low TTL renders more

current cached data, but also increases the traffic on your network. The expired record is deleted from the recursive cache after the specified timeout duration.

Only DNS members with recursion enabled can support this feature. You can enable this feature at the Grid level and override it at member level with recursion enabled. For information on enabling recursion for a Grid or member, see Enabling Recursive Queries. Note that DNS fault tolerant caching does not work when you set the **DNS Resolver Type** to **Unbound**.

To enable DNS fault tolerant caching, complete the following:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   To override Grid settings, click **Override** next to it and complete the appropriate fields.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click **Advanced** subtab of the **Queries** tab and complete the following:
   - **Enable Fault Tolerant Caching**: Select this checkbox to enable the retention of expired records in the recursion. When you enable this option, the appliance retains the expired records in the recursive cache. Whenever recursive queries times out or returns a SERVFAIL response, the appliance returns the cached response to the client instead of the SERVFAIL response. This is disabled by default.
     - **Expired Record TTL**: Specify the time duration that the appliance must serve the expired records from the recursive cache before attempting to refresh the records. The default is five seconds. Select the time period in minutes, hours, or days from the drop-down list.
     - **Expired Record Timeout**: Specify the time duration that the appliance waits before deleting the expired records from recursive cache. The default is 24 hours. Select the time period in minutes, hours, or days from the drop-down list.
3. Save the configuration.

Controlling AAAA Records for IPv4 Clients

By default, the NIOS appliance returns resource records, including AAAA records, in response to DNS queries. You can enable the appliance to filter and remove AAAA records in response to queries received over IPv4 for each name server and DNS view. This feature is useful in a configuration where a client issues a DNS query over IPv4 when it does not have the ability to use an IPv6 address. When a response returns an IPv6 address however, the client that sends the query over an IPv4 transport would lose connectivity. By enabling AAAA filtering, you can configure your name server not to return AAAA records to clients that request queries over an IPv4 transport. Presumably, these clients then re-query the name server for A records for the same domain name.
Depending on your configuration, the appliance can remove AAAA records for all queries over IPv4 (even when DNSSEC is enabled), or only for queries that are not DNSSEC-signed. You can also create a list of IPv4 networks and addresses to which the appliance applies AAAA filtering and vice versa. You can enable and configure AAAA filtering for the Grid, members, and DNS views.
To control whether you want the appliance to return AAAA records for queries sent over IPv4, you must first enable AAAA filtering, and then create a list of IPv4 networks and addresses that allow or deny AAAA filtering from the appliance, as described in Enabling AAAA Filtering.

Note

An AAAA record is filtered only when there is also an A record for the same domain name. In this case, the appliance still sends a response, but without any AAAA or A record in it. When a client queries for an AAAA record and there is no corresponding A record for it, the appliance returns the AAAA record even if you have enabled AAAA filtering for this client.

Enabling AAAA Filtering

To enable AAAA filtering and configure a list of IPv4 networks and addresses:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab > **Members** tab -> member checkbox -> Edit icon.
   DNS View: From the **Data Management** tab, click the **DNS** tab -> **Zones** tab> *dns_view* checkbox -> Edit icon.
   To override Grid settings, click **Override** and complete the appropriate fields.
2. In the editor, click the **Queries** tab and complete the following:
   Enable AAAA Filtering: From the drop-down list, select one of the following:
   - **Break DNSSEC**: Select this to remove AAAA records in response to queries sent over IPv4, including those that are signed by DNSSEC.
     Note: Be aware that when you select this option, DNSSEC configuration will no longer be in effect.
   - **No**: Select this to disable AAAA filtering for queries over IPv4. When you select this, the appliance returns AAAA records in response to all DNS queries issued over IPv4. This is selected by default.
   - **Yes**: Select this to enable AAAA filtering for queries over IPv4. When you select this, the appliance removes AAAA records in response to all DNS queries issued over IPv4, except for DNSSEC-signed requests.
3. In the *AAAA Filtering* section, select one of the following:
   - **None**: Select this if you want to configure access control for AAAA filtering. The appliance allows all clients to issue DNS queries over IPv4 when they do not have the ability to use IPv6 addresses. This is selected by default.
   - **Named ACL**: Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this, the appliance allows clients that have the **Allow** permission can filter AAAA responses. You can click **Clear** to remove the selected named ACL.
   - **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows.
     - **IPv4 Address**: Select this to add an IPv4 address. Click the **Value** field and enter the IP address of the client. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list. When you select **Allow**, the appliance applies AAAA filtering and removes AAAA records in response to queries sent by the specified IPv4 address. When you select **Deny**, the appliance does not apply AAAA filtering and thus returns AAAA records.
     - **IPv4 Network**: In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
     - **Address**: Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
     - **Permission**: Select **Allow** or **Deny** from the drop-down list.
   - **Any Address/Network**: Select to allow or deny AAAA filtering from any IP addresses.
     After you have added access control entries, you can do the following:
   - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
   - Reorder the list of ACEs using the up and down arrows next to the table.
   - Select an ACE and click the Edit icon to modify the entry.
   - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.

> ⚠ Note
>
> If you do not enter any addresses or networks in the table, the appliance applies AAAA filtering to all IPv4 clients. In other words, the appliance removes AAAA records in responses to all queries sent over IPv4.

About NXDOMAIN Redirection

When a DNS member with recursion enabled receives a recursive query for data for which it is not authoritative, it locates the data through queries to other servers. If the query is for a non-existent domain name, the DNS member receives an NXDOMAIN response from the authoritative name server, which the member then forwards to the DNS client. An NXDOMAIN response contains a "Name Error" RCODE, signifying that the domain name referenced in the query does not exist. (For information, you can refer to *RFC 1035, Domain Names — Implementation and Specification*.)
You can install a Query Redirection license on a recursive DNS member to control its response to queries for A records of non-existent domain names and other domain names that you specify. After the license is installed, Grid Manager displays the **NXDOMAIN Rulesets** tab where you can create rules that specify how a DNS member responds to queries for A/AAAA records for certain domain names and non-existent domain names. Each rule contains a domain name specification, and the action of the DNS member when the domain name in the query matches that in the rule. After you create the rules, you then enable the NXDOMAIN redirection feature and list the IP addresses that are included in the synthesized responses.
Recursive DNS members can redirect responses to queries for A/AAAA records only. DNS members resolve queries for all other records as they normally would.
In addition, you can enable DNS members to log queries that match rules with an action of "Redirect" or "Modify". You can view the logs in the *Syslog* viewer. The logs include the queried domain name, source IP address, the pattern of the matched rule, and the name of the corresponding ruleset.
When DNSSEC is enabled on the Infoblox DNS server, it does not redirect DNS clients that request DNSSEC data for a non-existent domain name. Instead, it returns an authenticated negative response in the form of an NSEC or NSEC3 RR. (For information about DNSSEC, see *Configuring DNSSEC*.) If DNSSEC is not enabled, the appliance ignores the request for DNSSEC data and redirects the clients.
To apply the configured NXDOMAIN rules regardless of whether a DNS query requests DNSSEC data, configure the appliance accordingly. For more information about how to configure this, see *Applying Policies and Rules to DNS Queries that Request DNSSEC Data*.
You can enable NXDOMAIN redirection at the Grid, member, and DNS view levels. Only recursive DNS servers can redirect DNS clients. Non-recursive DNS members do not redirect DNS clients. For information on enabling recursion on a DNS member, see *Enabling Recursive Queries*.

Note that if both NXDOMAIN redirection and the blacklisting feature are enabled, the DNS member applies the blacklist rulesets before the NXDOMAIN rulesets. For information about blacklisting domain names, see *Blacklists*.

About NXDOMAIN Rulesets

An NXDOMAIN ruleset is a list of rules that a DNS member uses to determine its response to recursive queries for A records it does not have. Each rule consists of a domain name specification or pattern, and an associated action.
Domain names can contain any printable character. You can use certain metacharacters to create domain name patterns that are used to match the domain names in DNS queries. Pattern matching is case-insensitive. Patterns support the following metacharacters:

- Use the caret character (**^**) to indicate the beginning of a pattern. For example, **^foo** matches **foo.com** but not **barfoo.com**. The caret character has a special meaning only if it is specified at the beginning of a pattern.
- Use the dollar sign character (**$**) to indicate the end of a pattern. The dollar sign character has a special meaning, only if it is specified at the end of the pattern. For example, **.com$** matches **corpxyz.com** but not **corpxyz.com.net**. When the pattern contains a **$** at the end, NIOS automatically adds a period (**.**) before the **$**. For example, if you enter **.com$**, NIOS saves it as **.com.$**. The period indicates that the pattern specifies a complete domain name that ends with the root label.
- Use the asterisk character ({**}**)* as a wildcard that can match zero or more characters in one or more labels of a domain name. For example, **xf*oy** matches **xfooy.com**, but not **xfoobary**.
  A pattern that contains a single asterisk ({**}) (or an equivalent expression, such as *"^$"{*}) matches any domain name.
- Use the backslash character (****) with one of the metacharacters (**$**, **^**, *** and {}) to remove their special meaning. If **** is followed by any other character, that character is taken as an ordinary character, as if \ is not present. For example, **foo\\\.bar** matches **foo\.bar**, and ***** matches a literal asterisk in a domain name.

No other characters have any special meaning. Note in particular that the period character (".") only matches a period used as a separator in a domain name.
The action specifies how the DNS member responds when a domain name in a query matches a pattern. The action can be one of the following: **Pass**, **Modify** or **Redirect**.

- **Pass:** The DNS member resolves the query and forwards the response to the DNS client, even if it is an NXDOMAIN response.
- **Modify:** The DNS member resolves the query and forwards the response to the DNS client, only if it is not an NXDOMAIN response. But if the member receives an NXDOMAIN response, it sends the client a synthesized response that includes predefined IP addresses.
- **Redirect:** The DNS member does not resolve the query. Instead, it sends the client a synthesized response that includes predefined IP addresses.

You can configure multiple rulesets. The DNS member applies the rulesets and their rules in the order in which they're specified in the configuration. If multiple rulesets contain rules with duplicate patterns, the DNS member applies the first rule it encounters and ignores the other rules.

Examples

The following example illustrates how the appliance applies NXDOMAIN rulesets. Ruleset 1:

Pattern	Action
a1.corpxyz.com	PASS
*.corpxyz.com	REDIRECT

- If the DNS member receives a query for a1.corpxyz.com, it resolves the query and forwards the response, even if it is an NXDOMAIN response, to the client. Note that if the order of the rules was switched, the DNS client would have been redirected immediately, because the domain name a1.corpxyz.com matches the *.corpxyz.com pattern.
- If the DNS member receives a query for b1.corpxyz.com, the member immediately redirects the DNS client to the specified IP address because the domain name in the query matches the second rule.
- If the DNS member receives a query for b1.corp200.com, it resolves the query because the domain name does not match any rule. If the DNS member receives an A record from an authoritative server, the member forwards the response to the client. However, if the member receives an NXDOMAIN response, it redirects the DNS client to the specified IP address.

In the following example, the rules redirect queries for dotted domain names that do not have ".com" As shown in the example, an explicit PASS rule is required at the end.
Ruleset 2:

Pattern	Action
*.com	PASS
.*.$	MODIFY
*	PASS

- If the DNS member receives a query for corpxyz.com which matches the pattern "*.com", the member resolves the query and forwards the response, even if it is an NXDOMAIN response, to the client.

- If the DNS member receives a query for corpxyz.org, which matches the pattern ".*.$", the member resolves the query. If the member receives an NXDOMAIN response, it redirects the client to the specified IP address. If the member receives a non-NXDOMAIN response, it forwards the response to the client.
- If the DNS member receives a query for corp200, the member resolves the query and forwards the response to the client.

NXDOMAIN Redirection Guidelines

The following summarizes how a DNS member responds to a query for an A record when the NXDOMAIN feature is enabled:

- If there are no rulesets configured, the DNS member queries other name servers.
    - If the DNS member receives a non-NXDOMAIN response from an authoritative server, it forwards the response to the DNS client.
    - If the DNS member receives an NXDOMAIN response from an authoritative server, it redirect the DNS client.
- If rulesets are configured, the DNS member tries to match the domain name in the query with a domain name in the rules.
    - If the DNS member finds a match, it perform the action specified in the rule.
        - If the action is "Redirect", the DNS member redirect the DNS client.
        - If the action is "Pass", the DNS member queries other name servers and forwards the response to the DNS client.
        - If the action is "Modify", the DNS member queries other name servers. If it receives a non-NXDOMAIN response, it forwards the response to the DNS client; if it receives and NXDOMAIN response, it redirects the DNS client.
    - If the DNS member does not find a match, the DNS member queries other name servers.
        - If the DNS member receives a non-NXDOMAIN response, it forwards the response to the DNS client.
        - If the DNS member receives an NXDOMAIN response from an authoritative server, it redirects the DNS client.

Note that if an A record with a dotted hostname is added to an authoritative zone through a dynamic DNS update, and that A record should actually belong in an existing delegation, the appliance may not redirect a query for that A record according to the Blacklist and NXDOMAIN guidelines.

Configuring NXDOMAIN Redirection

To enable NXDOMAIN redirection and configure its properties:

1. Configure NXDOMAIN rulesets. You can create NXDOMAIN rulesets through Grid Manager, as described in Creating Rulesets below. You can also specify the rulesets in a CSV file and import the file to the Grid, as described in *Importing and Exporting Data using CSV Import*.
2. Enable this feature and specify the redirection IP addresses, as described in Enabling NXDOMAIN Redirection below.

Creating Rulesets

To create a ruleset:

1. From the **Data Management** tab -> **DNS** tab -> **NXDOMAIN Rulesets** tab, click the Add icon.
2. In the **NXDOMAIN Ruleset** wizard, complete the following and click **Next**:
    - **Name:** Enter a name for the ruleset.
    - **Comment:** You can enter additional information.
    - **Disable:** You can disable this ruleset for use later on. The appliance ignores disabled rulesets.
3. Click the Add icon to add a rule to the ruleset table.
    - In the Pattern column, enter a domain name or pattern, using the guidelines specified in About NXDOMAIN Rulesets.
    - In the **Action** column, select **PASS**, **REDIRECT** or **MODIFY**.

- In the **Order** column, NIOS automatically displays the number of the entry in the list.
  The appliance applies the rules in the order they are listed. You can order the list as follows:
    - Use the up and down arrows to move rules up or down on the list.
    - Use the go-to-top or go-to-bottom arrow to move a rule to the top or bottom of the list.
    - Change the Order number of a rule to move it to the desired location.
    - Delete a rule by selecting it and clicking the Delete icon.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing NXDOMAIN Rulesets

To view NXDOMAIN rulesets, navigate to the **Data Management** tab -> **DNS** tab -> **NXDOMAIN Rulesets** tab. The panel lists the configured rulesets and their associated comments. You can also display the Disabled column which indicates which rulesets are disabled. From this panel, you can do the following:

- Add more rulesets, as described in the preceding section, Creating Rulesets.
- Edit a ruleset, by clicking its checkbox and clicking the Edit icon. You can set the following in the NXDOMAIN Ruleset editor:
    - In the **General Basic** tab, you can change entries in any of the fields.
    - In the **Rules** tab, you can do the following:
        - Add a rule by clicking the add icon and specifying the pattern and action.
        - Change the pattern or action of a rule, by clicking in the appropriate row.
        - Delete a rule by clicking its checkbox and clicking the Delete icon.
        - Move rules up and down, by using the arrows.
        - In the **Permissions** tab, you can set admin permissions for the ruleset. For information about admin permissions, see *Managing Administrators.*
    - Delete a ruleset, by clicking its checkbox and clicking the Delete icon.

Enabling NXDOMAIN Redirection

Only DNS members with recursion enabled can support NXDOMAIN redirection.
You can enable this feature at the Grid level, and override it for a member or DNS view with recursion enabled. You must specify at least one IP address as the redirection destination. You can specify different redirection IP addresses and rulesets for each Grid member or DNS view, and you can also define members that do not provide redirection. This is useful when you want to define a set of "opt out" servers for DNS clients that do not want to be redirected.
You can also enable the DNS member to log queries that match rules with an action of "Redirect" or "Modify". The logs include the queried domain name, source IP address, the pattern of the matched rule, and the name of the corresponding ruleset. The DNS member does not log queries that matched rules with an action of "Pass".
To enable NXDOMAIN redirection:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   DNS View: From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab -> *dns_view* checkbox -> Edit icon.
   Standalone DNS: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **System DNS Properties**.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. If the *Grid DNS Properties* or *Member DNS Properties* editor is in basic mode, click **Toggle Advanced Mode**.
3. Click **NXDOMAIN** and complete the following:
    - **Enable NXDOMAIN redirection (recursive members only):** Select this option to enable recursive DNS members to synthesize their responses to DNS queries for A records.
    - **Rulesets:** Click the Add icon to add an NXDOMAIN ruleset. Use the up and down arrows to move rulesets up and down in the list. The appliance applies them in the order they are listed.
    - **Redirect to IPv4 addresses:** Click the Add icon and enter the IPv4 addresses that the DNS server includes in its synthesized response for A type queries.
    - **Redirect to IPv6 addresses:** Click the Add icon and enter the IPv6 addresses that the DNS server includes in its synthesized response for AAAA type queries.
      Note that you can add up to 12 IP addresses, combination of both IPv4 and IPv6, for NXDOMAIN redirection.

- **TTL:** Specify how long the DNS client caches the A record with the redirected IP address.
- **Log redirected queries:** Select this checkbox to log the redirected queries to syslog.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring DNS over TLS and DNS over HTTPS Services

DNS queries and responses sent over port 53 without encryption are vulnerable to spoofing and eavesdropping. This issue is addressed in NIOS appliances that have DNS over TLS (Transport Layer Security) and DNS over HTTPS services enabled. These features encrypt DNS queries and responses to secure communication between a DNS server and a DNS client.

This topic details the requirements that NIOS appliances must meet for enabling the DNS over TLS and DNS over HTTPS services and has instructions to configure these services. The sections covered in this topic are as follows:

Licensing and Certificate Requirements

DNS over TLS and DNS over HTTPS require the vDCA (virtual DNS Cache Acceleration) or vADP (virtual Advanced DNS Protection Software) service to be licensed and enabled. If the DNS Cache Acceleration and/or Advanced DNS Protection Software services are not enabled, the DNS over TLS and DNS over HTTPS features will not work even if they are enabled. For more information about DNS Cache Acceleration and Advanced DNS Protection Software (threat protection), see *Configuring DNS Cache Acceleration* and *About Infoblox Advanced DNS Protection* respectively.

The DNS over TLS or the DNS over HTTPS service uses the same self-signed certificate that NIOS generates for HTTPS communication when it first starts. You can also generate a certificate signing request (CSR) and use it to obtain a signed certificate from your own trusted certificate authority (CA). For more information, see *Generating Certificate Signing Requests*.

The certificate is provisioned for each member. For more information about certificates, see *Managing Certificates*.

Note

NIOS generates a new self-signed certificate when the host name or the IP address of the member is changed or when a Grid Master Candidate is promoted. If the DNS over TLS or DNS over HTTPS feature is enabled on a member, then every time a new self-signed certificate, HTTPS certificate, or a CA certificate is generated, the DNS over TLS service or the DNS over HTTPS service (depending on which feature is enabled) automatically restarts to upload the new certificate.

Base Configuration Requirements

NIOS appliances must have the required base memory configuration to enable the DNS over TLS and the DNS over HTTPS features on their members. If the appliances do not meet the required criteria, the options to configure these

features are not displayed in the *Member DNS Properties* editor. The following table lists the base configuration required for enabling these features on IB-FLEX appliances.

> **Warning**
>
> The numbers in the following tables are for IB-FLEX appliances only. For information about CPU and memory requirements of NIOS appliances other than IB-FLEX, see the *NIOS Release Notes*.

IB-FLEX Flavor Configuration	Total CPU	Total System Memory in GB (With virtual Advanced DNS Protection Software only)	Total System Memory in GB (With virtual DNS Cache Acceleration and virtual Advanced DNS Protection Software)	Maximum Number of Concurrent Sessions Supported	Grid Master Capable
Small recursive DNS (with acceleration)	10	32	32	For vDCA only: 120,000 For vADP only: 50,000 For vDCA and vADP: 120,000	No
Medium recursive DNS (with acceleration)	16	64	40	For vDCA only: 150,000 For vADP only: 60,000 For vDCA and vADP: 150,000	No
Large recursive DNS (with acceleration)	26	80	50	For vDCA only: 240,000 For vADP only: 80,000 For vDCA and vADP: 240,000	No

The following table lists the maximum number of concurrent sessions supported by different NIOS appliance models (physical and virtual). For information about CPU and memory requirements, see the NIOS Release Notes.

> **Note**
>
> If the available memory does not meet the requirement defined in the above table, you may observe unexpected behavior. Infoblox recommends that you allocate slightly more memory to ensure that memory associated with the hypervisor is also accounted for.

NIOS Appliance (Physical and Virtual)	Maximum Number of Concurrent Sessions Supported
IB-14x5	For vADP only: 50,000

NIOS Appliance (Physical and Virtual)	Maximum Number of Concurrent Sessions Supported
IB-22x5	For vDCA only: 150,000 For vADP only: 60,000 For vDCA and vADP: 150,000
IB-40x5	For vDCA only: 240,000 For vADP only: 80,000 For vDCA and vADP: 240,000

Note

In an HA setup, ensure that both the active and passive nodes have the memory configuration required to enable the DNS over TLS or the DNS over HTTPS feature. If you enable the feature on an active node that has the required memory footprint but the passive node does not, then in case of a failover, the DNS over TLS or the DNS over HTTPS service does not start on the new active node. Therefore, requests coming to the DNS over TLS or the DNS over HTTPS stream are not honored.

Configuration Requirements if Parental Control is Enabled

NIOS appliances require additional memory if you intend to run DNS over TLS and/or DNS over HTTPS along with the Parental Control features such as proxy RPZ passthru, DCA subscriber query count logging, and DCA subscriber allowed and blocked listing simultaneously. The following table lists the base configuration required on IB-FLEX appliances for configuring these features simultaneously:

IB-FLEX Flavor Configuration	Total CPU	Total System Memory in GB (With virtual DNS Cache Acceleration only)	Total System Memory in GB (With virtual DNS Cache Acceleration and virtual Advanced DNS Protection Software)	Maximum Number of Concurrent Sessions Supported	Grid Master Capable
Medium recursive DNS (with acceleration)	16	64	64	For vDCA only: 150,000 For vADP only: 60,000 For vDCA and vADP: 150,000	No
Medium-Large recursive DNS (with acceleration)	16	86	86	For vDCA only: 150,000 For vADP only: 60,000 For vDCA and vADP: 150,000	No

IB-FLEX Flavor Configuration	Total CPU	Total System Memory in GB (With virtual DNS Cache Acceleration only)	Total System Memory in GB (With virtual DNS Cache Acceleration and virtual Advanced DNS Protection Software)	Maximum Number of Concurrent Sessions Supported	Grid Master Capable
Large recursive DNS (with acceleration)	26	100	100	For vDCA only: 240,000 For vADP only: 80,000 For vDCA and vADP: 240,000	No

⚠ Note

- When a NIOS appliance does not have the required base memory configuration, if you try to enable and run DNS over TLS, DNS over HTTPS, and Parental Control features simultaneously, all of these features will be disabled.
- For information about CPU and memory requirements of NIOS appliance models other than IB-FLEX, see the NIOS Release Notes.

Supported Cipher Suites

From NIOS 8.6.1 onwards, the DNS over TLS and DNS over HTTPS features support only TLS version 1.2 and TLS version 1.3 cipher suites. The cipher suite order preference is configured to improve the throughput in DNS over TLS and DNS over HTTPS communication.

Cipher suites supported for TLS 1.2 are as follows:

- ECDHE-ECDSA-CHACHA20-POLY1305
- ECDHE-RSA-CHACHA20-POLY1305
- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-RSA-AES256-GCM-SHA384
- ECDHE-RSA-AES128-SHA256
- ECDHE-RSA-AES256-SHA384
- DHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES128-SHA
- DHE-RSA-AES256-SHA
- DHE-RSA-AES128-SHA256
- DHE-RSA-AES256-SHA384

Cipher suites supported for TLS 1.3 are as follows:

- TLS_CHACHA20_POLY1305_SHA256
- TLS_AES_128_GCM_SHA256
- TLS_AES_128_CCM_SHA256
- TLS_AES_128_CCM_8_SHA256
- TLS_AES_256_GCM_SHA384

Limitations and Recommendations for DNS over TLS and DNS over HTTPS

Consider the following limitations and recommendations when you enable the DNS over TLS and/or the DNS over HTTPS features:

- If an appliance configured with DNS over TLS or DNS over HTTPS has both vDCA and vADP running, the configuration is set to the DCA-first mode.
- TSIG queries for which responses are larger than the max EDNS/UDP buffer size are not supported.
- DNS queries coming with EDNS padding over port 53 are dropped.
- DNS over TLS and DNS over HTTPS features are not supported on unbound-based DNS servers.
- When DNS over TLS or DNS over HTTPS is enabled, queries decrypted at DNS over TLS or DNS over HTTPS that do not receive a response from the vDCA cache are forwarded to the recursive DNS engine over UDP. Therefore, rules added for TCP requests over TLS or HTTPS may not be honored. Infoblox recommends that you add the corresponding UDP-specific rules instead of only the TCP request rules.
- For NIOS 8.5.2 only: Infoblox recommends that you manually set the maximum packet size of both the UDP buffer and the EDNS buffer to 4096 bytes. If the packet size exceeds 4096, packets are dropped by the DNS over TLS or the DNS over HTTPS server. For more information about setting buffer sizes, see *Configuring the EDNS0 Buffer Size and UDP Buffer Size*.
- DNS over TLS only:
    - The TLS versions that are currently supported by NIOS are TLS 1.2 and TLS 1.3.
    - DNS over TLS supports queries and responses from both DNS and DNS Cache Acceleration services.
    - DNS over TLS is not supported for recursive queries when performing upstream lookups.
    - DNS zone transfer requests over DNS over TLS are not supported.
    - For DNS over TLS clients that use systemd-resolved service, the Subject Alternative Name (SAN) must point to the IP address of the DNS service. By default, the self-signed certificates issued to Infoblox members do not meet this requirement. Therefore, for Infoblox to support systemd-resolved, you must install certificates that include SAN IP address from a trusted certificate authority.
- DNS over HTTPS only:
    - DNS over HTTPS is supported on the HTTP/2 protocol.
    - DNS over HTTPS is supported only if the NIOS appliance has an MGMT interface set up. The DNS over HTTPS module listens on port 443 for interfaces other than MGMT and any incoming UI request to the MGMT interface is bypassed directly to the host.
    - When DNS over HTTPS is enabled on a member, HTTP redirection from the member to its Grid Master is disabled.

DNS over TLS

NIOS appliances that support DNS Cache Acceleration or Advanced DNS Protection Software, include the DNS over TLS capability that helps increase DNS security and privacy. When you enable the DNS over TLS feature, DNS traffic is encrypted through the TLS protocol to prevent eavesdropping and tampering of DNS data. This feature is supported on both recursive and authoritative DNS servers only through port 853. It is available only for Grid members and for standalone systems. It supports the processing of multiple DNS queries/responses over a single TLS session.

You can configure and run the DNS over TLS service on a member only when the following prerequisites are met:

- Either the accelerated DNS Cache Acceleration (vDCA) or the Advanced DNS Protection Software (vADP) service is enabled.
- The memory required to support the DNS over TLS feature is available. For more information, see Base Configuration Requirements below.

Configuring DNS over TLS

To configure the DNS over TLS feature, complete the following steps:

1. **Grid member**: On the **Data Management** tab, click the **DNS** tab -> **Members** tab, select the *member* checkbox, and then click the Edit icon.
   Standalone system: On the **Data Management** tab, click the **DNS** tab, expand the Toolbar, and then click **System DNS Properties**.

2. In the *Member DNS Properties* editor/*System DNS Properties* editor, click **Toggle Advanced Mode** if the editor is in basic mode.
3. On the **Queries** tab -> **Advanced** tab, select the **Enable DoT Service** checkbox to enable the DNS over TLS feature.
   Note the options for DNS over TLS feature are displayed only if the appliance has the memory footprint that is required to support the feature and has the virtual DNS Cache Acceleration or Advanced DNS Protection Software license installed. For more information, see Base Configuration Requirements below.
4. In the **Maximum Session Timeout** field, specify the maximum time in seconds a session can remain idle before it times out and closes. The default value is 60 seconds.
   If your DNS forwarders are located at different geographical locations or if the network latency is high, you may observe session timeouts. If so, Infoblox recommends that you set the **Maximum Session Timeout** to more than 60 seconds. Increasing the session duration may impact concurrent open sessions.
5. Save the configuration.
6. As prompted, manually reboot the member to enable the DNS over TLS feature.

> ⚠ Note
> The DNS over TLS feature will not take effect until you reboot the member or the standalone system and ensure that either the DNS Cache Acceleration or Advanced DNS Protection Software service is running after the reboot.

CLI Support for DNS over TLS

You can view the status of the DNS over TLS service, configuration, and details of active sessions using the following commands:

- *show dns-over-tls-status*
- *show dns-over-tls-config*
- *show dns-over-tls-stats*

DNS over HTTPS

NIOS appliances that support DNS Cache Acceleration or Advanced DNS Protection Software, include the DNS over HTTPS capability that helps increase DNS security and privacy. When you enable the DNS over HTTPS feature, DNS traffic is encrypted through the HTTPS protocol to prevent eavesdropping and tampering of DNS data. This feature is supported on both recursive and authoritative DNS servers only through port 443. It is available only for Grid members and standalone systems. The feature supports the processing of multiple DNS queries/responses over a single TCP session.

You can configure and run the DNS over HTTPS service on a NIOS appliance only when the following prerequisites are met:

- An MGMT interface is set up.
- The memory required to support the DNS over HTTPS feature is available. For more information, see Base Configuration Requirements below.
- Either the accelerated DNS Cache Acceleration (vDCA) or the Advanced DNS Protection Software (vADP) service is enabled.

Configuring DNS over HTTPS

To configure the DNS over HTTPS feature, complete the following steps:

1. **Grid member**: On the **Data Management** tab, click the **DNS** tab -> **Members** tab, select the *member* checkbox, and then click the Edit icon.
   Standalone system: On the **Data Management** tab, click the **DNS** tab, expand the Toolbar, and then click **System DNS Properties**.
2. In the *Member DNS Properties* editor/*System DNS Properties* editor, click **Toggle Advanced Mode** if the editor is in basic mode.

3. On the **Queries** tab -> **Advanced** tab, select the **Enable DoH Service** checkbox to enable the DNS over HTTPS feature.
   Note the options for DNS over HTTPS feature are displayed only if the appliance has the memory footprint that is required to support the feature and has the virtual DNS Cache Acceleration or Advanced DNS Protection Software license installed. For more information, see Base Configuration Requirements below.
4. In the **Maximum Session Timeout** field, specify the maximum time in seconds a session can remain idle before it times out and closes. The default value is 10 seconds.
   If your DNS forwarders are located at different geographical locations or if the network latency is high, you may observe session timeouts. If so, Infoblox recommends that you set the **Maximum Session Timeout** to more than 10 seconds. Increasing the session duration may impact concurrent open sessions.
5. Save the configuration.
6. As prompted, manually reboot the member to enable the DNS over HTTPS feature.

> ⚠ Note
> The DNS over HTTPS feature will not take effect unless you reboot the member or the standalone system and ensure that either the DNS Cache Acceleration or Advanced DNS Protection Software service is running after the reboot.

Configuring DNS over HTTPS in Firefox

If you are using the developer version of the Firefox browser to initiate DNS queries, you must configure additional settings in the browser to enable the DNS over HTTPS support. Complete the following steps in Firefox to enable DNS over HTTPS and upload certificates:

1. In the **Network Settings** section, click **Settings** and complete the following steps to set the Grid IP address as the custom DNS over HTTPS server:
   a. In the *Connection Settings* dialog box select the **Enable DNS over HTTPS** checkbox.
   b. From the **Use Provider** drop-down list, choose **Custom**.
   c. In the **Custom** field, enter the Grid IP address in the format:
   https://<*dns-server*>/dns-query
2. Set the network.trr.mode preference in the configuration editor as follows:
   a. Enter **about:config** in the Firefox address bar.
   b. Click **Accept the Risk and Continue** to open the configuration editor.
   c. Search for **network.trr.mode**.
   d. Click the Edit icon and set the value to **3**.
3. If you are using a self-signed certificate, complete the following:
   a. From the address bar, open https://<*doh_server_IP*>.
   b. Accept the certificate.
4. If you are using a CA certificate, complete the following:
   a. Go to **Preferences/Options** -> **Privacy and Security** -> **View Certificates** -> **Authorities** -> **Import**.
   b. Choose the certificate.
   c. When prompted, select the **Trust this CA to identify websites** checkbox, and restart the browser.

> ⚠ Note
> For a member with the DNS Cache Acceleration service running and the DNS over HTTPS feature enabled, if you use the developer version of the Firefox browser (configured for DNS over HTTPS support) to initiate DNS queries, you must set the **network.trr.disable-ECS** preference in the configuration editor (about:config) to **false** for DNS data to be cached. DNS caching does not work if network.trr.disable-ECS is set to true.

CLI Support for DNS over HTTPS

You can view the status of the DNS over HTTPS service, configuration, and details of active sessions using the following commands:

- *show doh-status*
- *show doh-config*

- *show doh-stats*

Detecting and Mitigating DNS DDoS Attacks

DNS is a tempting target for attacks given that most traditional enterprise firewalls are configured to allow port 53 traffic to service DNS, which gives attackers an easy way to evade your firewall implementation. Since DNS queries are asymmetrical, they can result in a response many times larger than the query, which means that your DNS system can be used to amplify an attack.
To protect your DNS servers and DNS service performance, Infoblox provides the following features to detect and mitigate DNS DDoS attacks, such as NXDOMAIN attacks:

- Automated mitigation of phantom domain attacks (a subset of NXDOMAIN attacks), as described in *Automated Mitigation of Phantom Domain Attacks*.
- Configurable parameters used to detect possible NXDOMAIN attacks, as described in *Detecting NXDOMAIN Attacks.*
- Mitigation of NXDOMAIN responses by removing the LRU (Least Recently Used) items from the list of NX (non-existent) RRsets. The appliance uses the LRU list to select entries for removal from the cache when the cache utilization exceeds the allowed threshold. For more information, see *Mitigating Possible NXDOMAIN Attacks.*
- CLI commands for configuring RRL (Response Rate Limiting) to mitigate DNS DDoS attacks by reducing the rate at which authoritative servers respond to high volumes of malicious queries, as described in *Support for RRL (Response Rate Limiting).*

Infoblox also offers the following security features to fully protect your DNS infrastructure and implementation:

- *Infoblox Advanced DNS Protection*
- *Infoblox DNS Firewall*
- *Infoblox Threat Insight*

Automated Mitigation of Phantom Domain Attacks

A phantom domain attack happens when the attacker sets up "phantom" domains that do not respond to DNS queries. Under normal circumstances, the DNS recursive server contacts authoritative servers to resolve recursive queries. When phantom domain attacks happen, the recursive server continues to query non-responsive servers, which causes the recursive server to spend valuable resources waiting for responses. When resources are fully consumed, the DNS recursive server may drop legitimate queries, causing serious performance issues.
NIOS provides a few configurable parameters for mitigating phantom domain attacks in which recursive server continues to query non-responsive servers. Before you configure any of the parameters for mitigating phantom domain attacks, review the guidelines that might help you understand the relationship between these parameters. For information, see Guidelines for Mitigating Phantom Domain Attacks below.
To configure parameters for mitigating phantom domain attacks, see Configuring Parameters for Mitigating Phantom Domain Attacks.
All events related to these operations are logged to the syslog. For information about the syslog and how to use it, see *Using a Syslog Server*.

Guidelines for Mitigating Phantom Domain Attacks

To detect phantom domain attacks, you can review your log messages. One possible indication of attack is when you receive a log message similar to the following:

```
2015-04-29T10:20:06+00:00 daemon infoblox named\[25390\]: warning no more recursive clients: quota reached
```

Consider the following guidelines to mitigate the attack:

- Increase the number of recursive clients.
- Use a combination of the following parameters to achieve optimum results:
  - **Limit recursive queries per server** and **Limit recursive queries per zone**

    - **Enable holddown for non-responsive servers** and **Limit recursive queries per zone**
- When you enable any of the options, the default values are set at an optimum level for general operations. Infoblox recommends that you keep the default values when using these commands. Ensure that you understand the ramifications if you want to change the default values.

Configuring Parameters for Mitigating Phantom Domain Attacks

> **Note**
>
> Updating the parameter values for mitigating phantom domain attacks takes effect immediately through Grid replication. However, for these values to be updated in the named.conf file, you need to restart the DNS service. To restart the member service, see *Restarting Services*.

To adjust the parameters to mitigate phantom domain attack parameters, complete the following:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon. To override Grid settings, click **Override** and complete the appropriate fields.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click the **Security** tab and complete the following in the **Non-responsive servers** section:
    - **Enable holddown for non-responsive servers:** When you select this checkbox, the appliance stops sending queries to non-responsive servers for a specified time interval (**Hold down duration**) when the number of consecutive attempts to contact a non-responsive server exceeds the threshold value (**Timeouts to trigger**). No service restart is required when you change this. Clear this checkbox to disable the holddown. Note that disabling this does not clear any of the previously configured values. When you enable this feature again, the appliance preserves the previously configured values.
        - **Minimum timeout**: When the time taken for a timeout to happen exceeds this number, the timeout is counted towards the number of consecutive timeouts (**Timeouts to trigger**). You can specify a value between 0 and 5000 milliseconds. For example, if you set the minimum timeout to 1000 milliseconds, only timeouts that took longer than 1000 milliseconds are counted towards the number of consecutive timeouts. The default is 1000 milliseconds.
        - **Timeouts to trigger**: The number of consecutive timeouts before holding down a server. You can specify a value between 0 and 4294967295. For example, setting the threshold value to 5 means the appliance stops sending queries to the non-responsive server after five consecutive timeouts. The default is 5.
        - **Hold down duration**: The holddown duration for a server. You can specify a value between 1 and 86400 seconds. For example, if you set the holddown time to 60 seconds, the server stops sending queries for 60 seconds. The default is 60 seconds.
          Note in order to get enough upstream queries and for the appliance to effectively identify non-responsive servers and stop sending queries to them, do not set a high value for the **Minimum timeout** field. The higher the value you configure for this field, the longer it takes to capture a timeout and the harder it is to satisfy the total counts of consecutive timeouts (**Timeouts to trigger**). Until the total count of consecutive timeouts is exceeded, no mitigation happens against the non-responsive servers. As a result, it is less likely for the appliance to identify phantom domain attacks when you set the **Minimum timeout** field at a high value. Infoblox highly recommends that you keep the default **Minimum timeout** value to achieve optimum protection against these attacks.
    - **Limit recursive queries per server**: Select this checkbox to configure the maximum number of concurrent recursive queries that the appliance sends to a single upstream name server. Queries above the limit will be blocked and may result in a SERVFAIL response to the client. When you enable this option, the appliance dynamically adjusts the concurrent query limit for a specific server based on the ATR (Average Timeout Ratio). No service restart is required when you change this. Clear this checkbox to disable this option. Note that disabling this does not clear any of the previously configured values. When you enable this feature again, the appliance preserves the previously configured values.
        - **Maximum fetches per server**: The maximum number of concurrent recursive queries that the appliance sends to a single upstream name server before blocking additional queries to that server. You can specify a value between 0 and 4294967295. The default value is 500.

        - **Quota recalculation interval**: This determines how often (in number of recursive responses) the appliance recalculates the average timeout ratio. You can specify a value between 0 and 4294967295. The default value is 200. Note that if you set this value to 0 (zero), the appliance will never recalculate the ATR. Infoblox strongly recommends that you do not set this value to 0.
    - **Limit recursive queries per zone**: Select this checkbox to configure the maximum number of concurrent recursive queries the DNS server sends for a domain. If the number of recursive queries exceeds the configured value, the server blocks new queries for that domain and returns a SERVFAIL response to the client. No service restart is required when you change this. Clear this checkbox to disable the option. Note that disabling this does not clear any of the previously configured values. When you enable this feature again, the appliance preserves the previously configured values.
        - **Maximum fetches perzone**: The maximum number of concurrent recursive queries that a server sends for one of its domain. When the number of queries exceeds this number, the server blocks new queries for the domain. You can specify a value between 0 and 4294967295. The default value is 200.

Detecting NXDOMAIN Attacks

NXDOMAIN attacks are symmetrical DDoS attacks that involve a large number of DNS clients sending queries for invalid or non-existent domains, which results in DNS recursion and NXDOMAIN responses. As a result, the DNS server spends valuable resources processing spurious requests instead of providing legitimate DNS services. When a DNS server is under NXDOMAIN attack, clients cannot get valid responses because the cache of the DNS server is flooded with NXDOMAIN results.
Infoblox provides a few options for detecting possible NXDOMAIN attacks. You can track one or all of the following to raise alerts for these attacks:

- High percentage of NXDOMAIN responses, as described in Tracking NXDOMAIN Responses below.
- Low cache hit ratio for queries, as described in Tracking Cache Hit Ratio of Recursive Queries below.
- High number of dropped UDP packets, as described in Tracking Dropped UDP Packets below.

Each of these options provides configurable parameters that determine if an alert should be raised. When an alert is triggered, the appliance sends SNMP traps about possible NXDOMAIN attacks. All triggered events are logged to the syslog. Note that you must enable notifications in order for the appliance to send SNMP traps. For more information about how to enable this, see *Setting SNMP and Email Notifications*.

> **Note**
>
> The default values for these configurable parameters are set at an optimum level for general operations. Infoblox recommends that you keep the default values when using these features. Ensure that you understand the ramifications if you want to change the default values.

Tracking NXDOMAIN Responses

When under NXDOMAIN attack, the ratio of NXDOMAIN responses from upstream servers to all incoming recursive responses is typically high. When the ratio of NXDOMAIN responses to all incoming recursive responses exceeds the configured high water threshold, the appliance sends an alert. Note that timeouts are not counted as responses for this detection.

> **Note**
>
> Changes made to the configuration for tracking NXDOMAIN responses take effect immediately on active DNS service and do not require a service restart.

To configure the parameters for tracking NXDOMAIN responses, complete the following:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon. To override Grid settings, click **Override** and complete the appropriate fields.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click the **Security** tab and complete the following in the **Bogus-query alerting and mitigation** section:
   - **Track the percentage of NXDOMAIN responses to recursive queries:** Select this checkbox to track the percentage of NXDOMAIN responses from up-stream servers to all incoming recursive responses. Clear this checkbox to disable the detection. Note that disabling this does not clear any of the previously configured values. When you enable this feature again, the appliance preserves the previously configured values. This is selected by default.
     - **Minimum responses per interval**: Enter the minimum number of incoming DNS responses received (within the detection interval) before the appliance starts calculating the NXDOMAIN ratio at the end of the detection interval. The appliance then compares the calculated percentage to the high water threshold. If the percentage equals or exceeds the high water threshold, the appliance sends an SNMP trap (if enabled) about possible NXDOMAIN attacks. The default is 1000. Note that the **Minimum responses per interval** is implemented to ensure that enough incoming DNS responses are received so the appliance can calculate a meaningful NXDOMAIN ratio and does not declare possible attacks from a small response sample. Therefore, when you change the default value, ensure that you use a reasonable value so the appliance calculates the NXDOMAIN ratio from a reasonable amount of responses. Raising an alert using a small response sample may not be a reliable way for detecting possible NXDOMAIN attacks.
     - **NXDOMAIN threshold**: Enter the **Low** and **High** water thresholds at which an alert is triggered. The appliance sends an alert when the percentage equals or exceeds the **High** water threshold. When the percentage in subsequent detection intervals falls below the **Low** water threshold, the appliance sends another alert to notify that the percentage of NXDOMAIN responses has gone back to an acceptable level. The defaults are 70% for **Low** and 80% for **High**.
     - **Detection interval** and **Responses**: These parameters work as alternatives to each other in determining when the appliance starts calculating the NXDOMAIN ratio. In the case of a very low response rate when the total responses received within the **Detection interval** never reach the **Minimum responses per interval**, the response counters continue to cumulate into subsequent detection intervals until the **Minimum responses per interval** is met. The appliance then sends an alert at the end of the detection interval. On the other hand, in the case of a very high response rate when the total number of responses received equals or exceeds the **Responses** value before the **Detection interval** is reached, the **Minimum responses per interval** does not apply and the appliance sends an alert as soon as the total responses equal or exceed the **Responses** value you define here. It does not wait till the end of the **Detection interval**. Note that the number of **Responses** you define here must be the same or greater than the **Minimum responses per interval**. The defaults are 10 seconds for the **Detection interval** and 100000 for **Responses**.
3. Save the configuration.

Configuration Examples for Tracking NXDOMAIN Responses

The following examples demonstrate how different responses per second affect the calculation of NXDOMAIN ratio.
Example One: Total responses per second = 250 and parameters = default values

Detection Interval (10 seconds)											
Total Responses per Second	**0**	**1st**	**2nd**	**3rd**	**4th**	**5th**	**6th**	**7th**	**8th**	**9th**	**10th**
250/s	0	250	500	750	1000	1250	1500	1750	2000	2250	2500

In this example, the total number of responses is 250 per second and the total number of responses hits the **Minimum responses per interval** (default = 1000) at the 4th second of the detection interval. This meets the requirement for the **Minimum responses per interval** and triggers an NXDOMAIN ratio calculation at the end of the detection interval (default

= 10 seconds). If the percentage equals or exceeds the high water threshold, the appliance sends an alert and logs the event to the syslog to notify about possible NXDOMAIN flood attacks. The appliance resets the response counters for the next detection interval.

Example Two: Total responses per second = 40 per second and parameters = default values

1st Detection Interval (10 seconds)											
Total Responses per Second	**0**	**1st**	**2nd**	**3rd**	**4th**	**5th**	**6th**	**7th**	**8th**	**9th**	**10th**
40/s	0	40	80	120	160	200	240	280	320	360	400

2nd Detection Interval (10 seconds)											
Total Responses per Second	**0**	**1st**	**2nd**	**3rd**	**4th**	**5th**	**6th**	**7th**	**8th**	**9th**	**10th**
40/s		440	480	520	560	600	640	680	720	760	800

3rd Detection Interval (10 seconds)												
Total Responses per Second	**0**	**1st**	**2nd**	**3rd**	**4th**	**5th**	**6th**	**7th**	**8th**	**9th**		**10th**
40/s		840	880	920	960	1000	1040	1080	1120	1160	1200	

In this example, the total number of responses is 40 per second. During the first detection interval of 10 seconds, the total number of responses is 400, which does not reach the **Minimum responses per interval** (default = 1000); therefore, no NXDOMAIN ratio calculation occurs and the response counters continue to accumulate into the second detection interval. At the end of the second interval, the total number of responses still does not reach the **Minimum responses per interval**; therefore, no NXDOMAIN ratio calculation occurs and the counters continue to accumulate. Finally, the total number of responses meets the requirement of the **Minimum responses per interval** when the appliance receives 1000 responses at the 5th second during the third detection interval. This triggers an NXDOMAIN ratio calculation at the end of the third detection interval, and the counters reset for the next detection interval. If the NXDOMAIN percentage equals or exceeds the high water threshold, the appliance sends an alert and logs the event to the syslog to notify about possible NXDOMAIN flood attacks.

Example Three: Total responses per second = 50000 and parameters = default values

Detection Interval (10 seconds)											
Total Responses per Second	**0**	**1st**	**2nd**	**3rd**	**4th**	**5th**	**6th**	**7th**	**8th**	**9th**	**10th**
50000	0	50000	100000								

In this example, the total number of responses per second is 50000. When the total number of responses hits 100000, which equals to the **Responses** value, the appliance starts calculating the NXDOMAIN ratio and sends an alert without waiting until the end of the detection interval. If the percentage equals or exceeds the high water threshold, the appliance

sends an alert and logs the event to the syslog to notify about possible NXDOMAIN flood attacks. The appliance resets the response counters for the next detection interval.

> ⚠ Note
> The above configuration examples also apply to how the appliance tracks cache hit ratio of recursive queries, as described in Tracking Cache Hit Ratio of Recursive Queries below.

Tracking Cache Hit Ratio of Recursive Queries

Another way to track possible DNS attacks is to monitor the cache hit ratio of recursive queries. A cache hit means the response to a query can be found in the cache of the DNS server. When the response cannot be found, it is a miss. Cache hit ratio is the percentage of cache hits to the total number of queries. The higher the ratio, the more efficiently the cache is operating. When a server is under NXDOMAIN attack, the cache hit ratio tends to drop.
To track cache hit ratio, complete the following:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon.
   To override Grid settings, click **Override** and complete the appropriate fields.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click the **Security** tab and complete the following in the **Bogus-query alerting and mitigation** section:
   - **Track the cache hit ratio of queries:** Select this checkbox to track the cache hit ratio of recursive queries. Clear this checkbox to disable the detection. No service restart is required when you change this. Note that disabling this does not clear any of the previously configured values. When you enable this feature again, the appliance preserves the previously configured values. This is selected by default.
     - **Minimum queries per interval**: Enter the minimum number of incoming DNS queries received (within the detection interval) before the appliance starts calculating the cache hit ratio at the end of the detection interval. The appliance then compares the calculated percentage to the low water threshold. If the percentage equals or falls below the low water threshold, the appliance sends an SNMP trap (if enabled) about possible NXDOMAIN attacks. The default is 1000. Note that the **Minimum responses per interval** is implemented to ensure that enough incoming DNS queries are received so the appliance can calculate a meaningful cache hit ratio and does not declare possible attacks from a small number of incoming queries. When you change the default value, ensure that you use a number that is big enough so the appliance calculates the cache hit ratio from a reasonable amount of queries.
     - **Minimum cache utilization**: Cache hit ratio detection does not start until cache utilization hits this number. In other words, the appliance does not calculate the cache hit ratio until the cache utilization has reached or exceeded this number. The default is 75%.
     - **Hit ratio threshold**: Enter the **Low** and **High** thresholds at which an alert is triggered. The appliance sends an alert when the cache hit percentage equals or drops below the **Low** water threshold, which means the cache hit rate is low enough that the server is not operating efficiently, and there could be a high number of bogus queries that do not have matching responses in the cache. When the cache hit percentage in subsequent detection intervals reaches or exceeds the **High** water threshold, the appliance sends another alert to notify that the cache hit rate has gone back to an acceptable level. The defaults are 70% for **Low** and 80% for **High**.
     - **Hit ratio detection interval** and **Responses**: These parameters work as alternatives to each other in determining when the appliance starts calculating the cache hit ratio. In the case of a very low response rate when the total responses received within the **Hit ratio detection interval** never reach the **Minimum queries per interval**, the response counters continue to accumulate into subsequent detection intervals until the **Minimum queries per interval** is met. The appliance then sends an alert at the end of the detection interval. On the other hand, in the case of a very high response rate when the total number of responses received equals or exceeds the **Responses** value before the **Hit ratio detection interval** is reached, the **Minimum queries per interval** does not apply and the appliance sends an alert as soon as the total responses equal or exceed the **Responses** value you define here. It does not wait till the end of the **Hit ration detection interval**. Note that the number of **Responses** you define here must be the same or greater than the **Minimum queries per interval**. The defaults are 10 seconds for the **Hit ratio detection interval** and 100000 for **Responses**.

3. Save the configuration.

Tracking Dropped UDP Packets

When the DNS server starts dropping UDP packets from incoming traffic, it can be an indication of DNS attacks. Tracking dropped UDP packets can help raise awareness of possible DDoS attacks. For this features, the appliance tracks all UDP packets, not only DNS queries. When tracking dropped UDP packets, the appliance tracks IPv4 and IPv6 packets independently.
To track dropped UDP packets, complete the following:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.** **Member:** From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon. To override Grid settings, click **Override** and complete the appropriate fields.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click the **Security** tab and complete the following in the **Bogus-query alerting and mitigation** section:
    - **Track the number of UDP packets dropped:** Select this checkbox to track the number of dropped UDP packets. Clear this checkbox to disable the detection. No service restart is required when you change this. Note that disabling this does not clear any of the previously configured values. When you enable this feature again, the appliance preserves the previously configured values. This is selected by default.
        - **Packet drop detection interval**: Enter the time interval of each detection period for tracking dropped UDP packets. The default is 10 seconds.
        - **Minimum packets per interval**: Enter the minimum number of UDP packets the appliance allows (within the detection interval) before it starts calculating the percentage of dropped packets to the total number of packets. The appliance compares the calculated percentage to the high water threshold. If the percentage equals or exceeds the high water threshold, the appliance sends an SNMP trap (if enabled). The default is 1000.
        - **Packet drop threshold**: Enter the **Low** and **High** water thresholds at which an alert is triggered. The appliance sends an alert when the percentage equals or exceeds the **High** water threshold. When the percentage in subsequent detection intervals equals or falls below the **Low** water threshold, the appliance sends another alert to notify that the amount of dropped UDP packets has gone back to an acceptable level. The defaults are 20% for **Low** and 30% for **High**.
3. Save the configuration.

Mitigating Possible NXDOMAIN Attacks

To mitigate possible NXDOMAIN attacks, you can configure the appliance to split the LRU (Least Recently Used) list into two: one for NX (non-existent) RRsets and the other for all other RRsets. The LRU list is used to select entries that the appliance removes from the cache when the cache utilization exceeds the allowed threshold, which is a fraction of the configured maximum cache size.
While this option is enabled, the appliance removes the least recently used items from the LRU list for NX RRsets before removing items from the LRU list for other RRsets. Doing so helps preserves valid DNS responses in the cache while eliminating NXDOMAIN responses.
To mitigate NXDOMAIN responses. complete the following:

Note

Changes made to the configuration for mitigating possible NXDOMAIN attacks take effect immediately on active DNS service and do not require a service restart.

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.** **Member:** From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon. To override Grid settings, click **Override** and complete the appropriate fields.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click the **Security** tab and complete the following in the **Bogus-query alerting and mitigation** section:

- **Deprioritize caching of NXDOMAIN responses:** Select this checkbox to split the LRU list into two: one for NX RRsets and the other for all other RRsets, and to always remove the least recently used items from the list of NX RRsets first. This is selected by default.

3. Save the configuration.

Support for RRL (Response Rate Limiting)

RRL provides the ability to control excessive UDP responses that are identical or almost identical. For more information about how RRL works, refer to the *BIND Administrators Reference Manual* at *http://www.isc.org/downloads/bind/doc/* .

You can configure parameters for this feature through the following CLI commands: `set dns_rrl` and `show dns_rrl`. For more information about these commands, refer to the Infoblox CLI Guide.

You can also log RRL events to the syslog. To enable RRL logging, select **rate-limit** in the **Logging Category** when you configure logging for the Grid or member. For more information about how to select logging categories, see *Setting DNS Logging Categories*.

Blacklists

Your organization can prevent customers or employees from accessing certain Internet resources, particularly web sites, by prohibiting a recursive DNS member from resolving queries for domain names that you specify.

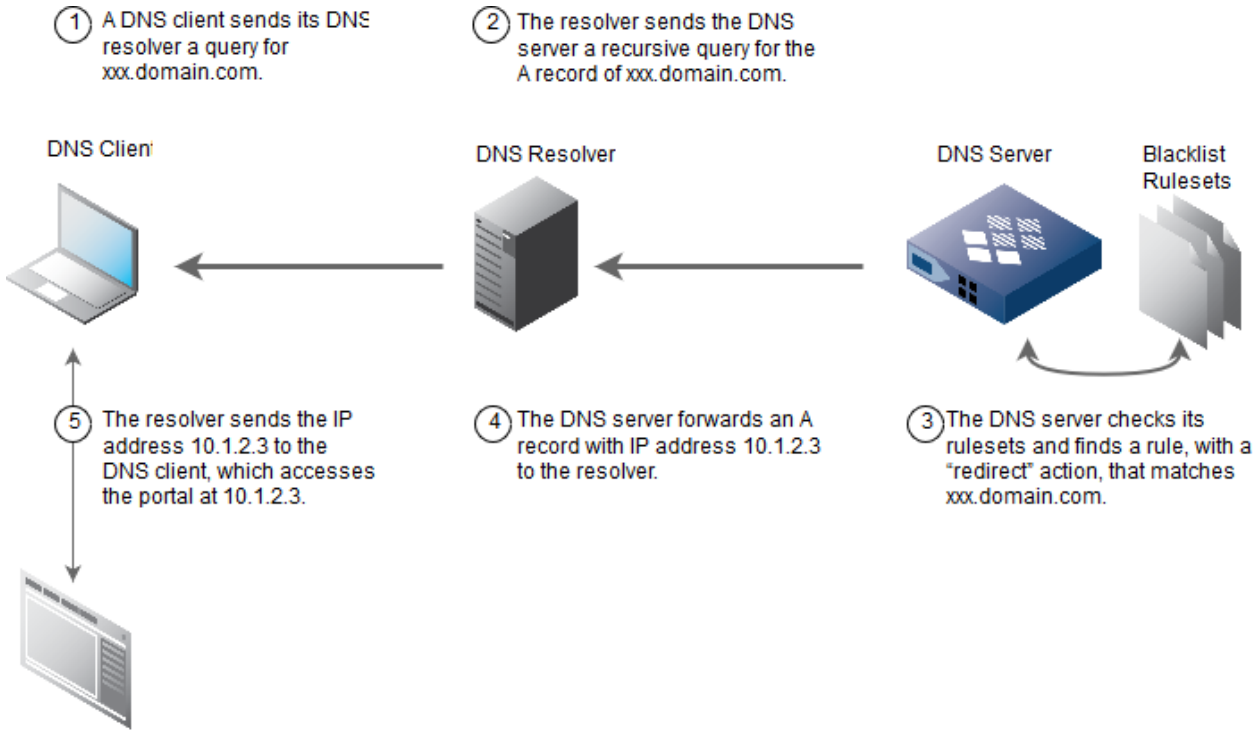
You can create blacklist rules that specify how a DNS member responds to recursive queries for data for which it is not authoritative. Each rule specifies a domain name and the action of the DNS member when the domain name in the query matches that in the rule. Instead of resolving the query, the DNS member can redirect the DNS client to predefined IP addresses or return a REFUSED response code indicating that resolution is not performed because of local policy.

When the DNS member receives a query for data for which it is not authoritative, it first tries to match the domain name in the query with a domain name in any of its rules. If it finds a match, it responds according to the action specified in the rule. If it does not find a match and the NXDOMAIN feature is enabled, the DNS member checks the NXDOMAIN rulesets for a match and responds accordingly. If the NXDOMAIN feature is not enabled, the DNS member resolves the query. (For information about the NXDOMAIN feature, see *About NXDOMAIN Redirection.*

Infoblox DNS members can modify their responses to queries for A records only. Therefore, if the matched query is for a record other than an A record, including a query with a type of "ANY", the DNS member sends a REFUSED response if the matched rule has an action of "Redirect".

In the figure Blacklist below, a DNS client opens a web browser and tries to access xxx.domain.com. When the DNS member receives the query for xxx.domain.com, it checks its blacklist rulesets and finds xxx.domain.com in a rule with an action of "Redirect". The DNS client is redirected to the configured redirection destination IP address 10.1.2.3.

Blacklist



This feature supports queries for data in IPv4 and IPv6 reverse-mapping zones, as well as forward-mapping zones. Note that when a user with a Windows DNS client with IPv6 installed tries to access a domain name, the Windows client sends queries for AAAA records before queries for A records. After the DNS member sends a Refused response to the query for the AAAA record, the DNS client then sends a query for the A record. The DNS member then responds according to the blacklist rules.

When DNSSEC is enabled on the Infoblox DNS server, it does not redirect DNS clients that request DNSSEC data. (For information about DNSSEC, see *Configuring DNSSEC*.) If DNSSEC is not enabled and the query includes a request for DNS data, the appliance ignores the request for DNSSEC data and redirects the clients.

To apply the configured DNS blacklist rules regardless of whether a DNS query requests DNSSEC data, configure the appliance accordingly. For more information about how to configure this, see *Applying Policies and Rules to DNS Queries that Request DNSSEC Data*.

You can enable the blacklist feature at the Grid, member, and DNS view levels. Note that only recursive DNS servers can support this feature. For information on enabling recursion on a DNS member, see *Enabling Recursive Queries Enabling Recursive Queries*.

About Blacklist Rulesets

A blacklist ruleset is a list of rules that a DNS member uses to determine its response to recursive queries for certain domain names. When you enable the blacklist feature, you must define at least one rule in a ruleset. Each rule consists of a domain name and an associated action. The DNS member matches the domain names in the rules with the entire domain name in the query, including its suffix. The domain name in the rule can contain any printable character. Domain name matching is case-insensitive. Unlike the NXDOMAIN rules, blacklist rules do not support metacharacters in domain names.

The action in a rule is either "Pass" or "Redirect".

- Pass: The DNS member resolves the query and forwards the response to the DNS client.
- Redirect: The DNS member does not resolve the query. The DNS member redirects the client to the predefined IP addresses or sends a REFUSED response, depending on your configuration. Note that the DNS member can redirect the client only if the query is for an A record. If the query is for another resource record, the DNS member sends a REFUSED response.

You can use the Blacklist wizard, described in Adding a Blacklist Ruleset, to add blacklist rulesets, but not rules. You can only add rules by importing them in a CSV file, as described in *Importing and Exporting Data using CSV Import*. Note that if a blacklist ruleset contains duplicate domain names, the DNS member loads the first rule in the ruleset and discards the other rules.

The following example illustrates how the DNS member applies blacklist rules. Ruleset 1:

Pattern	Action
a1.foo.com	PASS
foo.com	REDIRECT/BLOCK

- If the DNS member receives a recursive query for a1.foo.com, it resolves the query and forwards the response to the client.
- If the DNS member receives a recursive query for the A record of b1.foo.com, it redirects the DNS client to the specified IP address. If the query is for another record type, such as an MX record, the member sends a REFUSED response to the client.

Blacklist Guidelines

The following summarizes how a DNS member responds to a DNS client when the blacklist feature is enabled:

- If the domain name in the query matches a domain name in a rule, the member does the following:
  - If the query is for an A record, the member performs the action specified in the rule.
    - If the action is "Redirect", the member performs the action specified in the Blacklist wizard.
      - If the action in the wizard is to redirect, the DNS member redirects the client to the listed IP addresses.
      - If the action in the wizard is to return a REFUSED response, the DNS member sends a REFUSED response to the DNS client.
    - If the action in the rule is" Pass", the DNS member resolves the query and forwards the response to the DNS client.
  - If the query is for a non-A record, the member performs the action in the rule as follows:
    - If the action is "Redirect", the DNS member returns a REFUSED response to the DNS client.
    - If the action is "Pass", the DNS member resolves the query and forwards the response to the DNS client.
- If the domain name in the query does not match a domain name in a rule:
  - If the NXDOMAIN feature is enabled, the DNS member tries to find a match with the NXDOMAIN rules and responds accordingly.
  - If the NXDOMAIN feature is disabled, the DNS member resolves the query and forwards the response to the DNS client.Note that if an A record with a dotted hostname is added to an authoritative zone through a dynamic DNS update, and that A record should actually belong in an existing delegation, the appliance may not redirect a query for that A record according to the Blacklist and NXDOMAIN guidelines.

Configuring Blacklists

Configuring Blacklists

You can perform the following operations on the blacklist feature:

1. Add blacklist rulesets, as described in Adding a Blacklist Ruleset below.
2. Create one or more CSV files that contain the rules for each ruleset and import the files to the Grid. For information about importing CSV files, see *Importing and Exporting Data using CSV Import*.
3. Enable blacklisting, as described in Enabling Blacklisting below.

Adding a Blacklist Ruleset

To add the name of a blacklist ruleset:

1. From the **Data Management** tab -> **DNS** tab -> **Blacklist Rulesets** tab, click the Add icon.
2. In the *Blacklist* wizard, complete the following:
    - **Name:** Enter a name for the ruleset.
    - **Comment:** You can enter additional information.
    - **Disable:** You can disable this ruleset for use later on. The appliance ignores disabled rulesets.
3. Save the configuration and click **Restart** if it appears at the top of the screen. You can then use the CSV Import feature to import the rules for each ruleset.

Managing Blacklist Rulesets

To view rulesets, navigate to the **Data Management** tab -> **DNS** tab -> **Blacklist Rulesets** tab. The panel lists the configured rulesets and their associated comments. You can also display the Disabled column which indicates which rulesets are disabled. From this panel, you can do the following:

- Add more rulesets, as described in the preceding section, Adding a Blacklist Ruleset.
- Edit a ruleset, by clicking its checkbox and clicking the Edit icon. You can set the following in the Blacklist Ruleset editor:
    - In the **General Basic** tab, you can change entries in any of the fields.
    - In the **Permissions** tab, you can set admin permissions for the ruleset.
- Delete a ruleset, by clicking its checkbox and clicking the Delete icon.
- View the rules that were imported in each ruleset by selecting it. For each rule, the panel displays the following:
    - Domain name
    - The action of the recursive DNS member when the domain name in a query matches the domain name in the rule.

To delete or edit rules in a ruleset, you must delete the ruleset from this panel, edit the CSV file and re-import it.

Enabling Blacklisting

Only DNS members with recursion enabled can support this feature. You can enable this feature at the Grid level and override it for a member or DNS view with recursion enabled.
You can also enable the DNS member to log queries that matched blacklist rules. The logs include the queried domain name, source IP address, the pattern of the matched rule, and the name of the corresponding ruleset.
To enable blacklisting:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   DNS View: From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab -> *dns_view* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. If the *Grid DNS Properties* or *Member DNS Properties* editor is in basic mode, click **Toggle Advanced Mode**.
3. Click **Blacklist** and complete the following:
   Enable Domain Name Blacklist: Select this checkbox.
   Blacklist Rulesets: To add a ruleset, click the Add icon. If there are multiple rulesets, select one from the *Select Ruleset* dialog box. Use the up and down arrows to move rulesets up and down in the list. The appliance applies rulesets in the order they are listed.
   For blacklisted domain names,return: Select the action of the appliance when it receives a query for a record that matches a rule with an action of Redirect/Block.
   If you selected **This list of IP addresses**, add an IP address to the **Redirect to** table by clicking the Add icon and entering the address. The addresses are listed in round robin fashion in the synthesized response of the DNS member. You can enter up to 12 IP addresses.
   Blacklist TTL: Specify how long the DNS client caches the A record with the redirected IP address.
   Log queries for blacklisted domain names: Select this option to enable the appliance to log queries for blacklisted domain names, including the source IP address of the query.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Blacklists

About Root Name Servers

Root name servers contain the root zone file which lists the names and IP addresses of the authoritative name servers for each top-level zone. When a root name server receives a query for a domain name, it provides at least the names and addresses of the name servers that are authoritative for the top-level zone of the domain name.
You can configure the NIOS appliance to use Internet root name servers or custom root name servers. If you enable recursive queries and the appliance receives a recursive query that it cannot resolve locally, then it queries specified forwarders (if any) and then queries any root name servers that you configure. If you do not specify internal root name servers and the appliance can access the Internet, it queries the Internet root name servers.
You can specify root name servers for the Grid, individual members, and user-defined DNS views. You can specify root name servers for all DNS views except the default view. The default view uses either the member level root name servers (if specified) or the Grid level root name servers.
Every Grid member has a default view. If you want to specify root name servers for a default view, override the Grid root name server setting at the member level and the default view can use the member-level setting.

Specifying Root Name Servers

To specify root name servers for a Grid, member, or DNS view:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab, click the **Members** tab -> *member* checkbox -> Edit icon.
   DNS View: From the **Data Management** tab, select the **DNS** tab, click the **Zones** tab-> *dns_view* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the *Grid DNS Properties* and *Member DNS Properties* editors, you must click **Toggle Advanced Mode**.
3. When the additional tabs appear, click **Root Name Servers**.
4. Select one of the following options:
   - Use Internet root name servers: This option is selected by default.
   - **Use custom root name servers**:
     - Click the Add icon and enter the following information when a new row appears:
       - **Name:** Enter a name for the root name server.
       - **Address:** Enter the IP address of the root name server. The feature supports IPv4 or IPv6 values.
     - Optionally, you can perform the following:
       - Select a server from the custom root name servers list, and then click the Edit icon to modify its information.
       - Select a server from the custom root name servers list, and then click the Delete icon.
     - *Member DNS Properties* editor only: You can choose whether the DNS views should inherit the custom root name server from the member. Select one of the following:
       - **Applies to default DNS view only**: Select this option to apply the root name server only to the default DNS view on the selected member. This option is selected by default.
       - **Applies to all DNS Views on this member**: Select this option to apply the root name server for all DNS views on the selected member.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

About Sort Lists

A sort list prioritizes A and AAAA records on certain networks when those records are included in responses, sorting them to the beginning of the list in the response. For example, you can define a sort list when a server has two interfaces and

you want the DNS clients to prefer one interface because it has a faster link.
When you define a sort list on the NIOS appliance, you specify the following:

- The IP address or network of the source of the query
- The IP addresses or networks that the appliance lists first in its response when it receives a query from the corresponding source address

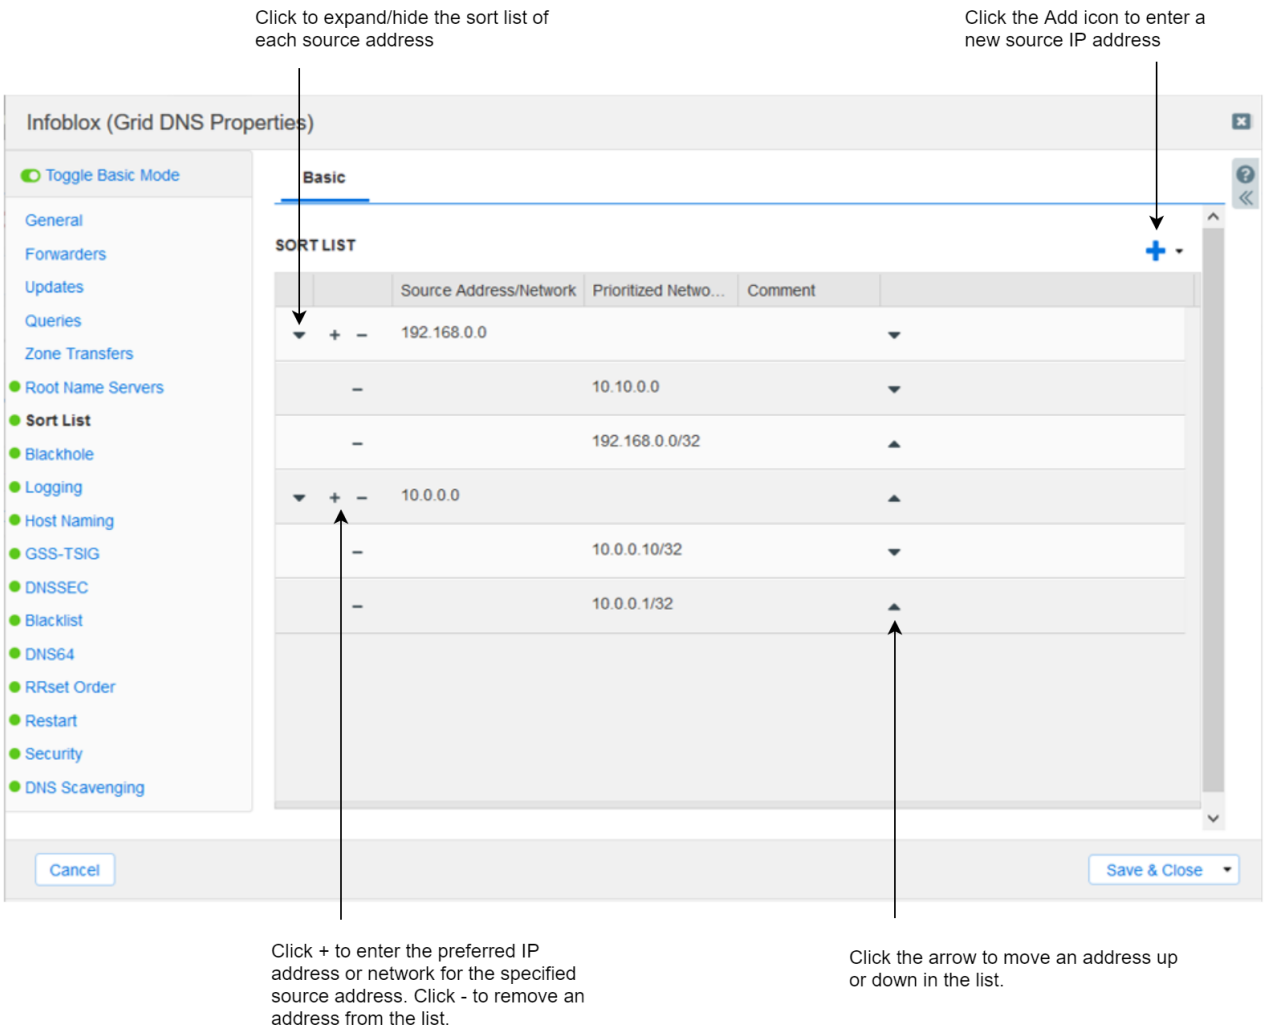
When the NIOS appliance receives a query from the specified IP address or network and the DNS lookup produces a response with multiple addresses, the NIOS appliance sorts the addresses so that those in the sort list are at the beginning of its response. For more information, refer to the *Infoblox DNS Cache Acceleration Application Guide*.

Defining a Sort List

To define a sort list for a Grid, member, or DNS view:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab > **Members** tab -> *member* checkbox -> Edit icon.
   DNS View: From the **Data Management** tab, click the **DNS** tab -> **Zones** tab> *dns_view* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the editor, click **Toggle Advanced Mode**.
3. When the additional tabs appear, click **Sort List**.
4. Click the Add icon and select either Any to define a sort list for any address and network, or Address/Network to define a sort list for a particular source IP address or network.
5. Do the following in the new row:
   - If you selected Address/Network, enter the IP address or network of the source of the query. The feature supports IPv4 or IPv6 values.
   - Click the Add icon beside the source IP address to add the preferred IP addresses or networks for the source. You can add as many IP addresses as necessary. When you add multiple IP addresses, you can change the order of the IP addresses. Select an IP address and drag it to its new position, or click the up or down arrow, as shown in the figure Sort List below.

Sort List



Configuring a DNS Blackhole List

The DNS blackhole feature provides the ability to specify IP and network addresses of network devices that you do not want to use in the DNS resolution process. The DNS blackhole feature is disabled by default. When enabled, the NIOS appliance does not accept queries from IP addresses in the blackhole list and does not use them to resolve queries. For example, you can add the IP addresses of name servers that are using DNS incorrectly to prevent the NIOS appliance from accepting their queries and from using them as resolvers. You can also use this feature to fix temporary network issues. For example, you can add the IP addresses of delegated servers, configured forwarders, and DHCP servers that have temporary DNS-related issues.

You can create a DNS blackhole list for the entire Grid or create a separate list for each Grid member. For example, if one of your Grid members is behind a firewall, you might need to configure a different DNS blackhole list for this member because the clients that can access it might be mapped differently.

The appliance accepts queries from addresses and networks that are excluded from the blackhole list and uses these addresses and networks as resolvers. To add an IP address to the blackhole list, enter it and set its permission to **Include**. You can also add an IP address to the blackhole list and set its permission to **Exclude** so its not in the blackhole list, effectively allowing the NIOS appliance to respond to queries from that address and to use it as a resolver.

When you add a network to a DNS blackhole list, all the IP addresses in the network are not used in the DNS resolution process. If you want to allow some IP addresses within the network, add these addresses to the list and set their permission to "Exclude." Ensure that you list these IP addresses before the network address because the appliance applies permissions to the addresses in the order they are listed. For example, when you add the network 10.10.0.0/24 to a DNS blackhole list, all 256 IP addresses in the network are put on the blackhole list. To allow DNS traffic to the IP addresses 10.10.0.55 and 10.10.0.88, add these two addresses before the network address in the DNS blackhole list,

and then set their permissions to **Exclude**.
You can define ACEs or a named ACL to determine the IPv4 and IPv6 addresses and networks that you want to include in or exclude from a blackhole list.

Defining a DNS Blackhole List

To enable the DNS blackhole feature and configure a DNS blackhole list for a Grid or member:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab, click the **Members** tab -> *member* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the editor, click the **Blackhole** tab and complete the following:
   Enable Blackhole: Select this checkbox to enable the DNS blackhole feature. This is disabled by default.
3. Select one of the following:
   - **Any**: Select this if you want to configure a blackhole list. The appliance will allow all clients to resolve DNS queries. This is selected by default.
   - **Named ACL:** Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this, the appliance uses clients that have the **Exclude** permission in the DNS resolution process. You can click **Clear** to remove the selected named ACL.
   - **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows.
     - **IPv4 Address** and **IPv6 Address:** Select this to add an IPv4 address or IPv6 address. Click the **Value** field and enter the IP address of the client. The **Permission** column displays **Include** by default. You can change it to **Exclude** by clicking the field and selecting **Exclude** from the drop-down list. When you select **Include**, the appliance adds the IP address to the blackhole list and does not allow DNS queries and DNS resolution for this address. When you select **Exclude**, the appliance excludes the address from the blackhole list and allows DNS queries and resolution for the address.
     - **IPv4 Network:** In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address:** Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
       - **Permission:** Select **Allow** or **Deny** from the drop-down list.
     - **IPv6 Network:** In the **Add IPv6 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address:** Enter an IPv6 network address and select the netmask from the drop-down list.
       - **Permission:** Select **Allow** or **Deny** from the drop-down list.
     - **Any Address/Network:** Select to include or exclude any IP addresses and networks for the DNS resolution process.

     After you have added access control entries, you can do the following:
       - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
       - Reorder the list of ACEs using the up and down arrows next to the table.
       - Select an ACE and click the Edit icon to modify the entry.
       - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.
4. Save the configuration.

Specifying Hostname Policies

You can enforce a naming policy for the hostnames of A, AAAA, Host, MX, NS, and bulk host records based on user-defined or default patterns. For MX and NS records, the hostname restrictions apply to the text in the RDATA field (right-hand side) of the resource record name.
Records that you created before you enabled the hostname checking policy need not comply with the hostname restriction that you specify.
You can select one of three preconfigured policies or define your own host naming policy with a POSIX regular expression. The policies Infoblox provides implement standard host naming restrictions according to *RFC 952, DOD Internet Host Table Specification*, and *RFC 1123, Requirements for Internet Hosts -- Application and Support*.

> ⚠ Note
>
> The hostname restriction limits the hostname of A, AAAA, Host, MX, NS, and bulk host records only.

You can define your own hostname restriction policy at the Grid level only. At the member and zone levels, you can select a predefined policy or a policy that was defined at the Grid level. The appliance supports IDNs for DNS zones and resource records. For more information about IDNs, see *Managing Internationalized Domain Names*. You can use UTF-8 characters when you configure your own hostname checking policy.

Defining Grid Hostname Policies

You can define new hostname policies and set the hostname policy for all zones in the Grid as follows:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
2. In the *Grid DNS Properties* editor, click **Toggle Advanced Mode**.
3. When the additional tabs appear, click **Host Naming**.
   The Host Name Policies section lists the following preconfigured record policies:
   - **Strict Hostname Checking**: You can only use hostnames that contain alphanumeric characters, dashes (-), and asterisks (*). You cannot use other special characters, such as underscore (_). Note that when you select this policy, the appliance automatically applies the policy to dynamic DNS updates and zone transfers it receives. When you select this, you can enter host names through Grid Manager using punycode, but not IDNs. The appliance stores IDNs that are created through DDNS updates and DNS transfers in punycode. You can monitor non-compliant host names using the Hostname Compliance report. For information, see Obtaining a List of Invalid Record Names below.
   - **Allow Underscore**: You can only use hostnames with alphanumeric characters, dashes, and underscores ("-" and "_"). This is the default.
   - **Allow Any**: You can use any hostname.

   Select **Default** from the drop-down list in the **Default** column to change the Grid default hostname policy.
   From NIOS 8.6.3 onwards, you have to manually clear the existing host name policy in the table and enter the new one.
4. Click **Add** to define your own hostname checking policy.
   Enter a record policy name and a regular expression string, and click **OK**. See *Supported Expressions for Search Parameters* for definitions of regular expressions.
   Note that Grid Manager does not validate the regular expressions that you enter. Therefore, you can inadvertently specify an invalid regular expression that might cause noncompliance errors when you create records.
5. If you select the Strict Hostname Checking policy, the **Apply policy to dynamic updates and inbound zone transfers (requires Strict Hostname Checking setting)** option is enabled by default. It enables the appliance to apply the policy to dynamic DNS updates and zone transfers that it receives. You can then select which action the appliance takes when it encounters names that do not conform to the policy. Select either **Fail** or **Warn.** If you select **Warn,** the appliance allows the dynamic DNS update or zone transfer, but logs a syslog message.
   Note that the Strict Hostname Checking policy only allows alphanumeric characters and dashes ("-"). In addition, this policy allows IDNs that are written in punycode. You cannot use other special characters, such as underscore ("_"). Therefore, DDNS updates from Microsoft Active Directory controllers may not be accepted.
6. Save the configuration and click **Restart** if it appears at the top of the screen.

After you specify a hostname restriction policy, if you create a record name that does not comply with this policy and try to save it, an error message appears.

Defining Hostname Restrictions

You can select a hostname restriction policy for an individual Grid member or zone. You can specify hostname restrictions for authoritative forward-mapping zones only. You cannot specify hostname restrictions for forward zones, stub zones, IPv4 reverse-mapping zones, and IPv6 reverse mapping zones.
To select a hostname restriction policy for a Grid member or zone:

1. **Member:** From the **Data Management** tab, select the **DNS** tab, click the **Members** tab -> *member* checkbox -> Edit icon.
   Zone: From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab-> *dns_view* -> *zone* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the *Member DNS Properties* editor, click **Toggle Advanced Mode**.
3. When the additional tabs appear, click **Host Naming**.
4. Click **Override**.
5. From the **Host Name Policy** drop-down list, select a predefined policy or a policy that was defined at the Grid level.
6. If you select the Strict Hostname Checking policy, the Apply policy to dynamic updates and inbound zone transfers (requires Strict Hostname Checking setting) is enabled by default. It enables the appliance to apply the policy to dynamic DNS updates and zone transfers that it receives. You can then select which action the appliance takes when it encounters names that do not conform to the policy. Select either Fail or Warn. If you select Warn, the appliance allows the dynamic DNS update or zone transfer, but logs a syslog message.
   Note that the strict hostname checking policy only allows alphanumeric characters and dashes. It does not allow for the use of other special characters, such as underscore ("_"). Therefore, DDNS updates from Microsoft Active Directory controllers might not be accepted.
7. Save the configuration and click **Restart** if it appears at the top of the screen.

Obtaining a List of Invalid Record Names

You can retrieve a list of all record names that do not comply with the current hostname checking policy of a zone. These could be records that were created before the current host naming policy was set. In addition, if you selected the Strict Hostname Checking policy and allowed illegal hostnames in DDNS updates and inbound zone transfers with a warning, those records are listed in this report as well.
To display the Hostname Compliance report:

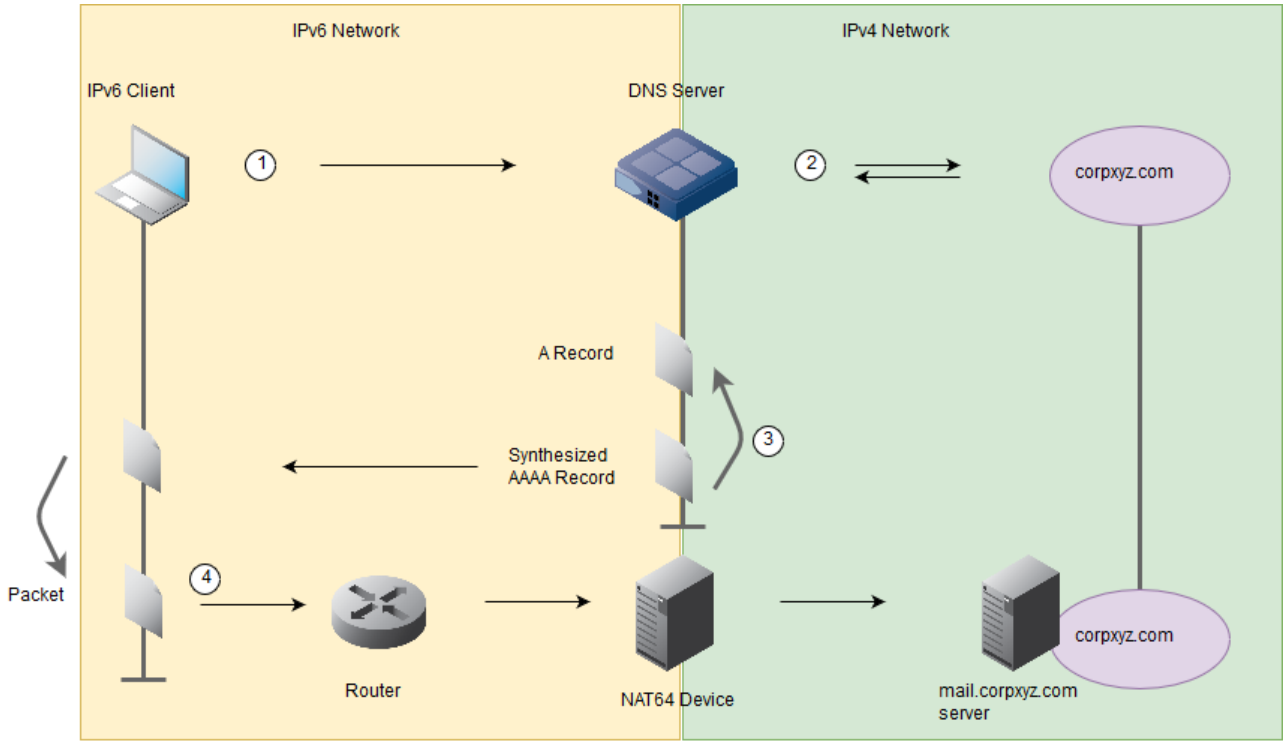
1. From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab-> *dns_view* -> *zone* checkbox.
2. Click **Hostname Compliance.**
   The Hostname Compliance Report for the zone displays. It lists the record name, type, value, and comment for all records that do not comply with the hostname restriction policy of the zone.

From the report, you can select a record and do the following:

- Click the Edit icon to open the record editor.
- Click the Delete icon to move it to the Recycle Bin.

About DNS64

To support the increasing number of IPv6 and dual-stack networks, Infoblox DNS servers now support DNS64, a mechanism that synthesizes AAAA records from A records when no AAAA records exist. When you enable DNS64 on an Infoblox DNS server, it can operate with a third-party NAT64 device so IPv6-only nodes can communicate with IPv4-only nodes without any changes to either of the devices.
As illustrated in the following figure, when an IPv6-only host requests the AAAA record of an IPv4-only server and none exists, a DNS64-enabled server can retrieve the A record of the IPv4 server and synthesize an AAAA record. The IPv6-only host can then use the synthesized AAAA record, which contains the IPv6 proxy address for the IPv4 address in the original A record, to initiate communication with the IPv4 host.



Following are the steps illustrated in the above figure:

1. An IPv6-only host sends a recursive query for the AAAA record of the IPv4 server mail1.corpxyz.com.
2. The Infoblox DNS server attempts to resolve the request for the AAAA record, and determines that an AAAA record for mail1.corpxyz.com does not exist. The DNS server then performs a query for the A record of mail1.corpxyz.com.
3. The DNS server creates a synthetic AAAA resource record from the information in the A record, and returns the synthesized AAAA record to the requesting IPv6 host.
4. The host receives the synthetic AAAA record and sends a packet to the destination address specified in the synthetic AAAA record. The packet is routed to the IPv6 interface of the NAT64 device, which translates the packet from IPv6 to IPv4 and forwards it to the server, mail1.corpxyz.com.

Infoblox DNS servers can return synthesized AAAA records to both IPv4 and IPv6 clients when the client explicitly requests an AAAA record and none exists for the requested host. If a host has multiple A records, the DNS server synthesizes an AAAA record for each A record.
Infoblox DNS servers can also synthesize records for reverse-mapping zones. When a DNS server receives a query for a PTR record in the IP6.ARPA domain whose address matches a configured DNS64 prefix, the server synthesizes a CNAME record that contains an IPv4 address derived from the IPv6 address in the query. The server then sends a query for the PTR record so it can resolve the IPv4 address to the hostname.
For example, if a DNS server that is configured to synthesize records for the prefix 2001:db8::/96 receives a query for the PTR record of 2001:db8::0102:0304, it synthesizes a CNAME record that contains the IPv4 address 4.3.2.1.in-addr.arpa. The server then resolves the PTR record of the IPv4 address 4.3.2.1.in-addr.arpa.
If the server obtains the PTR record, then it sends the synthesized CNAME record and the PTR record to the client. If the zone exists, but there is no PTR record, then the server sends the synthesized CNAME record only. If the zone does not exist, then the server responds with a SERVFAIL with no answers.
Additionally, Infoblox DNS servers can generate synthesized records for DNSSEC secure zones, but only for non-DNSSEC clients. A DNS client or resolver includes the EDNS OPT pseudo-RR with the DO (DNSSEC OK) bit set to indicate that they are requesting DNSSEC data. DNS servers can generate synthesized AAAA records only when the request does not have the DO bit set. This ensures that DNSSEC clients receive only valid responses.
For additional information about DNS64, refer to the following Internet drafts:

- *http://tools.ietf.org/html/draft-ietf-behave-dns64-11*
- *http://tools.ietf.org/html/draft-ietf-behave-address-format-10*

Configuring DNS64

You can enable DNS64 on both authoritative and recursive DNS servers. You can configure DNS64 at the Grid, member or DNS view level.
To configure DNS64 on Infoblox DNS servers:

1. Create at least one DNS64 synthesis group. A synthesis group specifies the IPv6 prefix of the synthesized AAAA records. For more information, see Adding a DNS64 Synthesis Group below.
2. Optionally, specify additional parameters for the synthesis group. For more information, see Setting DNS64 Group Properties below
3. Enable the DNS64 service and assign a synthesis group to the Grid, a member or a DNS view. For more information, see Enabling DNS64 Service below.

On the NAT64 device, you must specify the IPv6 prefixes that are configured on the DNS server.

About Synthesis Groups

A synthesis group specifies, among other things, the IPv6 prefix for the synthesized AAAA records. Infoblox DNS servers provide a default DNS64 synthesis group with the well-known prefix 64:ff9b::/96, which is reserved for representing IPv4 addresses in the IPv6 address space. You can keep the default group, change the prefix or delete the group. You can also add a synthesis group for a Network-Specific Prefix (NSP), which is an IPv6 prefix assigned to an organization to create IPv6 representations of IPv4 addresses.
After you create a synthesis group, you can define rules to restrict the synthesis of AAAA records to certain IPv4 addresses and networks, and specify the DNS clients and networks to which the server can send synthesized AAAA records. For more information, see Setting DNS64 Group Properties below.
Note that though you can control the synthesis of AAAA records, the DNS server always synthesizes CNAME records when it receives a query for an IPv6 PTR record whose address matches a prefix in a DNS64 synthesis group. You can also configure the DNS server to generate synthesized AAAA records for DNS queries that have the DO bit set.

Adding a DNS64 Synthesis Group

To add a synthesis group:

1. From the **Data Management** tab, select the **DNS** tab -> **DNS64 Groups** tab, and then click the Add icon.
2. In the *DNS64 Synthesis Group* wizard, complete the following:
   - **Name:** Enter a name for the group.
   - **Prefix:** The IPv6 prefix used for the synthesized AAAA records. The default is the well-known prefix 64:FF9B::/96. The prefix length must be /32, /40, /48, /56, /64, and /96, and all bits beyond the specified length must be zero.
   - **Comment:** Optionally, enter additional information about the group.
   - **Disabled:** Select this checkbox if you would like to disable the group at this time. Note that you cannot disable the group if it is the only group that is used by a Grid, member or DNS view that has DNS64 enabled.
   - **Apply to queries requesting DNSSEC records:** Select this to generate synthesized AAAA records for DNS64 synthesis groups that request DNSSEC data.
3. Click **Next** to define extensible attributes for the synthesis group. For information, see *Using Extensible Attributes.*
4. Save the configuration

Viewing DNS64 Synthesis Groups

To view synthesis groups, from the **Data Management** tab, select the **DNS** tab -> **DNS64 Groups** tab. This tab displays the following information about each group:

- **Name:** The group name.
- **Prefix:** The IPv6 prefix that is assigned to the group.
- **Comment:** The comment that was entered for the group.
- **Site:** The value of this attribute, if specified.

You can display the following additional column:

- **Disabled:** Indicates whether the group is disabled.

You can do the following:

- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- Edit the properties of a synthesis group.
  - Select the synthesis group, and then click the Edit icon.
- Move a synthesis group to the Recycle Bin.
  - Select the synthesis group, and then click the Delete icon. Note that you cannot delete a synthesis group that is assigned to a Grid, member or DNS view.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filter.*
- Export the synthesis groups to a .csv file.
  - Click the Export icon.
- Print the list of synthesis groups.
  - Click the Print icon.

Setting DNS64 Group Properties

After you create a DNS64 synthesis group, you can specify the following:

- The IPv4 and IPv6 DNS clients and networks to which the DNS server is allowed to send synthesized AAAA records with the specified IPv6 prefix.
- The IPv4 addresses and networks for which the DNS server can synthesize AAAA records with the specified prefix.
- IPv6 addresses or prefix ranges that cannot be used by IPv6 only hosts, such as IP addresses in the ::ffff:0:0/96 network. When the DNS server retrieves an AAAA record that contains an IPv6 address that matches an excluded address, it does not return the AAAA record. Instead, it synthesizes an AAAA record from the A record. Note that a DNS server synthesizes the AAAA record of a host that has both A and AAAA records when all the IPv6 addresses in the AAAA records match the excluded addresses. If the host has multiple AAAA records and some of them contain excluded IPv6 addresses, then the server returns the remaining AAAA records.

You can add individual access control entries (ACEs) or use a named access control list (ACL) to define these clients. For information about how to define named ACLs, see *Defining Named ACLs*.
To configure DNS64 group properties:

1. From the **Data Management** tab, select the **DNS** tab -> **DNS64 Groups** tab -> *group* checkbox -> Edit icon.
2. In the **General** tab of the *DNS64 Synthesis Groups* editor, you can do the following:
   - Modify the name, prefix or comment.
   - Select the **Disabled** checkbox, if you want to disable the group at this time.
   - Select the **Apply to queries requesting DNSSEC records** checkbox to have the DNS server generate synthesized AAAA records for DNS64 synthesis groups that request DNSSEC data.

   Perform DNS64 synthesis for these clients: Specify IPv4 and IPv6 hosts and networks to which Infoblox DNS servers can send synthesized AAAA records. The default is to allow any IPv4 and IPv6 address and network. Select one of the following:
   - **None**: Select this if you do not want to define specific addresses or networks to which the appliance sends synthesized AAAA records. When you select this, the appliance sends synthesized AAAA records to all clients. This is selected by default.
   - **Named ACL:** Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this option, the appliance sends synthesized AAAA records to the clients that have the **Allow** permission in the list. You can click **Clear** to remove the selected named ACL.
   - **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the

selected item or expands the panel so you can specify additional information about the item you are adding, as follows.

- **IPv4 Address** and **IPv6 Address:** Select this to add an IPv4 address or IPv6 address. Click the **Value** field and enter the IP address. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
- **IPv4 Network:** In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
  - **Address:** Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
  - **Permission:** Select **Allow** or **Deny** from the drop-down list.
- **IPv6 Network:** In the **Add IPv6 Network** panel, complete the following, and then click **Add** to add the network to the list:
  - **Address:** Enter an IPv6 network address and select the netmask from the drop-down list.
  - **Permission:** Select **Allow** or **Deny** from the drop-down list.
- **Any Address/Network:** Select this to allow or deny any IP addresses to which the appliance sends synthesized AAAA records.

Mapped IPv4 Addresses: Specify IPv4 addresses and networks for which the DNS server synthesizes AAAA records. The default is to allow the DNS server to synthesize AAAA records for any IPv4 address in any network. Select one of the following1:

- **None**: Select this if you do not want to define specific IPv4 addresses or networks for which the DNS server synthesizes AAAA records. The appliance synthesizes AAAA records for all IPv4 clients. This is selected by default.
- **Named ACL:** Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this option, the appliance synthesizes AAAA records for the clients that have the **Allow** permission in the list. You can click **Clear** to remove the selected named ACL.
- **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows.
- **IPv4 Address:** Select this to add an IPv4 address. Click the **Value** field and enter the IP address. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
- **IPv4 Network:** In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
  - **Address:** Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
  - **Permission:** Select **Allow** or **Deny** from the drop-down list.
- **Any Address/Network:** Select this to allow or deny any IPv4 addresses for which the appliance synthesizes AAAA records.

  After you have added access control entries, you can do the following:
  - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
  - Reorder the list of ACEs using the up and down arrows next to the table.
  - Select an ACE and click the Edit icon to modify the entry.
  - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.

Exclude IPv6 addresses: Specify IPv6 addresses of AAAA records that the appliance treats as nonexistent. The DNS server does not return the AAAA record of an address from this list. Instead, it synthesizes an AAAA record from the A record.

- **None**: Select this if you do not want to define specific IPv6 addresses or networks of AAAA records that the appliance treats as nonexistent. The appliance treats all IPv6 addresses as nonexistent. This is selected by default.
- **Named ACL:** Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this option, the appliance synthesizes

AAAA records from A records for the clients that have the **Allow** permission in the list. You can click **Clear** to remove the selected named ACL.

- **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows.
  - **IPv6 Address:** Select this to add an IPv6 address. Click the **Value** field and enter the IP address. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
  - **IPv6 Network:** In the **Add IPv6 Network** panel, complete the following, and then click **Add** to add the network to the list:
    - **Address:** Enter an IPv6 network address and select the netmask from the drop-down list.
    - **Permission:** Select **Allow** or **Deny** from the drop-down list.
  - **Any Address/Network:** Select this to allow or deny any IP addresses of AAAA records that the appliance treats as nonexistent.

  After you have added access control entries, you can do the following:
  - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
  - Reorder the list of ACEs using the up and down arrows next to the table.
  - Select an ACE and click the Edit icon to modify the entry.
  - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.
- **Extensible Attributes**: You can modify the attributes. For information, see *Using Extensible Attributes.*
- **Permissions**: This tab displays if you logged in as a superuser. For information, see *About Administrative Permissions.*

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Enabling DNS64 Service

You can enable DNS64 at the Grid, member, and DNS view level. At least one DNS64 synthesis group must be configured before you can enable DNS64.
To enable DNS64 and apply DNS64 synthesis groups:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon.
   DNS View: From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *dns_view* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the *Grid* and *Member DNS Properties* editor, click **Toggle Advanced Mode**, and then click **DNS64**. In the *View DNS Properties* editor, just click **DNS64**.
3. Do the following in the **DNS64** tab:
   - **Enable DNS64**: Select this checkbox.
   - **Synthesis Groups:** Click the Add icon and select a synthesis group.
4. Save the configuration and click **Restart** if it appears.

DNS Record Scavenging

The DNS scavenging feature allows you to remove unused DNS resource records from zone data to prevent the accumulation of unneeded records. A scavenging operation determines, based on predefined rules, which records are not needed, i.e. are reclaimable, and removes them. For information about scavenging rules, see ***Scavenging Rules*** in this topic..

Scavenging is used for records with the dynamic record source type. Dynamic records are those created automatically, for example, via a dynamic DNS update. Static records, i.e. records that you add manually, can be identified as reclaimable based on scavenging rules but are not subject to scavenging. You can see the source type for each record in the DNS Resource Records viewer in Grid Manager.

You can use the records scavenging feature at the following levels in NIOS:

- Grid: scavenging is performed in all views and zones of the Grid.
- DNS view: scavenging is performed in all zones of the view.
- Authoritative zone (a Grid primary or unassigned zone): scavenging is performed in the specified zone, but not in the subzones.

You can either scavenge DNS records immediately or schedule automatic scavenging. For more information, see ***Scavenging DNS Records Immediately*** and ***Scheduling Automatic Scavenging*** in this topic..

You can organize and monitor records identified as reclaimable by using Smart Folders. For information, see *Smart Folders*.

Scavenging events are logged in the NIOS syslog. You can view it, as described in *Viewing the Syslog* and *Searching in the Syslog*.

The records are removed to the Recycle Bin and can be restored from there. For more information, see ***Restoring Reclaimed Records*** in this topic..

> ⚠ Note
>
> Membership in the DNS Admin group is required to complete scavenging operations. For details, see *Administrative Permissions for DNS Records Scavenging* below. See *Forcing Creation Timestamp Initialization for Unchanged Records* for information on handling the creation timestamp of records that remain unchanged at DDNS updates.

Scavenging Rules

You can configure the following match rules to identify reclaimable DNS resource records:

- **Resource Record Type**: This rule allows you to specify the record type to run scavenging on. A record is reclaimable if its type matches or does not match the type specified in the rule. The record types that support scavenging include the following:
  - A
  - AAAA
  - PTR
  - CNAME
  - DNAME
  - MX
  - SRV
  - NAPTR
  - TXT
- **Creation Time**: This rule allows you to identify reclaimable records based on the record's creation timestamp. You can see the "Creation Time" value for the records in the DNS Resource Records viewer.
  Note that in the case of an upgrade to NIOS 7.3, the creation time is not initialized. Therefore, the "Creation Time" rule does not apply to the records created before the upgrade.
- **Last Queried Time**: This rule allows you to identify reclaimable records based on when they were last queried for their DNS data. You can see the last queried time for the records in the DNS Resource Records viewer.
  Note that if you use this rule, also select **Enable last queried time monitoring for resource records** in the Grid, view, or zone scavenging properties, as described in the next section.
- **Last Discovered Time**: This rule allows you to identify reclaimable records based on the record's last discovered timestamp. This rule is applicable to A, AAAA, and PTR records.
- **Record Source**: This rule allows you to specify the record source – static or dynamic – to be used as a filter when identifying reclaimable records.
- **Associated Records**: This rule allows you to identify reclaimable records based on whether they have or do not have associated records. Record associations are supported for address records (A, AAAA, and PTR). Additionally, you can reclaim the associated records when reclaiming the original ones by enabling the option

When reclaiming A, AAAA, or PTR records, also reclaim the corresponding, symmetric A, AAAA, and PTR records in the scavenging properties, as described in the next section.

- **Extensible Attributes**: You can specify extensible attributes that reclaimable records should match in addition to the scavenging rules described above.

Configuring DNS Record Scavenging Properties

You can configure the DNS record scavenging properties at the Grid, DNS view, or DNS zone level. According to the NIOS inheritance pattern for object properties, the scavenging properties configured at a given level are inherited by the level below, unless overridden.

To configure the DNS record scavenging properties, complete the following:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
   DNS view: From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab -> dns_view checkbox -> Edit icon.
   DNS zone: From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab -> click a DNS view -> zone checkbox -> Edit icon.
2. If the properties editor is in basic mode, click **Toggle Advanced Mode**.
3. Click **DNS Scavenging**.
4. **Enable last queried time monitoring for resource records**: Select this if you are going to use the Last Queried Time rule. This setting enables monitoring the time when the resource record was last queried for its DNS data. For more information on DNS queries monitoring for resource records, see *Monitoring DNS Queries*.
5. **Enable last queried time monitoring for zones**: This setting enables monitoring the time when the zone, or at least a single record in it, was last queried for its DNS data. The data resulting from zone last queries time monitoring is displayed in the zones viewer (**Data Management** -> **DNS** -> **Zones** -> click a *DNS view* to open zones list). Note that enabling monitoring for a zone does not enable monitoring for child zones.
6. You can configure the set of ACLs (Access Control Lists) to filter clients on DNS queries from updating the last-queried timestamp, under **Prevent the following ACLs or ACEs from updating the last queried timestamp**. To configure the ACLs, you should select either **Enable last queried time monitoring for resource records** or **Enable last queried time monitoring for zones** option, these options are disabled by default.
7. Select one of the following:
   - **None**: Select this option if you do not want to configure any access control for updating the last queried time stamp. When you select this option, NIOS will allow updates to the last queried time stamp for the queries received from any client. This is selected by default.
   - **Named ACL**: Select this option and click **Select Named ACL** to select a named ACL that you want to use. If you have only one named ACL, only that named ACL is displayed. When you select this option, the appliance prevents clients with the **Include** permission from updating the last queried timestamp. You can click **Clear** to remove the selected named ACL.
   - **Set of ACEs**: Select this option to configure individual access control entries (ACEs). Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so that you can specify additional information about the item you are adding.
     - **IPv4 Address and IPv6 Address**: Select this option to add an IPv4 or IPv6 address. Click the **Value** field and enter the IP address. The **Permission** column displays **Include** by default. You can change it to **Exclude** by clicking the field and selecting **Exclude** from the drop-down list. When you select **Include**, the appliance prevents the client from updating the last queried timestamp. When you select **Exclude**, the appliance allows the client to update the last queried timestamp.
     - **IPv4 Network**: In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address**: Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
       - **Permission**: Select **Include** or **Exclude** from the drop-down list.
     - **IPv6 Network**: In the **Add IPv6 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address**: Enter an IPv6 network address and select the netmask from the drop-down list.
       - **Permission**: Select **Include** or **Exclude** from the drop-down list.
     - **Any Address/Network**: Select this option to include or exclude all IP addresses and networks to the last queried ACL list. The default permission is **Include**, which means the appliance prevents

updating the last queried timestamp from all clients. You can change this to **Exclude** to allow all clients to update the last queried timestamp.

- After you have added access control entries, you can perform the following:
  - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
  - Reorder the list of ACEs using the up and down arrows next to the table.
  - Select an ACE and click the Edit icon to modify the entry.
  - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.

8. Select **Enable record scavenging**.
9. To override the inherited properties, click **Override** and complete the fields.
10. Under **Match the following rule**, create a rule as follows. For information about rules, see ***Scavenging Rules*** above.
    - **Choose Filter**: Select a criterion from the drop-down list.
    - **Choose Operator**: Select an operator for the filter criterion.
    - In the value field, enter the value for the filter field. To add another rule:
    - Click **+** to add another rule at the same level.
    - Click **|<-** to add an **all** (logical AND) or **any** (logical OR) operator line and a parenthetical rule that is indented one level and above the first rule.
    - Click **->|** to add an **all** (logical AND) or **any** (logical OR) operator line and a parenthetical rule that is indented one level.
      To logically combine the whole ruleset, select **Match all of the following rules** or **Match any of the following rules**.
      After you add all the match rules, you can click **Reset** to remove the previously configured rules and start again.
11. Under **Match records with the following extensible attribute**, add an extensible attribute to use as an additional criterion for finding necessary records.
    - **Choose Operator**: Select an operator for the filter criterion.
    - **Choose Filter**: Select a criterion from the drop-down list.
    - In the value field, enter the value for the filter field.

To add another extensible attribute, click **+**.

1. To logically combine the extensible attributes set, select **Match all records with the following extensible attributes** or **Match any records with the following extensible attributes**.
2. After you add all the extensible attributes, you can click **Reset** to remove the previously configured attributes and start again.
   Note that the extensible attributes rule is always combined with the rest of the match rules using the AND operator.
3. **When reclaiming A, AAAA or PTR records, also reclaim the corresponding, symmetric A, AAAA and PTR records**: Select this if you want to reclaim records associated to the ones identified as reclaimable.
4. To configure a schedule for automatic records scavenging, select **Enable scheduled record scavenging**. See ***Scheduling Automatic Scavenging*** in this topic.
5. Click **Save & Close** or **Save**.

Scheduling Automatic Scavenging

You can schedule a scavenging operation only at the Grid level. For a scavenging operation at the view or zone level, you can use the schedule inherited from the Grid.

> ⚠ Note
>
> Infoblox recommends manually testing the configured scavenging settings before enabling scheduled scavenging.

1. In the DNS record scavenging properties described in the previous section, select the **Enable scheduled record scavenging** checkbox.
2. To enable automatic scavenging after records are marked as reclaimable, select **After marking a record as reclaimable, automatically reclaim the record**.
3. Click the Scheduling icon and complete the following in the Scavenging Scheduler dialog:
    - Select how often you want to execute the scavenging. You can select **Once**, **Hourly**, **Daily**, **Weekly**, or **Monthly**.
    - If you select **Once**, complete the following:
        - Enter the day in the date picker and select a month from the drop-down list.
        - Enter a time in the hh:mm:ss AM/PM format. You can also select a time from the drop-down list.
        - Choose the **Time Zone**.
    - If you select **Hourly**, complete the following:
        - **Schedule every hour(s) at**: Enter the number of hours between each scavenging instance. You can enter a value from 1 to 24.
        - **Minutes past the hour**: Enter the number of minutes past the hour. For example, enter 5 if you want to schedule the scavenging operation five minutes after the hour.
        - Choose the **Time Zone**.
    - If you select **Daily**, complete the following:
        - Click either **Every day** or **Every weekday**.
        - Enter a time in the hh:mm:ss AM/PM format. You can also select a time from the drop-down list.
        - Choose the **Time Zone**.
    - If you select **Weekly**, complete the following:
        - **Schedule every week on**: Select any day of the week.
        - Enter a time in the hh:mm:ss AM/PM format. You can also select a time from the drop-down list.
        - Choose the **Time Zone**.
    - If you select **Monthly**, complete the following:
        - **Schedule the day of the month**: Enter the day of the month and the monthly interval. For example, to schedule the rule update on the first day after every 2 months, you can enter Day 1 every 2 month(s).
        - Enter a time in the hh:mm:ss AM/PM format. You can also select a time from the drop-down list.
        - Choose the **Time Zone**.
4. Click **OK**.

Scavenging DNS Records Immediately

To perform record scavenging for the Grid, a DNS view, or a zone according to the predefined rules, use the Scavenge Records command from the Toolbar. This adds a background task that starts immediately or, if another scavenging task is in progress, after its completion.

The scavenging is split into two stages that you can execute separately or together:

- **Mark records as reclaimable**: This stage analyzes the records against the scavenging rules. The records matching the rules are marked as reclaimable, i.e. their "Reclaimable" flag is set to "Yes" in the DNS Resource Records viewer. These records can be reclaimed by using the second stage, unless you disable scavenging for them as described in ***Disabling Scavenging for Individual Records*** in this topic.
- **Reclaim records marked as reclaimable**: This stage automatically removes the records marked as reclaimable in the result of the execution of the first option. Running only the "Reclaim records marked as reclaimable" stage without the analysis stage does not perform a new analysis on the affected records. It only removes the records marked as reclaimable during the previous analysis.

Also, you can reset the reclaimable flag of the records. As an example of when this may be useful: if records have previously been marked as reclaimable and under a revised scavenging policy some records may no longer be reclaimable.

Note

To start immediate scavenging of DNS records, you must first carefully define the scavenging properties, as described in ***Configuring DNS Record Scavenging Properties*** in this topic.

To scavenge DNS records immediately, complete the following:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Scavenge Records** -> **Scavenge Grid Records**.
   DNS view: From the **Data Management** tab, select the **DNS** tab, click a DNS view, expand the Toolbar, and then click **Scavenge Records** -> **Scavenge View Records**.
   DNS zone: From the **Data Management** tab, select the **DNS** tab, click a DNS view, click a zone, expand the Toolbar, and then click **Scavenge Records** -> **Scavenge Zone Records**.
2. Select one of the following:
   - **Scavenge Records**: Select this to proceed to the record scavenging. Go to the next step.
   - **Reset reclaimable flag**: Select this to set the "Reclaimable" flag of all affected records to "No".
3. If you chose **Scavenge Records**, select one of the following options or both of them:
   - **Mark records are reclaimable**
   - **Reclaim records marked as reclaimable**
     Note that static records are never reclaimed automatically even if they are marked as reclaimable. You can only delete static records manually from the DNS Resource Records viewer.
4. Click **Start**.

To check the progress of the current scavenging task, you can use the DNS Record Scavenging widget in the Dashboard. You can also view a scavenging report, as described in *DNS Scavenged Object Count Trend*.

The scavenging task may be subject to an approval workflow. For information on approval workflows, see *Configuring Approval Workflows*.

> ⚠ Note
>
> Keep in mind that the **Enable record scavenging** property for a lower scavenging scope (e.g. view or zone) can override this property for the upper scope (i.e., Grid or view respectively). For example, if you run scavenging on the Grid with the scavenging option disabled, and there are some views or zones on which scavenging is enabled, this results in the records of the affected views and zones being scavenged. Vice versa, if scavenging is disabled for certain views or zones and you run scavenging on the Grid with the scavenging option enabled, the corresponding views and zones are excluded from scavenging.

Disabling Scavenging for Individual Records

You can disable scavenging for individual records, even if they are marked as reclaimable. In this case, the record is never reclaimed unless you enable the scavenging for it again.

To disable scavenging for a record, complete the following:

1. In the *DNS Resource Records* viewer, select the appropriate record.
2. Click **Edit**.
3. In the record properties dialog, click **DNS Scavenging**.
4. Select the **Disable scavenging for this record** checkbox.
5. Click **Save & Close**.
   Additionally, you can see the following information in the resource record scavenging properties:

- Record creation time
- Record last queried time
- Whether the record is reclaimable

1. For records synced from MS servers, the creation timestamp is not synced. This implies the following limitations:
   - When a zone is converted from MS to NIOS, the timestamp is initialized to the time when the operation occurs.
   - When a zone is converted from NIOS to MS, the timestamp is reset.

Administrative Permissions for DNS Records Scavenging

By default, only superusers can perform DNS records scavenging. Limited-access users can use the scavenging functionality if they have the corresponding DNS scavenging permissions. For more information about admin permissions, see *About Administrative Permissions*.

The DNS scavenging permissions are global to Grid Manager. They are used in addition to the regular DNS global and object permissions. For more information about the DNS permissions, see *Administrative Permissions for DNS Resources*.

The following operations require scavenging permissions:

- Modifying scavenging properties for the Grid, a view, or a zone
- Configuring a scavenging schedule
- Performing a scavenging task
- Viewing the DNS Record Scavenging dashboard widget
- Viewing the DNS Scavenged Object Count Trend report

Restoring Reclaimed Records

A reclaimed record remains in the Recycle Bin until the bin is emptied. You can restore the deleted records from the Recycle Bin, as described in *Restoring Objects from the Recycle Bin*.

The Recycle Bin does not display information on whether a record was deleted during a scavenging process or manually.

Therefore, you cannot restore the reclaimed data only.

When a record is restored from the Recycle Bin, its Reclaimable flag is reset to "No".

> ⚠ Note
>
> Only a super user can restore records reclaimed during a recurring scavenging task.

Monitoring DNS Queries

You can monitor DNS resource records by their **Last Queried** time. You can configure this feature in the *Grid DNS Properties* editor -> **DNS Scavenging** tab. Infoblox recommends that you keep the number of zones or domains for monitoring below 1000; specifying more may adversely affect performance.
To view DNS queries by their **Last Queried** time:

1. From the **Data Management** tab -> **DNS** tab, click the **Query Monitoring** tab.
2. The **Query Monitoring** tab provides a **Last Queried** report for the monitored resource records, including the following information:
   - **Network View**: Network view name. You cannot sort on this column. This column is hidden by default.
   - **DNS View**: DNS view name. This column is hidden by default. **Zone**: FQDN of zone.
   - **Name**: FQDN of resource record.
   - **Record Type**: Resource record type.
   - **Record Data**: Value of resource record, such as address of an A record.
   - **Monitored Since**: Date monitoring started.
   - **Last Queried**: Displays "Not Monitored", "Not Queried Since xxxx", or date of last query.
     Note this report does not display the last queried information for automatically generated NS records.

To enable last queried time monitoring for resource records, do the following in the DNS scavenging properties for the Grid, a view, or a zone:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
   DNS view: From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab -> *dns_view* checkbox -> Edit icon.

DNS zone: From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab -> click a DNS view -> *zone* checkbox -> Edit icon.

2. If the properties editor is in basic mode, click **Toggle Advanced Mode**.
3. Click **DNS Scavenging**.
4. Select the **Enable last queried time monitoring for resource records** checkbox. For more information, see *Configuring DNS Record Scavenging Properties*.
5. Click **Save & Close**.

> ⚠ Note
>
> Exporting the query monitoring data may take longer than usual if the report contains a lot of records. Also, if a Grid secondary server uses zone transfer to update zone data from a Grid primary server, NIOS does not monitor queries made to the Grid secondary server and it does not update the last queried timestamp for the resource records in a zone.

When multiple values are specified with the same filter, the filter applies *or* logic, e.g. 'a' or 'b'. Other perspectives in NIOS UI apply *and* logic, e.g., 'a' and 'b'. You can use the following filters to get specific information in this report:

- **DNS View**: DNS view name.
- **Not Queried**: Specify a date when the last query was made. The only operator is "Since".
- **Zone**: FQDN of zone.
- **Type**: Only a single record type filter can be specified. This filter has the following resource records:
  - A Records
  - AAAA Records
  - BulkHost
  - CAA Records
  - CNAME Records
  - DNAME Records
  - DS Records
  - DTC LBDN Records
  - Host Address
  - Host Alias
  - Host Record
  - MX Records
  - NAPTR Records
  - NS Records
  - PTR Records
  - Resource Record
  - SRV Records
  - Shared A Record
  - Shared AAAA Record
  - Shared CNAME Record
  - Shared MX Record
  - Shared SRV Record
  - TXT Records
  - Other Records

> ⚠ Note
>
> NIOS does not monitor queries or update timestamp for DNSSEC records, except for DS records. As a result, the **QueryMonitoring** tab displays "Not Monitored" in the Last Queried column for all DNSSEC records. In addition, the Not Queried filter does not display any DNSSEC records.

Configuring DNS Traffic Control Properties

You can configure the DNS Traffic Control properties at the Grid or member level. The member DTC properties are inherited from the Grid DTC properties unless you override them.

The following sections explain how to configure DTC properties for the Grid or a Grid member.

Configuring Grid DNS Traffic Control Properties

To configure DNS Traffic Control properties for the Grid, complete the following:

1. From the **Data Management** tab, select the **DNS** tab, expand the toolbar, and then click **Grid DNS Properties**.
2. In the **Traffic Control** tab, complete the following:
    - **Extensible Attributes Source Types for Topology Rules**: Specify up to four extensible attributes to use as source types when defining DNS traffic control topology rules. For information about the extensible attribute topology rules, see *Defining Topology Rulesets*. You can use either predefined EAs or use your own. When using the predefined EAs you can select all or select specific types of IPAM objects, network containers, networks, ranges, and hosts and their EA values to be considered for the predefined EAs. For information about predefined extensible attributes, see . For information about creating custom extensible attributes, see *Adding Extensible Attributes*.
      You can select only string, enum, and integer types as the EAs to be used. Also, you cannot select EAs for which multiple values have been set. That is, the **Allow multiple values** checkbox must not be enabled for EAs that you want to use to define topology rules.
      Note that the enabled IPAM object for Extensible Attributes Source Types for Topology Rules depend on the upgrade history of the Grid. In case, Grid is upgraded from the earlier NIOS version to a later version which supports different IPAM object types, only IPAM Networks and IPAM Ranges types are enabled by default. However, in a Grid that is created with the possibility to select different IPAM object types, all the IPAM object types are enabled by default.
    - **When DNS Traffic Control is enabled, direct traffic according to EDNS0 Client Subnet when possible**: Select this checkbox to direct traffic according to EDNS0 client subnet option when DNS Traffic Control is processing DNS queries.
      You can enable the appliance to redirect traffic according to EDNS0 client subnet option when DNS Traffic Control is processing DNS queries that contain the EDNS0 client subnet option. When you enable this feature, DNS Traffic Control querying process uses the client address specified in the EDNS0 client subnet option of the DNS query and the appliance includes the EDNS0 client subnet option in the response message. If there are multiple EDNS0 client subnet options in a query, the appliance considers only the first option and ignores the other options. When this feature is disabled, DNS Traffic Control querying process ignores the EDNS0 client subnet option. For more information about EDNS0, see *Using Extension Mechanisms for DNS (EDNS0)*.
    - **Specific behavior for DNS queries**: Select one of the following options if you want the appliance to return DNS responses when no DNS traffic control responses are available. The **Return DNS response if there are no DNS Traffic Control responses available** option is selected by default.
        - **Return DNS response if there are no DNS Traffic Control responses available**: Select this option if you want the appliance to return DNS responses when DNS Traffic Control responses are not available.
        - **Drop LBDN matched DNS queries during full health update**: Select this option to drop all LBDN queries when the DNS service is waiting to receive a full health status update from the health monitor. The appliance drops the LBDN queries and returns a SERVFAIL response.
        - **No specific behavior**: Select this option when you do not want the appliance to return DNS responses when DNS Traffic Control responses are not available.
    - **Return the following type of response from DNSSEC signed zones**: Select one of the following response types for DNSSEC-signed zones:
        - Signed
        - Unsigned

          For more information on the Signed and Unsigned modes, see *Managing LBDN Records*.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring Member DNS Traffic Control Properties

To configure DNS Traffic Control properties for a Grid member, complete the following:

1. From the **Data Management** tab, click the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon. Alternatively, you can click the **DNS** tab -> **Traffic Control** tab, click **Member DNS Properties** in the toolbar, and then select the required member.
2. In the **Traffic Control** tab, complete the following:
    - **DTC Health Check Source**: Select which NIOS network interface to use for the DTC health check. Choose one of the following:
      Note that for vNIOS appliances, some of the options may vary depending on your vNIOS configuration. For example, if you are using a single network interface instance of vNIOS for GCP, you will see choices specific to the LAN1 interface only. For more information, see the vNIOS documentation specific to your product at *Appliances*.
        - ANY interface
        - VIP interface
        - LAN2
        - MGMT interface
        - IP (This is displayed only when you have configured additional IP addresses in the network settings. Specify the IP address of the source.)
    - **Specific Behavior for DNS queries**: Select one of the following options if you want the appliance to return DNS responses when no DNS traffic control responses are available. The **Return DNS response if there are no DNS Traffic Control responses available** option is selected by default. To override the Grid setting, click **Override**.
        - **Return DNS response if there are no DNS Traffic Control responses available**
        - **Drop LBDN matched DNS queries during full health update**
        - **No specific behavior**
          For more information, see Configuring Grid DNS Traffic Control Properties above.
    - **When DNS Traffic Control is enabled, direct traffic according to EDNS0 Client Subnet when possible**: To retain the same setting as the Grid, keep the inherited value. To override the Grid setting, click **Override**.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

DNS Views

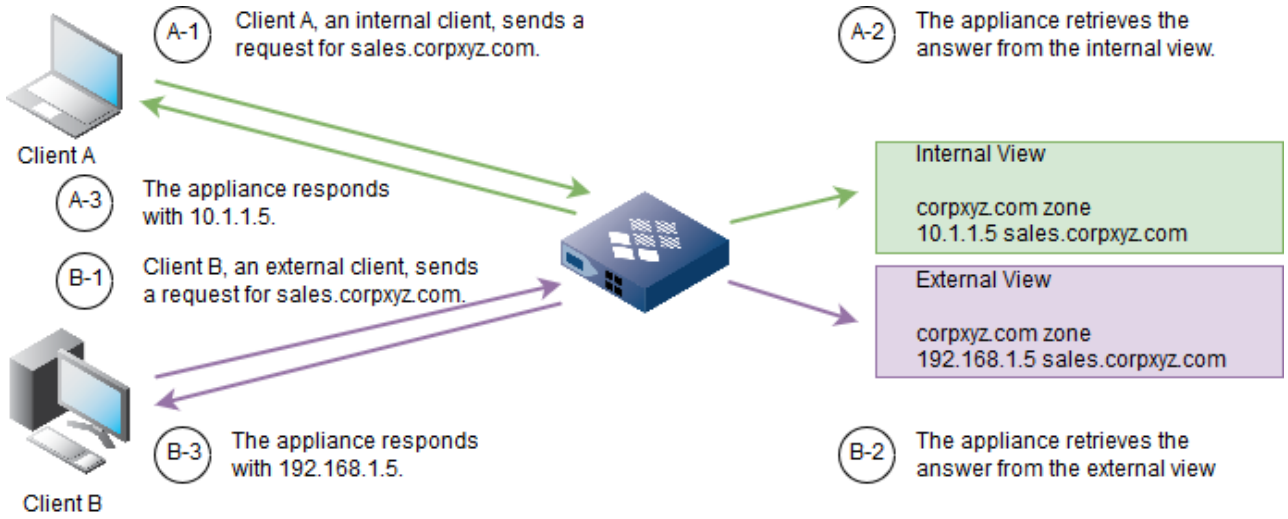
DNS views enable the NIOS appliance to serve different versions of DNS data based on the host accessing it. The topics in this section include:

- *About DNS Views*
- *Configuring DNS Views*
- *Configuration Example: Configuring a DNS View*

About DNS Views

DNS views enable the NIOS appliance to serve different versions of DNS data based on the host accessing it.

DNS views provide the ability to serve one version of DNS data to one set of clients and another version to another set of clients. With DNS views, the NIOS appliance can provide a different answer to the same DNS query, depending on the source of the query.
In the below figure, the appliance has two views: an Internal and an External DNS view. When the appliance receives queries from DNS clients, it responds with data from either the Internal or External DNS view, depending on the source IP address. When the appliance receives a query from Client A and determines that it can resolve the query from data in the Internal view, the appliance responds with the IP address of the site in the Internal view. When the appliance receives a query from Client B and determines that it can resolve the query from data in the External view, it responds with the IP address in the External view.
Internal and External Views



You can configure both forward and reverse mapping zones in DNS views and provide DNS services, such as name resolution, zone transfers and dynamic DNS updates. For information about these services, see *Configuring DNS Services*.

You can provide multiple views of a given zone with a different set of records in each DNS view. In the below figure, both views contain the corpxyz.com zone and the sales.corpxyz.com zone. The finance.corpxyz.com zone is only in the internal DNS view, and only internal users are allowed to access records in that zone. Resource records can also exist in multiple zones. In the example, the A records for serv1.sales.corpxyz.com and serv2.sales.corpxyz.com are in the sales.corpxyz.com zones in both views.

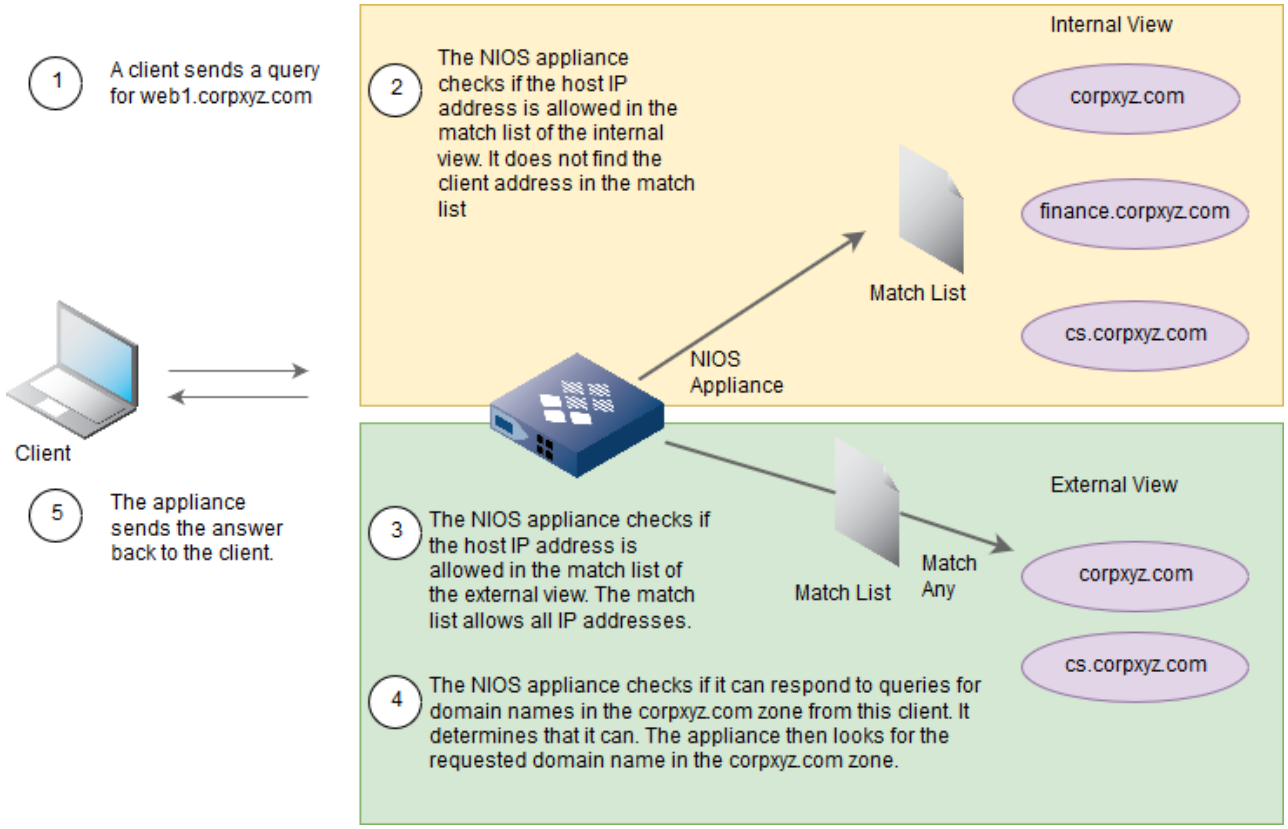
Zone Data in Each DNSView

Internal DNS View MX	**corpxyz.com** rmail.corpxyz.com	A	**sales.corpxyz.com** serv1.sales.corpxyz.com	A	**finance.corpxyz.com** server.finance.corpxyz.com
NS	dnsoneA.corpxyz.com	A	serv2.sales.corpxyz.com	A	printer.finance.corpxyz.com
A	host1.corpxyz.com	A	serv3.sales.corpxyz.com	A	fin1.finance.corpxyz.com
A	host2.corpxyz.com	A A A	printer.sales.corpxyz.com host1.sales.corpxyz.com host2.sales.corpxyz.com	A	fin2.finance.corpxyz.com
External DNS View	**corpxyz.com**		**sales.corpxyz.com**		
MX A A	email.corpxyz.com web1.corpxyz.com web2.corpxyz.com	A A A A	web3.sales.corpxyz.com ftp.sales.corpxyz.com serv1.sales.corpxyz.com serv2.sales.corpxyz.com		

You can control which clients access a DNS view through the use of a match list specifying IP addresses and/or TSIG (transaction signature) keys. When the NIOS appliance receives a request from a client, it tries to match the source IP address and/or TSIG key with its match list when determining which DNS view, if any, the client can access. After the appliance determines that a client can access a DNS view, it checks the zone level settings to determine if it can provide the service that the client is requesting. For information on TSIG keys or defining zone transfer settings, see *Enabling Zone Transfers*. For more information on match lists, see *Defining Match Clients Lists*. For information on defining query settings, refer to *Controlling DNS Queries*.

The figure Query Resolution below illustrates how the NIOS appliance resolves a query for a domain name in a zone of a DNS view. In the example, the internal DNS view is listed before the external DNS view. Therefore, when the appliance receives a query, it checks the match list of the internal DNS view first. If it does not find the source address in the match list of the internal DNS view, it checks the match list of the external DNS view. The match list of the external DNS view allows all IP addresses. Next, the NIOS appliance checks the zone level settings to determine if it is allowed to resolve queries from the client for domain names in that zone. After the appliance determines it is allowed to respond to queries from this client, it resolves the query and sends back the response to the client.

Query Resolution



When you create more than one DNS view, as shown in the figure Query Resolution above, the order of the views is important. View order determines the order in which the NIOS appliance checks the match lists. In the figure Query Resolution, the internal DNS view is listed before the external DNS view. If the views were reversed, no hosts would receive DNS replies from the internal DNS view because the match list of the external DNS view allows replies to clients with any IP address.

In a Grid, each Grid member can host its own set of views. A Grid member can serve as the primary or secondary server for multiple views of a particular zone. For information about specifying primary and secondary servers, see *Assigning Zone Authority to Name Servers*.

About DNS Views and Network Views

The NIOS appliance provides one default DNS view, which is always associated with the default network view. You can create additional network and DNS views. A network view is a single routing domain with its own networks. For information about network views, see *Managing IPv4 DHCP Data*.

The default DNS view initially allows all IP addresses access, and has the same recursion setting as the Grid. You can change these properties and rename the default DNS view, but you cannot delete it. When you upgrade or migrate from a name server, or an earlier version of software that does not support DNS views, the appliance places all the zones defined in the older release in the default DNS view. You can then create additional views and organize the zones in each view.

When you create a network view, the appliance automatically creates a corresponding DNS view with "default." prepended to the name of the network view. You can rename the system-defined DNS view and configure its properties. If the appliance contains only one network view, all DNS views are associated with that network view. If there are 20 or less network views configured, the appliance displays the network views in the drop-down list on the left of the top navigation bar of the **Data Management** tab of Grid Manager. The appliance displays the *Network View Selector* dialog box if there are more than 20 network views configured. You can adjust the page size of the selector by choosing the number of network views to be displayed on each page from the **Page Size** drop-down list. If the number of network views exceeds the selected number, the selector displays the data on multiple pages. If you have a large number of network views, select a larger page size so you can quickly locate a network view without excessive paging through the list. The default page size is 10.

A DNS view can be in one network view only, but a network view can have multiple DNS views. If you enable dynamic DNS updates, you must specify which DNS view receives the updates. In a network view, only one DNS view can receive the dynamic DNS updates. For information, see *Sending DDNS Updates to a DNS Server*.

Configuring DNS Views

Following are the tasks to configure a DNS view:

1. Add a DNS view, as described in Adding a DNS View below.
2. Add zones to the DNS view. You can add authoritative forward-mapping and reverse-mapping zones, as well as delegated, forward, and stub zones. For information about configuring each type of zone, see *Configuring Authoritative Zones* and *Configuring Delegated, Forward, and Stub Zones*.

You can optionally do the following:

1. Define a Match Clients list and a Match Destination list to restrict access to the DNS view. For more information, see Defining Match Clients Lists and Defining a Match Destinations List below.
2. Copy resource records from one zone to another. This is useful when different DNS views have the same zone and have multiple resource records in common. For information, see Managing DNS Views below.
3. Create resource records in a group and share the group among multiple zones. For information, see *Configuring Shared Record Groups*.
4. Specify which interface IP address is published in the glue A record of the DNS view. For information, see *Changing the Interface IP Address*.
5. Manage recursive views. For information, see Managing Recursive DNS Views below.
6. Manage the order of the DNS views, as this determines the order in which the NIOS appliance checks the Match Clients list. For information, see Managing the Order of DNS Views.
7. Configure forwarders for a DNS view. For more information, see *Using Forwarders*.
8. Enable AAAA filtering and configure a list of IPv4 networks and addresses for allowing or denying AAAA filtering from the appliance. For information, see *Controlling AAAA Records for IPv4 Clients*.

Adding a DNS View

You can add up to 1000 DNS views. When you add a DNS view, specify the following:

- The network view in which you are creating the DNS view.
  The appliance lists the network views only when there are multiple network views. Otherwise, it automatically associates the DNS view with the default network view.
- A Match Clients list specifying the hosts allowed access to the DNS view.
  If you do not define a list, the appliance allows all hosts to access the DNS view. For more information, see Defining Match Clients Lists below.
- Whether recursive queries are allowed.
  When a name server is authoritative for the zones in a DNS view, you can disable recursion since your name server should be able to respond to the queries without having to query other servers.
  if you want to allow a Grid member to respond to recursive queries from specific IP addresses, you can create an empty DNS view, that is, one that has no zones in it, and enable recursion. For information, see *Configuration Example: Configuring a DNS View*.

> **Note**
>
> This setting overrides the recursion setting at the Grid and member levels..

To configure a new DNS view:

1. If there is more than one network view in the Grid, select the network view in which you are creating the DNS view.
2. From the **Data Management** tab -> **DNS** tab, expand the Toolbar and click **Add** -> **Add DNS View**.
3. In the *Add DNS View* wizard, complete the following fields:
   - **DNS View:** Enter the name of the DNS view. It can be up to 64 characters long and can contain any combination of printable characters. Each DNS view must have a unique name. You cannot create two DNS views with the same name, even if they are in different network views.
   - **Comment:** Optionally, enter information about the DNS view. You can enter up to 256 characters.
   - **Enable Recursion:** This field's initial default state is inherited from the Grid. It is inactive and greyed out until you click **Override**. After you click override, you can select or clear the checkbox to define a setting that applies to the DNS view only.
     Note that a DNS view actually inherits its recursion setting from the Grid members that serve its zones. When you first create a DNS view though, it does not have any zones and therefore inherits its setting from the Grid. After you create zones in the DNS view, Grid Manager can then determine the associated members and display the resulting inheritance. If a DNS view has multiple zones served by multiple members with different recursion settings, you can view the different settings in the Multi-Inheritance viewer.
     You can click **Inherit** to have the DNS view inherit its recursion setting from the Grid.
     If the *set rpz_recursive_only* command is set to `no` for a DNS view or zone, you can deselect the **Enable Recursion** checkbox even if the RPZ zone is configured as the Grid secondary. In a single DNS view, if the *set rpz_recursive_only* command is set to `no` for one zone and not set to no for another zone, then you cannot disable recursion. Ensure that there is no conflict between *set rpz_recursive_only* `yes`, `none`, and `no` settings in different zones in the same view when you disable recursion. If a scheduled Grid upgrade is in progress, then you cannot deselect the **Enable Recursion** checkbox.
   - **Disable**: Select this checkbox to disable this DNS view. Note that disabling a DNS view may take a longer time to complete depending on the size of the data.
4. Save the configuration and click **Restart** if it appears at the top of the screen, or click **Next** to define a Match Clients list. For information, see Defining Match Clients Lists below or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Defining Match Clients Lists

When you configure a DNS view, you can create a Match Clients list to identify source IP addresses and TSIG keys that are allowed or denied access to the DNS view. The NIOS appliance determines which hosts can access a DNS view by matching the source IP address or TSIG key with its Match Clients list. After the appliance determines that a host can access a DNS view, it checks the zone level settings to determine whether it can provide the service that the host is requesting for that zone.
If you do not configure a Match Clients list, then all devices are allowed access to the DNS view. However, if you configure a Match Clients list, then only those devices in the list with "Allow" permission can access the DNS view. All other devices are denied access, including Grid members. Therefore, to allow a primary server of a zone to receive dynamic DNS updates from member DHCP servers, you must add the members to the Match Clients list as well. Note that if you "Deny" permission to certain IP addresses or networks, you must add the "Allow Any" permission at the end of the Match Clients list to ensure that all other IP addresses and networks that are not in the "Deny" list are allowed access to the DNS view. You can add individual ACEs (access control entries) or a named ACL (access control list) to the Match Clients list. For information about named ACLs and how to define them, see *Defining Named ACLs*.

Defining a Match Clients List for a DNS View

You can define a Match Clients list for a DNS view when you add a new DNS view (second step of the Wizard) or when you edit an existing DNS view.

To define a Match Clients list for an existing DNS view:

1. From the **Data Management** tab, click the **DNS** tab > **Zones** tab> *dns_view* checkbox -> Edit icon. Or, if there is only one DNS view, for example the predefined default view, you can just click the Edit icon beside it.
2. In the *DNS View* editor, select the **Match Clients** tab, and select one of the following:
    - **None**: Select this if you want to configure a Match Clients list. The appliance allows all clients to access the DNS view. This is selected by default.
    - **Named ACL**: Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this option, the appliance allow access to the DNS view from sources that have the **Allow** permission in the named ACL. You can click **Clear** to remove the selected named ACL.
    - **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding.
        - **IPv4 Address** and **IPv6 Address**: Select this to add an IPv4 address or IPv6 address. Click the **Value** field and enter the IP address. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
        - **IPv4 Network**: In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
            - **Address**: Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
            - **Permission**: Select **Allow** or **Deny** from the drop-down list.
        - **IPv6 Network**: In the **Add IPv6 Network** panel, complete the following, and then click **Add** to add the network to the list:
            - **Address**: Enter an IPv6 network address and select the netmask from the drop-down list.
            - **Permission**: Select **Allow** or **Deny** from the drop-down list.
        - **TSIG Key:** In the **Add TSIG Key** panel, complete the following, and then click **Add** to add the TSIG key to the list:
            - **Key name**: Enter a meaningful name for the key, such as a zone name or the name of the client or Grid member. This name must match the name of the same TSIG key on other name servers.
            - **Key Algorithm**: Select either **HMAC-MD5** or **HMAC-SHA256.**
            - **Key Data**: To use an existing TSIG key, type or paste the key in the **Key Data** field. Alternatively, you can select the key algorithm, select the key length from the **Generate Key Data** drop down list, and then click **Generate Key Data** to create a new key.
        - **DNSone 2.x TSIG Key**: Select this when the other name server is a NIOS appliance running DNS One 2.x code. The appliance automatically populates the value of the key in the **Value** field. The **Permission** column displays **Allow** by default. You cannot change the default permission.
        - **Any Address/Network**: Select this to allow or deny any IP addresses to access the DNS view. After you have added access control entries, you can do the following:
            - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
            - Reorder the list of ACEs using the up and down arrows next to the table.
            - Select an ACE and click the Edit icon to modify the entry.
            - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.
3. Save the configuration and click **Restart** if it appears at the top of the screen. You can also click the Schedule icon at the top of the editor to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone.

Defining a Match Destinations List

You can define a Match Destinations list that identifies destination addresses and TSIG keys that are allowed access to a DNS view. When the NIOS appliance receives a DNS request from a client, it tries to match the destination address or TSIG key in the incoming message with its Match Destination list to determine which DNS view, if any, the client can access. After the appliance determines that a host can access a DNS view, it checks the zone level settings to determine whether it can provide the service that the host is requesting for that zone.
You can define a Match Destination list when you edit an existing DNS view as follows:

1. From the **Data Management** tab, click the **DNS** tab > **Zones** tab> dns_view checkbox -> Edit icon. Or, if there is only one DNS view, for example the predefined default view, you can just click the Edit icon beside it.
2. In the *DNS View* editor, select the **Match Destinations** tab, and select one of the following:
    - **None**: Select this if you want to configure a Match Destinations list. The appliance allows all destination addresses to access the DNS view. This is selected by default.
    - **Named ACL:** Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this option, the appliance allows access to the DNS view from the destination addresses that have the **Allow** permission in the named ACL. You can click **Clear** to remove the selected named ACL.
    - **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows.
        - **IPv4 Address** and **IPv6 Address:** Select this to add an IPv4 address or IPv6 address. Click the **Value** field and enter the IP address. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
        - **IPv4 Network:** In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
            - **Address:** Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
            - **Permission:** Select **Allow** or **Deny** from the drop-down list.
        - **IPv6 Network:** In the **Add IPv6 Network** panel, complete the following, and then click **Add** to add the network to the list:
            - **Address:** Enter an IPv6 network address and select the netmask from the drop-down list.
            - **Permission:** Select **Allow** or **Deny** from the drop-down list.
        - **TSIG Key:** In the **Add TSIG Key** panel, complete the following, and then click **Add** to add the TSIG key to the list:
            - **Key name:** Enter a meaningful name for the key, such as a zone name or the name of the client or Grid member. This name must match the name of the same TSIG key on other name servers.
            - **Key Algorithm:** Select either **HMAC-MD5** or **HMAC-SHA256.**
            - **Key Data:** To use an existing TSIG key, type or paste the key in the **Key Data** field. Alternatively, you can select the key algorithm, select the key length from the **Generate Key Data** drop down list, and then click **Generate Key Data** to create a new key.
        - **DNSone 2.x TSIG Key**: Select this when the other name server is a NIOS appliance running DNS One 2.x code. The appliance automatically populates the value of the key in the **Value** field. The **Permission** column displays **Allow** by default. You cannot change the default permission.
        - **Any Address/Network:** Select this to allow or deny any IP addresses to access the DNS view.
        After you have added access control entries, you can do the following:
            - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
            - Reorder the list of ACEs using the up and down arrows next to the table.
            - Select an ACE and click the Edit icon to modify the entry.
            - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.

3. Save the configuration and click **Restart** if it appears at the top of the screen. You can also click the Schedule icon at the top of the editor to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone.

Enabling the Match Recursive Only Option

You can enable the match-recursive-only option for the DNS view. When you enable this option, only recursive queries from matching clients match the selected DNS view. This option can be used in conjunction with the match client list and match destination list. Ensure that you configure those options and the order of the DNS views accordingly if you want to also enable the match-recursive-only option.
To enable the match-recursive-only option, complete the following:

1. From the **Data Management** tab, click the **DNS** tab > **Zones** tab> dns_view checkbox -> Edit icon. Or, if there is only one DNS view, for example the predefined default view, you can just click the Edit icon beside it.
2. In the *DNS View* editor, select the **General** tab -> **Advanced** tab, and select the following:
    - **Enable match recursive only option**: This option is disabled by default. Select this option to enable the match-recursive-only option for the DNS view. When you select this option, only recursive queries from matching clients match this view. Note that this option can be used in conjunction with the match-clients and match-destinations options. Ensure that you configure those options and the order of the DNS views accordingly if you want to also enable match-recursive-only.
3. Save the configuration.

> ⚠ Note
>
> You can also enable or disable the match-recursive-only option for a specific DNS view on a specific member by using the CLI command **set enable_match_recursive_only**. For information about this command, refer to the *Infoblox CLI Guide*.

Copying Zone Records

Different views of the same zone may have a number of records in common. If this is the case, you can copy zone records between views and zones.

> ⚠ Note
>
> You cannot copy shared records and records that the NIOS appliance automatically creates, such as NS records and glue A records.

To copy zone records between DNS zones and views:

1. From the **Data Management** tab -> **DNS** tab, click **Copy Records** from the Toolbar.
2. In the *Copy Records* dialog box, Grid Manager displays the last selected zone or the zone from which you are copying zone records in the **Source** field. Complete the following to copy records:
    - **Destination**: Click **Select Zone** to select the destination zone. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box from which you can select one. After you select the zone, Grid Manager displays the associated DNS view.
    - **Copy All records:** Select this option to copy all the zone records.
    - **Copy Specific Records:** Select this option to copy specific types of records. Select a resource record type from the Available column and click the right arrow to move it to the Selected column.
    - **Copy Options:** Select one of the following:
        - Delete all records in destination before copying the records: Select to delete all resource records in the destination zone before the records are copied.
        - Overwrite existing records: Select to overwrite existing resource records that have the same domain name owners as the records being copied.

3. Click **Copy & Close**.

> **Note**
>
> When you copy resource records between zones and there are pending scheduled tasks associated with these records, the appliance allows the copying of zone records before it executes the scheduled tasks.

Managing the DNS Views of a Grid Member

A Grid member can serve zones in different DNS views. You can manage the DNS views associated with a Grid member as follows:

- You can specify which interface IP address is published in glue A records in the DNS view, as described in Changing the Interface IP Address below.
- You can assign an empty recursive view to a member, as described in Managing Recursive DNS Views.
- You can control the list of DNS views as described in Changing the Order of DNS Views.

Changing the Interface IP Address

By default, a Grid member publishes its LAN address in glue A records in the DNS view. You can change this default for each DNS view associated with a member. You can specify the NAT IP address or another IP address. To specify the interface IP address for glue A records in a view:

1. From the **Data Management** tab, click the **DNS** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *Member DNS Configuration* editor, click **Toggle Expert Mode** if the editor is in basic mode, and then select the **DNS Views** tab.
   The *Address Of Member Used in DNS Views* table lists the default DNS view and DNS views with zones that are served by the member.
3. To change the address, click the entry in the Interface column of a DNS view, and select one of the following:
   - **NAT IP Address**: Select this to use the member NAT address for glue A records in a Grid setting. Select this when you want to notify the Grid Master that it should expect packets from this member on the NAT address, not the configured interface address. The Grid Master broadcasts this NAT address to all NAT members outside of its NAT group. Do not use this option for an independent appliance serving as a DNS server. Select **Other IP Address** to publish the NAT address for the independent appliance. For information about NAT compatibility, see *NAT Groups.*
   - **Other IP Address**: Select this to specify another address for glue A records, or to publish the NAT address for an independent appliance. Enter the address in the **Address** field.
     Note that the 255.255.255.255 limited broadcast address is reserved. The appliance does not automatically create glue A records for this address. You can however create an NS record without the associated glue records.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing Recursive DNS Views

When you add a DNS view that has recursion enabled, the appliance resolves recursive queries from hosts on the Match Clients list of that view. If the DNS view contains zones and you delete those zones, the appliance retains the view in its configuration file, as long as recursion is enabled in the view. Such a view is called an empty recursive DNS view because it does not contain any zones. It enables the appliance to respond to recursive queries from the specified clients.
In a Grid, all members automatically store DNS views that have recursion enabled in their configuration files. If you do not want a Grid member to respond to recursive queries for clients in a particular DNS view, you can remove the view from the member's configuration file.
To delete or retain an empty recursive DNS view in the DNS configuration file of a Grid member:

1. From the **Data Management** tab, click the **DNS** tab > **Members** tab> *Grid_member* checkbox -> Edit icon.

2. In the *Member DNS Configuration* editor, click **Toggle Expert Mode** if the editor is in basic mode, and then select the **DNS Views** tab.
3. The *Recursive Views Assigned to this Member* section lists the empty recursive DNS views. Move a DNS view to the *Selected* column to explicitly assign the view to the Grid member and include it in the DNS configuration file of the member. Move a DNS view to the *Available* column to remove it from the configuration file of the member. Empty recursive DNS views that you retain in the configuration file are automatically listed at the bottom of the list of DNS views. You can move them up on the list when you manually change the order of the DNS views, as described in Managing the DNS Views of a Grid Member below.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing the Order of DNS Views

When a member receives a query from a DNS client, it checks the Match Client lists in the order the DNS views are listed in the *Order of DNS Views* table of the **DNS Views** tab in the DNS Member editor. The NIOS appliance can order DNS views automatically, or you can order the DNS views manually. If you choose to have the appliance automatically update the order of the DNS views, it does so after each of the following events:

- Adding a DNS view to a member.
- Removing a DNS view from a member.
- Changing the address match list of a DNS view hosted by the member.

About IP Addresses and the Order of DNS Views

NIOS appliances with both IPv4 and IPv6 enabled can contain both types of addresses in the Match Clients list. When you enable IPv6 on the appliance, the order of DNS views in the GUI may be affected. Views are ordered and sorted automatically based on Match Clients lists. Views with IPv6 enabled are sorted as follows:

- If the Match Clients lists of all views contain IPv4 addresses only—The appliance orders views based on IPv4 addresses.
- If the Match Clients lists of all views contain IPv6 addresses only—The appliance orders views based on IPv6 addresses.
- If the Match Clients list of one DNS view has IPv6 addresses and all other views have IPv4 addresses—The appliance orders views based on IPv4 addresses, and the IPv6 address is given lowest priority in the ordering.
- If the Match Clients list of one DNS view has IPv4 addresses and all other DNS views have IPv6 addresses—The appliance orders DNS views based on IPv6 addresses, and the IPv4 address is given lowest priority in the ordering.
- If the Match Clients list of one DNS view has both IPv4 and IPv6 addresses—The appliance orders DNS views based on both IPv4 and IPv6 addresses, but more priority is given to the IPv4 addresses in the ordering.

The DNS views are ordered based on the number of IP addresses that are matched by the Access Control Lists (ACLs). The order of the DNS view is as follows:

- ANY
- Large Network
- Small Network
- Multiple Addresses
- Single Address

The actual precedence of the order of the views is also based on the ACL elements:

- any match: precedence = UINT_MAX + 1
- address match: precedence += 1
- TSIG match: precedence += 1
- network match: precedence += 129 - split (BOTH v4 and v6)

Note that views with the same precedence are sorted based on the internal view name. For example, '_default' or '0'.

> ⚠ Note
> Only superusers can change the order of the views.

Changing the Order of DNS Views

To change the order of DNS views:

1. From the **Data Management** tab, click the **DNS** tab > **Members** tab> *Grid_member* checkbox -> Edit icon.
2. In the *Member DNS Configuration* editor, click **Toggle Expert Mode** if the editor is in basic mode, and then select the **DNS Views** tab.
3. In the Order of DNS Views section, select one of the following:
    - **Order DNS Views Automatically:** Click this to automatically order views after adding a new DNS view, removing a DNS view, or changing the match client list.
    - **Order DNS Views Manually:** This table lists the DNS views that have zones assigned to the Grid member and the empty recursive views associated with the member. Select a DNS view, then click an arrow to move it up or down in the list.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing DNS Views

You can list the DNS views, and then modify, disable, or remove any custom DNS view. You can modify and disable the default DNS view; however, under no circumstances can it be removed.

Listing DNS Views

After you configure additional DNS views, you can list all DNS views by navigating to the **Data Management** tab -> **DNS** tab -> **Zones** panel. This panel lists DNS views only after you modify the default DNS view or add a DNS view. If you never added DNS views or modified the default DNS view, this panel does not display the default DNS view. Instead, it lists the zones in the default DNS view. To display the properties of the default DNS view and edit it, use the Global Search function to locate and edit it.
Note that if you have not used Grid Manager to add a new DNS view, and you import DNS views through the Data Import Wizard or the API, you must log out and log back in to Grid Manager to display the newly imported DNS views.
For each DNS view, this panel displays the following by default:

- **Comment**: Comments that were entered for the DNS view.
- **Site**: Values that were entered for this pre-defined attribute. You can also display the following column:
- **Disabled**: Indicates if the DNS view is enabled or disabled. Disabled DNS views are excluded from the named.conf file. You can double click a row and select the checkbox in this column to disable the network. Grid Manager displays a warning message when you select the checkbox. Click **Yes** to confirm or **No** to cancel. Note that disabling a DNS view may take a longer time to complete depending on the size of the data.

From this list, you can do the following:

- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters.*
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- List the zones in a DNS view by clicking a DNS view name.
- Edit information about a DNS view, as described in the next section.
- Delete a DNS view, as described in Deleting DNS Views below.

Modifying DNS Views

To modify a DNS view:

1. From the **Data Management** tab, click the **DNS** tab > **Zones** tab> *dns_view* checkbox -> Edit icon.
2. In the *DNS View* editor, you can do the following:
    - In the **General** tab, you can change any of the information you entered through the wizard. You can also disable a DNS view to temporarily block access to a DNS view. Disabling a DNS view excludes it from the

named.conf file. For a description of the fields, see the online Help or *Configuring DNS Views* Note that disabling a DNS view may take a longer time to complete depending on the size of the data.

- In the **Match Clients** tab, define or update a Match Clients list, as described in Defining Match Clients Lists.
- In the Match Destinations tab, define or update match destinations, as described in Defining a Match Destinations List below.
- In the **Forwarders** tab, configure forwards for the view, as described in *Using Forwarders*.
- In the **Queries** tab, enable AAAA filtering and configure a list of IPv4 networks and addresses for allowing or denying AAAA filtering, as described in *Enabling AAAA Filtering*.
- In the **DNSSEC** tab, you can specify parameters for DNSSEC as described in *Configuring DNSSEC on a Grid.*
- In the **Root Name Servers** tab, you can configure root name servers, as described in *About Root Name Servers*.
- In the **Sort List** tab, define a sort list for the DNS view, as described in *Defining a Sort List*.
- In the **Blacklist** tab, define blacklist rulesets, as described in *Enabling Blacklisting*.
- In the **Extensible Attributes** tab, you can modify the attributes. For information, see *Using Extensible Attributes*.
- The **Permissions** tab displays if you logged in as a superuser. For information, see *About Administrative Permissions*.
- In the **Record Scavenging** tab, define the rules for DNS records scavenging in the DNS view, as described in *Configuring DNS Record Scavenging Properties*.
- In the **Updates** tab, specify the secure dynamic updates settings, as described in *Secure Dynamic Updates.*

3. Save the configuration and click **Restart** if it appears at the top of the screen.
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Deleting DNS Views

You can delete a DNS view if it is not the only view associated with a network view and if it is not selected for dynamic DNS updates. You cannot remove the system-defined default DNS view. When you remove a DNS view, the NIOS appliance removes the forward and reverse mappings of all the zones defined in the DNS view.
To delete a DNS view:

- From the **Data Management** tab, select the > **DNS** tab> **Zones** tab-> *dns_view* checkbox.
  To delete the DNS view immediately, click the Delete icon, and then click **Yes** to confirm the delete request. Grid Manager displays a warning message. Click **Yes** to continue or **No** to cancel the process. To schedule the deletion, click **Schedule Deletion** and in the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Deletions*.
  Grid Manager moves the view to the Recycle Bin, from which you can restore or permanently delete it. Click **Restore** in the Recycle Bin to recover the deleted data. Click **Yes** in the Restore Item dialog box to restore or **No** to cancel the process. Note that deleting and restoring a DNS view may take a longer time to complete depending on the size of the data.

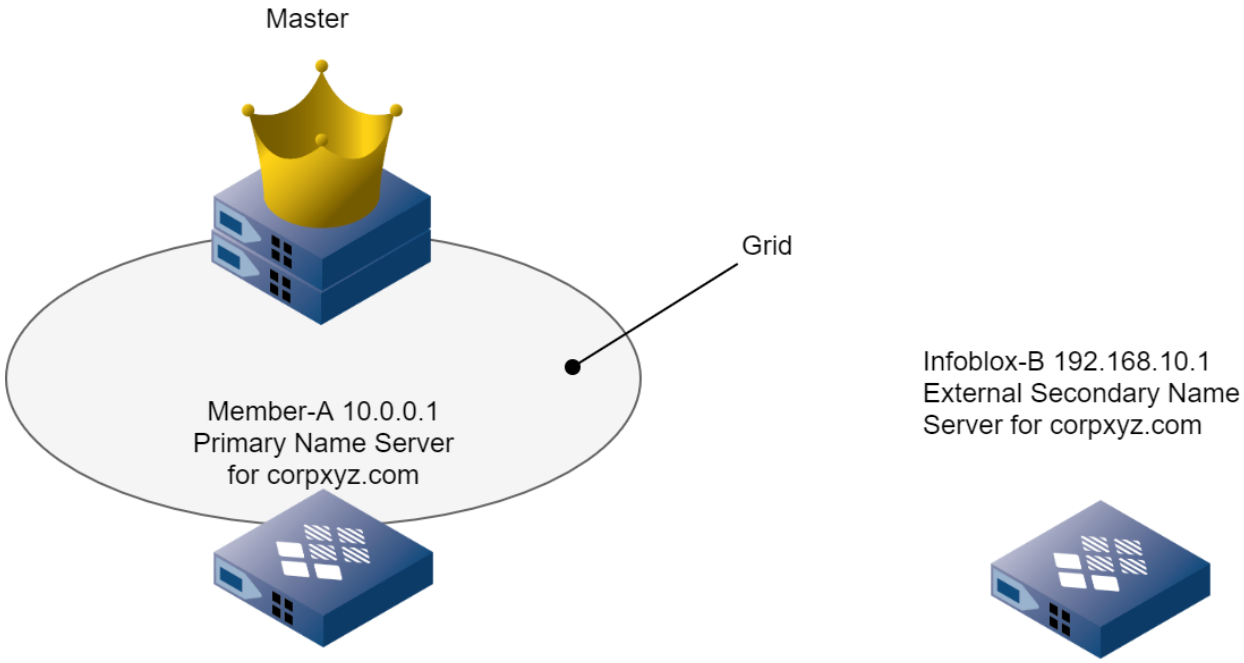
Configuration Example: Configuring a DNS View

In the figure *C*onfiguring a DNS View below, Member-A is a member of a Grid. It is the primary name server for the corpxyz.com zone in the internal DNS view. It allows the IP address 192.168.10.1 and the 10.2.2.0/24 subnet access to DNS zone data in the internal DNS view. At the zone level, it allows transfers to an external secondary server, Infoblox-B, with an IP address of 192.168.10.1. Infoblox-B is a secondary server for the corpxyz.com zone. The process follows these steps:

1. Adding an Internal DNS View on Member-A
2. Adding a Zone to a DNS View

3. Copying Records Between DNS Zones from the corpxyz.com zone in the default DNS view to the corpxyz.com zone in the internal DNS view
4. Verifying the Configuration

Configuring a DNS View



Adding an Internal DNS View

1. Expand the Toolbar and click **Add** -> **Add DNS View**.
2. In the *Add DNS View* wizard, specify the following, and then click **Next**:
    - **Name:** internal
    - **Comment:** internal DNS view
3. In the *Match Clients* panel, click **Add** and select **IPv4 Network** from the drop-down list.
4. Do the following for IP addresses in the network 10.2.2.0/24:
    - Enter **10.2.2.0/24** in the in the **Address** field.
    - The **Permission** field displays **Allow** by default. Leave it as is.
    - Click **Add**.

   You will have 255 allowed client addresses in the Match Clients list when you are done.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Adding a Zone to a DNS View

1. Expand the Toolbar and click **Add** -> **Zone** -> **Add Auth Zone**.
2. In the *Add Auth Zone* wizard, click **Add an authoritative forward-mapping zone** and click **Next**.
3. Specify the following, and then click **Next**:
    - **Name:** Enter **corpxyz.com**.
    - **DNS View:** Select **Internal** from the drop-down list.
4. In step 3 of the wizard, do the following:
    a. Select **Use this set of name servers.**
    b. Click the Add icon and select **Grid Primary**.
    c. Click **Select Member** and select **Member A** from the *Select Grid Member* dialog box.
    d. Click **Add** to add the Grid member to the list of name servers.
    e. Click the Add icon again and select **External Secondary**.
    f. Enter the following information, and then click **Add:**
        - **Name:** Infoblox

        - **IP Address:** 192.168.10.1
5. Click1 **Save & Edit** to display the *Authoritative Zone* editor and continue with the zone configuration.
6. Click **Queries**.
7. Click **Override**, and then click the Add icon and select **IPv4 Network**.
    - Enter **10.2.2.0/8** in the in the **Address** field.
    - The **Permission** field displays **Allow** by default. Leave it as is.
    - Click **Add**.
8. This allows queries that the appliance answers from its internal DNS view.
9. Save the configuration and click **Restart** if it appears at the top of the screen.

Copying Records Between DNS Zones

1. Navigate to the default DNS view and select the corpxyz.com zone.
2. Expand the Toolbar and click **Copy Records**.
3. In the **Destination** field, click **Select Zone**, and then select the **corpxyz.com** zone in the Internal DNS view.
4. Select **Copy all records**, and then click **OK**.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

The records from corpxyz.com in the default DNS view are copied to corpxyz.com in the internal DNS view.

> ⚠ Note
>
> Only superusers can copy A, AAAA, shared A, and shared AAAA records with a blank name. Limited-access users must have read/write permission to **Adding a blank A/AAAA record** in order to copy A, AAAA, shared A, and shared AAAA records with a blank name, otherwise the copying records operation might fail. You can assign global permission for specific admin groups and roles to allow to copy A, AAAA, shared A, and shared AAAA records with a blank name. For more information, see *Administrative Permissions for Adding Blank A or AAAA Records*.

Verifying the Configuration

1. In the **DNS** tab, click **Members** and select the **Member-A** checkbox .
2. Expand the Toolbar and click **View** -> **View DNS Configuration**.
3. In the *DNS Configuration File* viewer, scroll through the contents of the file.

Verify that the internal DNS view section is similar to the configuration file shown.

Configuring DNS Zones

This section provides general information about DNS zones that you can configure and manage on the Infoblox appliance. The topics in this section include:

- *Configuring Authoritative Zones*
- *Creating an Authoritative Forward-Mapping Zone*
- *Creating an Authoritative Reverse-Mapping Zone*
- *Adding an Authoritative Subzone*
- *Locking, Unlocking, Enabling, Disabling Zones*
- *Configuring Authoritative Zone Properties*
- *Enabling Fixed RRset Ordering for NAPTR Records*
- *Configuring DNS Integrity Check for Authoritative Zones*
- *Domains and Zones*
- *Assigning Zone Authority to Name Servers*
- *Configuring Domain Controller List*
- *Importing Zone Data*
- *Enabling Zone Transfers*

- *Removing Zones*
- *Restoring Zone Data*
- *Configuring Delegated, Forward, and Stub Zones*
- *Viewing Zones*
- *Using Name Server Groups*
- *Viewing Name Server Groups*

Configuring Authoritative Zones

An authoritative zone is a zone for which the local (primary or secondary) server references its own data when responding to queries. The local server is authoritative for the data in this zone and responds to queries for this data without referencing another server.
There are two types of authoritative zones:

- Forward-mapping – An authoritative forward-mapping zone is an area of domain name space for which one or more name servers have the responsibility to respond authoritatively to name-to-address queries.
- Reverse-mapping – A reverse-mapping zone is an area of network space for which one or more name servers have the responsibility to respond to address-to-name queries.

You can configure and manage authoritative forward-mapping and IPv4 and IPv6 reverse-mapping zones on an Infoblox appliance. In a Grid, an authoritative forward-mapping zone is an area of domain name space for which one or more Grid members have the responsibility to respond authoritatively to name-to-address queries. The Grid members can function as primary or secondary servers for the zone.
You can add arpa as the top-level forward-mapping zone and manage its resource records. You can also add in-addr.arpa (for ipv4 addresses) and ip6.arpa (for ipv6 addresses) as the top-level reverse-mapping zones.
You can create these top-level reverse-mapping zones under an arpa or a root parent forward-mapping zone or without a parent zone. If you want arpa, in-addr.arpa, and ip6.arpa zones on the appliance, you must manually create them. These zones are not auto-created.
Sample IPv4 reverse-mapping zone hierarchy:

```
. (root zone) > arpa > in-addr.arpa > 10.in-addr.arpa
```

Sample IPv6 reverse-mapping zone hierarchy:

```
. (root zone) > arpa > ip6.arpa > a.ip6.arpa
```

Following are the tasks to configure an authoritative zone:

1. Create the zone. The following sections explain how to create authoritative forward-mapping zones, reverse-mapping zones, subzones, and a custom root zone:
    - *Creating an Authoritative Forward-Mapping Zone*
    - *Creating an Authoritative Reverse-Mapping Zone*
    - *Creating a Root Zone*
2. Assign an Infoblox appliance as the primary or secondary server of the zone. For information, see *Assigning Zone Authority to Name Servers*.
3. Import resource records or add resource records manually. The following provides information about resource records:
    - *Managing Resource Records*
    - *Importing Zone Data*
4. Configure additional parameters. For information, see *Configuring Authoritative Zone Properties*.
5. Optionally, associate the zone with one or more networks. This is useful when you want to restrict the A, AAAA and host records to IP addresses from specific networks. For information, see *Associating Networks with Zones*.

Creating an Authoritative Forward-Mapping Zone

An authoritative forward-mapping zone is an area of domain name space for which one or more Grid members have the responsibility to respond authoritatively to name-to-address queries.

> **Note**
>
> A single forward-mapping zone can map names to both IPv4 and IPv6 addresses.

To create an authoritative forward-mapping zone:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar, and click **Add** -> **Zone** -> **Add Auth Zone**.
2. In the *Add Authoritative Zone* wizard, click **Add an authoritative forward-mapping zone** and click **Next**.
3. Specify the following:
   - **Name:** Enter the domain name for the zone. Omit the trailing period (" . ") that signifies the root zone. You can use IDNs as well. For information about IDNs, see *Support for Internationalized Domain Names*.
   - **DNS View:** This field displays only when there is more than one DNS view in the current network view. Select a DNS view from the drop-down list.
   - **Comment:** Enter a descriptive comment about the zone.
   - Disable: Click this checkbox to temporarily disable this zone. For information, see *Enabling and Disabling Zones*. Note that disabling a zone may take a longer time to complete depending on the size of the data.
   - **Lock**: Click this checkbox to lock the zone so that you can make changes to it and prevent others from making conflicting changes. For information, see *Locking and Unlocking Zones*.
4. Save the configuration, or click **Next** to continue to the next steps in the wizard as follows:
   - Define the name servers for the zone. For information on specifying primary and secondary servers, see *Assigning Zone Authority to Name Servers*. For information on specifying authoritative name server groups, see *Using Authoritative Name Server Groups*.
   - If you have assigned a Microsoft server as the primary server for the zone and if the zone is AD-integrated, you can configure a list of domain controllers that are allowed to add NS records to the zone. For information see, *Configuring Domain Controller List*.
   - Define extensible attributes. For information, see *Using Extensible Attributes*.

   or

   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.
5. Click **Restart** if it appears at the top of the screen.

Creating a Root Zone

The NIOS appliance allows you to create an internal root zone for your organization. When the appliance receives a query for DNS data that is not in its cache or authoritative data, it can query an internal root server after querying any specified forwarders. If you do not specify an internal root server and the appliance can access the Internet, it queries the Internet root servers. For information on root name server, see *About Root Name Servers*.
To create a root zone, create an authoritative forward-mapping zone as described in Creating an Authoritative Forward-Mapping Zone above and specify the following:

- Enter a period (.) in the **Name** field.
- Optionally, enter a comment.
- Select a Grid member as the primary name server for the root zone.

Once created, the root zone automatically becomes the parent of all the zones under the root zone.

Creating an Authoritative Reverse-Mapping Zone

An authoritative reverse-mapping zone is an area of network space for which one or more name servers—primary and secondary—have the responsibility to respond to address-to-name queries. Infoblox supports reverse-mapping zones for both IPv4 and IPv6 addresses. You can add in-addr.arpa and ip6.arpa as the top-level reverse-mapping zones. Note that you cannot add these zones using their IP addresses or netmasks, however, you can add them by name "in-addr.arpa" and "ip6.arpa" respectively.

Specifying an RFC 2317 Prefix

RFC 2317, Classless IN-ADDR.ARPA delegation is an IETF (Internet Engineering Task Force) document that describes a method of delegating parts of the DNS IPv4 reverse-mapping tree that correspond to subnets smaller than a /24 (from a /25 to a /31). The DNS IPv4 reverse-mapping tree has nodes broken at octet boundaries of IP addresses, which correspond to the old classful network masks. So, IPv4 reverse-mapping zones (and delegation points) usually fall on /8, /16, or /24 boundaries.
With the proliferation of CIDR (Classless Inter-Domain Routing) support for routing, ISPs no longer assign entire /24 networks to customers that only need a handful of IPv4 addresses. In general, IPv4 address assignments no longer fall on classful boundaries. For DNS, a problem comes into play when an ISP gives a customer an address range that is smaller than a /24, but the customer also wants to be delegated the DNS reverse-mapping zone.
If the ISP gives you, for example, a subnet with a 25-bit mask, then you only have half of the /24 address range. If you configure your DNS server to be authoritative for the zone corresponding to a /24 subnet, the DNS server cannot resolve half of the possible reverse-mapping records in the zone. RFC 2317 defines an approach, considered a best practice, which addresses this issue.
In addition to IPv4 reverse-mapping zones, you can also configure IPv4 reverse-mapping delegation zones that have an RFC2317 prefix. For more information about configuring a delegation for a reverse-mapping zone, see *Configuring a Delegation*.

> **Note**
>
> Before enabling RFC 2317 support for zones, disable forwarders for the zone, especially when any sort of delegation (including RFC 2317) is being used. If you do not, reverse lookups may fail. For more information, contact Infoblox Support for the Tech Note on RFC 2317 delegation.

Adding an IPv4 Reverse-Mapping Zone

To add an IPv4 reverse-mapping zone:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Zone** -> **Add Auth Zone**.
2. In the *Add Authoritative Zone* wizard, click **Add an authoritative IPv4 reverse-mapping zone** and click **Next**.
3. Specify the following zone information:
    - Enter one of the following to identify the zone:
        - **IPv4Network:** Enter the IPv4 address for the address space for which you want to define the reverse-mapping zone and select a netmask from the **Netmask** drop-down list. Alternatively, you can specify the address in CIDR format, such as 192/8.
          To use an RFC 2317 prefix, select a netmask value that is between 25 to 31, inclusive. Grid Manager displays the **RFC 2317 Prefix** field. Enter a prefix in the text field. Prefixes can include alphanumeric characters. For information, see Specifying an RFC 2317 Prefix above.
        - **Name:** Enter the domain name of the reverse-mapping zone.
    - **DNS View:** This field displays only when there is more than one DNS view in the current network view. Select a DNS view from the drop-down list.
    - **Comment:** Optionally, enter additional information about the zone.
    - **Disable this zone:** Select this option to temporarily disable this zone. For information, see *Enabling and Disabling Zones*. Note that disabling a zone may take a longer time to complete depending on the size of the data.
    - **Lock this zone**: Select this option to lock the zone so that you can make changes to it and prevent others from making conflicting changes. For information, see *Locking and Unlocking Zones*.
4. Save the configuration, or click **Next** to continue to the next steps in the wizard as follows:
    - Define the name servers for the zone. For information on specifying primary and secondary servers, see *Assigning Zone Authority to Name Servers*. For information on specifying authoritative name server groups, see *Using Authoritative Name Server Groups*.

- If you have assigned a Microsoft server as the primary server for the zone and if the zone is AD-integrated, you can configure a list of domain controllers that are allowed to add NS records to the zone. For information see, *Configuring Domain Controller List*.
- Define extensible attributes. For information, see *Using Extensible Attributes*.

or

Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

5. Click **Restart** if it appears at the top of the screen.

Adding an IPv6 Reverse-Mapping Zone

To add an IPv6 reverse-mapping zone:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Zone** -> **Add Auth Zone**.
2. In the *Add Authoritative Zone* wizard, click **Add an authoritative IPv6 reverse-mapping zone** and click **Next**.
3. Enter the following zone information:
   - Enter one of the following to identify the zone:
     - **IPv6 Network Prefix:** Enter the 128-bit IPv6 address for the address space for which you want to define the reverse-mapping zone. When you enter an IPv6 address, you can use double colons to compress a contiguous sequence of zeros. You can also omit any leading zeros in a four-hexadecimal group. For example, the complete IPv6 address 2006:0000:0000:0123:4567:89ab:0000:cdef can be shortened to 2006::123:4567:89ab:0:cdef. Note that if there are multiple noncontiguous groups of zeros, the double colon can only be used for one group to avoid ambiguity. The NIOS appliance displays an IPv6 address in its shortened form, regardless of its form when it was entered. Choose the network prefix that defines the IPv6 network address space.
     - **Name:** Enter the domain name of the reverse-mapping zone.
   - **DNS View:** This field displays only when there is more than one DNS view in the current network view. Select a DNS view from the drop-down list.
   - **Comment:** Enter a descriptive comment about the zone.
   - Disable: Click this checkbox to temporarily disable this zone. For information, see *Enabling and Disabling Zones*. Note that disabling a zone may take a longer time to complete depending on the size of the data.
   - **Lock**: Click this checkbox to lock the zone so that you can make changes to it and prevent others from making conflicting changes. For information, see *Locking and Unlocking Zones*.
4. Save the configuration, or click **Next** to continue to the next steps in the wizard as follows:
   - Define the name servers for the zone. For information on specifying primary and secondary servers, see *Assigning Zone Authority to Name Servers*. For information on specifying authoritative name server groups, see *Using Authoritative Name Server Groups*.
   - Define extensible attributes. For information, see *Using Extensible Attributes*.

   or

   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

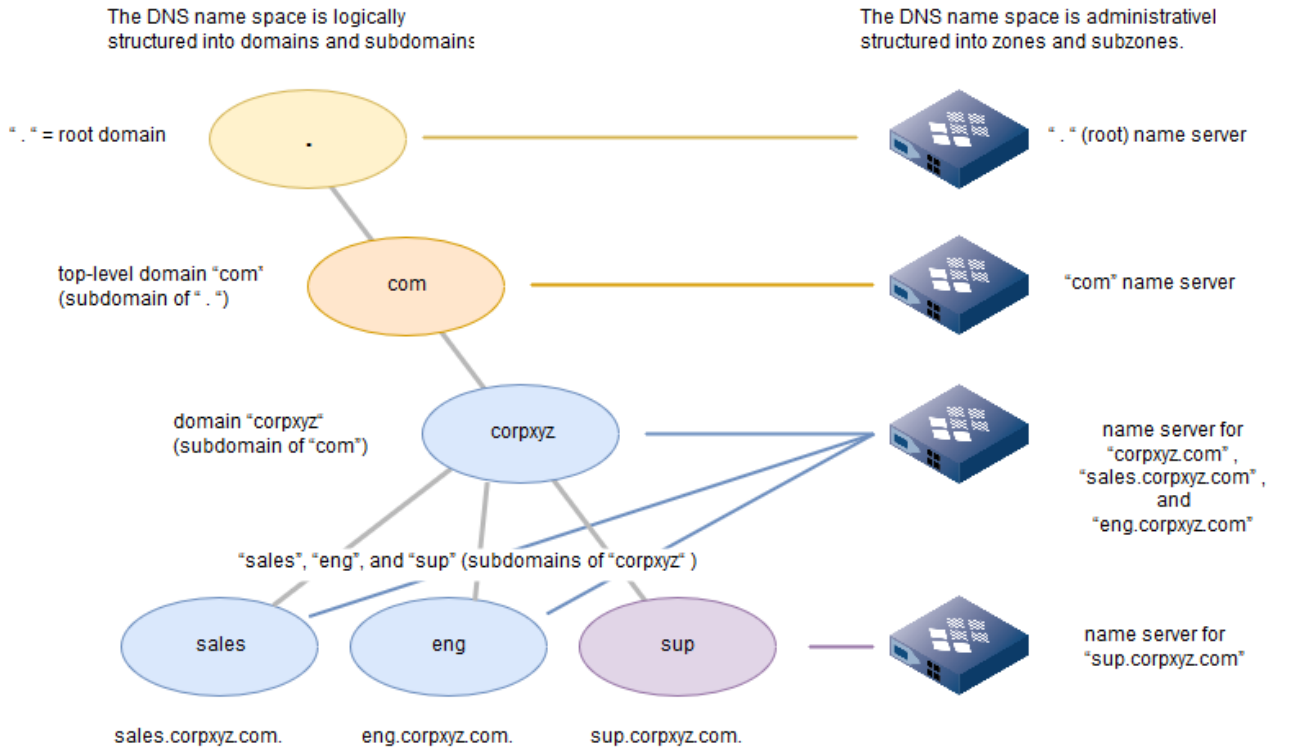
Adding an Authoritative Subzone

After creating a zone, you can add more zones at the same level, or add subordinate zones (*subzones*). The subzones can be authoritative, delegated, forward, or stub. For simplicity, the zones created in this example are authoritative (as are all zones by default). For information about configuring the other zone types, see *Configuring Delegated, Forward, and Stub Zones*.

You create an authoritative zone when you assign authority for all the resource records of a particular domain to one or more name servers. You create a subzone when you assign authority for all the resource records of a subdomain to name servers. The name servers can be the same as, or different from, the name servers that serve resource records for the parent domain.

The distinction between domains and zones is that domains provide a logical structure to the DNS name space while zones provide an administrative structure. The difference between domains and subdomains and zones and subzones is

that the terms *subdomains* and *subzones* reference their relationship to a parent domain or zone. With the exception of the root domain and root zone, all domains are subdomains and all zones are subzones.
You can organize a domain based on logical divisions such as type (.com, .gov, .edu; or sales, eng, sup) or location (.uk, .jp, .us; or hq, east, west). The below figure shows one way to organize the external (public) name space and the internal (private) name space for a corporation with the domain name *corpxyz.com*. The external name space follows standard DNS conventions. Internally, you create an individual subdomain and corresponding subzone for each department.
Domains and Subdomains, and Forward-Mapping Zones and Subzones



> **Note**
>
> Throughout this documentation, the trailing dot indicating the root zone is not shown, although its presence is assumed.

The procedure for adding a subzone is the same as that used to add an authoritative zone. The only difference is that you specify the subzone name in the **Name** field. For information about adding authoritative zones, see *Configuring Authoritative Zones*.

Locking, Unlocking, Enabling, Disabling Zones

You can lock a zone when you create or edit it to prevent other administrators from making conflicting changes.

Locking and Unlocking Zones

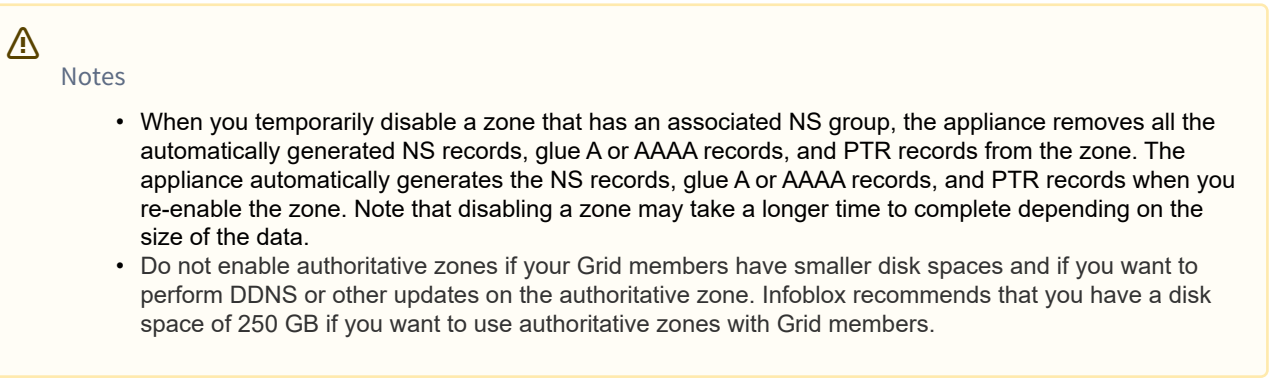
When you lock a zone, Grid Manager displays **LOCKED** beside the zone name when you view the records and subzones of the zone in the Zones panel. When other administrators try to make changes to a locked zone, the system displays a warning message that the zone is locked by *admin_name*.

You can perform dynamic updates through mechanisms such as DDNS and nsupdate on a locked zone. The system can also add auto-generated records such as glue A records and NS records to a locked zone. Locks on a zone do not

impact its child zones.
Only a superuser or the administrator who locked the zone can unlock it. Locks do not expire; you must manually unlock a locked zone.

Enabling and Disabling Zones

The NIOS appliance allows you to disable and enable a zone when you create or edit it. When you disable a zone, Grid Manager removes it from the DNS configuration file, but not from the database. This feature is especially helpful when you have to move or repair the server for a particular zone. You can easily disable a zone temporarily, and then enable it after the move or repair is completed.



Configuring Authoritative Zone Properties

A zone inherits some of its properties from the Grid or from the member that serves it as a primary or secondary server. When you edit a zone, you can override properties set at the Grid or member level and modify the original zone settings, as well.
To configure authoritative zone properties:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and then click the Edit icon.
2. In the *Authoritative Zone* editor, you can do the following in each tab:
    - **General:** Modify the original zone settings, except the zone name.
    - **Name Servers:** Specify primary and secondary servers as described in *Assigning Zone Authority to Name Servers*.
    - **Settings:** Set certain properties if the primary server is a Grid member. If the zone's primary server is an external server, then all these fields, except **Don't use forwarders to resolve queries in subzones**, are read-only with the information derived from the SOA record of the zone.
        - The **Serial Number** field displays the zone's current serial number. You can change the serial number in an SOA record only if the primary server of the zone is a Grid member.
          The serial number in the SOA record increments every time the record is modified. This serial number plays a key role when and how zone data is updated via zone transfers. The NIOS appliance allows you to change the serial number (in the SOA record) for the primary server so it is higher than the secondary server, thereby ensuring zone transfers come from the primary server (as they should).
        - Set **Refresh** intervals above 300 seconds, as Refresh intervals below 300 seconds may not work.
        - Override the Grid or member TTL settings as described in *About Time To Live Settings*.
        - Override the email settings, as described in *Adding an Email Address to the SOA Record*.
        - Change the primary name server that is specified in the SOA MNAME of a zone, as described in *Changing the SOA Name for a Zone*.
        - **Don't use forwarders to resolve queries in subzones** : If the DNS members are configured to use forwarders to resolve queries that they cannot resolve locally, you can select this checkbox to disable the use of forwarders to resolve queries for data in the subzones.
    - **Queries:** Set restrictions for queries as described in *Controlling DNS Queries*.

- **Zone Transfers:** Specify to which servers zone transfers are allowed as described in *Enabling Zone Transfers*.
- **Updates:** Set dynamic DNS update properties as described in *Configuring DNS Servers for DDNS*.
- **Active Directory:** Set parameters to allow zones to receive GSS-TSIG authenticated DDNS updates from DHCP clients and servers in an AD domain. For information, see *Supporting Active Directory*.
- **Extensible Attributes:** Define extensible attributes. For information, see *Using Extensible Attributes*.
- **Permissions:** Define administrative permissions. For information, see *About Administrative Permissions*.

3. Click **Toggle Advanced Mode** if the editor is in basic mode. When the additional tabs appear, you can do the following in each tab:
   - **General:** Click the **Advanced** subtab and view the networks associated with the zone. This tab is visible only if the primary server is a Grid member, a Microsoft server, or unassigned.
     If a zone is associated with one or more networks, the IP addresses of its host, A and AAAA records must belong to the associated networks. You cannot change the network associations in this editor. Navigate to the *DHCP Network* editor of the network, to change the zone associations. For information, see *Associating Networks with Zones.*
     You can enable fixed RRset ordering for the authoritative zone to save the order of the NAPTR records that are added to the zone using CSV import. Select the **Enable fixed RRset ordering** checkbox to enable fixed RRset ordering for the NAPTR records that are added to the authoritative zone through CSV import. There are a few best practices you should consider when enabling this feature. For more information, see *Enabling Fixed RRset Ordering for NAPTR Records.*
   - **DNS Integrity Check**: Configure the appliance to monitor DNS data in the NS RRsets for authoritative zones. The appliance generates alerts when data discrepancies have been detected so you can mitigate possible DNS domain hijacking. For more information, see *Configuring DNS Integrity Check for Authoritative Zones*.
   - **Host Naming:** Set restrictions for host names. For information, see *Specifying Hostname Policies*.
   - **Shared Record Groups:** Add shared record groups to a zone. For information, see *Configuring Shared Record Groups*.
   - **DNSSEC:** Configure DNSSEC properties. For information, see *Configuring DNSSEC*.
     Record Scavenging: Define the rules for DNS records scavenging in the zone, as described in *DNS Record Scavenging*.
   - **Updates**: Click the **Advanced** subtab and specify the secure dynamic updates settings, as described in *Secure Dynamic Updates.*
4. Save the configuration and click **Restart** if it appears at the top of the screen.
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Enabling Fixed RRset Ordering for NAPTR Records

You can enable fixed RRset ordering for the authoritative zone to save the order of the NAPTR records that are imported to the zone using CSV import. When you enable fixed RRset ordering for the zone, the NAPTR records are saved in the same order as received in the CSV file and the appliance returns the NAPTR records in the fixed order in response to a query. If you enable fixed RRset ordering for an authoritative zone, the zone data is read-only and you cannot add, delete, or modify DNS records of the zone using GUI or API. You can add, delete, or modify DNS records of the zone using CSV import only. The fixed RRset ordering for the NAPTR records is retained only when the NAPTR records are imported to the zone through CSV import. If you change the position of the NAPTR records by disabling fixed RRset ordering, then the changes made for the position of the records will not be retained when you later enable fixed RRset ordering.
Note the following:

- When you import NAPTR records to an empty zone, you must use the **Add** CSV import option and to update the zone data you must use the **Replace** CSV import option to ensure that the RRset order of the NAPTR records is the same as specified in the CSV import file. For more information about CSV import feature, see *Guidelines for CSV Import.*

- It is not recommended to configure DDNS updates for a zone, if you have enabled fixed RRset ordering for the zone.
- If you enable fixed RRset ordering for an authoritative zone with existing NAPTR records, the RRset order of the existing records will not change.
- The RRset order for NAPTR records imported to the zone through DNS zone transfers or DIW (Data Import Wizard) will not be preserved.
- You cannot enable fixed RRset ordering for an authoritative zone if the zone has subzones.
- You cannot enable fixed RRset ordering for an authoritative zone, if the zone has bulk hosts or if the zone is associated with a shared record group.
- This feature is applicable only for forward-mapping authoritative zones.
- This feature is not supported for Microsoft zones.

To enable fixed RRset ordering for NAPTR records imported to the zone using CSV import:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and then click the Edit icon.
2. In the *Authoritative Zone* editor, click **Toggle Advanced Mode** if the editor is in the basic mode.
3. Click the **Advanced** subtab of the **General** tab and then complete the following:
    - **Enable fixed RRset ordering**: Select this checkbox to enable fixed RRset ordering for the NAPTR records that are added to the authoritative zone through CSV import, as described in *Guidelines for CSV Import*.
4. Save the configuration and restart DNS service for the change to take effect.

Configuring DNS Integrity Check for Authoritative Zones

In certain DNS domain hijacking scenarios, hijackers alter the DNS data of a domain after gaining control of it. They consequently redirect users to a fraudulent site, instead of the legitimate site, on the Internet. To protect your authoritative DNS server against this type of DNS domain hijacking, you can configure the appliance to periodically monitor DNS data for top-level or parent authoritative zones. Based on your configuration, the appliance periodically checks DNS data in the NS RRsets for these zones and compares the data with that in the appliance database. It then reports data discrepancies through SNMP traps and logs related events in the syslog. You can also monitor the status of DNS data discrepancies, if any, through the *DNS Integrity Check* widget on the Task Dashboard. The severity in data discrepancies can help identify possible domain hijacking.
DNS integrity check is supported on all Infoblox appliances, including Advanced Appliances used primarily for Infoblox. For information, see *About Infoblox Advanced DNS Protection*. You can configure DNS integrity check for any selected authoritative zones, but you cannot configure it at the Grid, member, or DNS view level.
When you enable this feature, the appliance queries the NS RRsets and glue records for the top-level authoritative zones and compare the data with that in the appliance database. It does not query data for sub zones or delegated zones in the Grid.

Note

DNS integrity check is not supported on authoritative zones configured to use primary DNS servers in stealth mode.

Configuring DNS Integrity Check

To configure the appliance to check NS and glue records for a top-level or parent authoritative domain, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> top-level *authoritative zone* that you want to monitor, and then click the Edit icon from the Toolbar. Note that you can configure this feature only at the zone level. You can also configure zones that have the same name in different DNS views.
   Note that once you configure a zone for DNS integrity check, you will not be able to add a parent zone above this zone. You must disable DNS integrity check for this zone before you can add the parent zone.
2. In the *Authoritative Zone* editor, toggle to the **Advanced Mode**, select the **DNS Integrity Check** tab -> **Basic** tab and complete the following:

- **Enable**: Select this checkbox to enable the DNS integrity check feature.
- **Member**: Click **Select Member** to select the Grid member you want to use for DNS integrity check. When you select a member, ensure that the member is configured to send and receive DNS queries and responses from Grid primaries (excluding stealth primaries) for the zone being monitored. Note that queries generated by DNS integrity check for the first reachable internal Grid primary are logged in relevant DNS reports. For information about reports, see *Infoblox Reporting and Analytics*.
- **Check Frequency**: Enter how often the appliance monitors DNS data for the authoritative zone. Select the time unit from the drop-down list. The appliance periodically queries DNS data for the top-level zone based on the time interval you configure here. The default value is one hour, and the minimum configurable value is 15 minutes.
- **Enable Verbose Logging**: Select this to enable detailed logging of events related to DNS integrity check. When you select this option, the appliance logs additional information in the syslog when DNS data discrepancies are detected. It also logs a message when no data discrepancies are found during a DNS data check. When you clear this checkbox, the appliance logs standard information in the syslog and does not log an event when no data discrepancies are found during a DNS integrity check. This is disabled by default. For information about the syslog, see *Viewing the Syslog*.

3. Save the configuration.

Monitoring DNS Data Discrepancies for Authoritative Zones

When the appliance detects DNS data discrepancies between the authoritative and delegated zones, it reports the discrepancies through SNMP traps and email notifications, if configured. For more information, see *Setting SNMP and Email Notifications*. The appliance classifies data discrepancies by severity, as follows:

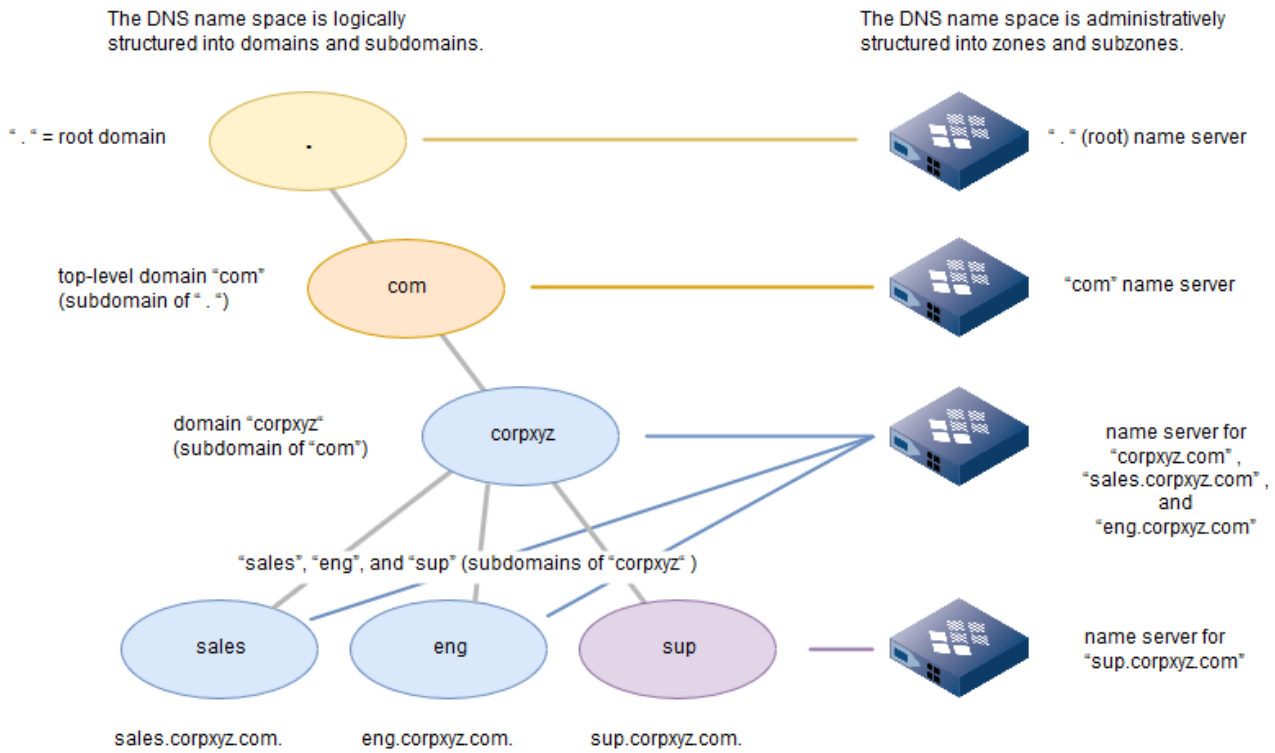
- **Critical**: Data in the NS RRsets for the authoritative and delegate zones are completely out of synchronization.
- **Severe**: Some data in the NS RRset between the authoritative and delegate zones overlaps and some data is different.
- **Warning**: The NS RRset for the authoritative zone is a subset of the NS RRset for the delegate zone. It is possible that incorrect IP addresses have been entered at the registrar.
- **Informational**: The NS RRset for the delegate zone is a subset of the NS RRset for the authoritative zone. This could indicate a possible delay in domain registration.
- **Normal**: There are no DNS data discrepancies between the NS RRsets for the authoritative and delegated zones.
- **None**: No DNS discrepancies data has been collected or DNS integrity check has not been performed.

When different Grid primaries report different severity levels for the same data check, the appliance reports the most severe discrepancy level. When different Grid primaries report the same severity for the data check, the appliance reports only the first check.
You can use the following methods to monitor DNS data discrepancies for selected authoritative zones:

- Viewing syslog events, as described in *Viewing the Syslog*.
- Monitoring DNS data discrepancy status through the *DNS Integrity Check* dashboard widget, as described in *DNS Integrity Check*.
- Receiving SNMP traps and email notifications, as described in *Setting SNMP and Email Notifications*.

Domains and Zones

After creating a zone, you can add more zones at the same level, or add subordinate zones (*subzones*). The subzones can be authoritative, delegated, forward, or stub.
The distinction between domains and zones is that domains provide a logical structure to the DNS name space while zones provide an administrative structure. The difference between domains and subdomains and zones and subzones is that the terms *subdomains* and *subzones* reference their relationship to a parent domain or zone. With the exception of the root domain and root zone, all domains are subdomains and all zones are subzones.
You can organize a domain based on logical divisions such as type (.com, .gov, .edu; or sales, eng, sup) or location (.uk, .jp, .us; or hq, east, west). The following figure shows one way to organize the external (public) name space and the internal (private) name space for a corporation with the domain name *corpxyz.com*. The external name space follows standard DNS conventions. Internally, you create an individual subdomain and corresponding subzone for each department.
Domains and Subdomains, and Forward-Mapping Zones and Subzones



On the Infoblox appliance, you can configure and manage DNS zones and subzones.

IDN Support For DNS Zones

Grid Manager supports IDNs for DNS zones and resource records. For information about IDN, see *Managing Internationalized Domain Names*. You can use either IDN or punycode (representation of IDN) to create DNS zones. Even if you use punycode to create a zone, the appliance automatically generates the corresponding IDN and displays the zone name in its native characters. Make sure that you use valid punycode to create a DNS zone. If you specify an invalid punycode, the appliance retains the punycode and does not convert it into IDN. Note that the appliance displays both the IDN and punycode for an IDN zone.

The following table summarizes how the appliance displays IDNs at the DNS zone level:

Input	NIOS Displays...	NIOS DNS Domain (Punycode in the GUI)	Conversion Guidelines
hello.com	hello.com	hello.com	No conversion
прывітанне.com	прывітанне.com	xn--80adk5aaihr3f9e.com	IDN to punycode
xn--80adk5aaihr3f9e.com	прывітанне.com	xn--80adk5aaihr3f9e.com	Punycode to IDN
\xyz format	\xyz format	\xyz format	No conversion

Assigning Zone Authority to Name Servers

Forward-mapping zones answer name-to-address queries, and reverse-mapping zones answer address-to-name queries. When you create an authoritative forward-mapping zone or reverse-mapping zone, you assign zone authority to a name server and define it as the primary server for the zone. A primary server is designated as the primary source for

the zone and maintains a master copy of the zone data.
In a traditional DNS configuration, zone updates are performed based on a model that consists of a single primary server and one or multiple secondary servers, which receive read-only zone updates from the primary through database replications or zone transfers. Since the primary server contains editable zone data and is designated as the primary source for the zone, it can become a single point of failure when it becomes unavailable. To avoid a single point of failure for zone transfers, you can configure multiple primary servers for an authoritative zone.
When you define multiple primary servers for a zone, each primary has a copy of the zone's authoritative data that can be updated independently. When you modify zone data, the appliance replicates updated data among all primary servers. When there are conflicts between zone updates, the appliance generally selects the latest updates based on the timestamps the updates were made by the clients to the primary servers. Therefore, accurate time synchronization among all servers in the DNS configuration is very important. For more information about other best practices for configuring multiple primaries for an authoritative zone, see Best Practices for Defining Multiple Primaries for Authoritative Zones below.
You can also create one or more secondary name servers for a zone. A secondary server for a zone receives read-only zone data from the primary server. If a zone is part of an internal DNS structure for a private network, the inclusion of a secondary DNS server is optional, though highly recommended. If a zone is part of an external DNS structure for a public network such as the Internet, then a secondary server in a different subnet from the primary server is required. This requirement provides an additional safeguard against localized network failures causing both primary and secondary name servers for a zone to become inaccessible.

Note

You can enter, modify, and remove zone data on the primary servers, which can then send new and modified data in a read-only format to the secondary servers. Both primary and secondary name servers are authoritative for the zone data they serve. The distinction between them is how they get their zone data.

In Grid Manager, you can specify the primary and secondary servers for a zone or you can specify a name server group. A name server group is a collection of one or more primary servers and one or more secondary servers. For information on name server groups, see *Using Name Server Groups*.

Best Practices for Defining Multiple Primaries for Authoritative Zones

Before you configure multiple primary servers for a zone, consider the following guidelines to ensure data integrity:

- This feature is designed to increase availability of the DNS service by allowing multiple primaries for a zone. It will not increase overall throughput of DNS update traffic, as ultimately all updates must be replicated to (and processed by) all of the primaries.
- When determining which appliances should act as primaries for the zone, consider that an additional SOA record will be required in the database for each primary. This will add to the overall record count for the zone, and each SOA will need to be updated for any change to the zone, which can impact performance.
- Enable NTP for all members (at the member level) and ensure that their times are properly synchronized with their local time servers. Ensure that you select the "Exclude the Grid Master as an NTP server" option. The appliance selects the latest zone updates based on the timestamps the updates were made by clients to the primary servers. This is especially important when there are conflicts between two or more zone updates. For information about NTP, see *Using NTP for Time Settings*.
- When specifying the primary server for secondaries, you can choose to have the appliance automatically select it for you based on latency determination or you can manually specify it. When manually selecting a primary for zone updates, consider using one that is close in proximity to the secondary servers, which can result in better service performance. For information about setting preference for the primary server, see Adding Grid Secondaries below.
- You can configure a default primary for DDNS updates to a zone with multiple primary servers. To enhance service performance, select a default primary that is close in proximity to the DHCP server that provides DDNS updates. This is especially useful if you have DHCP members that are located in different locations. You can configure a different default primary for each DHCP member based on their locations. For more information, see *Defining the Default Primary for DDNS Updates to Zones with Multiple Primaries*.
- DNSSEC is not supported for zones with multiple primary servers. These zones must be unsigned. For information about DNSSEC, see *Configuring DNSSEC*.

- When determining which appliances should act as primaries for the zone, consider that an additional SOA record will be required in the database for each primary. This will add to the overall record count for the zone, and each SOA will need to be updated for any change to the zone, which can impact performance.

Specifying a Primary Server

When you create a zone, the primary server can be a Grid member, an external DNS server that you specify, or a Microsoft DNS server that is managed by a Grid member. For information about managing Microsoft Windows DNS servers, see *About Managing Microsoft Windows Servers*.

Although a zone typically has only one primary server, you can specify multiple primary servers for an authoritative zone. You can configure multiple Grid primaries or multiple external primaries (including Microsoft AD-integrated servers) for a zone, but you cannot configure both at the same time for the same zone. In addition, you can configure one Microsoft server, but not multiple Microsoft servers (except for Microsoft AD-integrated servers), as the primary server for a zone. Note that each primary server that you configure for a zone has its own MNAME for the SOA record and serial number. For information about how to view and modify certain values in the SOA record, see *Viewing and Modifying SOA Records* .

A hidden primary provides data to its secondary servers, which in turn respond to DNS queries using this data. One of several advantages of this approach is that you can take the primary server offline for administrative or maintenance reasons without causing a disruption to DNS service (within the expiration interval set for the validity of its zone data—the default is 30 days).

When you add an authoritative forward-mapping zone and assign responsibility for the zone to a primary name server whose host name belongs to the name space of the zone, the NIOS appliance automatically generates an NS (name server) record and an A (address) record for the name server. This type of A record is called a glue record because it "glues" the NS record to the IP address (in the A record) of the name server.

In Grid Manager, you can specify the primary server for a zone when you create it using the *Add Authoritative Zone* wizard or when you edit an existing zone using the *Authoritative Zone* editor. For information on how to add a new zone through the wizard, see *Configuring Authoritative Zones*. The following procedure describes how to access the editor of a zone. To specify a primary server for an existing zone:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and then click the Edit icon.
2. In the *Authoritative Zone* editor, click **Name Servers**.
3. Select **Use this set of name servers.**
4. Click the Add icon and select one of the following options for a primary server:
    - **Grid Primary:** Choose this option to select a Grid member as the primary server for the zone. See Specifying Grid Primary Servers below.
    - **Microsoft Primary:** Choose this option to select a Microsoft DNS server as the primary server for the zone. See Specifying Microsoft Primary Servers below.
    - **External Primary:** Choose this option if the appliance is in a Grid and you want to specify a primary server outside the Grid ("external" to the Grid). See Specifying External Primary Servers below.
5. Save the configuration and click **Restart** if it appears at the top of the screen. or

Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Specifying Grid Primary Servers

In the *Add Grid Primary* panel, do the following, and then click **Add** to add the Grid member to the list of name servers for the zone as primary:

- If no member is displayed, click **Select** to specify a Grid member. When there are multiple members, Grid Manager displays the *Member Selector* dialog box from which you can select a primary name server. To select multiple primary servers, click **Select** and then **Add** again.
- **Stealth:** Click this to hide the NS record for the primary name server from DNS queries. The NIOS appliance does not create an NS record for the primary name server in the zone data. Clear the checkbox to display the NS record for the primary name server in responses to queries.

Changing the SOA Name for a Zone

If the primary name server of a zone is a Grid member, the NIOS appliance allows you to change the SOA (start of authority) name that is automatically created when you initially configure the zone. For example, you might want to hide the primary server for a zone. If your appliance is named dns1.zone.tld, and for security reasons, you may want to show

a secondary server called dns2.zone.tld as the primary server. To do so, you would go to dns1.zone.tld zone (being the true primary) and change the SOA to dns2.zone.tld to hide the true identity of the real primary server.
To change the SOA name for a zone:

1. From the **Data Management** tab, select the **DNS** tab > **Zones** tab> *dns_view -> zone* checkbox -> Edit icon.
2. In the *Authoritative Zone* editor, click **Settings**.
3. Click **Override** beside the **Primary name server** field and enter the new SOA name. This field supports IDN.
4. Save the configuration and click **Restart** if it appears at the top of the screen.
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Specifying Microsoft Primary Servers

You can assign a Microsoft server as the primary server of a zone when it is managed by a Grid member in read/write mode. For information, see *About Managing Microsoft Windows Servers*. When a Microsoft server is the primary server of a zone, the zone supports only standard DNS resource records. It does not support the Infoblox record types host records, bulk host records, and shared record groups. You cannot add any of these records to the zone nor assign a DNS zone with these records to a Microsoft server as the primary server.
In the Add Grid Primary panel, do the following to assign a Microsoft primary server:

1. Complete the following:
   - Select **Use this set of name servers**.
   - Click the *Add* icon and select **Microsoft Primary**.
2. In the *Add Microsoft Primary* panel, do the following, and then click **Add** to add the Microsoft primary server to the list of name servers for the zone:
   - If no server is displayed, click **Select Server** to specify a Microsoft server. When there are multiple servers, Grid Manager displays the *Server Selector* dialog box from which you can select a Microsoft server. Grid Manager lists Microsoft servers that are managed in read/write mode. It does not include Microsoft servers managed in read-only mode.
   - **Information to create NS record:** Grid Manager automatically creates the NS record. After you select a server, Grid Manager populates the **Name** and **IP Address** fields. Grid Manager uses this information when it creates the NS record, unless you select **Stealth**. You can specify a different FQDN or IP address for the NS record; for example, for a multihomed server.
   - Store the zone in Active Directory (AD Integrated Zone): This is enabled and selected by default only if the Microsoft server is a domain controller. Note that you can enable Active Directory integration only after the Microsoft server has been synchronized at least once because its AD ability is not known before the synchronization. This is disabled when the Microsoft server is not a domain controller.
   - **Stealth:** Select this option to hide the NS record for the primary name server from DNS queries. Grid Manager does not create an NS record for the primary name server in the zone data. Clear this option to display the NS record for the primary name server in responses to queries. Note that this option is not available for AD-integrated zones.

Specifying External Primary Servers

In the Add External Primary panel, do the following, and then click **Add** to add the external primary server to the list of name servers for the zone:

- **Name:** Type a resolvable domain name for the external primary server.
- **Address:** Type the IP address of the external primary server.
- **Multi-master**: This appears only when there is more than one external primary assigned to the zone. Select this checkbox for external primary servers when the zone is in another Grid and has multiple Grid primaries. When you select this option, it is selected for all external primaries assigned to the zone. This zone is identified as an external zone with multiple primary servers.
- **Use TSIG:** To authenticate zone transfers between the local appliance and the external primary server using a TSIG (transaction signature), select this checkbox. Infoblox TSIGs use HMAC-MD5 hashes. These are keyed one-way hashes for message authentication codes using the Message Digest 5 algorithm. For details, see *RFC 1321, The MD5 Message-Digest Algorithm*, and *RFC 2104, HMAC: Keyed-Hashing for Message Authentication*.

- **Key name:** Type or paste the name of the TSIG key you want to use. This must be the same name as that of the TSIG key on the external primary server.
- **Key Data:** Type or paste a previously generated key. This key must also be present on the external primary server. You can generate a TSIG key, or obtain the TSIG key name and key from the external name server, by accessing the server yourself or by requesting the server administrator to deliver them to you through some out-of-band mechanism. Then type or copy-and-paste the name and key into the appropriate fields.
- **Use 2.x TSIG:** If you want to use TSIG authentication and the external primary name server is a NIOS appliance running DNS One 2.x code, select this checkbox. The local appliance generates the required TSIG key for authenticating DNS messages to and from appliances running DNS One 2.x code.

> ⚠ Note
> On the appliance you configure as a secondary server for a zone, you must associate a TSIG key for each primary server to which the secondary server requests zone transfers. On the appliance you configure as a primary server for a zone, you can set a TSIG key at the Grid, member, or zone level. Because the secondary server requests zone transfers, it must send a specific key in its requests to the primary server. Because the primary server responds to the requests, it can have a set of TSIG keys from which it can draw when responding. As long as the primary server can find the same TSIG key that the secondary sends it, it can verify the authenticity of the requests it receives and authenticate the responses it sends. Use NTP to synchronize the time on both name servers that use TSIG-authenticated zone transfers.

Specifying Secondary Servers

A secondary name server is as authoritative for a zone as a primary server. Like a primary server, a secondary server answers queries from resolvers and other name servers. The main difference between a secondary and primary server is that a secondary server receives all its data from a primary server, or possibly from another secondary server that relays zone data it receives. The zone data passes from a primary to a secondary server (and possibly from that secondary server on to another secondary server). This process is called a zone transfer.
The advantage of using primary and secondary name servers is that you enter and maintain zone data in one place— on the primary server. The data is then distributed to the one or more secondary servers.
Secondary servers can be Grid members, external DNS servers or Microsoft DNS servers that are managed by Grid members. In Grid Manager, you can specify the secondary server for a zone when you create it using the *Add Authoritative Zone* wizard and when you edit an existing zone using the *Authoritative Zone* editor. For information on how to add a new zone through the wizard, see *Configuring Authoritative Zones*. The following procedure describes how to access the editor of a zone.
To specify a secondary server for an existing zone:

1. From the **Data Management** tab -> **DNS** tab -> **Zones** tab -> *zone* checkbox, and then click the Edit icon.
2. In the *Authoritative Zone* editor, click **Name Servers**.
3. Select **Use this set of name servers.**
4. Click the Add icon and select one of the following options:
    - **Grid Secondary:** Selects the local appliance as the secondary server (or if the appliance is deployed in a Grid and you want to make a different member the secondary server). See Adding Grid Secondaries below.
    - **Microsoft Secondary:** Select this option if you want to specify a managed Microsoft DNS server as a secondary server. See Specifying Microsoft Secondary Servers below.
    - **External Secondary**: Select this option if the appliance is in a Grid and you want to specify a secondary server outside the Grid ("external" to the Grid), or if the appliance is deployed independently from a Grid. See Specifying External Secondaries below.
5. Save the configuration and click **Restart** if it appears at the top of the screen. or

Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Adding Grid Secondaries

When adding Grid secondaries to a zone that has multiple primary servers, the appliance selects a primary server as the active server based on the method that you have selected. If you select **Automatic**, the primary is selected based on latency determination, which occurs separately on each primary. When available, the primary server that has the lowest latency is preferred. When you select **Manual**, latency determination is ignored, and the first available primary server in

the list is selected as the active server. Thus if the first primary on the list is not available, the next available primary is used. Depending on which primary server is selected, the Grid secondary returns the FQDN of the primary in the MNAME field of the zone SOA record. It also includes the version of the zone content that it serves.
In the Add Grid Secondary panel, enter the following, and then click **Add** to add the Grid secondary server to the list of name servers for the zone**:**

- If no member is displayed, click **Select** to specify a Grid member. When there are multiple members, Grid Manager displays the *Member Selector* dialog box from which you can select a secondary name server.
- **Stealth:** This setting applies only if the primary server is a Grid member or Microsoft server. Select this to hide the NS record for the secondary name server from DNS queries. The NIOS appliance does not create an NS record for this name server in the zone data. Select the checkbox again to display the NS record for the secondary name server in responses to queries. A secondary server in stealth mode is also known as a "hidden secondary".
  For example, you can configure a hidden secondary when a secondary server is at a branch office with a slow connection to the rest of corporate network. Configure local hosts at the branch office to send DNS queries to the secondary server, but keep it hidden from other name servers on the rest of the network so that they do not send it queries. Instead, they use a server located in a different part of the network that has faster connection speeds.
- **Lead Secondary:** This option becomes available only after you specify the primary name server as external. When a primary server is external to a Grid whose members are secondary servers, you can select this checkbox to designate one member as a lead secondary. The primary server sends zone transfers to the lead secondary, which distributes the zone data to the other secondary servers in the Grid using zone transfers (not the Grid data replication mechanism). After you designate a Grid member as a lead secondary for a zone, you do not have to configure members to use the lead secondary server. All other Grid members acting as secondary servers for the zone automatically use the lead secondary to get zone data. Using a lead secondary simplifies the addition, modification, and removal of other secondary servers in the Grid. As long as the lead secondary remains unchanged, you need not update intervening firewall policies or the external primary server whenever you make changes to non-lead secondary Grid members. This approach also reduces the amount of traffic between primary and secondary servers.
- **Update Zones Using:** This option becomes available only after you specify a Grid member as the primary server.
  - **Grid Replication (recommended):** Select this checkbox to use Grid replication to move zone data from the primary to secondary servers.
  - **DNS Zone Transfers:** Select this checkbox to use the DNS zone transfer process to move zone data from the primary to secondary servers.
- **Primary Preference**: This appears only for Grid secondaries that are assigned to zones with multiple primaries. Select one of the following to set preference for selecting the primary server:
  - **Automatic:** Choose this to allow the appliance to select the optimum primary server for zone updates based on latency determination, which prefers the primary server that has the lowest latency. This is selected by default.
  - **Manual:** Choose this to manually select primaries for zone updates. In the Available Primaries and Selected Primaries tables, click a name server and use the arrows to select and deselect primaries between the tables. Then use the up and down arrows next to the Selected Primaries table to put the selected primaries in a preferred order. The secondary servers will get zone updates from the selected primary server based on the given order. To optimize service performance, select primary servers that are close in proximity to the secondary servers.

Specifying Microsoft Secondary Servers

You can assign a Microsoft server as the primary server of a zone when it is managed by a Grid member in read/write mode. For information, see *About Managing Microsoft Windows Servers*.
Since Microsoft servers cannot replicate data from the Grid, when a DNS zone is defined as a secondary on a Microsoft server, the Microsoft server obtains the content of the zone only through DNS zone transfers.

- In the Add Microsoft Secondary panel, do the following:
  - If no server is displayed, click **Select Server** to specify a Microsoft server. When there are multiple servers, Grid Manager displays the *Server Selector* dialog box from which you can select a Microsoft server. Grid Manager lists Microsoft servers that are managed in read/write mode. It does not include Microsoft servers managed in read-only mode.
  - **Information to create NS record:** Grid Manager automatically creates the NS record. After you select a server, Grid Manager populates the **Name** and **IP Address** fields. Grid Manager uses this information when it creates the NS record, unless you select Stealth.

- **Stealth:** This setting applies only if the primary server is a Grid member or a Microsoft server. Select this option to hide the NS record for the secondary name server from DNS queries. Grid Manager does not create an NS record for this name server in the zone data. Clear this option to display the NS record for the secondary name server in responses to queries.

Specifying External Secondaries

In the Add External Secondary panel, enter the following, and then click **Add** to add the external secondary server to the list of name servers for the zone**:**

- **Name:** Enter a resolvable domain name for the external secondary server.
- **Address:** Enter the IP address of the external secondary server.
- **Stealth:** This setting applies only if the primary server is a Grid member or a Microsoft server. Click this checkbox to hide the NS record for the secondary name server from DNS queries. The NIOS appliance does not create an NS record for the secondary name server in the zone data. Select the checkbox again to display the NS record for the secondary name server in response to queries.
  Note that to avoid an impact on your database performance, Infoblox recommends that you do not configure a large number of external secondary servers in stealth mode. To ensure that these secondary servers receive notifications about zone updates, you can allow zone transfers for these IP addresses and then enable the appliance to add them to the also-notify statement. For information about how to configure this feature, see *Configuring Zone Transfers*.
- **Use TSIG:** To authenticate zone transfers between the local appliance and the external secondary server using a TSIG (transaction signature), select this checkbox. Infoblox TSIGs use HMAC-MD5 hashes. These are keyed one-way hashes for message authentication codes using the Message Digest 5 algorithm. For details, see RFC 1321, *The MD5 Message-Digest Algorithm*, and RFC 2104, *HMAC: Keyed-Hashing for Message Authentication*.
- **Key name:** Type or paste the name of the TSIG key you want to use. This must be the same name as that of the TSIG key for this zone on the external secondary server.
- **Key:** Type or paste a previously generated key. On the external secondary server, this key must also be present and associated with this zone. You can generate a TSIG key, or you can obtain the TSIG key name and key from the external name server, either by accessing the appliance yourself or by requesting the appliance administrator to deliver them to you through some out-of-band mechanism. Then, type or copy-and-paste the name and key into the appropriate fields.
- **Use 2.x TSIG**: Select this checkbox to use TSIG authentication and the external secondary name server is a NIOS appliance running DNS One 2.x code. The local appliance generates the required TSIG key for authenticating DNS messages to and from appliances running DNS One 2.x code.

> ⚠ Note
> On the appliance you configure as a secondary server for a zone, you must associate a TSIG key for each primary server to which the secondary server requests zone transfers. On the appliance you configure as a primary server for a zone, you can set a TSIG key at the Grid, member, or zone level. Because the secondary server requests zone transfers, it must send a specific key in its requests to the primary server. Because the primary server responds to the requests, it can have a set of TSIG keys from which it can draw when responding. As long as the primary server can find the same TSIG key that the secondary sends it, it can verify the authenticity of the requests it receives and authenticate the responses it sends. Use NTP to synchronize the time on both name servers that use TSIG-authenticated zone transfers.

Configuring Domain Controller List

When you configure an AD-integrated authoritative zone, by default all the domain controllers that belong to the domain automatically add NS records to the AD-integrated zone, which might be undesirable in some deployment scenarios. For example, if a domain controller is deployed in a company's branch office, it is unlikely that the domain controller should be registered as the name server for the company's top-level zones. By configuring a domain controller list for the AD-integrated zone, you can control which domain controllers are allowed to add NS records to the zone. If you configure a domain controller list for an AD-integrated zone, only those in the list can add NS records to the zone. You can configure the domain controller list for AD-integrated zones either on the NIOS appliance or on the Microsoft server.

Configuring Domain Controller List on NIOS

You can configure a domain controller list for an AD-integrated authoritative zone to allow NS record creation for specific domain controllers. You can add, modify, and delete the entries in the domain controller list if the Microsoft server assigned to the zone is managed in read/write mode. If you have not configured the domain controller list while configuring an AD-integrated zone, you can perform the configuration later while editing the zone.
Note the following about the domain controller list:

- If the domain controller list is empty for an AD-integrated zone, all domain controllers that belong to the domain can add NS records to the AD-integrated zone.
- If you remove a domain controller from the domain controller list of an AD-integrated zone, the NS record that belongs to the domain controller is not automatically deleted. You must manually delete the NS record from the AD-integrated zone.

To configure a domain controller list for an AD-integrated zone:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> click the Add icon and select **Authoritative Zone** from the drop-down menu.
2. Complete the details as mentioned in *Configuring Authoritative Zones* and then complete the following to specify a list of domain controllers that are allowed to add NS records to the AD-integrated zone:
    - **No**: Select **No** if you do not want to configure a domain controller list for the AD-integrated zone. If you select **No**, all domain controllers that belong to the domain can add NS records to the AD-integrated zone.
    - **Yes**: Select **Yes** to configure a domain controller list for the AD-integrated zone.
      If you select **Yes**, click the Add icon of the **Domain Controller** table and select one of the following from the drop-down menu:
    - **Add**: Select this to manually add the IP addresses of the domain controllers to the list. Grid Manager adds a new row to the table. Specify the following:
        - **Address**: Enter the IP address of the domain controller.
        - **Comment**: Enter information about the domain controller.

      To remove an entry from the list, select the entry and click the Delete icon.
    - **Auto-populate**: Select this to automatically populate the **Domain Controller** table with the list of domain controllers. In the *Add Prepopulated Domain Controllers* panel, select one of the following options:
        - **Zone**: Select this to copy the list of domain controllers from an existing AD-integrated zone in the NIOS database. Click **Select** to select the AD-integrated zone. Click **Clear** to remove the selected zone.
        - **Servers in Domain**: Select this to add the IP addresses of all the Microsoft servers available in the NIOS database which belong to the same AD domain as the primary Microsoft server assigned to the zone.
    - Click **Add** to add the list of domain controllers to the table. Grid Manager automatically populates the **Domain Controller** table with the list of domain controllers in ascending order by IP address.
      Note that the **Auto-populate** option to add the domain controller list is only available while configuring the AD-integrated zone. It is not available when you edit the domain controller list in the *Authoritative Zone* editor.
3. Save the configuration.

Configuring Domain Controller List on the Microsoft Server

You can configure a list of domain controllers that are allowed to add NS records to an AD-integrated zone on the Microsoft server using the dnscmd command line utility as follows:

```
dnscmd DNS Server /Config Zone Name /AllowNSRecordsAutoCreation Ip Addresses
```

For example, if you are configuring a domain controller list for an AD-integrated zone foo.net on the DNS server, 192.69.0.1, use the following command:

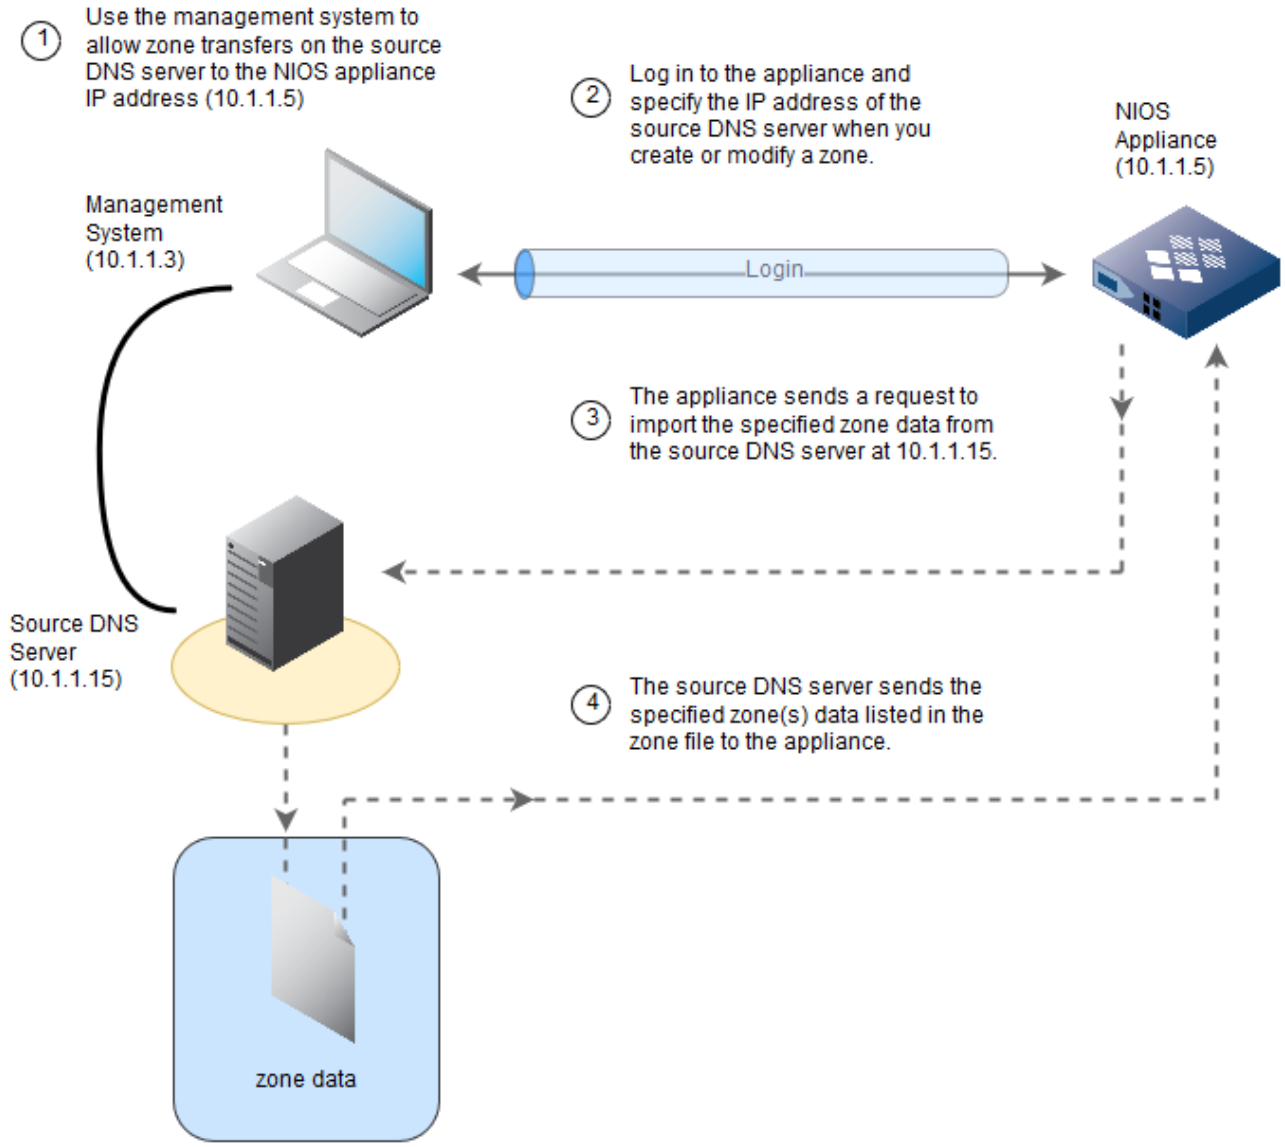
```
dnscmd 192.69.0.1 /config foo.net /AllowNSRecordsAutoCreation 192.69.0.6
192.69.0.9
```

For more information about configuring a domain controller list for an AD-integrated zone on the Microsoft server see *https://technet.microsoft.com/en-us/library/cc755848%28v=ws.10%29.aspx.*

Importing Zone Data

Importing zone information alleviates having to manually enter data through the Infoblox GUI. You can import data from existing name servers, as well as from NIOS appliances running version 3.1r4 or later. You can import existing zone data when you create a new zone and when you edit an existing zone. You can import one zone (and its subzones) at a time. For the remainder of this section, the name server that stores the existing zone data (which is imported) is referred to as the *source* name server (regardless of whether it is a third-party server or another NIOS appliance). The appliance that receives the zone data is referred to as the *destination* appliance. The following illustration shows the import zone data process.

Importing Zone Data Process



The appliance imports zone data through a zone transfer. Therefore, the source name server must be authoritative for the zone data being imported. You must also configure the source name server to allow zone transfers to the destination appliance. On the source name server, you might need to modify the *allow-transfer* substatement to include the IP address of the destination appliance prior to importing the data. If you are importing zone data to an HA pair, use the VIP (virtual IP) address shared by the HA pair. For a single independent appliance, use the LAN IP address. If you are importing zone data to a Grid, always use the IP address of the Grid Master.

If the source name server is an Infoblox appliance, you can configure it to allow zone transfers as described in *Enabling*

Zone Transfers. Note that a NIOS appliance, acting as the primary name server for a zone, by default allows zone transfers to its secondary name servers. If the zone import fails, the zone to which the data is imported will be disabled and the system does not create records and delegated subzones.

> **Note**
>
> The appliance does not encode punycode when you import zone data containing punycode. For example, a zone data containing IDNs in punycode is stored in punycode for the data being imported. The data is managed in punycode only.

About Importing Data into a New Zone

When the appliance imports data to a newly created zone, it imports the existing A, CNAME, DNAME, SRV, TXT, MX, PTR, host, and bulk host records, but creates NS (and A records matching that NS record) and SOA records appropriate for the destination server. The NS and SOA records are auto-created when a destination appliance is specified as the primary or secondary name server for the new zone. If the imported zone has extra NS records, they are rewritten to specify the source server as an external secondary. Delegation is also added for any subzones. The subzone records are not imported.

About Importing Data into an Existing Zone

When you import zone data into an existing zone, the zone retains the NS and SOA records automatically created when the zone was originally created and replaces all other records—A, PTR, MX, TXT, SRV, CNAME, DNAME, host, and bulk host. The local appliance also retains subzones and records in the subzones that exist locally. If there are no duplicates, the destination appliance records are retained. If the imported zone has extra NS records, those records change to designate the source server as an external secondary.

Importing Data into Zones

In Grid Manager, you can import zone data when you create the zone using the *Add Authoritative Zone* wizard and when you edit an existing zone. For information on how to add a new zone through the wizard, see *Configuring Authoritative Zones*. The last step of the wizard provides the option to import zone data. The following procedure describes how to import data into an existing zone.

Note: Only superusers can import zone data that contains A, AAAA, shared A, or shared AAAA records with a blank name. Limited-access users must have read/write permission to **Adding a blank A/AAAA record** in order to import zone data that contains A, AAAA, shared A, or shared AAAA records with a blank name, otherwise the import zone data operation might fail. You can assign global permission for specific admin groups and roles to allow to import A, AAAA, shared A, or shared AAAA records with a blank name. For more information, see *Administrative Permissions for Adding Blank A or AAAA Records.*

To import data into an existing zone:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and then click **Import Zone** in the Toolbar.
2. In the *Import Zone* dialog box, specify the following:
   - The IP address of the name server from which you want to import data.
   - Optionally, click the **Automatically create Infoblox host records from A records** checkbox.
3. Click **Import**.

When the local server successfully imports the zone data, a *Confirmation* message appears. If the local server cannot import the zone data, an *Error* message appears, recommending that you verify the correctness of the IP address of the remote server and zone information.

Note

If NIOS resolves the IP address of the imported zone data, an external secondary member is added to the list of name servers with the exact IP address. If NIOS cannot resolve the IP address of the imported zone data, it adds an external secondary member with the IP address 255.255.255.255 to the list of name servers.

Enabling Zone Transfers

A zone transfer is the process of sending zone data across a network from one name server to another. When the primary server detects a change to its zone data, it notifies the secondary servers. The secondary servers reply by checking to see if the serial number they have for the zone is as large as the serial number for the zone on the primary server. If not, the secondary servers request a zone transfer.

In addition to receiving zone change notifications, a secondary server periodically polls the primary server to see if their zone data is in sync. In response, the primary server can send a DNS message containing just the changed zone data, or the entire data set. The first type of transfer is known as an incremental zone transfer, or IXFR. The second type of transfer is known as a full zone transfer, or AXFR.

A NIOS appliance, acting as the primary name server for a zone, allows zone transfers to secondary name servers by default. This includes all servers listed in the NS records for that zone. (Secondary name servers in a Grid, however, receive updated zone data via database replication by default, as explained later in this section.) You can also specify zone transfers to other name servers, such as when migrating zone data to a new server or to a management system. You can specify one or more destinations to which the local appliance sends zone transfers. You can also specify the security and format of the transfers.

Note that secondary name servers periodically query the primary name server to find out if zone data has been changed. Each query takes a certain amount of time and bandwidth on the network. By default, secondary name servers limit the rate (serial-query-rate) at which these queries are being sent. Thus when the secondary name servers are serving a large number of zones, it may take a long time to detect changes to their zone data. You can configure this value to optimize the query rate on the network. In addition, when you have set up a few secondary name servers for a large number of zones, a delay in zone transfers may occur due to the default zone transfer configuration that limits concurrent zone transfers to 10 per secondary server. You can configure the maximum value of concurrent zone transfers to optimize the zone transfer operation. For information about how to optimize zone transfers, see Configuring Concurrent Zone Transfers below.

By default, Grid members automatically receive updated zone data via database replication (through an encrypted VPN tunnel). You can change the default behavior to allow Grid members to use zone transfers instead of Grid replication. Keep in mind that a database replication updates zone data for both the active and passive nodes of an HA member. Therefore, if there is a failover, the new active node (the previous passive node) immediately begins serving zone data with fresh information. In the case of a zone transfer, the passive node does not receive zone data until after a failover, when it becomes an HA master. At that time, it performs a zone transfer. If there is a lot of zone data, the transfer can take up to several minutes, thereby causing a break in the availability of the new HA master.

If you have HA members as secondary servers, zone transfers can result in service interruption when there is a failover. Furthermore, if the primary server is down when the HA member fails over, the new active node cannot receive zone data until the primary server comes back online.

You can use TSIG (transaction signature) keys to authenticate zone transfer requests and replies. The same key name and key value must be on the primary and secondary name servers for TSIG-authenticated zone transfers to occur. When using TSIG, it is important that both appliances involved with the authentication procedure use NTP (Network Time Protocol) for their time settings (see *Using NTP for Time Settings*).

You can control zone transfers at the Grid, member, and zone levels. This enables you to specify a different set of name servers for a Grid, member, and zone, if necessary. You can also control which external secondary servers should receive notifications about zone updates by adding their IP addresses to the also-notify statement for each authoritative zone that is served by a Grid member. Infoblox recommends that you use this feature to notify hidden external secondary servers about zone updates, instead of putting them in stealth mode, especially when you plan to configure a large number of them. For information about how to add IP addresses to the also-notify statement, see Configuring Zone Transfers below.

Configuring Zone Transfers

To configure zone transfers, you identify the servers to which zone data is transferred and optionally, servers to which data must not be transferred. For example, you can allow transfers to a network, but not to a specific server in the network.
You can specify a different set of servers for specific Grid members and zones. For example, if certain Grid members are primary servers for a zone, then you can specify the secondary servers to which that member is allowed to transfer zones.
You can also enable the appliance to add all IPv4 and IPv6 addresses for which you allow zone transfers to the also-notify statement for each authoritative zone that is served by a Grid member. The also-notify statement defines a list of addresses that receive notifications about zone updates, in addition to the IP addresses listed in the NS records for the zone. Use this feature to configure a large number of external secondary servers, instead of putting them in stealth mode.
To configure zone transfer properties:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab, click the **Members** tab -> *member* checkbox -> Edit icon.
   Zone: From the **Data Management** tab, select the **DNS** tab, click the **Zones** tab -> **DNS View** column -> select the *zone_name* checkbox, and click the Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the editor, click **Toggle Advanced Mode**, select the **Zone Transfers** tab.
3. In the *Allow zone transfers to* section, select one of the following:
   - **None**: Select this to deny all clients for DNS zone transfers. This is selected by default.
   - **Named ACL**: Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this, the appliance allows remote name servers that have the **Allow** permission to send and receive zone transfer data. You can click **Clear** to remove the selected named ACL.
   - **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows.
     - **IPv4 Address** and **IPv6 Address**: Select this to add an IPv4 address or IPv6 address. Click the **Value** field and enter the IP address of the remote name server. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
     - **IPv4 Network**: In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address**: Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
       - **Permission**: Select **Allow** or **Deny** from the drop-down list.
     - **IPv6 Network**: In the **Add IPv6 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address**: Enter an IPv6 network address and select the netmask from the drop-down list.
       - **Permission**: Select **Allow** or **Deny** from the drop-down list.
     - **TSIG Key**: In the **Add TSIG Key** panel, complete the following, and then click **Add** to add the TSIG key to the list:
       -
         - **Key name:** Enter a meaningful name for the key, such as a zone name or the name of the remote name server with which the local server authenticates zone transfer requests and replies. This name must match the name of the same TSIG key on other name servers that use it to authenticate zone transfers with the local server.
         - **Key Algorithm:** Select either **HMAC-MD5** or **HMAC-SHA256.**
         - **Key Data:** To use an existing TSIG key, type or paste the key in the **Key Data** field. Alternatively, you can select the key algorithm, select the key length from the **Generate Key Data** drop down list, and then click **Generate Key Data** to create a new key.

- **DNSone 2.x TSIG Key**: Select this when the other name server is a NIOS appliance running DNS One 2.x code. The appliance automatically populate the value of the key in the **Value** field. The **Permission** column displays **Allow** by default. You cannot change the default permission.
- **Any Address/Network**: Select to allow or deny the local appliance to send zone transfers to any IP address.

  After you have added access control entries, you can do the following:
  - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
  - Reorder the list of ACEs using the up and down arrows next to the table.
  - Select an ACE and click the Edit icon to modify the entry.
  - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.

4. Optionally, select the **Add allowed IP addresses to also-notify** checkbox to add all IPv4 and IPv6 addresses listed in the "Allow zone transfers to" table to the also-notify statement for each authoritative zone served by a Grid member. When you enable this, all external secondary servers that are not defined for the zone and are allowed zone transfers will receive notifications about zone updates, in addition to name servers assigned to the zone. Infoblox recommends that you do not configure a large number of external secondary servers in stealth mode. To ensure that these secondary servers receive notifications about zone updates, add their addresses to the "Allow zone transfers to" table and grant them the "Allow" permission, and then select this checkbox.
   Note that the appliance includes only IPv4 and IPv6 addresses. It does not include network addresses, TSIG keys, and denied addresses. When you configure a named ACL, all allowed IPv4 and IPv6 addresses in the named ACL are added to the also-notify statement.
5. Optionally, you can:
   - Modify an item on the list by selecting it and clicking the Edit icon.
   - Remove an item from the list by selecting it and clicking the Delete icon.
   - Move an item up or down the list. Select it and drag it to its new position, or click the up or down arrow.
6. Save the configuration and click **Restart** if it appears at the top of the screen.

Specifying a Zone Transfer Format

The zone transfer format determines the BIND format for a zone transfer. This provides tracking capabilities for single or multiple transfers and their associated servers.
To specify a zone transfer format:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab, click the **Members** tab -> *member* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the editor, click **Toggle Advanced Mode**.
3. When the additional tabs appear, click the **Advanced** subtab of the **Zone Transfers** tab to specify the zone transfer format. *S*elect one of the following options from the **Default Zone Transfer Format** drop-down menu:
   - **many-answers** (Secondaries run BIND 8/9): includes as many records as the packet size allows
   - **one-answer** (Secondaries run BIND 4): includes one record per packet
4. To exclude servers, click the Add icon in the **Zone Transfer Format Exceptions** table and enter the IP address of the server in the Addresses field.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring Concurrent Zone Transfers

The default number of zone transfers that are allowed is set at the Grid or member level. However, you can override the default value and configure the required concurrent zone transfers. Note that when you increase the number of concurrent zone transfers, there will be an impact on CPU and memory usage.

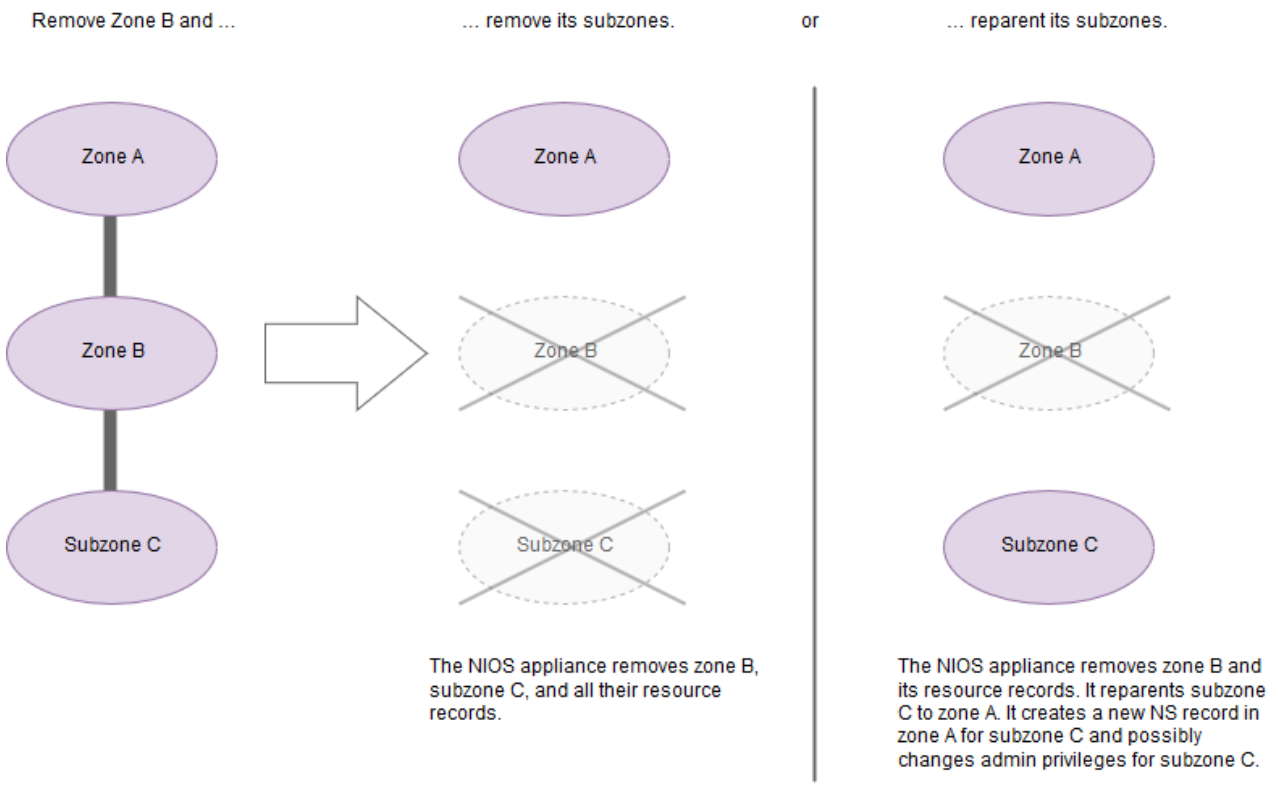
> **Note**
>
> The tcp-client value is unconditionally set to 1000 to control the total number of simultaneous TCP connections, which cap the maximum inbound and maximum outbound transfer plus any DNS request made with the TCP. The tcp-client value specifies the maximum number of simultaneous DNS clients that can be handled with TCP connections and does not account for UDP connections. The UDP connection accounts for the regular DNS requests and TCP is used only for AXFR and rare DNS requests that don't fit in a UDP connection. You can change the tcp-client value by running the *set named_tcp_clients_limit* command.

To specify concurrent zone transfers:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Independent appliance: From the **System** tab, select the **System Manager** tab, expand the Toolbar and click **System Properties** -> **Edit**.
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> **Edit**.
2. In the editor, click **Toggle Advanced Mode**.
3. When the additional tabs appear, click the **Advanced** subtab of the **General** tab.
4. You can change the zone transfer settings as follows:
   - Maximum inbound concurrent zone transfers: The maximum number of inbound zone transfers that can be performed concurrently. Click **Override** to override the value inherited from the Grid and enter the required value. The default value is 10. Make sure that you specify a value from 10 to 100. Otherwise, the appliance displays an error message. To retain the same value as the Grid, click Inherit.
   - Maximum outbound concurrent zone transfers: The maximum number of outbound zone transfers that can be performed concurrently. Click **Override** to override the value inherited from the Grid and enter the required value. The default value is 10. Make sure that you specify a value from 1 to 100. Otherwise, the appliance displays an error message. To retain the same value as the Grid, click Inherit.
   - Maximum concurrent inbound zone transfers per remote name server: The maximum number of zone transfers that can be performed concurrently from a given remote name server. This configuration can be done on a per server basis. Click **Override** to override the value inherited from the Grid and enter the required value. The default value is 2. Make sure that you specify a value from 2 to 100. Otherwise, the appliance displays an error message. To retain the same value as the Grid, click Inherit.
   - Maximum concurrent SOA queries: The maximum number of concurrent queries a secondary name server sends to the primary server to find out if the zone serial numbers have been changed. Click **Override** to override the value inherited from the Grid and enter the required value. The default value is 20. Make sure that you specify a value from 20 to 1000. Otherwise, the appliance displays an error message. To retain the same value as the Grid, click Inherit.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Removing Zones

Depending on the configuration, you may or may not be able to delete or schedule the deletion of a zone and all its contents. Superusers can determine which group of users are allowed to delete or schedule the deletion of a zone and all its contents. For information about how to configure the recursive deletion of zones, see *Configuring Recursive Deletions of Networks and Zones.*
Note that you must have Read/Write permission to all the subzones and resource records in order to delete a zone. The possible effects of removing or re-parenting are illustrated in the following figure Removing or Reparenting Subzones. The appliance puts all deleted objects in the Recycle Bin, if enabled. You can restore the objects if necessary. When you restore a parent object from the Recycle Bin, all its contents, if any, are re-parented to the restored parent object. For information about the Recycle Bin, see *Using the Recycle Bin.*
Removing or Reparenting Subzones



If you choose to reparent the subzones, be aware of the following caveats and possible effects of the reparenting:

- You cannot remove a zone and reparent its subzones if at least one of the subzones is a delegated zone. You must first remove any delegated subzones, and then you can remove the zone and reparent its subzones.
- If there are AD (Active Directory) subzones (_msdcs, _sites, _tcp, _udp, domaindnszones, foresetdnszones) and you opt to remove the parent zone only, the NIOS appliance reparents all subzones except the AD subzones, which it removes regardless of the removal option you specify.
- The subzone reparenting option is unavailable when you select multiple zones for removal.
- A record created under a top-level reverse-mapping zone is reparented when its immediate parent zone is created. If that parent zone is deleted, the record is restored to the top-level reverse-mapping zone.

Examples:

`Example 1:`

`Step 1 -` Add `10.in-addr.arpa` under . (root zone)

`Step 2 -` If you add `10.in-addr.arpa, it is created under . (root zone)`

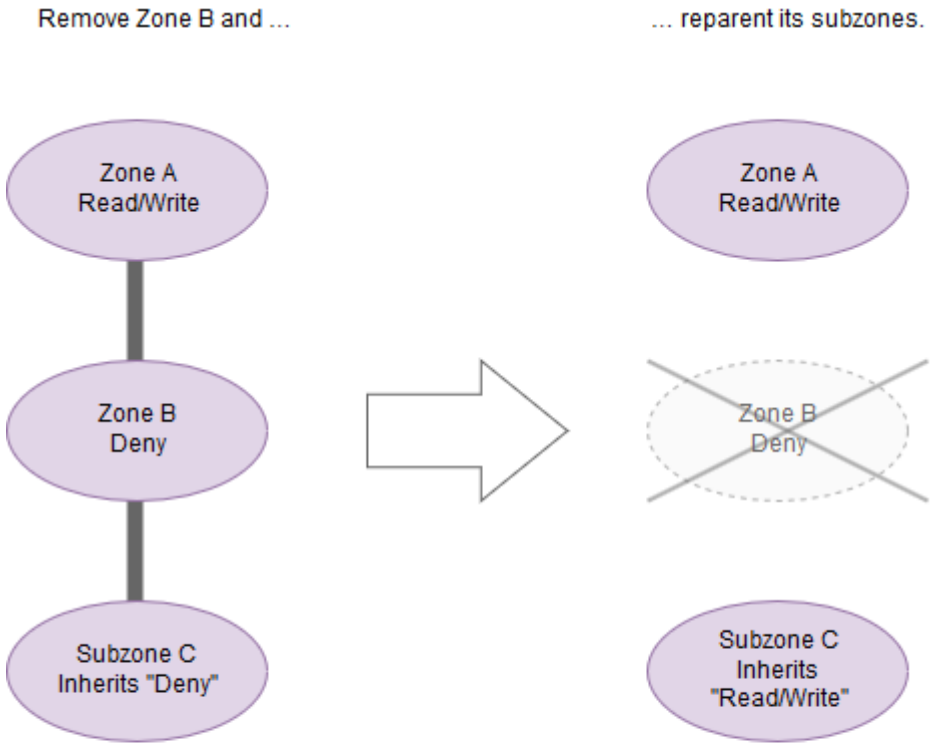
`Step 3 -` if you add `in-addr.arpa,` then `10.in-addr.arpa` is reparented under `in-addr.arpa`

`Example 2`

- Deleting `in-addr.arpa` from the hierarchy might lead to `10.in-addr.arpa` reparenting under . (root zone), depending on the **Remove zone only**/ **Remove all subzones** option you select.
- If `in-addr.arpa` is restored, it is restored under . (root) zone with all its resource records.

`Example 3`

- Consider `in-addr.arpa` zone having `10.10.in-addr.arpa + 10.0.0.1` (PTR record)
- If you add `10.in-addr.arpa`, then `10.10.in-addr.arpa` is reparented under `10.in-addr.arpa`
- and `10.0.0.1` PTR record is reparented from `in-addr.arpa` to `10.in-addr.arpa.`
- If you delete `10.in-addr.arpa`, then `10.10.in-addr.arpa` is reparented under in-addr.arpa (depending on the **Remove zone only**/ **Remove all subzones** option) and 10.0.0.1 PTR record is deleted along with 10.in-addr.arpa zone.
- When you remove a zone and reparent its subzones, any subzone that inherited its admin access settings from its previous parent zone (as opposed to having specific access settings for the subzone) now receive their settings from its new parent zone, which might be different. See the following figure Changed Admin Access Settings after Reparenting Subzones.
  Changed Admin Access Settings after Reparenting Subzones



... the admin access settings for subzone C change because the privileges for its new parent zone (zone A) are different from those of its previous parent zone (zone B).

Before you remove zone B, subzone C inherits a "Deny" admin access setting from zone B. After the removal, subzone C inherits "Read/Write" access from its new parent zone, zone A.

Note that if you set a specific "Deny" admin access privilege for subzone C before removing its parent zone (zone B), subzone C retains its specified "Deny" setting.

… the admin access settings for subzone C change because the privileges for its new parent zone (zone A) are different from those of its previous parent zone (zone B).
Before you remove zone B, subzone C inherits a "Deny" admin access setting from zone B. After the removal, subzone C inherits "Read/Write" access from its new parent zone, zone A.
Note that if you set a specific "Deny" admin access privilege for subzone C before removing its parent zone (zone B), subzone C retains its specified "Deny" setting.

> **Note**
>
> Instead of removing a zone, you can also disable it. For more information, see *Enabling and Disabling Zones.*

To remove a zone:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab.
2. Click the checkbox of the zones you want to delete.
3. Click the Delete icon.
4. Select one of the following. Note that these options appear only if you are allowed to delete zones and all its contents. For information about how to configure this, see *Configuring Recursive Deletions of Networks and Zones.*
    - **Remove zone only:** Select this to remove the zone and all its content. The appliance reparents all subzones to the parent zone of the zone that you want to remove, except for the automatically created AD (Active Directory) subzones.
    - **Remove all subzones:** Select this to remove the selected zone, all its subzones, and all the resource records of the selected zone and its subzones.
5. Click **Yes**. Grid Manager displays a warning message. Click **Yes** to continue or **No** to cancel the process. Note that this process may take a longer time to complete depending on the size of the data.

You can also schedule the deletion for a later time. Click **Schedule Deletion** and in the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Deletions*. For information about scheduling recursive deletions of zones, see *Scheduling New IPAM/DHCP Objects and Associated Port Configurations*.

Restoring Zone Data

After you import or delete a zone, if you want the original zone back, you can restore it using the Recycle Bin. When you import a zone for the first time, the appliance saves the zone and its resource records as a single object in the Recycle Bin. It keeps the subzones with the zone. See Restoring Zone Data After a Zone Import Example below.
When you reimport data into a zone, the software saves the zones, its resource records, and the delegated subzones created by the previous import operation in the Recycle Bin. It keeps the subzones (not created during the zone import) with the zone. See Restoring Zone Data After a Zone Reimport Example below.
If the zone import succeeds, the system adds resource records from the source to the target zone. It also adds delegated subzones for the source subzones. If the zone import fails, the system does not create records and delegated subzones. In either case, you can retrieve the original zone and its subzones from the Recycle Bin as follows:

1. Delete the zone using the steps described in the section *Removing Zones.*
2. Select **Remove zone only** to remove the zone and its resource records. The NIOS appliance reparents all subzones to the parent zone of the zone that you remove. Do not select **Remove all subzones**.
   Automatically created AD (Active Directory) subzones are an exception. Even if you select **Remove zone only**, the NIOS appliance still removes AD subzones.
3. In the Finder panel, click **Recycle Bin**.
4. Select the zone you want to restore and click the Restore icon. Click **Yes** in the *Restore Item* dialog box to restore or **No** to cancel the process. Note that restoring a zone may take a longer time to complete depending on the size of the data.
   The zone is restored back to its original state. The resource records are reparented back under it.

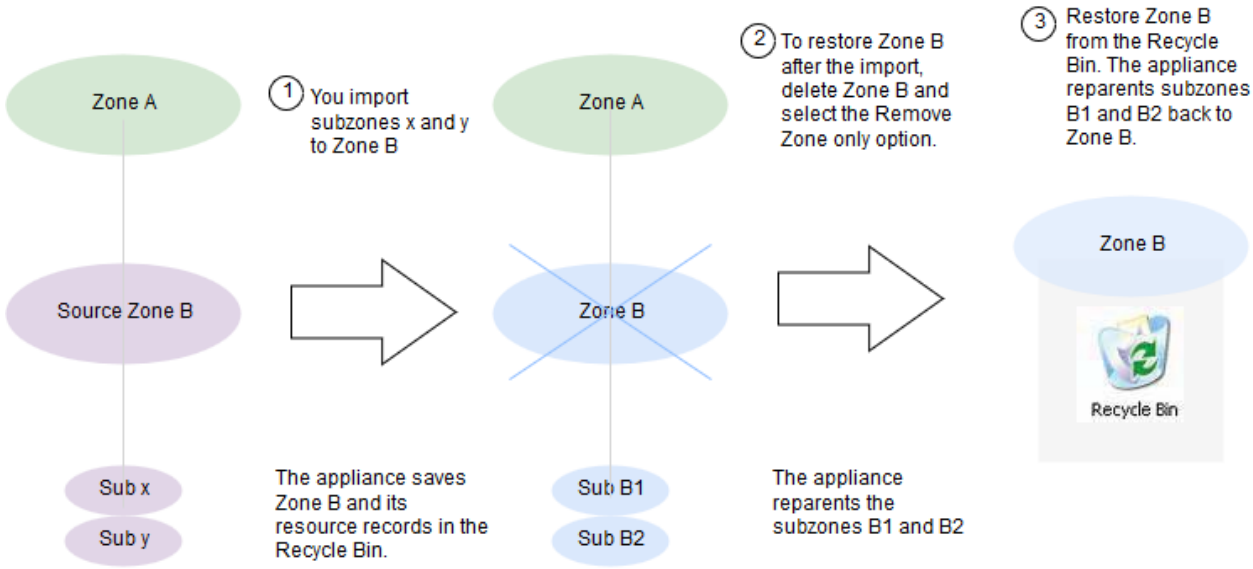
Restoring Zone Data After a Zone Import Example

In the example shown in the figure Restoring Zones After a Zone Import below:

1. Import data from a source zone with subzones Sub x and Sub y into zone B with subzones Sub B1 and Sub B2. The appliance stores zone B and its resource records in the Recycle Bin.
   To retrieve zone B after the import:
2. Delete subzone B using the **Remove zone only** option.
   The appliance reparents subzones Sub B1 and Sub B2 to the Zone A, which is the zone above Zone B.

3. After the import, you can restore zone B from the Recycle Bin. The appliance reparents the subzones Sub B1 and Sub B2 back to zone B.

Restoring Zones After a Zone Import

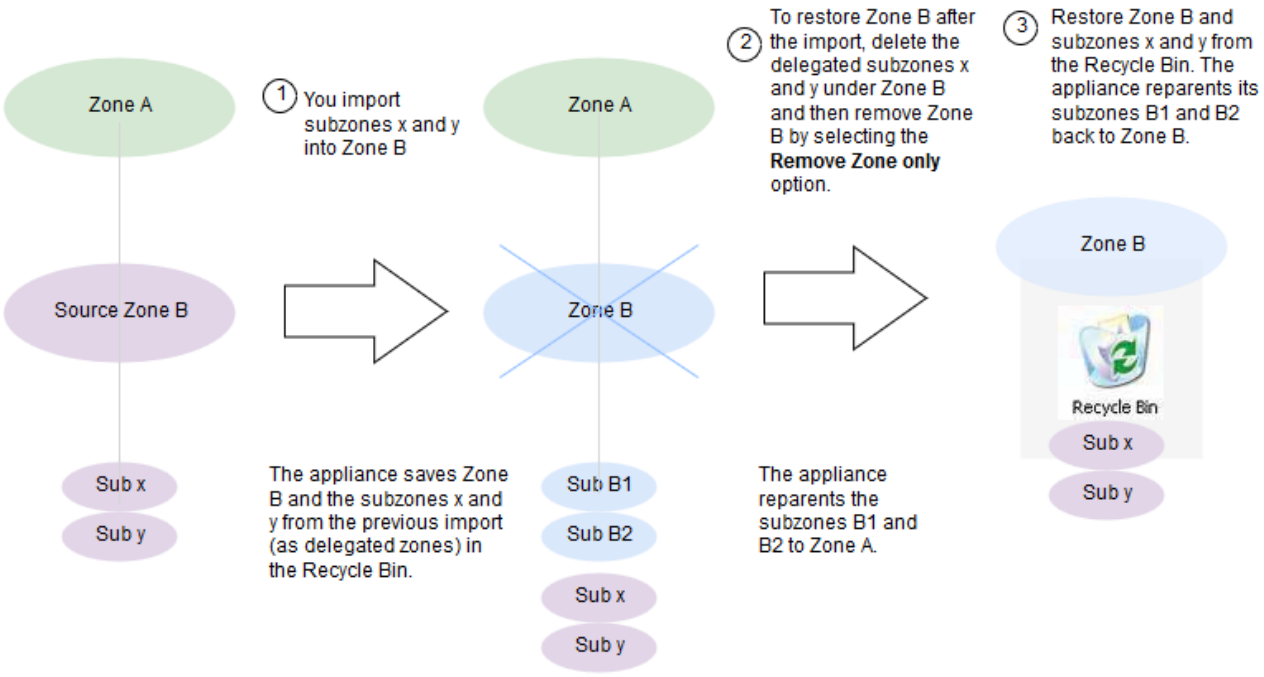


Restoring Zone Data After a Zone Reimport Example

In the example shown in the figure Restoring Zones After a Zone Reimport below:

1. You reimport data from the source zone with subzones Sub x and Sub y into zone B with subzones Sub B1 and Sub B2.
   To retrieve zone B after the import:
2. Delete the delegated subzones x and y and then remove subzone B using the **Remove zone only** option.
   The appliance stores zone B and its resource records and the previously-imported subzones Sub x and Sub y (as delegated subzones) in the Recycle Bin. It reparents subzones Sub B1 and Sub B2 to the zone above zone B (Zone A).
3. After the import, you can restore zone B and the subzones Sub x and Sub y from the Recycle Bin. The appliance reparents the subzones Sub B1 and Sub B2 back to zone B.

Restoring Zones After a Zone Reimport



Configuring Delegated, Forward, and Stub Zones

In addition to authoritative zones, the NIOS appliance allows you to configure delegated, forward, and stub zones. A delegated zone is a zone managed by (delegated to) another name server who owns the authority for the zone. A forward zone is where queries are sent before being forwarded to other remote name servers. A stub zone contains records that identify the authoritative name servers in another zone. This section covers the following topics:

- *Configuring a Delegation*
- *Configuring a Delegation for a Forward-Mapping Zone*
- *Configuring a Delegation for a Reverse-Mapping Zone*
- *Configuring a Forward Zone*
- *Configuring Stub Zones*
  - *Creating Stub Zones*
  - *Maintaining Stub Zones*
  - *Adding Stub Zones*
  - *Viewing and Modifying SOA Records*
  - *Configuration Example: Configuring a Stub Zone in a Grid*

Configuring a Delegation

Instead of a local name server, remote name servers (which the local server knows) maintain delegated zone data. When the local name server receives a query for a delegated zone, it either responds with the NS record for the delegated zone server (if recursion is disabled on the local server) or it queries the delegated zone server on behalf of the resolver (if recursion is enabled).

For example, there is a remote office with its own name servers, and you want it to manage its own local data. On the name server at the main corporate office, define the remote office zone as delegated, and then specify the remote office name servers as authorities for the zone.

You can delegate a zone to one or more remote name servers, which are typically the authoritative primary and secondary servers for the zone. If recursion is enabled on the local name server, it queries multiple delegated name servers based on their round-trip times. You can also add arpa as a top-level forward-mapping zone and delegate its subzones.

You can also configure TTL settings of auto-generated NS records and glue A and AAAA records for delegated zones in forward-mapping, IPv4 reverse-mapping, and IPv6 reverse-mapping zones. For information, see *Specifying Time To Live Settings*.

The delegation must exist within an authoritative zone with a Grid primary server.

Configuring a Delegation for a Forward-Mapping Zone

To create a delegation for a forward-mapping zone:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab.
2. Click the parent zone to open it.
   Grid Manager displays the **Records** and **Subzones** tabs of the zone.
3. From the **Subzones** tab, click the Add icon -> **Zone** -> **Add Delegation**.
4. In the *Add Delegation* wizard, specify the following:
   - **Name:** This field displays a dot followed by the domain name of the current zone. Enter one or more labels before the dot to specify the domain name of the subzone.
   - **DNS View:** This field displays only when there is more than one DNS view in the network view. Displays the DNS view of the current zone.
   - **Comment:** Optionally, enter additional text about the zone.
   - Disable: Click this checkbox to temporarily disable this zone. For information, see *Enabling and Disabling Zones*. Note that disabling a zone may take a longer time to complete depending on the size of the data.
   - **Lock**: Click this checkbox to lock the zone so that you can make changes to it, and also prevent others from making conflicting changes. For information, see *Locking and Unlocking Zones*.
5. Click **Next** to assign a delegation name server group or define the name servers for the zone. Select one of the following:
   - **Use this nameserver group**: Select this to assign a delegation NS group for the delegated zone. You can select the delegation NS group from the drop-down list.
   - **Use this set of nameservers**: Select this to define name servers for the delegated zone. In the *Name Servers* panel, click the Add icon and specify the following information**:**
     - **Name:** Enter the name of a remote name server to which you want the local server to redirect queries for zone data. This is a name server that is authoritative for the delegated zone.
     - **Address:** Enter the IP address of the delegated server.

   For information about delegation NS group, see *Using Delegation Name Server Groups*.
6. Save the configuration and click **Restart** if it appears at the top of the screen, or click **Next** to define extensible attributes as described in *Using Extensible Attributes*. or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

> ⚠ Note
> The DNS server resolves the FQDN of the delegated name server and does not use the IP address that you specify when assigning the delegated name servers.

Configuring a Delegation for a Reverse-Mapping Zone

To create a delegation for a reverse-mapping zone:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab.
2. Click the parent zone to open it.
   Grid Manager displays the **Records** and **Subzones** tabs of the zone.
3. From the **Subzones** tab, click the Add icon -> **Zone** -> **Add Delegation**.
4. In the *Add Delegation* wizard, specify the following:
   - **IPv4 Network:** This field displays if you are creating a delegation zone for an IPv4 reverse-mapping zone. Enter the IPv4 address for the address space for which you want to define the reverse-mapping zone and

select a netmask from the Netmask drop-down list. Alternatively, you can specify the address in CIDR format, such as 192/8.
- To use an RFC 2317 prefix, select a netmask value that is between 25 to 31, inclusive. Grid Manager displays the following fields:
- **RFC2317 Prefix:** Enter a prefix in this field. Prefixes can include alphanumeric characters.
- **Allow manual creation of PTR records in parent zone:** Select this checkbox to allow users to create labels that correspond to IP addresses in the delegated address space in the parent zone.
- For information about RFC 2317, see *Specifying an RFC 2317 Prefix.*
- **IPv6 Network Prefix:** This field displays if you are creating a delegation zone for an IPv6 reverse-mapping zone. Enter the IPv6 prefix for the address space for which you want to define the reverse-mapping zone and select the prefix length from the drop-down list.
- **Name:** This field displays a dot followed by the domain name of the current zone. Enter one or more labels before the dot to specify the domain name of the subzone.
- **DNS View:** This field displays only when there is more than one DNS view in the network view. Select a DNS view from the drop-down list.
- **Comment:** Optionally, enter additional text about the zone.
- **Disable:** Select this option to temporarily disable this zone. Note that disabling a zone may take a longer time to complete depending on the size of the data.
- **Lock:** Select this option to lock the zone so that you can make changes to it and prevent others from making conflicting changes.

5. Click **Next** to assign a delegation name server group or define the name servers for the zone. Select one of the following:
   - **Use this name server group**: Select this to assign a delegation NS group for the delegated zone. You can select the delegation NS group from the drop-down list.
   - **Use this set of name servers**: Select this to define name servers for the delegated zone. In the *Name Servers* panel, click the Add icon and specify the following information**:**
     - **Name:** Enter the name of a remote name server to which you want the local server to redirect queries for zone data. This is a name server that is authoritative for the delegated zone.
     - **Address:** Enter the IP address of the delegated server.

   For information about delegation NS groups, see *Using Delegation Name Server Groups.*
6. Save the configuration and click **Restart** if it appears at the top of the screen, or click **Next** to define extensible attributes as described in *Using Extensible Attributes.* or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

> ⚠ Note
> The DNS server resolves the FQDN of the delegated name server and does not use the IP address that you specify when assigning the delegated name servers.

Configuring a Forward Zone

When you want to forward queries for data in a particular zone, define the zone as a forward zone and specify one or more name servers that can resolve queries for the zone. You can also assign one or more external name servers as default forwarders for a forward zone. For example, define a forward zone so that the NIOS appliance forwards queries about a partner's internal site to a name server, which the partner hosts, configured just for other partners to access.

You can override the default forwarders for a forward-mapping zone at a Grid member level and configure custom forwarders. In other words, each Grid member can have its own forwarders for the forward zone. For example: a forward-mapping zone foo.com served by two Grid members M1 and M2 with M1 forwarding queries to 10.1.0.1 and 10.1.0.2 and M2 forwarding queries to 90.3.3.3 and 90.4.4.1. Note that the Grid member uses the default forwarders unless you override them at any level. For more information about domains and zones, see *Configuring Authoritative Zone Properties.*

Note
The use of a forward zone is different from that of a forwarder. (A forwarder is a name server that performs recursive lookups on behalf of the name servers that forward queries to it. For more information, see *Using Forwarders*.) A NIOS appliance forwards queries to the name server of a forward zone because the name server can resolve queries for the zone. A NIOS appliance forwards queries to a forwarder regardless of zones.

The NIOS appliance automatically generates a name server record in the parent authoritative zone when a subdomain associated with the parent is conditionally forwarded. For example, consider that you configure the following within a single DNS view:

- An authoritative zone *parent.tld* where Grid member is the default primary.
- A subdomain *subdomain.parent.tld*, which is a conditional forwarding zone, and forwards queries to the *ns1.abczone.tld* zone with the IP address *1.2.3.4*.

NIOS automatically creates an *RDATA ns1.abczone.tld* name server record for *subdomain.parent.tld* in the *parent.tld* authoritative zone. You can however disable the generation of name server records and the NIOS appliance deletes all the existing name server records from the parent zone.

Note that a name server can have only one definition for a zone in any given DNS view; a forward zone cannot be configured on a member that already has a zone with the same domain name configured on it in the same DNS view. To configure a forward-mapping zone:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Zone** -> **Add Forward Zone**.
2. In the *Add Forward Zone* wizard, click **Add a forward forward-mapping zone** and click **Next**.
3. Enter the following information, and then click **Next**:
    - **Name:** Enter the domain name of the zone for which you want the NIOS appliance to forward queries.
    - **DNS View:** This field displays only when there is more than one DNS view in the current network view. Select the DNS view of the forward zone.
    - **Comment:** Enter a descriptive comment.
    - **Disable**: Click this checkbox to temporarily disable this zone. Note that disabling a zone may take a longer time to complete depending on the size of the data.
    - **Lock**: Click this checkbox to lock the zone so that you can make changes to it and prevent others from making conflicting changes.
4. Click **Next** to assign a forward/stub server name server group or define the default zone forwarders to which the NIOS appliance forwards queries for the zone. Select one of the following:
    a. Select **Use this name server group** to assign a forward/stub server NS group for the zone. You can select the forward/stub server NS group from the drop-down list. For information about forward/stub server NS groups, see *Using Forward/Stub Server Name Server Groups*.
    b. Select **Use this set of name servers** to specify the default servers for the zone. Click the Add icon and specify the following:
        - **Name:** Enter a domain name of the server to which you want the NIOS appliance to forward queries.
        - **Address:** Enter the IP address of the server to which you want the NIOS appliance to forward queries.
    c. Select **Disable auto-generation of NS records in parent authoritative zone** to disable generation of name server records in a parent authoritative zone that has a subzone, which is conditionally forwarded. The NIOS appliance will not generate name server records and deletes the existing records from the parent authoritative zone when you select the checkbox. Note that the checkbox is clear, by default, which means that the NIOS appliance automatically generates name server records in a parent authoritative zone.
    d. Select **Use Forwarders Only** if you want the NIOS appliance to query forwarders only (not root servers) to resolve domain names in the zone.
5. Click **Next** to assign a forwarding member name server group or define Grid members to serve the forward-mapping zone. Select one of the following:
    Note that if you do not define any Grid members to serve the forward-mapping zone, then the named.conf file will not contain the configuration of the newly created forward zone. Hence, the Infoblox DNS server will not be authoritative to the forward zone and by default, the Infoblox DNS server will query the root servers to resolve queries for the forward zone.

a. Select **Use this name server group** to assign a forwarding member NS group for the zone. You can select the forwarding member NS group from the drop-down list. For information about forwarding member NS groups, see *Using Forwarding Member Name Server Groups*.
b. Select **Use this set of name servers** to define the Grid members and use the default forwarders or you can override default forwarders and configure custom forwarders. Click the Add icon to select the NIOS appliance on which the forward zone is configured. For an independent deployment, select the local appliance (it is the only choice). If there are multiple Grid members, the *Member Selector* dialog box is displayed. Select the required member by clicking the member name.
The following is displayed for each Grid member:
   - **Name**: Displays the name of the Grid member.
   - **IPv4 Address**: Displays the IPv4 address of the Grid member.
   - **IPv6 Address**: Displays the IPv6 address of the Grid member.
   - **Override Default Forwarders**: Displays **Yes** when you override default forwarders. Otherwise, this field displays **No**.
   - **Custom Forwarders**: Displays the IP address of the custom forwarders. Otherwise, this field is blank.
   Note to skip the following two steps if you want to use the default forwarders.

6. Select a member and click the Edit icon.
7. In the *Edit Per-Member Forwarders* editor, select the **Override Default Forwarders** checkbox to override the default forwarders. The Default Zone Forwarders table becomes available only after you select the **Override Default Forwarders** checkbox. Click the Add icon to specify the servers to which the NIOS appliance forwards queries for the zone:
   - **Name:** Enter a domain name for the server to which you want the NIOS appliance to forward queries for the specified domain name.
   - **Address:** Enter the IP address of the server to which you want the NIOS appliance to forward queries.
   - Select **Use Forwarders Only** if you want the NIOS appliance to query forwarders only (not root servers) to resolve domain names in the zone.
   - Save the configuration. After successfully saving the configuration, the **Override Default Forwarders** column displays **Yes** and the **Custom Forwarders** column displays the IP address of the forwarders.
   To configure forwarders for multiple members, repeat the steps for each Grid member.
8. Save the configuration, or click **Next** to continue to the next step where you define extensible attributes as described in *Using Extensible Attributes,* and then optionally proceed to the next step where you define admin permissions as defined in *About Administrative Permissions*.
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.
9. Click **Restart** if it appears at the top of the screen.

To configure a forward IPv4 reverse-mapping zone:

1. From the **Data Management** tab, select the **Zones** tab, expand the Toolbar and click **Add** -> **Zone** -> **Add Forward Zone**.
2. In the *Add Forward Zone* wizard, click **Add a forward IPv4 reverse-mapping zone** and click **Next**.
3. Enter the following information, and then click **Next**:
   a. **IPv4 Network:** Enter the IPv4 address for the address space for which you want to define the reverse-mapping zone and select a netmask from the **Netmask** drop-down list. Alternatively, you can specify the address in CIDR format, such as 192/8.
   To use an RFC 2317 prefix, select a netmask value that is between 25 to 31, inclusive. Grid Manager displays the **RFC 2317 Prefix** field. Enter a prefix in the text field. Prefixes can be alphanumeric characters. For information, see *Specifying an RFC 2317 Prefix*.
   or
   Name: Enter the domain name of the reverse-mapping zone.
   b. **DNS View:** This field displays only when there is more than one DNS view in the network view. Select a DNS view from the drop-down list.
   c. **Comment:** Optionally, enter additional information about the zone.
   d. **Disable:** Click this checkbox to temporarily disable this zone. Note that disabling a zone may take a longer time to complete depending on the size of the data.
   e. **Lock**: Click this checkbox to lock the zone so that you can make changes to it, and also prevent others from making conflicting changes.

4. Click **Next** to assign a forward/stub server name server group or define the default zone forwarders to which the NIOS appliance forwards queries for the zone. Select one of the following:
    - Select **Use this name server group** to assign a forward/stub server NS group for the zone. You can select the forward/stub server NS group from the drop-down list. For information about forward/stub NS groups, see *Using Forward/Stub Server Name Server Groups*.
    - Select **Use this set of name servers** to specify the default servers for the zone. Click the Add icon and specify the following:
        - **Name:** Enter a domain name for the server to which you want the NIOS appliance to forward queries.
        - **Address:** Enter the IP address of the server to which you want the NIOS appliance to forward queries.
        - Select **Use Forwarders Only** if you want the NIOS appliance to query forwarders only (not root servers) to resolve domain names in the zone.
5. Click **Next** to assign a forwarding member name server group or define Grid members to serve the forward-mapping zone. Select one of the following:
    - Select **Use this name server group** to assign a forwarding member NS group for the zone. You can select the forwarding member NS group from the drop-down list. For information about forwarding member NS groups, see *Using Forwarding Member Name Server Groups*.
    - Select **Use this set of name servers** to define the Grid members and use the default forwarders or you can override default forwarders and configure custom forwarders. Click the Add icon to select the NIOS appliance on which the forward zone is configured. For an independent deployment, select the local appliance (it is the only choice). If there are multiple Grid members, the *Member Selector* dialog box is displayed. Select the required member by clicking the member name.
      The following is displayed for each Grid member:
        - **Name**: Displays the name of the Grid member.
        - **IPv4 Address**: Displays the IPv4 address of the Grid member.
        - **IPv6 Address**: Displays the IPv6 address of the Grid member.
        - **Override Default Forwarders**: Displays **Yes** when you override default forwarders. Otherwise, this field displays **No**.
        - **Custom Forwarders**: Displays the IP address of the custom forwarders. Otherwise, this field is blank.
          Note to skip the following two steps if you want to use the default forwarders.
6. Select a member and click the Edit icon.
7. In the *Edit Per-Member Forwarders* editor, select the **Override Default Forwarders** checkbox to override the default forwarders. The Default Zone Forwarders table becomes available only after you select the **Override Default Forwarders** checkbox. Click the Add icon to specify the servers to which the NIOS appliance forwards queries for the zone:
    a. **Name:** Enter a domain name for the server to which you want the NIOS appliance to forward queries for the specified domain name.
    b. **Address:** Enter the IP address of the server to which you want the NIOS appliance to forward queries.
    c. Select **Use Forwarders Only** if you want the NIOS appliance to query forwarders only (not root servers) to resolve domain names in the zone.
    d. Save the configuration. After successfully saving the configuration, the **Override Default Forwarders** column displays **Yes** and the **Custom Forwarders** column displays the IP address of the forwarders.
    To configure forwarders for multiple members, repeat the steps for each Grid member.
8. Save the configuration, or click **Next** to continue to the next step where you define extensible attributes as described in *Using Extensible Attributes.*
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.
9. Click **Restart** if it appears at the top of the screen.

To configure a forward IPv6 reverse-mapping zone:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Zone** -> **Add Forward Zone**.
2. In the *Add Forward Zone* wizard, click **Add a forward IPv6 reverse-mapping zone** and click **Next**.
3. Enter the following zone information:

- **IPv6 Network Address:** Enter the 128-bit IPv6 address for the address space for which you want to define the reverse-mapping zone. When you enter an IPv6 address, you can use double colons to compress a contiguous sequence of zeros. You can also omit any leading zeros in a four-hexadecimal group. For example, the complete IPv6 address 2006:0000:0000:0123:4567:89ab:0000:cdef can be shortened to 2006::123:4567:89ab:0:cdef. Note that if there are multiple noncontiguous groups of zeros, the double colon can only be used for one group to avoid ambiguity. The NIOS appliance displays an IPv6 address in its shortened form, regardless of its form when it was entered. Choose the network prefix that defines the IPv6 network address space.
  or
  Name: Enter the domain name of the reverse-mapping zone.
- **DNS View:** This field displays only when there is more than one DNS view in the network view. Select a DNS view from the drop-down list.
- **Comment:** Enter a descriptive comment about the zone.
- **Disable:** Click this checkbox to temporarily disable this zone. Note that disabling a zone may take a longer time to complete depending on the size of the data.
- **Lock**: Click this checkbox to lock the zone so that you can make changes to it, and also prevent others making conflicting changes.

4. Click **Next** to assign a forward/stub server name server group or define the default zone forwarders to which the NIOS appliance forwards queries for the zone. Select one of the following:
   - Select **Use this name server group** to assign a forward/stub server NS group for the zone. You can select the forward/stub server NS group from the drop-down list. For information about forward/stub NS groups, see *Using Forward/Stub Server Name Server Groups*.
   - Select **Use this set of name servers** to specify the default servers for the zone. Click the Add icon and specify the following:
     - **Name:** Enter a domain name for the server to which you want the NIOS appliance to forward queries.
     - **Address:** Enter the IP address of the server to which you want the NIOS appliance to forward queries.
     - Select **Use Forwarders Only** if you want the NIOS appliance to query forwarders only (not root servers) to resolve domain names in the zone.
5. Click **Next** to assign a forwarding member name server group or define Grid members to serve the forward-mapping zone. Select one of the following:
   - Select **Use this name server group** to assign a forwarding member NS group for the zone. You can select the forwarding member NS group from the drop-down list. For information about forwarding member NS groups, see *Using Forwarding Member Name Server Groups*.
   - Select **Use this set of name servers** to define the Grid members and use the default forwarders or you can override default forwarders and configure custom forwarders. Click the Add icon to select the NIOS appliance on which the forward zone is configured. For an independent deployment, select the local appliance (it is the only choice). If there are multiple Grid members, the *Member Selector* dialog box is displayed. Select the required member by clicking the member name.
     The following is displayed for each Grid member:
     - **Name**: Displays the name of the Grid member.
     - **IPv4 Address**: Displays the IPv4 address of the Grid member.
     - **IPv6 Address**: Displays the IPv6 address of the Grid member.
     - **Override Default Forwarders**: Displays **Yes** when you override default forwarders. Otherwise, this field displays **No**.
     - **Custom Forwarders**: Displays the IP address of the custom forwarders. Otherwise, this field is blank.

Configuring Stub Zones

A stub zone contains records that identify the authoritative name servers in the zone. It does not contain resource records for resolving IP addresses to hosts in the zone. Instead, it contains the following records:

- SOA (Start of Authority) record of the zone
- NS (name server) records at the apex of the stub zone
- A (Address) records that map the name servers to their IP addresses

Stub zones, like secondary zones, obtain their records from other name servers. Their records are read only; therefore, administrators do not manually add, remove, or modify the records.

Stub zone records are also periodically refreshed, just like secondary zone records. However, secondary name servers contain a complete copy of the zone data on the primary server. Therefore, zone transfers from a primary server to a secondary server, or between secondary servers, can increase CPU usage and consume excessive bandwidth. A name server hosting a stub zone maintains a much smaller set of records; therefore, updates are less CPU intensive and consume less bandwidth.

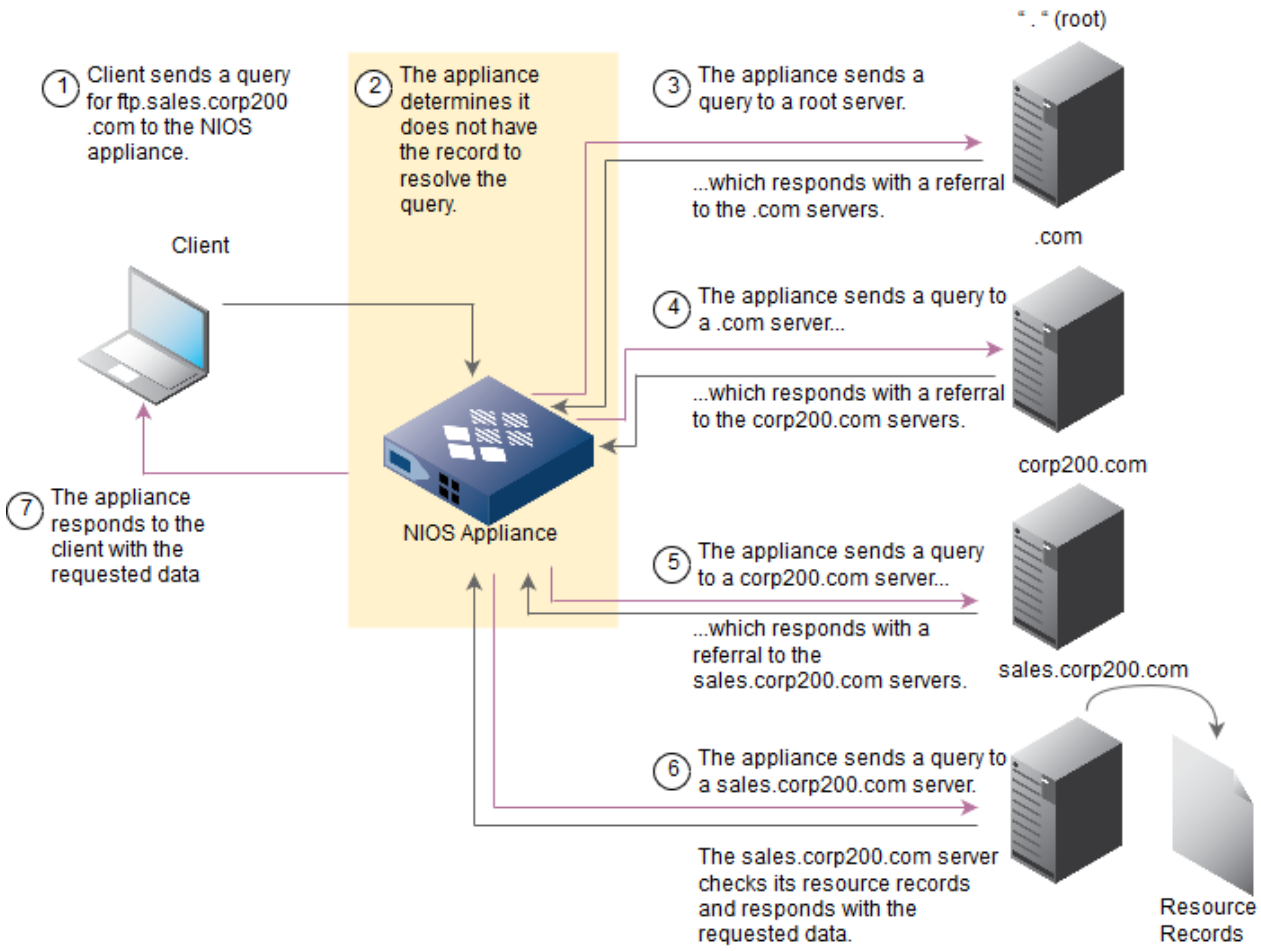
When a name server hosting a stub zone receives a query for a domain name that it determines is in the stub zone, the name server uses the records in the stub zone to locate the correct name server to query, eliminating the need to query the root server.

The figures Processing a Query without a Stub Zone and Processing a Query with a Stub Zone below illustrate how the NIOS appliance resolves a query for a domain name for which it is not authoritative. The following figure illustrates how the appliance resolves a query when it does not have a stub zone.

The figure *Processing a Query with a Stub Zone* illustrates how the appliance resolves the query with a stub zone.

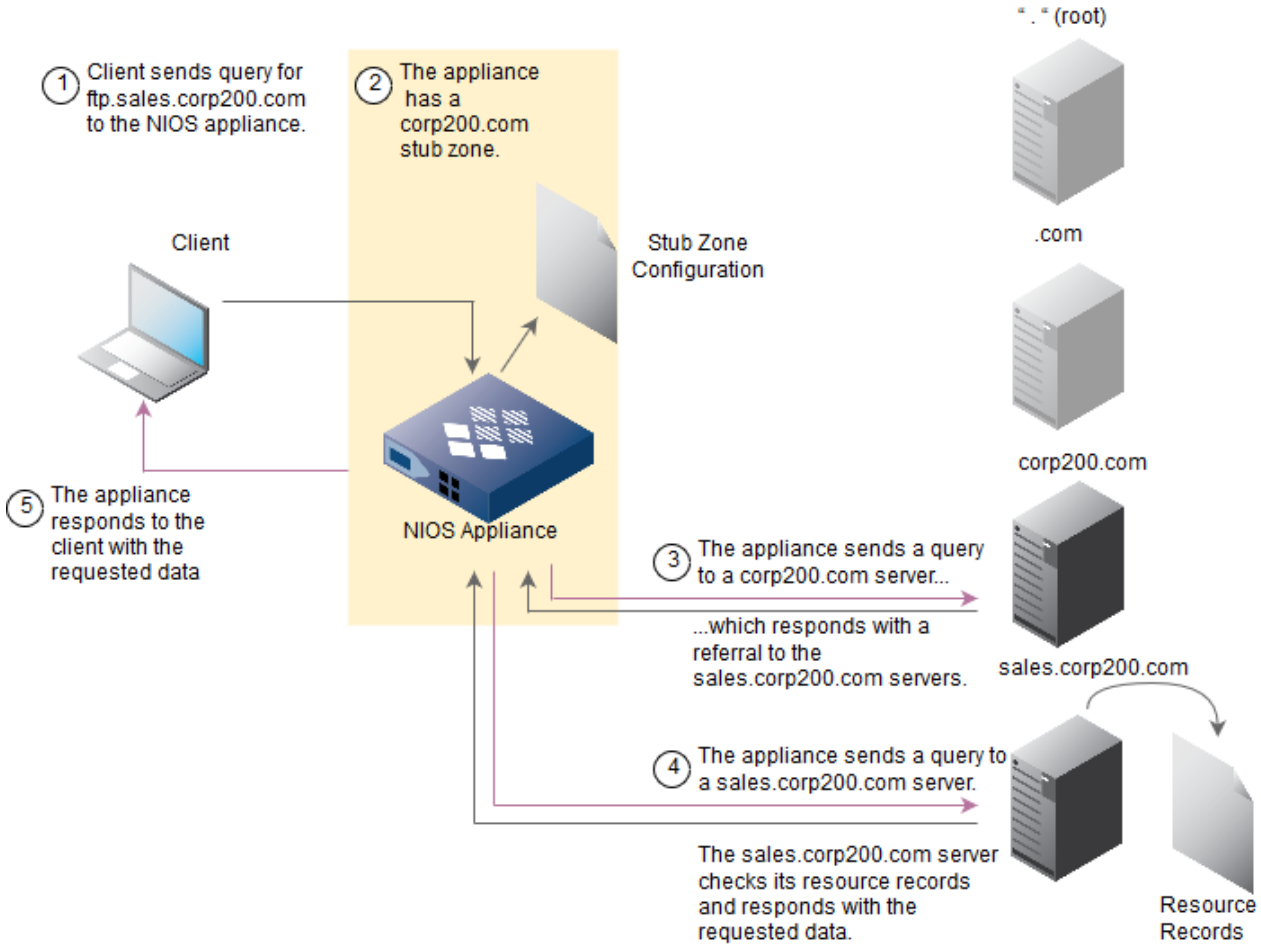
In the figure Processing a Query without a Stub Zone, a client sends a query for ftp.sales.corp200.com to the NIOS appliance. When the appliance receives the request from the client, it checks if it has the data to resolve the query. If the appliance does not have the data, it tries to locate the authoritative name server for the requested domain name. It sends nonrecursive queries to a root name server and to the closest known name servers until it learns the correct authoritative name server to query.

Processing a Query without a Stub Zone



In the following figure Processing a Query with a Stub Zone, when the NIOS appliance receives the request for the domain name in corp200.com, it determines it does not have the resource records to resolve the query. It does, however, have a list of the authoritative name servers in the stub zone, corp200.com. The appliance then sends a query directly to the name server in corp200.com.

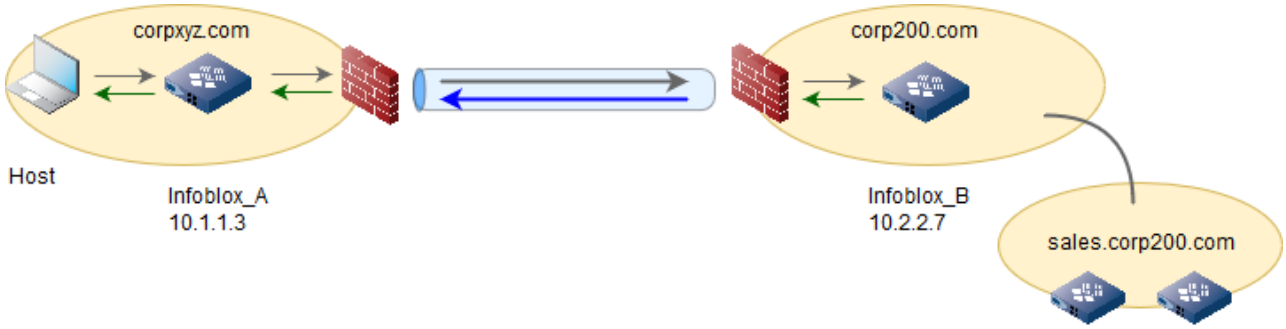
Processing a Query with a Stub Zone



Stub zones facilitate name resolution and alleviate name server traffic in your network. For example, the client in the previous examples is in corpxyz.com. The corpxyz.com and corp200.com zones are partners, and send all their communications through a VPN tunnel, as shown in the figure Stub Zone Configuration above. The firewall protecting corpxyz.com is configured to send all messages for the 10.2.2.0/24 network through the VPN tunnel. Infoblox_A hosts the stub zone for corp200.com. Therefore, when the host in corpxyz.com sends a query for ftp.sales.corp200.com, Infoblox_A obtains the IP address of Infoblox_B (10.2.2.7) from its stub zone records and sends the query to the firewall protecting corpxyz.com.

Because the destination of the query is in the 10.2.2.0/24 network, the firewall (configured to encrypt all traffic to the network) sends the request through a VPN tunnel to Infoblox_B. Infoblox_B resolves the query and sends back the response through the VPN tunnel. All name server traffic went through the VPN tunnel to the internal servers, bypassing the root servers and external name servers.

Stub Zone Configuration



In parent-child zone configurations, using stub zones also eases the administration of name servers in both zones. For example, as shown in figure Stub Zone Configuration above, sales.corp200.com is a child zone of corp200.com. On the corp200.com name servers, you can create either a delegated zone or a stub zone for sales.corp200.com.

When you create a delegated zone, you must first specify the name servers in the delegated zone and manually maintain information about these name servers. For example, if the administrator in sales.corp200.com changes the IP address of a name server or adds a new name server, the sales.corpxyz.com administrator must inform the corp200.com administrator to make the corresponding changes in the delegated zone records.

If, instead, you create a stub zone for sales.corp200.com, you set up the stub zone records once, and updates are then done automatically. The name servers in corp200.com that are hosting a stub zone for sales.corp200.com automatically obtain updates of the authoritative name servers in the child zone.

In addition, a name server that hosts a stub zone can cache the responses it receives. Therefore, when it receives a request for the same resource record, it can respond without querying another name server.

Creating Stub Zones

When you create a stub zone on the NIOS appliance, you specify the following:

- The Grid member that is hosting the stub zone.
  You can specify multiple appliances if you want the stub zones on multiple name servers. If you do, the appliances store identical records about the stub zone. You can also specify a stub member NS group for the zone. For information on specifying a stub member NS group, see *Using Stub Member Name Server Groups.*
- The IP address of the primary server(s) that the NIOS appliance can query in the stub zone.

The primary server can be a Grid member or an external primary server. If you specify multiple primary servers, the appliance queries the primary servers, starting with the first server on the list. You can also specify a forward/stub server NS group for the zone. For information on specifying a forward/stub server NS group, see *Using Forward/Stub Server Name Server Groups*.

The primary server and the name server hosting the stub zone can belong to the same Grid, as long as the authoritative zone and the stub zone are in different DNS views. You cannot configure one zone as both authoritative and stub in the same view.

After you create a stub zone, the NIOS appliance does the following:

1. It sends a query to the primary server for the SOA (Start of Authority) record of the stub zone. The primary server returns the SOA record.
2. Then, it sends a query for the NS (name server) records in the zone.
   The primary server returns the NS records and the A (address) records of the name servers. (These A records are also called glue records.)
   If the primary server is a NIOS appliance, you might have to manually create the A record and add it to the stub zone. A NIOS appliance that is the primary server for a zone always creates an NS record, but does not always create an A record.

- The appliance automatically creates an A record when its host name belongs to the name space of the zone. For example, if the zone is corpxyz.com and the primary server host name is server1.corpxyz.com, the appliance automatically creates the NS and A records and sends these records when it is queried by the stub zone name server.
- The appliance does not automatically create an A record when its host name is in a name space that is different from the zone. For example, if the zone is corp200.com and the primary server host name is server1.corpxyz.com, then the appliance creates the NS record only and sends it when it is queried by the stub zone name server. In this case, you must manually create the A record.

Maintaining Stub Zones

The NIOS appliance maintains the stub zone records and updates them based on the values in the SOA record as follows:

- The refresh interval indicates when the appliance sends a discrete query to the primary name server for the stub zone. The appliance learns about any changes in the stub zone and updates the NS and A records in the stub zone accordingly.
- If the update fails, the retry interval indicates when the appliance resends a discrete query.
- If the query continues to fail, the expiry value indicates when the appliance stops using the zone data.

Adding Stub Zones

To add a stub zone, you must identify the Infoblox appliance that hosts the stub zone, and provide the IP address of the primary server.

You can also add stub zones for Microsoft servers that are managed by Grid members. For information, see *Managing Microsoft Windows Servers*.

You can configure a stub zone for forward mapping or reverse mapping zones.

To add a forward-mapping stub zone:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Zone** -> **Add Stub Zone**.
2. In the *Add Stub Zone* wizard, click **Add a stub forward-mapping zone** and click **Next**.
3. Specify the following, and then click **Next**:
    - **Name:** Enter the name for the stub zone.
    - **Comment:** Enter a useful comment, such as the admin to contact for the stub zone.
    - **Disable:** Click this checkbox to temporarily disable this zone. Note that disabling a zone may take a longer time to complete depending on the size of the data.
    - **Lock**: Click this checkbox to lock the zone so that you can make changes to it, and also prevent others from making conflicting changes.
4. Click **Next** to define primary servers in the stub zone. You can specify a forward/stub server NS group or define the servers individually. Select one of the following:
    - Select **Use this name server group** to assign a forward/stub server NS group for the stub zone. You can select the forward/stub server NS group from the drop-down list. For information about forward/stub server NS groups, see *Using Forward/Stub Server Name Server Groups*.
    - Select **Use this set of name servers** to define primary servers for the stub zone. Click the Add icon and enter the **Name** and **IP Address** of the primary server in the stub zone.
      If the primary server is a Grid member, you must enter the host name and IP address of the Grid member. The NIOS appliance does not validate these entries. Therefore, if you change the IP address of a Grid member listed here, you must update the Grid member information in this list as well.
      You can specify multiple primary servers for redundancy. If the primary server is a NIOS appliance, the appliance must have the Minimal Response feature disabled so it can propagate the data to the stub server. For information about the Minimal Response feature, see *Specifying Minimal Responses*.
      Optionally, click the **Don't use forwarders to resolve queries in subzones** checkbox to indicate that the name servers hosting the stub zone must not use forwarders to resolve queries for domain names in the stub zone or in its subzones.

5. Click **Next** to specify a stub member NS group or define the name servers individually to serve the forward-mapping stub zone. Select one of the following:
    - Select **Use this name server group** to assign a stub member NS group for the zone. You can select the stub member NS group from the drop-down list. For information about stub member NS group, see *Using Stub Member Name Server Groups*.
    - Select **Use this set of name servers** to define the servers individually. Click the Add icon and select one of the following:
        - **Add Infoblox Member**: Select this and select the Grid member that hosts the stub zone.
        - **Add Microsoft Server**: Select this and select the Microsoft server that hosts the stub zone. The following is displayed for each name server:
        - **Name**: Displays the name of the name server.
        - **IPv4 Address**: Displays the IPv4 address of the name server.
        - **IPv6 Address**: Displays the IPv6 address of the name server.
6. Click **Next** to continue to the next step where you define extensible attributes as described in *Using Extensible Attributes*.
7. Save the configuration and click **Restart** if it appears at the top of the screen
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

You can define two types of reverse-mapping stub zones, one for IPv4 addresses and one for IPv6 addresses. To configure an IPv4 reverse-mapping stub zone:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Zone** -> **Add Stub Zone**.
2. In the *Add Stub Zone* wizard, click **Add a stub IPv4 reverse-mapping zone** and click **Next**.
3. Specify the following:
    - **IPv4 Network:** Enter the IPv4 address for the address space for which you want to define the
    - reverse-mapping zone and select a netmask from the **Netmask** drop-down list. Alternatively, you can specify the address in CIDR format, such as 192/8.
    - To use an RFC 2317 prefix, select a netmask value that is between 25 to 31, inclusive. Grid Manager displays the **RFC 2317 Prefix** field. Enter a prefix in the text field. Prefixes can be alphanumeric characters. For information, see *Specifying an RFC 2317 Prefix*.
      or
    - **Name:** Enter the domain name of the reverse-mapping zone.
    - **DNS View:** This field displays only when there is more than one DNS view in the network view. Select a DNS view from the drop-down list.
    - **Comment:** Optionally, enter additional information about the zone.
    - **Disable:** Click this checkbox to temporarily disable this zone. Note that disabling a zone may take a longer time to complete depending on the size of the data.
    - **Lock**: Click this checkbox to lock the zone so that you can make changes to it, and also prevent others from making conflicting changes.
4. Click **Next** to define primary servers in the stub zone. You can specify a forward/stub server NS group or define the servers individually. Select one of the following:
    - Select **Use this name server group** to assign a forward/stub server NS group for the stub zone. You can select the forward/stub server NS group from the drop-down list. For information about forward/stub server NS group, see *Using Forward/Stub Server Name Server Groups*.
    - Select **Use this set of name servers** to define primary servers for the stub zone. Click the Add icon and enter the **Name** and **IP Address** of the primary server in the stub zone.
      If the primary server is a Grid member, you must enter the host name and IP address of the Grid member. The NIOS appliance does not validate these entries. Therefore, if you change the IP address of a Grid member listed here, you must update the Grid member information in this list as well.
      You can specify multiple primary servers for redundancy. If the primary server is a NIOS appliance, the appliance must have the Minimal Response feature disabled so it can propagate the data to the stub server. For information about the Minimal Response feature, see *Specifying Minimal Responses*.
      Optionally, click the **Don't use forwarders to resolve queries in subzones** checkbox to indicate that the name servers hosting the stub zone should not forward queries that end with the domain name of the stub zone to any configured forwarders.

5. Click **Next** to specify a stub member NS group or define the name servers individually to serve the reverse-mapping stub zone. Select one of the following:
    - Select **Use this name server group** to assign a stub member NS group for the zone. You can select the forward/stub server NS group from the drop-down list. For information about stub member NS group, see *Using Stub Member Name Server Groups*.
    - Select **Use this set of name servers** to define the servers individually. Click the Add icon and select one of the following:
        - **Add Infoblox Member**: Select this and select the Grid member that hosts the stub zone.
        - **Add Microsoft Server**: Select this and select the Microsoft server that hosts the stub zone. The following is displayed for each name server:
        - **Name**: Displays the name of the name server.
        - **IPv4 Address**: Displays the IPv4 address of the name server.
        - **IPv6 Address**: Displays the IPv6 address of the name server.
6. Click **Next** to continue to the next step where you define extensible attributes as described in *Using Extensible Attributes*.
7. Save the configuration and click **Restart** if it appears at the top of the screen
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

To configure an IPv6 reverse-mapping stub zone:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Zone** -> **Add Stub Zone**.
2. In the *Add Stub Zone* wizard, click **Add a stub IPv6 reverse-mapping zone** and click **Next**.
3. Specify the following:
    - **IPv6 Network Prefix** and **Prefix Length:** Enter the 128-bit IPv6 address for the address space for which you want to define the reverse-mapping zone. When you enter an IPv6 address, you can use double colons to compress a contiguous sequence of zeros. You can also omit any leading zeros in a four-hexadecimal group. For example, the complete IPv6 address 2006:0000:0000:0123:4567:89ab:0000:cdef can be shortened to 2006::123:4567:89ab:0:cdef. Note that if there are multiple noncontiguous groups of zeros, the double colon can only be used for one group to avoid ambiguity. The NIOS appliance displays an IPv6 address in its shortened form, regardless of its form when it was entered. You can enter a slash and prefix length in the IPv6 Network Prefix field or you can choose a value from the Prefix Length drop-down list.
      or
    - **Name:** Enter the domain name of the reverse-mapping zone.
    - **DNS View:** This field displays only when there is more than one DNS view in the current network view. Select a DNS view from the drop-down list.
    - **Comment:** Enter a descriptive comment about the zone.
    - **Disable:** Click this checkbox to temporarily disable this zone. Note that disabling a zone may take a longer time to complete depending on the size of the data.
    - **Lock**: Click this checkbox to lock the zone so that you can make changes to it and prevent others from making conflicting changes.
4. Click **Next** to define primary servers in the stub zone. You can specify a forward/stub server NS group or define the servers individually. Select one of the following:
    - Select **Use this name server group** to assign a forward/stub server NS group for the stub zone. You can select the forward/stub server NS group from the drop-down list. For information about forward/stub server NS group, see *Using Forward/Stub Server Name Server Groups*.
    - Select **Use this set of name servers** to define primary servers for the stub zone. Click the Add icon and enter the **Name** and **IP Address** of the primary server in the stub zone.
      If the primary server is a Grid member, you must enter the host name and IP address of the Grid member. The NIOS appliance does not validate these entries. Therefore, if you change the IP address of a Grid member listed here, you must update the Grid member information in this list as well.
      You can specify multiple primary servers for redundancy. If the primary server is a NIOS appliance, the appliance must have the Minimal Response feature disabled so it can propagate the data to the stub server. For information about the Minimal Response feature, see *Specifying Minimal Responses*.
      Optionally, click the **Don't use forwarders to resolve queries in subzones** checkbox to indicate that the

name servers hosting the stub zone should not forward queries that end with the domain name of the stub zone to any configured forwarders.

5. Click **Next** to specify a stub member NS group or define the name servers individually to serve the reverse-mapping stub zone. Select one of the following:
   - Select **Use this name server group** to assign a stub member NS group for the zone. You can select the stub member NS group from the drop-down list. For information about stub member NS group, see *Using Stub Member Name Server Groups*.
   - Select **Use this set of name servers** to define the servers individually. Click the Add icon and select one of the following:
     - **Add Infoblox Member**: Select this and select the Grid member that hosts the stub zone.
     - **Add Microsoft Server**: Select this and select the Microsoft server that hosts the stub zone.
     The following is displayed for each name server:
     - **Name**: Displays the name of the name server.
     - **IPv4 Address**: Displays the IPv4 address of the name server.
     - **IPv6 Address**: Displays the IPv6 address of the name server.
6. Click **Next** to continue to the next step where you define extensible attributes as described in *Using Extensible Attributes*.
7. Save the configuration and click **Restart** if it appears at the top of the screen
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Viewing and Modifying SOA Records

The timer values in the SOA record determine when the zone data is updated. The MNAME field and the RNAME field of the SOA record display the FQDN of the primary server and the administrative email address respectively. You can view these default values and override them when necessary. For a zone that has multiple primary servers, Grid Manager displays all configured primaries for the zone. You can click **Override** to override the Grid-level settings. If the primary server is a Microsoft server however, the **Override** option does not appear. You can only change certain values in the SOA record.

To view and modify zone SOA record values:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and then click the Edit icon.
2. In the *Authoritative Zone* or *Stub Zone* editor, click the **Settings** tab to view the following values. You can also click **Override** to modify some of the values.
   - **Serial number**: The current serial number for the primary server. This number is automatically increased when changes are made to the zone or its record. The serial number plays a key role in determining when and whether zone data is updated. You can change the serial number only if the primary server of the zone is a Grid member. When the zone has multiple primary servers, each primary can have its own serial number. In this case, the serial number displayed here is always that of the Grid Master, which will also appear in the primary name server list if it is one of the primaries for the zone.
     Note that if you change the serial number of the Grid Master, serial numbers for all primaries will be changed to the same number. A warning is displayed when you try to decrement the serial number.
   - **Refresh:** This interval tells secondary servers how often to send a message to the primary server for a zone to check that their data is current, and retrieve fresh data if it is not. The default is three hours.
   - **Retry:** This interval tells the secondary server how long to wait before attempting to recontact the primary server after a connection failure between the two occurs. The default is one hour.
   - **Expire:** If the secondary fails to contact the primary for the specified interval, the secondary stops giving out answers about the zone because the zone data is too old to be useful. The default is 30 days.
   - **Default TTL:** Specifies how long name servers can cache the data. The default is eight hours.
   - **Negative-caching TTL (Time to Live):** Specifies how long name servers can cache negative responses. The default is 15 minutes.
   - **Primary name server (for SOA MNAME field):** If the primary name server of a zone is a Grid member, the MNAME is inherited from its corresponding member, and you can change the name of the primary name server that is published in the MNAME field of the SOA record. This field accepts names in native character sets. If the zone has multiple primary name servers, a list of all primaries is displayed in this section. Each primary has its own serial number and the number can be different among them. Note that

the serial numbers for these primaries are read-only and you cannot modify them. If you change the serial number of the Grid Master, serial numbers for all primaries will be changed to the same number.
    - **Email Address (for SOA RNAME field):** If the primary name server of a zone is a Grid member, you can enter an administrator email address to the SOA record to help people determine who to contact about this zone. The appliance supports IDN for the host name of the Email address. For example, you can create admin@инфоблокс.рф but not админ@инфоблокс.рф.com.
    - **Don't use forwarders to resolve queries in subzones:** Select this option to disable the use of forwarders to resolve queries for data in subzones.
3. Save the configuration and click **Restart** if it appears at the top of the screen.
   To schedule this task, click the Schedule icon at the top of the wizard. In the Schedule Change panel, click **Later**, and then specify a date, time, and time zone. The Schedule icon is green when there is a pending scheduled task. You can reschedule the task if you have the applicable permissions.

Configuration Example: Configuring a Stub Zone in a Grid

This example illustrates how to configure a stub zone and assign it to a Grid member. You configure a Grid, corpxyz, with a single Grid Master and Grid member. The Grid member, member1.corpxyz.com, is the primary name server for the corpxyz.com zone in the internal view. The Grid Master, gm-corpxyz.com, hosts the stub zone for corpxyz.com in the external view. Thus, when the Grid Master receives a query for the corpxyz.com zone, it sends it directly to member1.corpxyz.com, the primary name server for the zone.

In this example, you configure the following:

1. Turn off minimal responses on member1.corpxyz.com, the primary name server for the corpxyz.com zone. See Disable Minimal Responses below.
2. Create the internal and external views. See Create the Views below.
3. Create the corpxyz.com authoritative zone and stub zone. See Create the Zones below.

Disable Minimal Responses

After you create the Grid, turn off minimal responses for member1.corpxyz.com. Disabling minimal responses ensures that member1.corpxyz.com propagates the required data to the server hosting the stub zone.

1. From the **Data Management** tab, select the **DNS** tab, click **Members** -> **member1.corpxyz.com** checkbox -> Edit icon.
2. In the *Member DNS Configuration* editor, click the **General** -> **Basic** tab.
3. Clear the **Return minimal responses** checkbox.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Create the Views

Create the internal and external views. To create each view:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add DNS View**.
2. In the *Add DNS View* wizard, enter the name of the view. In this example, enter either **External** or **Internal**.
3. Click **Save & New** and create the other DNS view.

Create the Zones

Create the corpxyz.com zone in the internal view and assign member1.corpxyz.com as the Grid primary server:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Zone** -> **Add Auth Zone**.
2. In the *Forward Authoritative Zone* wizard, do the following:
    - Select **Add an authoritative forward-mapping zone** and click **Next**.
    - Enter the zone name, **corpxyz.com** and select the **Internal** DNS view. Click **Next.**
    - Select **Use this set of name servers** and select **member1.corpxyz.com** as the Grid primary server.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

After you create the zone, you can view the NS and A records which were automatically created.
Create the stub zone, corpxyz.com, in the external view, assign gm-corpxyz.com as the stub member and member1.corpxyz.com as the stub primary server.

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Zone** -> **Add Stub Zone**.
2. In the *Stub Zone* wizard, do the following:
    - Select **Add a stub forward-mapping zone** and click **Next**.
    - Enter the name of the stub zone, **corpxyz.com** and select the **External** DNS view. Click **Next**.
    - In the *Master Name Servers* panel, click the Add icon and enter the following for the primary name server, and then click **Next**:
        - **Name**: member1.corpxyz.com
        - **Address**: 10.35.0.222
    - In the *Name Servers* panel, click the Add icon and select **gm-corpxyz.com**.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

After you create the stub zone, the server hosting the stub zone, gm-corpxyz.com, sends queries to the primary server, member1.corpxyz.com, for the SOA and NS records. member1.corpxyz.com then returns its NS records and A (address) records.

Viewing Zones

To list zones, navigate to the **Data Management** tab -> **DNS** tab -> *Zones* panel. If there is more than one DNS view in the Grid, this panel lists the DNS views. Select a DNS view to list its zones. (For information, see *Listing DNS Views*.)

- Click Toggle flat view to display a flat list of all the zones in the view.
- Click Toggle hierarchical view to display only the apex zones.

In the hierarchical view, you can see one entry for the host that represents the entire host object. In a host record, there can be multiple DNS resource records (A, PTR, CNAME) and some DHCP data (fixed addresses) as well. In the flat view, each of the DNS resource records in the host are listed separately.
For example, the host called server1.infoblox.com contains 2 A records and an ALIAS (which is a host naming convention for CNAME records). If you view the infoblox.com zone using the hierarchical view option, you will see one entry host for server1.infoblox.com. In the flat view, you will see three records (one for each IP address/A record, and one host Alias for the CNAME). In the flat view, you cannot delete one piece of the host record. You can edit the host record and you can remove information. Deleting host records deletes the entire host record only.
This panel displays the following information for each zone, by default:

- **Name**: The domain name of the zone.
- **MS Sync Server**: When a zone is served by multiple Microsoft servers, this column shows which Microsoft server is actually performing the synchronization of that zone with the Grid.
- **MS Zone Sync**: Displays **Yes** if you have enabled zone synchronization, and displays **No** when the zone synchronization is disabled. This column appears only when you have the Microsoft license installed.
- **Grid Primary Server**: The primary name server configured for an authoritative zone in the DNS view.
- **Type**: The zone type. Possible values are Authoritative, Forward, Stub and Delegation.
- **Multi-master Zone**: Indicates whether this zone has multiple primary name servers.
- **Comment**: Comments that were entered for the zone.
- **Site**: Values that were entered for this pre-defined attribute.

You can also display the following columns:

- **Locked**: Displays Yes when a zone is locked by an admin, and displays No when the zone is unlocked.
- **Function**: Indicates whether the zone is a forward-mapping, or an IPv4 or IPv6 reverse-mapping zone.
- **ZSK rollover date**: Displays the date when the ZSK is due for next rollover. The appliance performs a rollover automatically at this time.
- **KSK rollover date**: Displays the date when the KSK is due for next rollover. The appliance performs a rollover automatically at this time if you have enabled automatic KSK rollover. For more information, see *Configuring Automatic KSK Rollovers and Notifications*. You must perform the rollover manually, if you have disabled this option.
- **Disabled**: This field displays **Yes** if the zone is disabled. Otherwise, this field displays **No**. You can double click a row and select the checkbox in this column to disable the zone. Grid Manager displays a warning message when you disable the zone. Click **Yes** to confirm or **No** to cancel.
- **Signed**: This field displays Yes if the zone is a DNSSEC-signed zone. Otherwise, this field displays No. You can do the following:

- List the resource records and subzones of a DNS zone.
    - Click a DNS zone name.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters.*
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- Edit the properties of a DNS zone.
    - Click the checkbox beside a DNS zone, and then click the Edit icon.
- Delete a DNS zone.
    - Click the checkbox beside a DNS zone, and then click the Delete icon. Grid Manager displays a warning message. Click **Yes** to continue or **No** to cancel the process. Note that this process may take a longer time to complete depending on the size of the data.
- Export the list of DNS zones to a .csv file.
    - Click the Export icon.
- Print the list of DNS zones.
    - Click the Print icon.

Using Name Server Groups

A name server (NS) group is a collection of one or more DNS servers. Grouping a commonly used set of DNS servers together simplifies zone creation by enabling you to specify a single NS group instead of specifying multiple name servers individually.
You can configure the following types of name server groups:

- Authoritative name server group
- Delegation name server group
- Forwarding member name server group
- Stub member name server group
- Forward/Stub server name server group

Using Authoritative Name Server Groups

An authoritative name server group is a collection of one or more primary DNS servers and secondary DNS servers. After you create an authoritative NS group, you can then assign it to serve authoritative forward-mapping and reverse-mapping zones. When you assign an authoritative NS group to an authoritative zone, Grid Manager automatically generates an NS record, a glue A or AAAA record, and a PTR record for each name server available in the NS group. But if the zone is disabled, Grid Manager does not generate these records.
Grid Manager generates authoritative A, AAAA, and PTR records when:

- A Grid member is added to a Grid, whose host name belongs to the name space of the authoritative zone and vice versa.
- An external name server is assigned to a zone, whose host name belongs to the name space of the authoritative zone.

Note

Grid Manager does not generate an NS record when the DNS service for the member is disabled.

The performance of the following functions significantly improve when you assign an NS group to a zone instead of specifying multiple name servers individually:

- Starting and Stopping the DNS service.
- Reparenting the zones after removing or restoring a zone.
- Modifying the zone data.

> **Note**
>
> Only superusers can create and manage name server groups

Adding Authoritative Name Server Groups

To add an authoritative name server group:

1. From the **Data Management** -> **DNS** tab, do one of the following:
   - Click the **Name Server Groups** tab -> Add icon -> **Group** -> **Authoritative**.
   - From the Toolbar, click the Add icon -> **Group** -> **Authoritative.**
2. In the *Add Name Server Group* wizard, do the following:
   - **Name:** Type a name that provides a meaningful reference for this set of servers.
   - **Name Servers:** Click the Add icon and select one of the following options for every server that you are adding to the NS group:
     - **Grid Primary:** Choose this option to select a primary name server or multiple primary servers for the zone. See *Specifying Grid Primary Servers*.
     - **Grid Secondary:** Choose this option to select a Grid member as a secondary server for the zone. See *Adding Grid Secondaries*.
     - **External Primary:** Choose this option if the appliance is in a Grid and you want to specify a primary server outside the Grid ("external" to the Grid). See *Specifying External Primary Servers*.
     - **External Secondary**: Choose this option if the appliance is in a Grid and you want to specify a secondary server outside the Grid ("external" to the Grid), or if the appliance is deployed independently from a Grid. See *Specifying External Secondaries*.
   - **Default NS Group:** Select this to specify this authoritative name server group as the default.
   - **Comment:** Optionally, enter additional information about the authoritative NS group.

3. Save the configuration and click **Restart** if it appears at the top of the screen, or click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.
A newly created authoritative name server group appears in the **Name Server Groups** tab. For information about viewing the name server groups, see *Viewing Name Server Groups*. You can then associate it with forward-mapping and reverse-mapping authoritative zones.

Applying Authoritative Name Server Groups

In Grid Manager, you can assign an authoritative name server group to an authoritative zone when you first create it using the *Add Authoritative Zone* wizard and when you edit an existing authoritative zone using the *Authoritative Zone* editor. For information on creating an authoritative zone using the wizard, see *Configuring Authoritative Zones*. The panels used to assign a name server group to a zone are the same in the wizard or and editor. The only difference is the way you access it. The following procedure describes how to specify an authoritative NS group when editing a forward-mapping zone:

1. From the **Data Management** tab -> **DNS** tab -> **Zones** tab -> *zone* checkbox, and then click the Edit icon.
2. In the *Authoritative Zone* editor, click **Name Servers**.
3. Select **Use this name server group**, and then select the authoritative NS group from the drop-down list.

> **Note**
> If you apply a name server group to at least one zone or specify it as the default group, you cannot rename or remove it. To rename or remove a group, you must first disassociate it from all zones and unassign it as the default group.

Using Delegation Name Server Groups

A delegation name server group is a collection of external name servers for delegated zones. Adding a set of external name servers to a single delegation name server group can significantly reduce configuration efforts. While configuring delegated zones, you can specify a single delegation NS group instead of configuring multiple name servers individually.

After you create a delegation NS group, you can then assign it to serve only delegated zones. When you assign a delegation NS group to a delegated zone, Grid Manager automatically generates an NS record, a glue A or AAAA record, and a PTR record for each name server available in the delegation NS group. But if the zone is disabled, Grid Manager does not generate these records.
Note the following while adding a delegation NS group:

- You cannot add a delegation NS group if a NS group with the same name already exists and vice versa.
- If a Grid has any Microsoft servers configured, delegation NS groups are not allowed and vice versa.
- You cannot delete a delegation NS group if it is assigned to a zone.
- The DNS server resolves the FQDN of the delegated name server and does not use the IP address that you specify when assigning the delegated name servers.

Adding Delegation Name Server Groups

To add a delegation name server group:

1. From the **Data Management** -> **DNS** tab, do one of the following:
   - Click the **Name Server Groups** tab -> Add icon -> **Delegation**.
   - From the Toolbar, click the Add icon -> **Group** -> **Delegation**.
2. In the *Add Delegation Name Server Group* wizard, complete the following:
   - **Name:** Enter the name of the delegation NS group.
   - **Comment:** Optionally, enter additional information about the delegation NS group.
3. Click **Next** to define the external name servers for the delegation NS group.
4. In the *Name Server* panel, click the Add icon and specify the following for every server that you are adding to the delegation NS group:
   - **Name:** Enter the name of the delegated name server.
   - **Address:** Enter the IP address of the delegated name server.
5. Save the configuration and click **Restart** if it appears at the top of the screen, or click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.
   A newly created delegation NS group appears in the **Name Server Groups** tab. For information about viewing the name server groups, see *Viewing Name Server Groups*. You can then associate it with delegated zones.

> ⚠ Note
> You will not be able to add a delegated name server group if DNS synchronization is enabled on any Microsoft server configured in NIOS.

Applying Delegation Name Server Groups

You can assign a delegation NS group to a delegated zone when you first create it using the *Add Delegation* wizard and when you edit an existing delegated zone using the *Delegation Zone* editor. For information about creating a delegated zone using the wizard, see *Configuring a Delegation*.
Complete the following to assign a delegation NS group to a delegation zone:

1. From the **Data Management** tab -> **DNS** tab -> **Zones** tab -> *delegation zone* checkbox, and then click the Edit icon.
2. In the *Delegation Zone* editor, click **Delegated Name Servers**.
3. Select **Use this name server group**, and then select the delegation NS group from the drop-down list.

Using Forwarding Member Name Server Groups

A forwarding member NS (Name Server) group is a collection of one or more forwarding name servers. Grouping a set of forwarding name servers together reduces the configuration efforts. When you configure a forwarding zone, you can specify a single forwarding member NS group instead of specifying multiple forwarding name servers individually. After you create a forwarding member NS group, you can assign it to a forward forward-mapping zone and a forward reverse-mapping zone.
Note the following while adding a forwarding member NS group:

- Only superusers can add, modify, and delete a forwarding member NS group.

- You cannot add a forwarding member NS group if a NS group with the same name already exists and vice versa.
- You cannot delete a forwarding member NS group if it is assigned to a zone.

Adding Forwarding Member Name Server Groups

To add a forwarding member NS group:

1. From the **Data Management** -> **DNS** tab, do one of the following:
   - Click the **Name Server Groups** tab -> Add icon -> **Forwarding Member**.
   - From the Toolbar, click the Add icon -> **Group** -> **Forwarding Member**.
2. In the *Forwarding Member Name Server Group* wizard, complete the following:
   - **Name:** Enter the name of the forwarding member NS group.
   - **Name Servers:** In this section, you can add the Grid members to the forwarding member NS group and use the default forwarders or you can override default forwarders and configure custom forwarders. Click the Add icon and select a Grid member from the *MemberSelector* dialog box.
     The following is displayed in the table for each member:
     - **Name:** The name of the Grid member.
     - **IPv4 Address:** The IPv4 address of the Grid member.
     - **IPv6 Address:** The IPv6 address of the Grid member.
     - **Override Default Forwarders**: Displays **Yes** when you override default forwarders. Otherwise, this field displays **No**.
     - **Custom Forwarders**: Displays the IP address of the custom forwarders. Otherwise, this field is blank.
   - **Comment:** Optionally, enter additional information about the forwarding member NS group.
3. Save the configuration or click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.

A newly created forwarding member NS group appears in the **Name Server Groups** tab. For information about viewing the name server groups, see *Viewing Name Server Groups*. You can then associate it with forward forward-mapping zones and forward reverse-mapping zones.

Applying Forwarding Member Name Server Groups

You can assign a forwarding member NS group to a forward zone when you first create it using the *Add Forward Zone* wizard and when you edit an existing forward zone using the *Forward Zone* editor. For information about creating a forward zone using the wizard, see *Configuring a Forward Zone*.
Complete the following to assign a forwarding member NS group to a forward zone:

1. From the **Data Management** tab -> **DNS** tab -> **Zones** tab -> *forward zone* checkbox, and then click the Edit icon.
2. In the *Forward Zone* editor, click **Name Servers**.
3. Select **Use this name server group**, and then select the forwarding member NS group from the drop-down list.

Using Stub Member Name Server Groups

A stub member NS (Name Server) Group is a collection of one or more Grid members for stub zones. When you configure a stub zone, you can specify a single stub member NS group instead of specifying multiple Grid members individually, thus reducing the configuration efforts. After you create a stub member NS group, you can assign it to forward-mapping stub zones and reverse-mapping stub zones.
Note the following while adding a stub member NS group:

- Only superusers can add, modify, and delete a stub member NS group.
- You cannot add a stub member NS group if a NS group with the same name already exists and vice versa.
- You cannot delete a stub member NS group if it is assigned to a zone.

Adding Stub Member Name Server Groups

To add a stub member NS group:

1. From the **Data Management** -> **DNS** tab, do one of the following:

- Click the **Name Server Groups** tab -> Add icon -> **Stub Member**.
- From the Toolbar, click the Add icon -> **Group** -> **Stub Member**.

2. In the *Stub Member Name Server Group* wizard, complete the following:
   - **Name:** Enter the name of the stub member NS group.
   - **Name Servers:** In this section, you can add the Grid members to the stub member NS group. Click the Add icon and select a Grid member from the *MemberSelector* dialog box.
     The following is displayed in the table for each member:
     - **Name:** The name of the Grid member.
     - **IPv4 Address:** The IPv4 address of the Grid member.
     - **IPv6 Address:** The IPv6 address of the Grid member.
   - **Comment:** Optionally, enter additional information about the stub member NS group.
3. Save the configuration or click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.

A newly created stub member NS group appears in the **Name Server Groups** tab. For information about viewing the name server groups, see *Viewing Name Server Groups*. You can then associate it with stub forward-mapping zones and stub reverse-mapping zones.

Applying Stub Member Name Server Groups

You can assign a stub member NS group to a stub zone when you first create it using the *Add Stub Zone* wizard and when you edit an existing stub zone using the *Stub Zone* editor. For information about creating a stub zone using the wizard, see *Configuring Stub Zones*.
Complete the following to assign a stub member NS group to a stub zone:

1. From the **Data Management** tab -> **DNS** tab -> **Zones** tab -> *stub zone* checkbox, and then click the Edit icon.
2. In the *Stub Zone* editor, click **Name Servers**.
3. Select **Use this name server group**, and then select the stub member NS group from the drop-down list.

Using Forward/Stub Server Name Server Groups

A forward/stub server NS (Name Server) group is a collection of one or more external name servers. Grouping a set of external name servers together to a forward/stub server NS group reduces the configuration efforts. You can assign a single forward/stub server NS group as default forwarders for a forward zone or as primary servers for a stub zone instead of specifying multiple name servers individually.
Note the following while adding a forward/stub server NS group:

- Only super-users can add, modify, and delete a forward/stub server NS group.
- You cannot add a forward/stub server NS group if a NS group with the same name already exists and vice versa.
- You cannot delete a forward/stub server NS group if it is assigned to a zone.

Adding Forward/Stub Server Name Server Groups

To add a forward/stub server NS group:

1. From the **Data Management** -> **DNS** tab, do one of the following:
   - Click the **Name Server Groups** tab -> Add icon -> **Forward/Stub Server**.
   - From the Toolbar, click the Add icon -> **Group** -> **Forward/Stub Server**.
2. In the *Forward/Stub Server Name Server Group* wizard, complete the following:
   - **Name**: Enter a name that provides a meaningful reference for this set of external name servers for the forward and stub zones.
   - **Name Servers**: Click the Add icon and specify the following for every external name server that you are adding to the forward/stub server NS group:
     - **Name**: The name of the external name server.
     - **IP Address**: The IP address of the external name server.
   - **Comment**: Optionally, enter additional information about the forward/stub server NS group.
3. Save the configuration or click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.

A newly created forward/stub server NS group appears in the **Name Server Groups** tab. For information about viewing the name server groups, see *Viewing Name Server Groups*. You can then associate it with forward zones as default forwarders and as primary servers for stub zones.

Applying Forward/Stub Server Name Server Groups

You can assign a forward/stub server NS group to a forward zone as default forwarders and as primary servers to a stub zone when you first create it and when you edit an existing forward zone and stub zone. For information about creating a forward zone using the wizard, see *Configuring a Forward Zone*. For information about creating a stub zone using the wizard, see *Configuring Stub Zones*.
Complete the following to assign a forward/stub server NS group to a forward zone:

1. From the **Data Management** tab -> **DNS** tab -> **Zones** tab -> *forward zone* checkbox, and then click the Edit icon.
2. In the *Forward Zone* editor, click **Forwarders**.
3. Select **Use this name server group**, and then select the forward/stub server NS group from the drop-down list.
Complete the following to assign a forward/stub server NS group to a stub zone:
4. From the **Data Management** tab -> **DNS** tab -> **Zones** tab -> *stub zone* checkbox, and then click the Edit icon.
5. In the *Stub Zone* editor, click **Masters**.
6. Select **Use this name server group**, and then select the forward/stub server NS group from the drop-down list.

Viewing Name Server Groups

You can view the configured authoritative, delegation, forwarding member, stub member, and forward/stub server name server groups by navigating to the **Data Management** tab -> **DNS** tab -> **Name Server Groups** tab.
The panel displays the following information about each name server group:

- **Name**: The name of the name server group.
- **Type**: The name server group type. Possible values are **Authoritative**, **Delegation**, **Forwarding Member**, **Stub Member**, and **Forward/Stub Server.**
- **Comment**: Comments that were entered for the name server group.
- **Site**: Values that were entered for this pre-defined attribute. You can do the following:
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- Edit the properties of a name server group.
    - Select the checkbox beside a name server group, and then click the Edit icon.
- Delete a name server group.
    - Select the checkbox beside a name server group, and then click the Delete icon. Note that you cannot delete a delegation name server group that is assigned to a zone.
- Export the list of Grid members to a .csv file.
    - Click the Export icon.
- Print the list of Grid members.
    - Click the Print icon.

Configuring DNS Resource Records

If you need to add a large number of A and PTR records, you can have the NIOS appliance add them as a group and automatically assign host names based on a range of IP addresses and the host name format you specify. Such a group of records is called a *bulk host*, which the appliance manages and displays as a single bulk host record.

This section provides general information about Infoblox host records and DNS resource records. The topics in this section include:

- *Adding Bulk Hosts*
- *Specifying Bulk Host Name Formats*
- *Managing Resource Records*
- *Configuring Shared Record Groups*

Adding Bulk Hosts

To add a bulk host:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Host** -> **Add Bulk Host**.
2. In the *Add Bulk Host* wizard, complete the following fields:
    - **Prefix**: If Grid Manager displays a zone name, enter a prefix (or series of characters) to insert at the beginning of each host name. The displayed zone name can either be the last selected zone or the zone from which you are adding the bulk host record. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click a zone name in the dialog box, and enter a prefix for the bulk host record. You can enter any printable character that complies with the zone host name policy or you can also leave this blank.
      The sum of the bulk host prefix length and suffix length must not exceed 63 characters. When you enter a prefix, the NIOS appliance computes the maximum length of the bulk host suffix to verify that the total prefix and suffix length does not exceed 63 characters. If it does, the appliance displays an error message indicating the number of characters that you must remove to make a valid prefix.
        - DNS View: Displays the DNS view of the zone to which the bulk host records belong.
        - Host Name Policy: Displays the host name policy of the selected DNS zone.
          From NIOS 8.6.3 onwards, you have to manually clear the existing host name policy in the table and enter the new one.
        - Name Format: To override the default four-octet suffix format or the format set at the Grid level, and specify a different format, click **Override** and select a host name format from the **Name Formats** drop-down menu.
        - The *Name Format*s drop-down menu lists the formats **Four Octets**, **Three Octets**, **Two Octets**, and **One Octet** along with any other bulk host name formats that you have defined.
        - Starting IP Address: Enter the first IP address in the range of addresses for the group.
        - End IP Address: Enter the last IP address in the range of addresses for the group.
        - Comment: Optionally, enter additional information for this record.
        - **Automatically Add Reverse Mapping:** Click to have the appliance automatically create a PTR record for each IP address within the bulk host range.
        - **Disable:** Clear the checkbox to enable the record. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes for the bulk host record. For information, see *Using Extensible Attributes*.
4. Save the configuration and click **Restart** if it appears at the top of the screen.
   To modify or delete a bulk host, see *Modifying, Disabling, and Deleting Host and Resource Records*.

Example 1 - Responding to DNS AXFR Queries

This example shows the responses the bulk host foo/1.2.3.10/1.2.3.20 returns to DNS AXFR (Full Zone Transfers) queries.
If the bulk host uses the template **-$3-$4**, the query returns:

```
foo-3-10.test.com foo-3-11.test.com
 ......
 foo-3-20.test.com
```

If the bulk host uses the template **-#2-#3-#4**, the query returns:

```
foo-002-003-010.test.com foo-002-003-011.test.com
 ......
 foo-002-003-020.test.com
```

Example 2 - Importing Zones with Bulk Hosts

When you import zones with bulk hosts, the system selects the most specific match.
The following example can possibly match three octet, two octet, and one octet formats; however, the system selects the most specific four octet default format.
The query:

```
foo-1-2-3-4 IN A 1.2.3.4
 foo-1-2-3-5 IN A 1.2.3.5
```

Results in the match:

```
foo/1.2.3.4/1.2.3.5(Four Octets)
 Not in any of the following:
 foo-1/1.2.3.4/1.2.3.5(Three Octets) foo-1-2/1.2.3.4/1.2.3.5(Two Octets)
foo-1-2-3/1.2.3.4/1.2.3.5(One Octet)
```

Specifying Bulk Host Name Formats

Bulk host name formats provide a flexible way to define bulk host names. You create multiple bulk host formats at the Grid level. Either select from the default bulk host formats or create your own. You can specify a different format for each bulk host. When you assign a bulk host name format to a bulk host in a zone, the system applies the zone's host name policy to it.
A bulk host name consists of a prefix, a suffix, and the name of the domain to which the host belongs. The prefix can contain any printable character that complies with the zone host name policy. It can also be blank. The suffix is derived from an IP address in the bulk host IP address range. The appliance also supports IDNs for bulk host names. You can use IDNs or their punycode representations while creating bulk hosts.
The following table summarizes how the appliance displays bulk host names that contain IDNs:

Input	NIOS Displays...	NIOS DNS Domain (Punycode in the GUI)	Conversion Guidelines
hello	hello	hello	No conversion
прывітанне	прывітанне	xn--80adk5aaihr3f9e	IDN to punycode
xn--80adk5aaihr3f9e	xn--80adk5aaihr3f9e	xn--80adk5aaihr3f9e	No conversion
\xyz format	\xyz format	\xyz format	No conversion

The suffix format is a string of ASCII characters that uses $ (unpadded) or # (zero-padded) followed by 1,2,3,4 to refer to the first, second, third, or fourth IP address octet; it uses $1,$2,$3,$4 or #1,#2,#3,#4. $2 refers to the second unpadded octet and #4 refers to the fourth zero-padded octet. For example:

> The prefix of a bulk host = *info* IP address = *10.19.32.133* Domain name = *infoblox.com*.
> If you specify the default four-octet format *$1$2-$3-$4*, the bulk host name is *info-10-19-23-133.infoblox.com*.

If you specify a custom name format such as ***#1#2*#3*#4***, the bulk host name is *info*010*019*023*133.infoblox.com*.

Before Defining Bulk Host Name Formats

Before you specify a bulk host name format, ensure that it complies with the following rules:

- The NIOS appliance uses <*prefix*>-xx-xx-xx-xx for bulk hosts. Ensure that the bulk host name does not conflict with CNAMEs, DNAMEs, or host name aliases.
- When you add a bulk host, if you enable the **Automatically add reverse mapping** option and there is a CNAME record in the corresponding reverse zone that conflicts with a PTR record generated by the bulk host, the bulk host insertion fails and an error message appears. For example, if there is a CNAME with the alias **15** in a reverse zone **1.168.192.in-addr.arpa** and if you add a bulk host **foo/192.168.1.10/192.168.1.20** with the **Automatically add reverse mapping** option selected, the insertion fails and an error message appears because both the bulk host and the CNAME generate a record **15.1.168.192.in-addr.arpa** in the reverse zone.
- You cannot create or change a bulk host if a zone is locked by another user. If you select a different template for the Grid, it changes each record associated with the bulk host.
- You can define bulk host name formats only at the Grid level and override them at the bulk host level; not at the zone or bulk host object level.
- When you upgrade to NIOS 4.3r3 or earlier releases, the system migrates existing bulk hosts as follows:
  - If you did not customize the bulk host IP format, there is no action required. All migrated bulk hosts continue to use the Grid-level default four-octet format **$1$2-$3-$4**.
  - If you customized the bulk host IP format, the system creates a new template called *Migrated Default* template. All migrated bulk hosts override the Grid default template and use the *Migrated Default* template.

> **Note**
>
> The NIOS appliance considers two bulk hosts that have the same prefix, start address, and end address as duplicate hosts; even if they use different bulk host formats.

Bulk Host Name Format Rules

The below table describes the rules that you should follow when you create bulk host name formats. It also provides examples of valid and invalid formats for each rule.

Bulk Host Name Format Rules and Examples

Rule	Example
The suffix format cannot have more than four octets.	**$4-$5** is invalid.
The octets must be in order.	**-$2-$3-$4** is valid but **-$3-$2-$4** is invalid.
Do not skip octets.	**-$2-$3-$4** is valid but -$2-$4 is invalid.
Do not use a combination of both the **$** and **#** symbols together as octet references; use only one of them.	-$2-#3-$4 is invalid.
The suffix format must contain at least the fourth octet. You must define at least one **-$4** or #4.	**$4** is valid but **$3** is invalid.
If the suffix format uses $ references, it cannot be preceded by a digit. You must add a non-digit prefix to each $ or # reference.	-$2-$3-$4

The \ character is the designated escape character for the $, # and \ characters. You cannot use the $ or # symbols as separators unless you prefix them with an escape character \.	For the IP address **10.19.32.133**, the format **#-#1-#2-#3-#4** expands to #-010-019-032-133.
The bulk host name format must comply with its zone host name policy.	You cannot insert a bulk host name format **-?-$4** in a zone that uses Allow Underscore as host name policy because the policy does not allow you to use the ? character in the host name.
The bulk host name must comply with the maximum label length.	The sum of the bulk host name prefix and suffix cannot be greater than 63 characters. When you enter a suffix format, the NIOS appliance determines the length of the longest bulk host defined, and checks that the sum of the bulk host prefix and suffix length does not exceed 63 characters; if it does, an error message appears.
The bulk host name cannot result in an FQDN with more than 255 characters.	
The NIOS appliance computes the maximum length of the bulk host suffix by expanding the bulk host IP format using 255.255.255.255.	For the format string **-$1-$2-$3-$4**, the maximum length of the suffix is **-255-255-255-255**; that is, 16 characters. Therefore, the maximum length of the host prefix is 47 characters.
The bulk host name must not be the same as a CNAME/DNAME.	If there is a CNAME record with alias **foo-003-015**, you cannot insert a bulk host **foo/1.2.3.10/1.2.3.20** using template **#3#4** because **foo-003-015** is also one of the synthetic host names in the bulk host.
Each host name in the bulk host must be unique.	You cannot insert a bulk host **foo/1.2.3.10/1.2.4.20** using the template **$4** because the system resolves the host name **foo-10** to both **1.2.3.10** and **1.2.4.10**. To ensure that the bulk host name is unique, use the template **$3-$4**.
You cannot insert a bulk host that violates the uniqueness of two bulk hosts that have the same prefix and use the same name format.	If there is a bulk host **foo/1.2.3.10/1.2.4.20** using the template **-$3-$4**, you cannot insert another bulk host **foo/1.3.4.10/1.3.5.20** using the same template because the system resolves host name **foo-4-15** to both **1.2.4.15** and **1.3.4.15**. Instead, use the template **-$2-$3-$4** to ensure that the two bulk hosts are unique.

The appliance provides four predefined formats. You can define additional formats or change the default format at the Grid level only. To define new bulk host name formats:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
2. Select the Host Naming tab of the Grid DNS Properties editor.
   The Bulk Host Name Formats table displays four predefined name suffix formats. The following examples show the host name that each format generates for the zone test.com:
   Four Octets: $1-$2-$3-$4 (Default)—Generates foo-192-168-1-15.test.com. Three Octets: $2$3-$4—Generates foo-168-1-15.test.com
   Two Octets: **-$3-$4**—Generates foo-1-15.test.com One Octet: -$4—Generates foo-15.test.com
   For the IP address 10.100.0.10, the format **-$1$2-$3-$4** generates the host name suffix 10-100-0-10 . The format **#1#2-#3-#4** generates the host name suffix -010-100-000-010.
3. Click **Add** to enter the name and format of a new bulk host name format.
4. Optionally, click the Default column of a format and select **Default** to make it the Grid default.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing Resource Records

DNS resource records provide information about objects and hosts. DNS servers use these records to respond to queries for hosts and objects. The appliance supports IDNs for all DNS resource records. For information about IDNs, see *Support for Internationalized Domain Names*. Note that the appliance does not decode the IDN of a resource

record to punycode. In other words, a record that contains a domain name in punycode is displayed in punycode and a record that contains an IDN is displayed in its native characters.

The following sections define the types of DNS resource records you can manage and the operations you can perform:

- *Managing ALIAS Records*
- *Managing NS Records*
- *Managing AAAA Records*
- *Managing PTR Records*
- *Managing MX Records*
- *Managing SRV Records*
- *Managing TXT Records*
- *Managing TLSA Records*
- *Managing CAA Records*
- *Managing CNAME Records*
- *Managing DNAME Records*
- *Managing NAPTR Records*
- *Managing LBDN Records*
- *Managing Unknown Records*
- *Viewing Resource Records*
- *Modifying, Disabling, and Deleting Host and Resource Records*

Managing A Records

An A (address) record is a DNS resource record that maps a domain name to an IPv4 address. To define a specific name-to-address mapping, you can add an A record to a previously defined authoritative forward-mapping zone. If the zone is associated with one or more networks, the IP address must belong to one of the associated networks. For example, if the A record is in the corpxyz.com zone, which is associated with 10.1.0.0/16 network, then the IP addresses of the A record must belong to the 10.1.0.0/16 network. For information about associating zones and networks, see *Associating Networks with Zones*.

The appliance also supports wildcard A records. For example, you can use a wildcard A record in the corpxyz.com domain to map queries for names such as www1.corpxyz.com, ftp.corpxyz.com, main.corpxyz.com, and so on to the IP address of a public-facing web server. Note that wildcard names only apply when the domain name being queried does not match any resource record.

NIOS allows superusers to add A records with a blank name. Limited-access users must have read/write permission to **Adding a blank A/AAAA record** to add A records with a blank name. You can assign global permission for specific admin groups and roles to allow limited-access users to add blank A records. For more information, see *Administrative Permissions for Adding Blank A or AAAA Records*.

Note

If an A record with the domain name in its native characters is added to the Infoblox Grid through DDNS updates, the **Name** field displays the record name in UTF-8 encoded format. For example, an A record with the domain name 工作站 .test.com added through DDNS updates displays \229\183\165\228\189\156\231\171\153.test.com in the **Name** field.

Adding A Records

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **Add A Record**.
2. In the *Add A Record* wizard, do the following:
   - **Name**: If Grid Manager displays a zone name, enter the host name that you want to map to an IP address. The displayed zone name can either be the last selected zone or the zone from which you are adding the host record. If no zone name is displayed or if you want to specify a different zone, click **Select**

Zone. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click a zone name in the dialog box and then enter the host name. The name you enter is prefixed to the DNS zone name that is displayed, and the complete name becomes the FQDN (fully qualified domain name) of the host. For example, if the zone name displayed is corpxyz.com and you enter admin, then the FQDN becomes admin.corpxyz.com. Ensure that the domain name you enter complies with the host name restriction policy defined for the zone. To create a wildcard A record, enter an asterisk (*) in this field.

- **DNS View**: This field displays the DNS view to which the DNS zone belongs.
- **Shared Record Group**: This field appears only when you are creating a shared record. Click **Select Shared Record Group**. If you have only one shared record group, the appliance displays the name of the shared record group here. If you have multiple shared record groups, select the shared record group in the *Shared Record Group Selector* dialog box. You can use filters or the **Go to** function to narrow down the list.
- **Host Name Policy**: Displays the host name policy of the zone.
- In the **IP Addresses** section, click the Add icon and do one of the following:
    - Select **Add Address** to enter the IPv4 address to which you want the domain name to map. or
    - Select **Next Available IPv4** to retrieve the next available IP address in a network.
    - If the A record is in zone that has associated networks, the *Network Selector* dialog box lists the associated networks. If the zone has no network associations, the *Network Selector* dialog box lists the available networks. When you select a network, Grid Manager retrieves the next available IP address in that network.
- **Comment**: Optionally, enter additional information about the A record.
- **Create associated PTR record:** Select this option to automatically generate a PTR record that maps the specified IP address to the host name. To create the PTR record, the reverse-mapping zone must be in the database.
- **Disable**: Select this checkbox to disable the record. Clear the checkbox to enable it.

3. Click **Next** to define extensible attributes. For information, see *Managing Extensible Attributes*.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Modifying A Records

When you modify an A record, you can do the following:

- In the **General** tab, you can change the information you previously entered through the wizard.
- The **Discovered Data** tab displays discovered data, if any, for the record. For information, see *Viewing Discovered Data*.

You can also enter or edit information in the **TTL**, **Extensible Attributes**, and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

Managing ALIAS Records

An ALIAS record is a virtual DNS record type created for a standard record type to alias the root domain (apex zone) to another name. You can use an ALIAS record to host a website at a domain name without the "www" (or other) prefix when using the cloud services, such as Amazon Web Services, Azure VMs, GitHub pages, Heroku, and so on. For example, you can use an ALIAS record to point your domain foo.com to a host name like mail.foo.com. When you perform a DNS lookup on an ALIAS record, the authoritative DNS server dynamically resolves an ALIAS record for the matching alias target. The response contains the aliased records, that can be A, AAAA, MX, NAPTR, PTR, SPF, SRV, or TXT values. You can alias the same domain with multiple target types.

You can synchronize ALIAS records from your AWS to NIOS using Amazon Route 53. For information about AWS deployments, refer to the *Installation Guide for vNIOS for AWS.*

Following are some guidelines to remember when you use ALIAS records:

- ALIAS records are not supported on DNS zones that are assigned to a Microsoft primary server. This means that you cannot assign a DNS zone containing an ALIAS record to a Microsoft primary server and you cannot add an ALIAS record to a DNS zone that is assigned to a Microsoft primary server.
- You cannot add an ALIAS record to a DNSSEC signed zone and you cannot sign a zone containing an ALIAS record.

- You cannot add an ALIAS record to a DNS zone if there is a secondary server that is using zone transfer as an update mechanism. Also, you cannot use zone transfer process to update zones containing ALIAS records in the Grid secondaries.
- You cannot update any ALIAS record using a DNS request. You can create and update ALIAS records only by using the NIOS UI or API.
- An ALIAS record can coexist with other types of records for the same owner name unless there is another configured record at the owner name whose type is an allowed target type for ALIAS. You cannot configure an ALIAS record whose target type is the same as the configured record type.
- You cannot use DDNS updates to add or delete an ALIAS record.

Adding ALIAS Records

To add an ALIAS record, perform the following steps:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **ALIAS Record**.
2. In the *Add ALIAS Record* wizard, do the following:
    - **Name**: The ALIAS record name. The displayed zone name can either be the last selected zone or the zone from which you are adding the ALIAS record. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. If you do not specify the record name, then it resumes the name of the Zone Apex.
    - **Record Type**: You can configure any record type - A, AAAA, MX, NAPTR, PTR, SPF, SRV, TXT.
    - **Target**: For for A, AAAA, and MX records, enter the host name as the target. For other record types, enter the domain name that is used to reply to any DNS request. You can also type the domain name for the resource. Examples:
        - CloudFront distribution domain name: d111111abcdef8.cloudfront.net
        - ELB load balancer DNS name: example-1.us-east-1.elb.amazonaws.com
        - S3 website endpoint: s3-website.us-east-2.amazonaws.com
        - Resource record set in this hosted zone: *www.example.com*
    - **Comment**: Enter additional information about the ALIAS record.
    - **Disable**: Select this checkbox to disable the record. Clear the checkbox to enable it.
3. Click **Next** to define extensible attributes. For information, see *Managing Extensible Attributes.*
4. Save the configuration or click **Next** to schedule this task. Click **Now** in the **Schedule Change** panel to immediately execute this task or click **Later** and specify a date, time, and time zone. For information about how to schedule a task, see *Scheduling Tasks*.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Modifying ALIAS Records

When you modify an ALIAS record, you can perform the following step:

- In the **General** tab, you can change the information you previously entered through the wizard.

You can also enter or edit information in the **TTL**, **Extensible Attributes**, and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

Managing NS Records

An NS record identifies an authoritative DNS server for a domain. Each authoritative DNS server must have an NS record. Grid Manager automatically creates NS records when you assign a Grid member as the primary server for a zone or when you assign an NS group to a zone. Grid Manager generates two NS records; an authoritative NS record for the current zone; and a delegation NS record for the parent zone for each name server available in the NS group. You cannot edit an automatically generated NS record. Note that when you delete a name server from an NS group, the NS record associated with the name server is deleted. For information about using NS Groups, see *Importing Zone Data*. You can manually create NS records for other zones. NS records associated with one or more IP addresses are used for related A record and PTR record generation. You can configure an NS record for anycast IP addresses on the appliance. For more information about anycast, see *About Anycast Addressing for DNS*.

Adding NS Records

To add an NS record, perform the following steps:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **Add NS Record**.
2. In the *Add NS Record* wizard, complete the following fields:
    - **Zone**: The displayed zone name can either be the last selected zone or the zone from which you are adding the NS record. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box.
    - **DNS View:** Displays the DNS view to which the selected zone belongs.
    - **Hostname Policy:** Displays the host name policy of the selected zone.
    - **Name Server:** Enter the host name that you want to configure as the name server for the zone. IDN is not supported in this field. You can use the punycode representation of an IDN in this field.
3. Click Next to enter IP addresses for the name server.
4. In the *Name Server Addresses* panel, click the Add icon and complete the following fields:
    - Address: Enter the IP address of the name server.
    - **Add PTR Record:** This field displays Yes by default, enabling the automatic generation of a PTR record for the IP address. You can select **No** to disable the generation of the PTR record.
5. Click **Next** to define extensible attributes or save the configuration and click **Restart** if it appears at the top of the screen.

Modifying and Deleting NS Records

When you modify an NS record, you can change the following information:

- In the **General** tab, you can change the name server name.
- In the **Addresses** tab, you can do the following:
    - Delete an address by selecting it and clicking the Delete icon.
    - Add an address by clicking the Add icon, and then entering the IP address and completing the **Add PTR Record** field.

Managing AAAA Records

An AAAA (quad A address) record maps a domain name to an IPv6 address. To define a specific name-to-address mapping, add an AAAA record to a previously defined authoritative forward-mapping zone. If the zone is associated with one or more networks, the IP address must belong to one of the associated networks. For example, if the AAAA record is in the corpxyz.com zone, which is associated with the 1111:0001/32 network, then the IP addresses of the A record must belong to that network. For information about associating zones and networks, see *Associating Networks with Zones*.

Note

If an AAAA record with the domain name in its native characters is added to the Infoblox Grid through DDNS updates, the **Name** field displays the record name in UTF-8 encoded format. For example, an AAAA record with the domain name 工作站 .*test.com* added through DDNS updates displays \229\183\165\228\189\156\231\171*153.test.com* in the **Name** field.

NIOS allows superusers to add AAAA records with a blank name. Limited-access users must have read/write permission to **Adding a blank A/AAAA record** to add AAAA records with a blank name. You can assign global permission for specific admin groups and roles to allow limited-access users to add blank AAAA records. For more information, see *Administrative Permissions for Adding Blank A or AAAA Records*.

Adding AAAA Records

To create an AAAA record, perform the following steps:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **Add AAAA Record**.
2. In the *Add AAAA Record* wizard, complete the following:
    - **Name:** If Grid Manager displays a zone name, enter the host name that you want to map to an IP address. The displayed zone name can either be the last selected zone or the zone from which you are adding the AAAA record. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click a zone name in the dialog box, and then enter the host name. The name you enter is prefixed to the DNS zone name that is displayed, and the complete name becomes the FQDN (fully qualified domain name) of the host. For example, if the zone name displayed is corpxyz.com and you enter admin, then the FQDN becomes admin.corpxyz.com.
    - **DNS View**: Displays the DNS view to which the selected DNS zone belongs.
    - **Shared Record Group**: This field appears only when you are creating a shared record. Click **Select Shared Record Group**. If you have only one shared record group, the appliance displays the name of the shared record group here. If you have multiple shared record groups, select the shared record group in the *Shared Record Group Selector* dialog box. You can use filters or the **Go to** function to narrow down the list.
    - **Hostname Policy**: Displays the host name policy of the zone.
    - **IP Address:** Enter the IPv6 address to which you want the domain name to map. When you enter an IPv6 address, you can use double colons to compress a contiguous sequence of zeros. You can also omit any leading zeros in a four-hexadecimal group. For example, the complete IPv6 address 2006:0000:0000:0123:4567:89ab:0000:cdef can be shortened to 2006::123:4567:89ab:0:cdef. Note that if there are multiple noncontiguous groups of zeros, the double colon can only be used for one group to avoid ambiguity. The NIOS appliance displays an IPv6 address in its shortened form, regardless of its form when it was entered.
    - **Comment:** Optionally, enter additional information about this record.
    - **Create associated PTR record:** Select this option to automatically generate a PTR record that maps the specified IP address to the host name. To create the PTR record, the reverse-mapping zone must be in the database.
    - **Disable:** Clear the checkbox to enable the record. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes. For information, see *Managing Extensible Attributes*.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Modifying AAAA Records

When you modify an AAAA record, you can perform the following steps:

- In the **General** tab, you can change the information you previously entered through the wizard.
- In the **Discovered Data** tab, you can view discovered data, if any, for the record. For information, see *Viewing Discovered Data*.

You can also enter or edit information in the **TTL**, **Extensible Attributes** and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

Managing PTR Records

In a reverse-mapping zone, a PTR (pointer) record maps an IP address to a host name. Before adding a PTR record to a reverse-mapping zone, you must first create the zone. You can also add PTR records to forward-mapping zones to support zeroconf (zero configuration networking), such as wide-area Bonjour. For information about the Bonjour protocol, refer to *http://www.apple.com/support/bonjour*. Though adding PTR records to forward-mapping zones supports some of the use cases in RFC 1101, it does not support the network name mapping use case described in the RFC. For more information, refer to *http://tools.ietf.org/html/rfc1101*.

Note

If a PTR record with the domain name in its native characters is added to the Infoblox Grid through DDNS updates, the **Name** and **Domain Name** fields display the record name in UTF-8 encoded format. For example, a PTR record with the domain name 工作站 .*test.com* added through DDNS updates displays \229\183\165\228\189\156\231\171\153.test.com in the **Name** and **Domain Name** fields.

Adding PTR Records

To add a PTR record, perform the following steps:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **Add PTR Record**.
2. In the *Add PTR Record* wizard, do the following:
   - **Name** or **IP Address**: From the drop-down list, select **Name** or **IP Address**. When you select **Name**, click **Select Zone** to select a zone, and then enter a value for the PTR record. When you are adding a PTR record to a reverse-mapping zone, you can enter a value from 0 to 255 in the **Name** or **IP Address** field. Note that when you launch this wizard from the **IPAM** tab, you can only select a reverse-mapping zone. When you launch this from a reverse-mapping zone, the IP address field is populated with the prefix that corresponds to the selected zone. When you launch this from a forward-mapping zone, you can only specify the host name, not an IP address.
   - When you select **IP Address**, enter the IPv4 or IPv6 address that you want to map to the domain name.
   - **DNS View**: If you entered an IP address, you must select the DNS view of the PTR record. If you entered a name, this field displays the DNS view of the selected zone.
   - **Domain Name**: Enter the domain name to which you want the PTR record to point. For example, you can enter corpxyz.com.
   - **Comment**: Optionally, enter information about the PTR record.
   - **Disable**: Select this checkbox to disable the record. Clear the checkbox to enable it.
3. Save the configuration or click **Next** to define extensible attributes. For information, see *Managing Extensible Attributes*.
4. Click **Restart** if it appears at the top of the screen.

To schedule this task, click the Schedule icon at the top of the wizard. In the *Schedule Change* panel, click **Later**, and then specify a date, time, and time zone.

Note
When you add a PTR record to a forward-mapping zone, a message may appear on the top of the wizard if a Grid member is configured to ignore DNS queries for PTR records in forward-mapping zones. Contact Infoblox Technical Support for more information about this message.

Modifying PTR Records

To modify a PTR record, perform the following steps:

- In the **General** tab, you can change the information you previously entered through the wizard. Note that you cannot change an IPv4 address to an IPv6 address or move a PTR record from a forward-mapping zone to a reverse-mapping zone and vice versa. When you modify a PTR record that belongs to a forward-mapping zone, you can only modify the name since there is no IP address for such record.
- In the **Discovered Data** tab, you can view discovered data, if any, for the record. For information, see *Viewing Discovered Data*.

You can also enter or edit information in the **TTL**, **Extensible Attributes,** and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

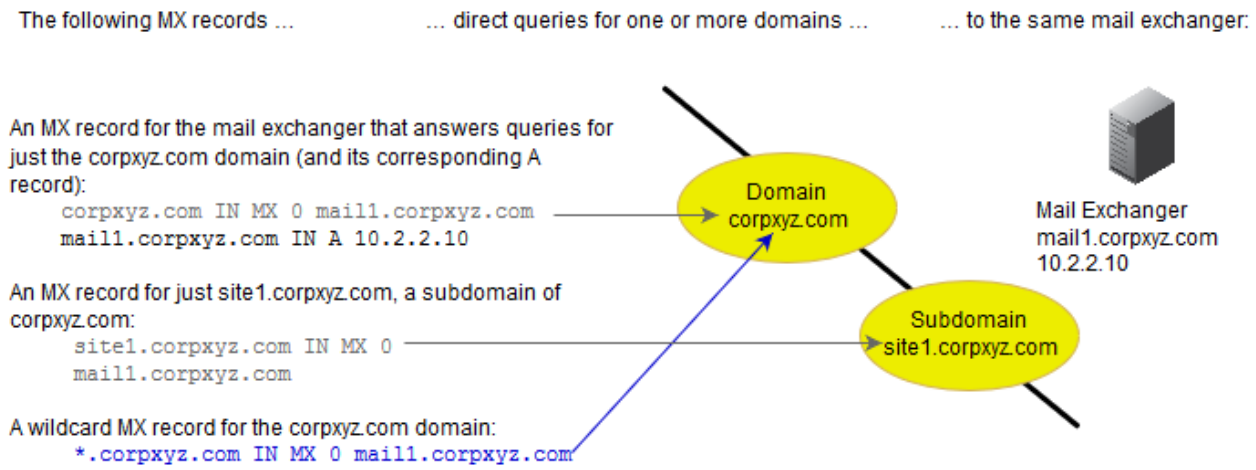
Managing MX Records

An MX (mail exchanger) record maps a domain name to a mail exchanger. A mail exchanger is a server that either delivers or forwards mail. You can specify one or more mail exchangers for a zone, as well as the preference for using each mail exchanger. A standard MX record applies to a particular domain or subdomain.

You can use a wildcard MX record to forward mail to one mail exchanger. For example, you can use a wildcard MX record in the corpxyz.com domain to forward mail for eng.corpxyz.com and sales.corpxyz.com to the same mail exchange, as long as the domain names do not have any matching resource record. Wildcards only apply when the domain name being queried does not match any record.

> **Note**
>
> If an MX record with the domain name in its native characters is added to the Infoblox Grid through DDNS updates, the **Mail Destination** and **Mail Exchanger** fields display the record name in UTF-8 encoded format. For example, an MX record with the domain name 工作站 .test.com added through DDNS updates displays \229\183\165\228\189\156\231\171\153.test.com in the **Mail Destination** and **Mail Exchanger** fields.

MX Records



> **Note**
>
> You must also create an A record for the host defined as a mail exchanger in an MX record.

Adding MX Records

To add an MX record from the Tasks Dashboard, see as described in *Add MX Record*. You can also add MX records from the **Data Management** tab -> **DNS** tab by clicking **Add** -> **Record** -> **Add MX Record** from the Toolbar.

Modifying and Deleting MX Records

When you modify an MX record, you can change the information you previously entered in the **General** tab. You can also enter or edit information in the **TTL**, **Extensible Attributes,** and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

Managing SRV Records

An SRV (service location) record directs queries to hosts that provide specific services. For example, if you have an FTP server, then you might create an SRV record that specifies the host which provides the service. You can specify more than one SRV record for a host. For more information about SRV records, see *RFC2052,ADNSRRforspecifyingthelocationofservices(DNSSRV)*.

> ⚠ Note
>
> If an SRV record with the domain name in its native characters is added to the Infoblox Grid through DDNS updates, the **Name** and **SRV Target** fields display the domain name in UTF-8 encoded format. For example, an SRV record with the domain name 电脑 .test.com added through DDNS updates displays \231\148\181\232\132\145.test.com in the **Name** and **SRV Target** fields.

Adding SRV Records

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **Add SRV Record**.
2. In the *Add SRV Record* wizard, complete the following fields:
   - **Display input as**: Select the format in which you want the SRV record to be displayed. When you select RFC 2782 format, the appliance follows the *_service._protocol.name* format as defined in RFC 2782. When you select Free format, enter the entire name in the Domain field.
   - **Service:** Specify the service that the host provides. You can either select a service from the list or type in a service, if it is not on the list. For example, if you are creating a record for a host that provides FTP service, select _ftp. To distinguish the service name labels from the domain name, the service name is prefixed with an underscore. If the name of the service is defined at *http://www.iana.org/assignments/service-names-port-numbers/service-names-port-numbers.xml*, use that name. Otherwise, you can use a locally-defined name.
   - Protocol: Specify the protocol that the host uses. You can either select a protocol from the list or type in a protocol, if it is not on the list. For example, if it uses TCP, select _tcp. To distinguish the protocol name labels from the domain name, the protocol name is prefixed with an underscore.
   - **Domain:** If Grid Manager displays a zone name, enter the name here to define an SRV record for a host or subdomain. The displayed zone name can either be the last selected zone or the zone from which you are adding the SRV record. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click a zone name in the dialog box, and then enter the name to define the SRV record. The NIOS appliance prefixes the name you enter to the domain name of the selected zone. For example, if you want to create an SRV record for a web server whose host name is www2.corpxyz.com and you define the SRV record in the corpxyz.com zone, enter www2 in this field. To define an SRV record for a domain whose name matches the selected zone, leave this field blank. The NIOS appliance automatically adds the domain name (the same as the zone name) to the SRV record. For example, if you want to create an SRV record for the corpxyz.com domain and you selected the corpxyz.com zone, leave this field blank.
   - **Preview**: After you have entered all the information, this field displays the FQDN, which is the concatenation of the Service, Protocol, and Domain fields.
   - **Shared Record Group**: This field appears only when you are creating a shared record. Click **Select Shared Record Group**. If you have only one shared record group, the appliance displays the name of the shared record group here. If you have multiple shared record groups, select the shared record group in the *Shared Record Group Selector* dialog box. You can use filters or the **Go to** function to narrow down the list.
   - **Priority:** Select or enter an integer from 0 to 65535. The priority determines the order in which a client attempts to contact the target host; the domain name host with the lowest number has the highest priority and is queried first. Target hosts with the same priority are attempted in the order defined in the **Weight** field.

- **Weight:** Select or enter an integer from 0 to 65535. The weight allows you to distribute the load between target hosts. The higher the number, the more that host handles the load (compared to other target hosts). Larger weights give a target host a proportionately higher probability of being selected.
- **Port:** Specify the appropriate port number for the service running on the target host. You can use standard or nonstandard port numbers, depending on the requirements of your network. You can select a port number from the list or enter an integer from 0 to 65535.
- **Target:** Enter the canonical domain name of the host (not an ALIAS); for example, www2.corpxyz.com. In addition, you need to define an A record mapping the canonical name of the host to its IP address.
- **Comment:** Enter a descriptive comment for the record.
- **Disable:** Clear the checkbox to enable the record. Select the checkbox to disable it.

3. Save the configuration or click **Next** to define extensible attributes. For information, see *Managing Extensible Attributes*.
4. Click **Restart** if it appears at the top of the screen.

Modifying and Deleting SRV Records

To modify an SRV record, perform the following steps:

- In the **General** tab, the **Display input as** field displays the format in which the SRV record was configured. For RFC 2782 format, the appliance matches the *{}*service.*protocol.name* format and displays the corresponding information in the Service and Protocol fields. If the appliance cannot match the service and protocol, it displays the entire name in the Domain field. For Free format, the entire name is displayed in the Domain field.

> **Note**
> The appliance does not match the service and protocol names to exactly how they appear in the drop-down lists. It only checks whether the first two parts of the names start with an underscore. If the first two parts do not start with an underscore, the appliance assumes it is a free format. For example, _abc._xyz.name is considered as RFC 2782 format even though _abc is not in the **Service** drop-down list, and _xyz is not in the **Protocol** drop-down list. Grid Manger displays _abc in the **Service** field and _xyz in the **Protocol** field. On the other hand, "abc.xyz.name" is considered as a free format because the first two parts do not start with underscores, and Grid Manager displays this in its entirety in the **Domain** field.

You can also enter or edit information in the **TTL**, **Extensible Attributes,** and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

Managing TXT Records

A TXT (text record) record contains supplemental information for a host. For example, if you have a sales server that serves only North America, you can create a text record stating this fact. You can create more than one text record for a domain name.

> **Note**
>
> If a TXT record with the domain name in its native characters is added to the Infoblox Grid through DDNS updates, the **Name** field displays the domain name in UTF-8 encoded format. For example, a TXT record with the domain name 电脑 .test.com added through DDNS updates displays \231\148\181\232\132\145.test.com in the **Name** field.

Using TXT Records for SPF

SPF (Sender Policy Framework) is an anti-forgery mechanism designed to identify spam e-mail. SPF fights e-mail address forgery and makes it easier to identify spam, worms, and viruses. Domain owners identify sending mail servers in DNS. SMTP receivers verify the envelope sender address against this information, and can distinguish legitimate mail from spam before any message data is transmitted.

SPF makes it easy for a domain to say, "I only send mail from these machines. If any other machine claims that I'm

sending mail from there, they're not valid." For example, when an AOL user sends mail to you, an email server that belongs to AOL connects to an email server that belongs to you. AOL uses SPF to publish the addresses of its email servers. When the message comes in, your email servers can tell if the server that sent the email belongs to AOL or not.

You can use TXT records to store SPF data that identifies what machines send mail from a domain. You can think of these specialized TXT records as *reverse MX records* that e-mail servers can use to verify if a machine is a legitimate sender of an e-mail.

SPF Record Examples

```
corpxyz.com. IN TXT "v=spf1 mx -all"
 corpxyz.net. IN TXT "v=spf1 a:mail.corpxyz.com -all" corpxyz.net. IN TXT
"v=spf1 include:corpxyz.com -all" corpxyz.net. IN TXT "v=spf1 mx -all
exp=getlost.corpxyz.com" corpxyz.com. IN TXT "v=spf1 include:corp200.com
-all"
```

> ⚠ Note
> If an SPF record goes beyond the BIND limit of 255 characters, Infoblox recommends that you break up the record into two TXT records.

Adding TXT Records

To add an TXT record from the Tasks Dashboard, see *Add TXT Record*. You can also add TXT records from the **Data Management** tab -> **DNS** tab by clicking **Add** -> **Record** -> **Add TXT Record** from the Toolbar.

Modifying and Deleting TXT Records

When you modify a TXT record, you can change the information you previously entered in the **General** tab. You can also enter or edit information in the **TTL**, **Extensible Attributes,** and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

Managing TLSA Records

A TLSA record is used to associate a TLS (Transport Layer Security) server certificate or a public key with a domain name. For example, you can define whether a certificate or a public key must be associated with a domain name when you define a TLSA resource record through Grid Manager. When you define your own TLSA record, you do not have to depend on an external Certificate Authority to issue a digitally signed TLS certificate for your domain name. When a client queries the domain name, TLSA records are matched to authenticate associated TLS certificates.

Using TLSA Records for DANE

Infoblox supports DANE (DNS-based Authentication of Named Entities) protocol to secure information about domain names. DANE uses DNSSEC to sign certificates and keys that are used by the TLS and distributes secure information about the domain name using DNS. With DANE, you can make an authoritative binding between the domain name and a certificate or a public key, whichever is used by a host for the respective domain. You can define what kind of certificates or public keys must be associated with a domain name to prevent vulnerability attacks and to reduce or prevent the interaction of third-party Certification Authorities to issue PKIX certificates. For detailed information about the TLSA record format and certificate usage, refer to *RFC 6698 The DNS-Based Authentication of Named Entities (DANE) Transport Layer Security (TLS) Protocol: TLSA.*

Adding TLSA Records

In NIOS 8.5, you can add a TLSA record to a DNSSEC signed zone only. You cannot unsign a zone that contains a TLSA record. In NIOS 8.5.1 or later, you can add a TLSA record to a DNSSEC signed zone or an unsigned zone. To add a TLSA record:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **TLSA Record**.
2. In the *Add TLSA Record* wizard, complete the following fields:
   - **Display input as**: Select either **Strict format (_port._protocol.domain)** or **Free format**. Grid Manager selects **Strict format** by default. In this format, you can choose port and protocol values from the list. When you select **Free format**, you cannot specify these values.
   - **Port**: Select a value from the drop-down list to indicate the port on which the TLS-based service is active. The values in the drop-down list are:
     - 21 (FTP)
     - 22 (SSH)
     - 23 (Telnet)
     - 25 (SMTP)
     - 80 (HTTP)
     - 88 (Kerberos)
     - 389 (LDAP)
     - 443 (HTTPS)
     - 464 (KPASSWD)
     - 3268 (GC)
   - **Protocol**: Select a value from the drop-down list to indicate the protocol that is used for secure communication. The values in the drop-down list are:
     - _msdcs
     - _sites
     - _tcp
     - _udp

     When you select **Strict format, Port** and **Protocol** values are set to **443 (HTTPS)** and **_tcp**, by default. You can change these values. When you select **Free format**, you cannot edit the mentioned values.
   - **Name**: Enter a name for the TLSA resource record. You can specify a name only when you select **Free format**.
   - **Select Zone**: Click to select a zone. In NIOS 8.5, you must select only a signed zone to associate with a TLSA resource record. In NIOS 8.5.1 or later, you can select a signed zone or an unsigned zone. For more information, see *Signing a Zone*. Click **Clear** to clear the **Name** that you have entered.
   - **FQDN**: This is displayed by default. You cannot modify the value. TLSA resource records are stored using the domain name that you select. When you select **Free format**, *name.domain* is displayed as the FQDN. Example: abc.example.com. When you select **Strict format**, *_port._protocol.domain* is displayed as the FQDN, where:
     - *_port* indicates the port on which the TLS-based service is active.
     - *_protocol* indicates the name of the transport protocol that you have selected.

     Consider an example where you are the owner of the domain www.example.com and you have set the **Port** to **443(HTTPS)** and **Protocol** to ***tcp*** , which indicates that the HTTP server is running TLS on port 443. To request TLSA record for www.example.com, you must use *__443._tcp. www.example.com.* Similarly, to request a TLSA resource record for an SMTP server running the STARTTLS protocol on port 25 at mail.example.com, you must use *_25._tcp.mail.example.com*.
   - **DNS View**: The DNS View associated with the selected DNS zone is displayed.
   - **Certificate Usage**: Select a value from the drop-down list to indicate how the certificate or the public key associated with the domain name is matched when the client queries for the domain name on the TLS server. The values in the drop-down list are: **PKIX-TA**, **PKIX-EE**, **DANE-TA**, and **DANE-EE**.
     - With **PKIX-TA** and **PKIX-EE**, you need additional Trust Anchors to validate peer certificate chains. These Trust Anchors must be mutually trusted by both the TLS server and the client. For more information, refer to *RFC 6698 The DNS-Based Authentication of Named Entities (DANE) Transport Layer Security (TLS) Protocol: TLSA.*

        - When you select **DANE-TA** and **DANE-EE**, the TLSA records that you define using Grid Manager are sufficient to verify the client's certificate chain and additional Trust Anchors are not required to authenticate the public key or certificate data. For more information, refer to *RFC 6698 The DNS-Based Authentication of Named Entities (DANE) Transport Layer Security (TLS) Protocol: TLSA.*
    - **Selector**: Select a value from the drop-down list to indicate whether you are associating an entire certificate or only the public key with the domain. When you select a value, it indicates which part of the TLS certificate presented by the server is matched with the associated data. The values in the drop-down list are **Full certificate** and **Subject Public Key Info**. NIOS builds a hexadecimal format for the entire certificate when you select **Full certificate**. If you select **Subject Public Key Info**, NIOS extracts the public key and builds a hexadecimal format for it.
    - **Matched Type**: Select a value from the drop-down list to indicate how a TLS certificate or the public key of the domain received from the client must be matched with the certificate or the key that you have specified for the respective domain in the TLS server. You can select to match the entire content or only the hash of the selector. The values in the drop-down list are: **No hash**, **SHA 256 bit**, and **SHA 512 bit.** If you select **No hash**, the TLS server performs an exact match on the selected content. When you select either **SHA 256 bit** or **SHA 512 bit**, only the hash of the selected content is matched by the TLS server.
    - **Certificate Data**: Enter the certificate data that must be matched for authentication. You can either paste the full certificate or the corresponding public key when the **Matched Type** is set to **No hash**. Based on the values that you select for the **Selector** and the **Matched Type**, the server builds a hexadecimal format for the TLSA record. If you set the **Matched Type** to **SHA 256 bit** or **SHA 512 bit**, you must specify only the hash of the full certificate or the public key.
    - **Get From File**: Click this to upload the certificate or the public key to the server.
      Note the following:
        - When you select **Strict format**, you must provide either the certificate or public key or hash of any of them. The value must be based on the **Selector** and **Matched Type** field values.
        - When you select **Free format,** you must upload the certificate in DER format. The server builds an appropriate hexadecimal format for the TLSA record based on the **Selector** value.
    - **Comment**: Optionally, enter a descriptive comment for the TLSA record.
    - **Disable:** Clear the checkbox to enable the record. Select the checkbox to disable it.

You can also perform the following steps:

- Use **Global Search** to search for TLSA records. For information, see *Global Search*.
- Use **Copy Records** to copy TLSA records between DNS zones. For information, see *Copying Zone Records.*
- Define global permission for **All TLSA records** with read-only, read/write or deny access. You can also define object level permission for TLSA records. For information, see *Defining Global Permissions* and *Defining Object Permissions*.
- Import and export records in CSV format. For information, see *Importing and Exporting Data using CSV Import*.
- View audit log entries for the TLSA record. For information, see *Viewing the Audit Log*.

Modifying and Deleting TLSA Records

When you modify a TLSA record, you can change the information you previously entered in the **General** tab. You can also enter or edit information in the **TTL**, **Extensible Attributes,** and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

Managing CAA Records

A Certification Authority Authorization (CAA) DNS resource record enables domain owners to define the Certificate Authorities (CAs) that can issue certificates for a domain. When you define a CAA record, only the CAs listed in the records can issue certificates for the respective domain. With CAA, you can also define notification rules to manage requests for a certificate from a non-authorized CA. If you do not define a CAA resource record, any CA can issue a certificate for the domain. For detailed information about the CAA record format and certificate usage, refer to *RFC 6844 DNS Certification Authority Authorization (CAA) Resource Record*. You can add, edit, or delete a CAA resource record through Grid Manager or the Infoblox API. The following are a few examples of CAA resource records:

- example.com. CAA 0 issue “ssl.com; policy=ev”

- example.com. CAA 0 issuewild ";"
- example.com. CAA 0 iodef "mailto:certissues@example.com"
- example.com. CAA 0 iodef "certissues.example.com"

> **Note**
>
> When you enable threat protection on a member, you must configure either a pass rule or rate limiting rule for CAA DNS resource record types. This is specific to record types that use threat protection rule templates to allow incoming DNS queries for the respective CAA record. If you do not configure these rules, the threat protection service that is running on the member blocks the DNS queries of the CAA record.

Adding CAA Records

To add a CAA record, perform the following steps:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **CAA Record**.
2. In the *Add CAA Record* wizard, complete the following fields:
   - **Name**: Enter a name for the CAA record. Click **Select Zone** to select a zone. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click **Clear** to clear the zone that you have entered.
   - **DNS View**: The DNS view associated with the selected DNS zone is displayed.
   - **Flag**: Select a checkbox to set the flag value. When the flag is set to **Bit 0 (Critical)**, it tells the CA that it must completely understand the property tag to proceed. A CA does not issue certificates for any domain when the flag is set to **Bit 0 (Critical)** and the property tag is not understood. NIOS considers the flag value as zero, if you do not select any checkbox.

     Note that the flags are unsigned integers between 0 and 255. Infoblox represents these integers in the form of bits. When you select the checkbox for **Bit 0 (Critical)**, the flag value is set to binary 10000000, which is decimal 128. Example: CAA 128 xyz "Unknown".
     You can select only **Bit 0 (Critical)** as the flag value and the remaining checkboxes are reserved for future use. The appliance displays a warning message when you select a checkbox other than **Bit 0 (Critical)**.
     Consider the following example with two CAA records:
     - CAA 0 issue "ca.example.net; policy=ev"
     - CAA 128 xyz "Unknown"

     In the above example, the property tag **xyz** is flagged as unknown. The CA associated with example.net or any other issuer cannot issue a certificate unless the processing rules for the **xyz** property tag are clearly understood by the CA.
   - **Type(Tag)**: Indicates the type of CAA record. The supported CAA record types are:
     - **Issue**: Select this to explicitly authorize a single CA to issue a certificate for the domain and subdomains of the specified domain.
     - **Issuewild**: Select this to explicitly authorize a single CA to issue a wildcard certificate for the domain. It allows the domain holder or anyone acting under the authority of the domain holder to issue wildcard certificates for the domain.
       Note that **Issue wild** type takes precedence over **Issue.**
     - **Iodef**: Select this to specify an email address or URL of the web service to report invalid certificate requests or issued certificates that violate your CAA policy.
       Infoblox allows you to enter a new CAA record type other than those displayed in the drop-down list. The maximum length allowed is 255 characters.
   - **Certificate Authority**: Indicates the CA that is authorized to issue a certificate for the domain. The maximum length for certificate authority is 8192 characters. You can also specify the email address or the URL to report CAA policy violation for the domain. This is valid for **Iodef** only. Infoblox recommends that you add either the **http://** or **https://** prefix to the domain name. You must explicitly add "mailto" when specifying the email address. For example, "mailto:admin@*example.com*".
   - **Comment**: Optionally, enter a descriptive comment for the CAA record.
   - **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.

3. Save the configuration or click **Next** to define extensible attributes. For information, see *Managing Extensible Attributes*.
4. Save the configuration or click **Next** to schedule this task. Click **Now** in the **Schedule Change** panel to immediately execute this task or click **Later** and specify a date, time, and time zone. For information about how to schedule a task, see *Scheduling Tasks*.
5. Click **Save & Close** to complete the configuration.

> ⚠ Note
> Infoblox does not support shared CAA records and does not provide Windows 2016 MS Server support for CAA records.

You can also perform the following steps:

- Use **Global Search** to search for CAA records. For information, see *Global Search*.
- Use **Copy Records** to copy CAA records between DNS zones. For information, see *Copying Zone Records.*
- Define global permission for **All CAA records** with read-only, read/write or deny access. You can also define object level permission for CAA records. For information, see *Defining Global Permissions* and *Defining Object Permissions*.
- Import and export records in CSV format. For information, see *Importing and Exporting Data using CSV Import*.
- View audit log entries for the CAA record. For information, see *Viewing the Audit Log*.
- Use Smart Folders to organize threat protection profiles by name, comment or object type. For information, see *Smart Folders*.
- You can view the status of the import process and a summary report in the Data Import Wizard Log. For large data sets, this option is an efficient approach. To download the Data Import Wizard, visit *https://data-import-wizard.infoblox.com/#/overviewDashboard*.

Modifying and Deleting CAA Records

When you modify a CAA record, you can change the information you previously entered in the **General** tab. You can also enter or edit information in the **TTL**, **Extensible Attributes,** and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

Managing CNAME Records

A CNAME record maps an ALIAS to a canonical name. You can use CNAME records in both forward- and IPv4 reverse-mapping zones to serve two different purposes. (At this time, you cannot use CNAME records with IPv6 reverse-mapping zones.)

> ⚠ Note
>
> If a CNAME record with the domain name in its native characters is added to the Infoblox Grid through DDNS updates, the **ALIAS** and **Canonical Name** fields display the domain name in UTF-8 encoded format. For example, a CNAME record with the domain name 电脑 .*test.com* added through DDNS updates displays \231\148\181\232\132*145.test.com* in the **Canonical Name** and **ALIAS** fields.

CNAME Records in Forward-Mapping Zones

In a forward-mapping zone, a CNAME record maps an ALIAS to a canonical (or official) name. CNAME records are often more convenient to use than canonical names because they can be shorter or more descriptive. For example, you can add a CNAME record that maps the ALIAS *qa.engr* to the canonical name *qa.engr.corpxyz.com*.

> ⚠ Note

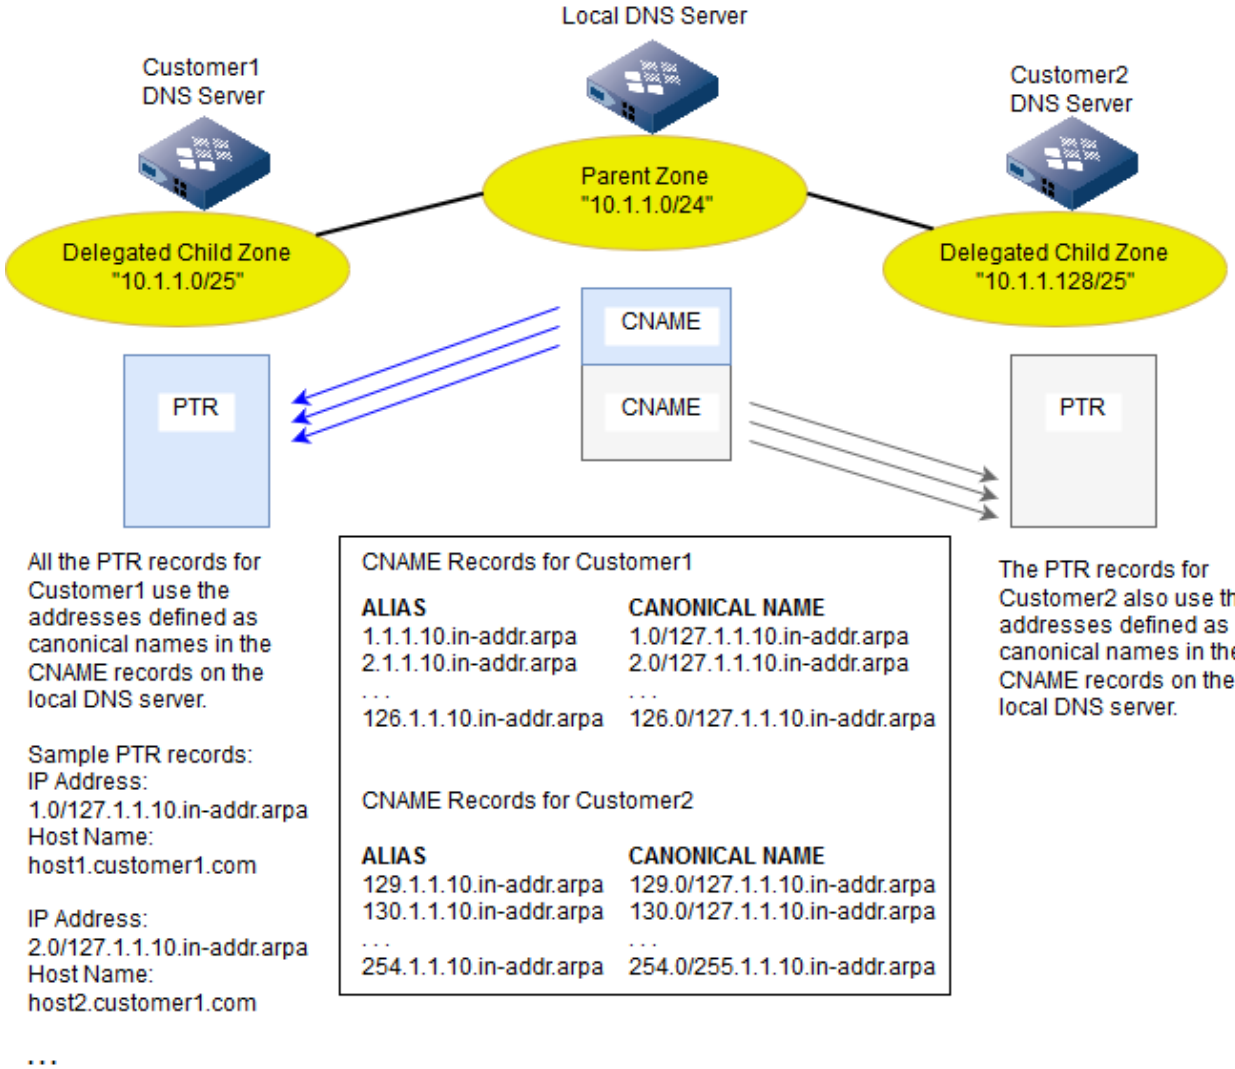
A CNAME record does not have to be in the same zone as the canonical name to which it maps. In addition, a CNAME record cannot have the same name as any other record in that zone.

To add a CNAME record to a forward-mapping zone from the Tasks Dashboard, see *Add CNAME Record*. You can also add CNAME records from the **Data Management** tab -> **DNS** tab by clicking **Add** -> **Record** -> **Add CNAME Record** from the Toolbar.

CNAME Records in IPv4 Reverse-Mapping Zones

You can add CNAME records to an IPv4 reverse-mapping zone to create ALIASes to addresses maintained by a different name server when the reverse-mapping zone on the server is a delegated child zone with fewer than 256 addresses. This technique allows you to delegate responsibility for a reverse-mapping zone with an address space of fewer than 256 addresses to another authoritative name server. See the following figure and *RFC 2317, Classless IN-ADDR.ARPA delegation*.

CNAME Records in a Reverse-Mapping Zone



You add CNAME records in the parent zone on your name server. The ALIASes defined in those CNAME records point to the addresses in PTR records in the child zone delegated to the other server.

When you define a reverse-mapping zone that has a netmask from /25 (255.255.255.128) to /31 (255.255.255.254), you must include an RFC 2317 prefix. This prefix can be anything, from the address range (examples: 0-127, 0/127) to descriptions (examples: first-network, customer1). On a NIOS appliance, creating such a reverse-mapping zone automatically generates all the necessary CNAME records. However, if you need to add them manually to a parent zone that has a child zone with fewer than 255 addresses.

Adding CNAME Records

To add a CNAME record to a forward-mapping or reverse-mapping zone from the Tasks Dashboard, see *Add CNAME Record*. You can also add CNAME records from the **Data Management** tab -> **DNS** tab by clicking **Add** -> **Record** -> **Add CNAME Record** from the Toolbar.

Modifying and Deleting CNAME Records

When you modify a CNAME record, you can change the information you previously entered in the **General** tab. You can also enter or edit information in the **TTL**, **Extensible Attributes,** and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

Managing DNAME Records

A DNAME record maps all the names in one domain to those in another domain, essentially substituting one domain name suffix with the other (see RFC 2672, *Non-Terminal DNS Name Redirection*). For example, adding a DNAME record to the corpxyz.com domain mapping "corpxyz.com" to "corp200.com" maps *name-x*.corpxyz.com to *name-x*.corp200.com:

Domain Name		Target Domain Name
server1.**corpxyz.com**	—>	server1.**corp200.com**
server2.**corpxyz.com**	—>	server2.**corp200.com**
server3.**corpxyz.com**	—>	server3.**corp200.com**
. . . .corpxyz.com	—>	. . . .**corp200.com**

> **Note**
>
> If a DNAME record with the domain name in its native characters is added to the Infoblox Grid through DDNS updates, the **ALIAS** and **Target** fields display the domain name in UTF-8 encoded format. For example, a DNAME record with the domain name 电脑 .test.com added through DDNS updates displays \231\148\181\232\132\145.test.com in the **ALIAS** and **Target** fields.

When a request arrives for a domain name to which a DNAME record applies, the NIOS appliance responds with a CNAME record that it dynamically creates based on the DNAME definition. For example, if there is a DNAME record:

```
corpxyz.com.
DNAME                                   corp200.com.
```

and a request arrives for server1.corpxyz.com, the NIOS appliance responds with the following CNAME record:

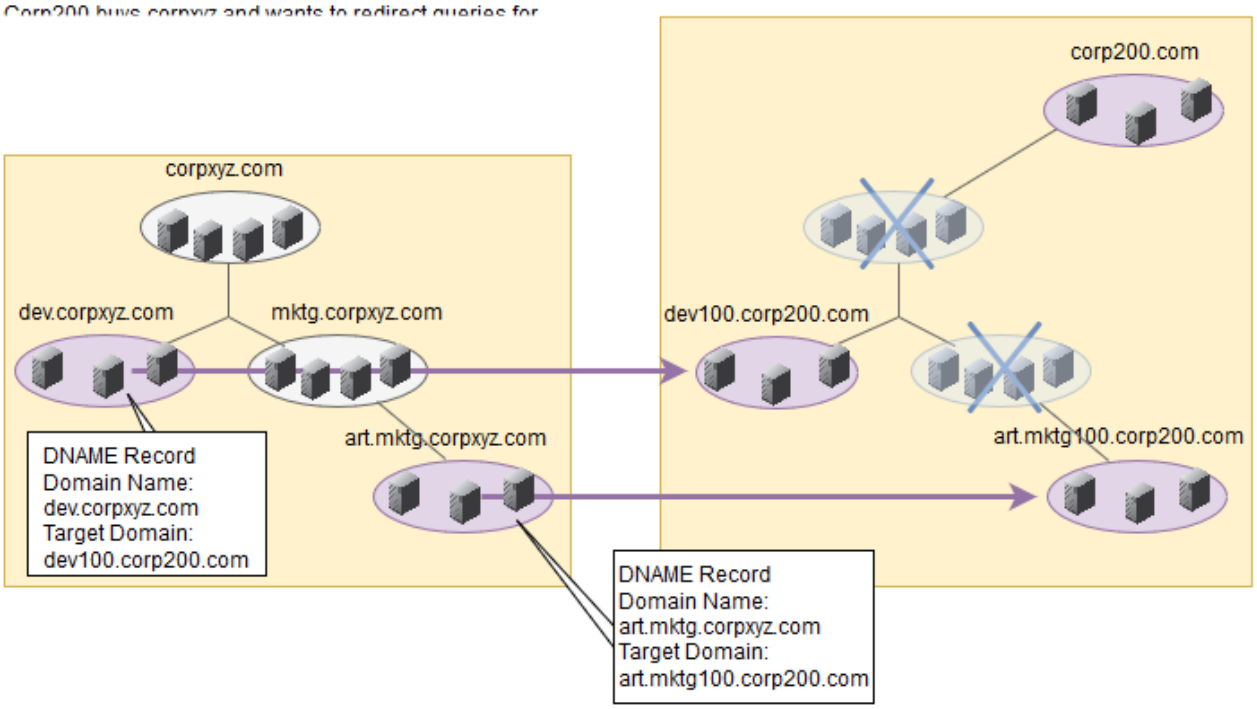
```
server1.corpxyz.com.
CNAME                                    server1.corp200.com.
```

If responding to a name server running BIND 9.0.0 or later, the NIOS appliance also includes the DNAME record in its response, so that name server can also create its own CNAME records based on the cached DNAME definition.

The following are two common scenarios for using DNAME records:

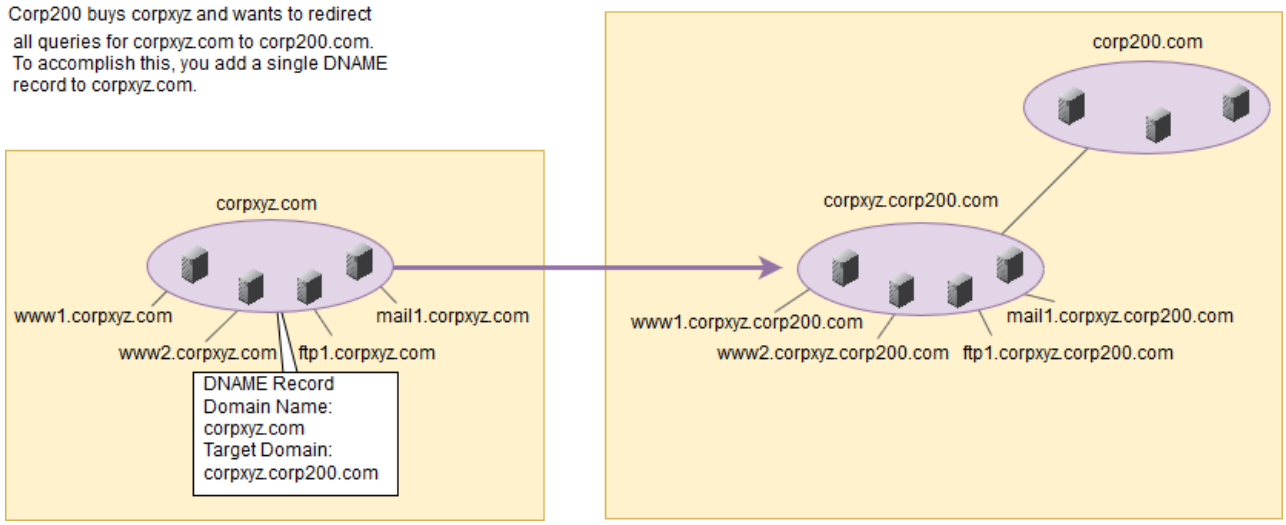
- One company buys another and wants people using both the old and new name spaces to reach the same hosts.
- A virtual Web hosting operation offers different "vanity" domain names that point to the same server or servers. There are some restrictions that apply to the use of DNAME records:
- You cannot have a CNAME record and a DNAME record for the same subdomain.
- You cannot use a DNAME record for a domain or subdomain that contains any subdomains. You can only map the lowest level subdomains (those that do not have any subdomains below them). For an example of using DNAME records in a multi-tiered domain structure, see the following figure.

Adding DNAME Records for the Lowest Level Subdomains



In the case of a domain structure consisting of a single domain (no subdomains), adding a DNAME record redirects queries for every name in the domain to the target domain, as shown in the following figure.

Adding a DNAME Record for a Single Domain



When using a DNAME record, you must copy the resource records for the source domain to the zone containing the target domain, so that the DNS server providing service for the target domain can respond to the redirected queries.

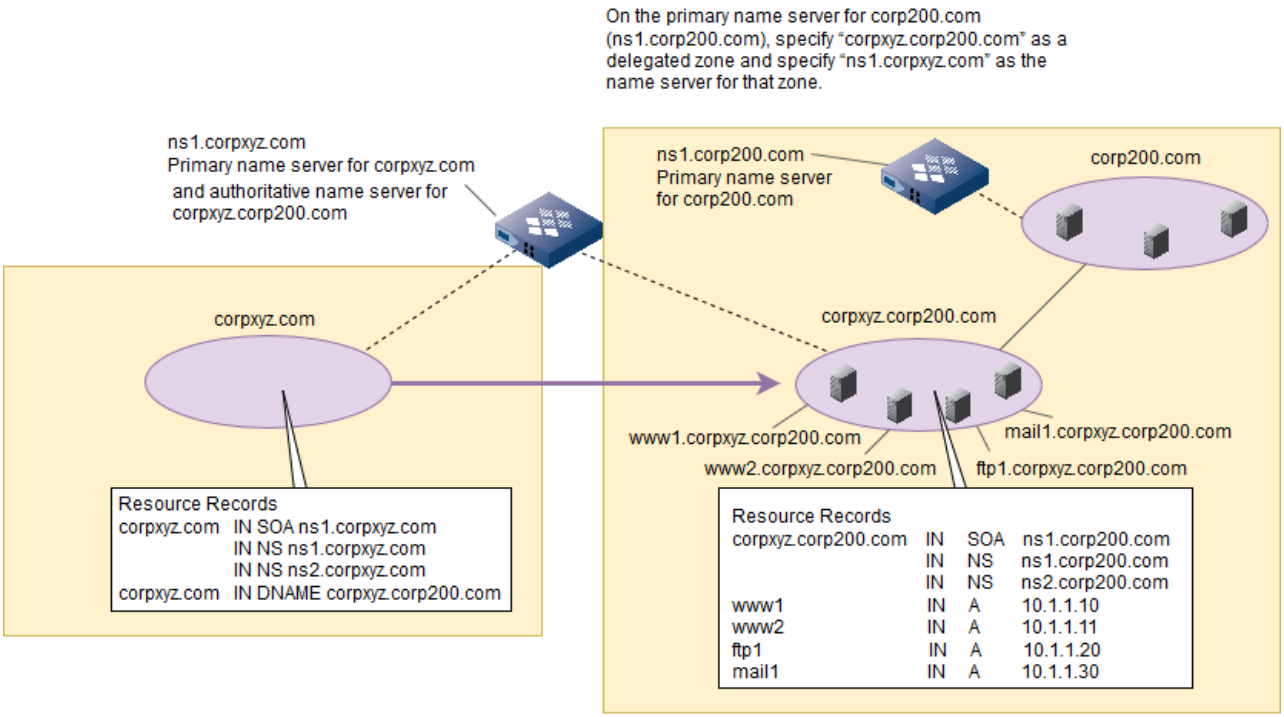
Copy from corpxyz.com	to corpxyz.corp200.com
www1 IN A 10.1.1.10	www1 IN A 10.1.1.10
www2 IN A 10.1.1.11	www2 IN A 10.1.1.11
ftp1 IN A 10.1.1.20	ftp1 IN A 10.1.1.20
mail1 IN A 10.1.1.30	mail1 IN A 10.1.1.30

After copying these records to the zone containing the corpxyz.corp200.com domain, delete them from the zone containing the corpxyz.com domain.

If DNS service for the source and target domain names is on different name servers, you can import the zone data from the NIOS appliance hosting the source domain to the appliance hosting the target domain. For information about this procedure, see *Importing Zone Data*.

If DNS service for the source and target domain names is on the same name server and the parent for the target domain is on a different server, you can delegate DNS services for the target domain name to the name server that provided—and continues to provide—DNS service for the source domain name (see the figure below). By doing this, you can continue to maintain resource records on the same server, potentially simplifying the continuation of DNS administration.

Making the Target Zone a Delegated Zone



Note: This is a conceptual representation of domain name mapping and depicts the resulting hierarchical relationship of corp200.com as the parent zone for corpxyz.corp200.com. The hosts are not physically relocated.

> **Note**
>
> This is a conceptual representation of domain name mapping and depicts the resulting hierarchical relationship of corp200.com as the parent zone for corpxyz.corp200.com. The hosts are not physically relocated.

The following tasks walk you through configuring the two appliances in the *Making the Target Zone a Delegated Zone* figure to redirect queries for corpxyz.com to corpxyz.corp200.com using a DNAME record:

On the ns1.corpxyz.com name server, perform the following steps:

1. Create a new forward-mapping zone called corpxyz.corp200.com. See *Creating an Authoritative Forward-Mapping Zone*.
2. Copy all the resource records for the domain or subdomain to which the DNAME record is going to apply from corpxyz.com to corpxyz.corp200.com.
   Because you can only specify the records by type, not individually, you might have to copy some records that you do not want and then delete them from the *corpxyz.corp200.com* zone.
3. In the corpxyz.com zone, delete all the resource records for the domain or subdomain to which the DNAME record is going to apply.
4. Add a DNAME record to the corpxyz.com zone specifying "corpxyz.com" as the domain and "corpxyz.corp200.com" as the target domain. Adding a DNAME record is explained in the next section.
5. On the ns1.corp200.com name server, add corpxyz.corp200.com as a delegated zone and specify ns1.corpxyz.com as the name server for it. See *Configuring a Delegation*.

DNAME Records for Forward-Mapping Zones

To add a DNAME record to a forward-mapping zone:

- From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **Add DNAME Record**.

In the *Add DNAME Record* wizard, complete the following fields:

> ⚠ Note
> If you specify a subdomain in the Domain Name field when configuring a DNAME record and the subdomain is also a subzone, the DNAME record appears in the list view for the subzone, not in the list view for the parent zone selected in the process of adding the record.

- **ALIAS**: If Grid Manager displays a zone name, enter the name of a subdomain here. If you are adding a DNAME record for the entire zone, leave this field empty. This field is for adding a DNAME record for a subdomain within the selected zone. The displayed zone name can either be the last selected zone or the zone from which you are adding the CNAME record. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click a zone name in the dialog box, and then enter the name of a subdomain.
- **Target:** Enter the domain name to which you want to map all the domain names specified in the ALIAS field.
- **Comment:** Enter identifying text for this record, such as a meaningful note or reminder.
- **Disable:** Clear the checkbox to enable the record. Select the checkbox to disable it.
- Save the configuration or click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.
- Click **Restart** if it appears at the top of the screen.

DNAME Records for Reverse-Mapping Zones

You can use DNAME records to redirect reverse lookups from one reverse-mapping zone to another. You can use DNAME records for reverse-mapping zones to simplify the management of subzones for classless address spaces larger than a class C subnet (a subnet with a 24-bit netmask).

RFC 2672, *Non-Terminal DNS Name Redirection*, includes an example showing the delegation of a subzone for an address space with a 22-bit netmask inside a zone for a larger space with a 16-bit netmask:

$ORIGIN 0.192.in-addr.arpa.

8/22	NS	ns.slash-22-holder.example.
8	DNAME	8.8/22
9	DNAME	9.8/22
10	DNAME	10.8/22
11	DNAME	11.8/22

The reverse-mapping zone 0.192.in-addr.arpa. applies to the address space 192.0.0.0/16. Within this zone is a subzone and subdomain with the abbreviated name *8/22*. (Its full name is *8/22.0.192.in-addr.arpa*.) This subdomain contains its own subdomains corresponding to the 1024 addresses in the 192.0.8.0/22 subnet:

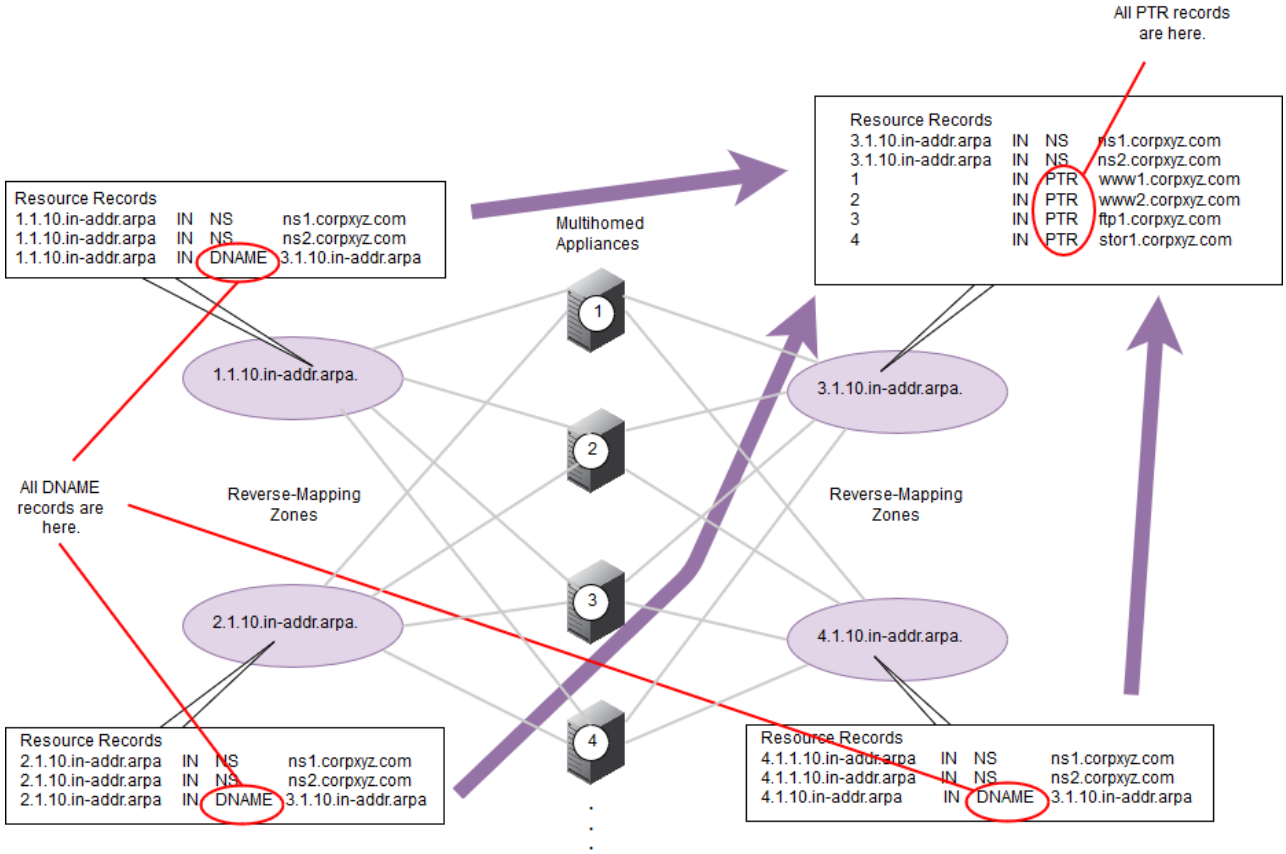
- Subdomain 8/22 (8/22.0.192.in-addr.arpa)
  - Subdomain 8.8/22 for addresses 192.0.8.0 – 192.0.8.255 (or 192.0.8.0/24)
  - Subdomain 9.8/22 for addresses 192.0.9.0 – 192.0.9.255 (or 192.0.9.0/24)
  - Subdomain 10.8/22 for addresses 192.0.10.0 – 192.0.10.255 (or 192.0.10.0/24)
  - Subdomain 11.8/22 for addresses 192.0.11.0 – 192.0.11.255 (or 192.0.11.0/24)

The NS record delegates authority for the reverse-mapping subzone 8/22 to the DNS server ns.slash-22-holder.example. Finally, the DNAME records provide ALIASes mapping domain names that correspond to the 192.0.8.0/24, 192.0.9.0/24, 192.0.10.0/24, and 192.0.11.0/24 subnets to the respective subdomains 8.8/22, 9.8/22, 10.8/22, and 11.8/22 in the 8/22.0.192.in-addr.arpa subzone.

> **Note**
> NIOS appliances support DNAME records in reverse-mapping zones that map addresses to target zones with a classless address space larger than a class C subnet. However, NIOS appliances do not support such target zones.

You might also use DNAME records if you have a number of multihomed appliances whose IP addresses must be mapped to a single set of domain names. An example of this is shown in the below figure.

DNAME Records to Simplify DNS for Multihomed Appliances



To add a DNAME record to a reverse-mapping zone, perform the following steps:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **Add DNAME Record**.
2. In the *Add DNAME Record* wizard, complete the following fields:
   If you specify a subdomain in the Domain Name field when configuring a DNAME record and the subdomain is also a subzone, the DNAME record appears in the list view for the subzone, not in the list view for the parent zone selected in the process of adding the record.
   - **ALIAS**: If Grid Manager displays a zone name, enter the name of a subdomain here. If you are adding a DNAME record for the entire zone, leave this field empty. This field is for adding a DNAME record for a subdomain within the selected zone. The displayed zone name can either be the last selected zone or the zone from which you are adding the CNAME record. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click a zone name in the dialog box, and then enter the name of a subdomain.

- **Target:** Type the name of the reverse-mapping zone to which you want to map all the addresses specified in the Domain Name field.
- **Comments:** Enter identifying text for this record, such as a meaningful note or reminder.
- **Disable:** Clear the checkbox to enable the record. Select the checkbox to disable it.

3. Save the configuration or click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.
4. Click **Restart** if it appears at the top of the screen.

Modifying and Deleting DNAME Records

When you modify a CNAME record, you can change the information you previously entered in the **General** tab. You can also enter or edit information in the **TTL**, **Extensible Attributes** and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

Managing NAPTR Records

A NAPTR (Name Authority Pointer) record specifies a rule that uses a substitution expression to rewrite a string into a domain name or URI (Uniform Resource Identifier). A URI is either a URL (Uniform Resource Locator) or URN (Uniform Resource Name) that identifies a resource on the Internet.
NAPTR records are usually used to map E.164 numbers to URIs or IP addresses. An E.164 number is a telephone number, 1-555-123- 4567 for example, in a format that begins with a country code, followed by a national destination code and a subscriber number. (E.164 is an international telephone numbering system recommended by the International Telecommunication Union.) Thus, NAPTR records allow us to use telephone numbers to reach devices, such as fax machines and VoIP phones, on the Internet.
To map an E.164 to a URI, the E.164 number must first be transformed into a domain name. ENUM (E.164 Number Mapping) specifies a method for converting E.164 numbers to domain names. For example, using the method specified by ENUM, the telephone number 1-555-123-4567 becomes the domain name 7.6.5.4.3.2.1.5.5.5.1.e164.arpa. For details about ENUM, refer to *RFC 3761, The E.164 to Uniform Resource Identifiers (URI) Dynamic Delegation Discovery System (DDDS) Application (ENUM).*
After the E.164 number is converted to a domain name, a DNS client can then perform a DNS lookup for the NAPTR records of the domain name. The following example illustrates how a DNS client processes NAPTR records.
In this example, the telephone number 1-555-123-4567 is converted to the domain name 7.6.5.4.3.2.1.5.5.5.1.e164.arpa. The DNS client then sends a query to the Infoblox DNS server for the NAPTR records associated with 7.6.5.4.3.2.1.5.5.5.1.e164.arpa. The Infoblox DNS server returns the following NAPTR record:

```
$ORIGIN 7.6.5.4.3.2.1.5.5.5.1.e164.arpa
       IN NAPTR 10 100 "U" "sip + E2U" "!^.*$!sip:jdoe@corpxyz.com!" .
```

The DNS client then examines the fields in the NAPTR record as follows:

- If a DNS client receives multiple NAPTR records for a domain name, the value in the Order field determines which record is processed first. It processes the record with the lowest value first.
- The DNS client uses the Preference value when the Order values are the same. Similar to the Preference field in MX records, this value indicates which NAPTR record the DNS client should process first when the records have the same Order value. It processes the record with the lowest value first.
  In the example, the DNS client ignores the Order and Preference values because it received only one NAPTR record.
- The Flag field indicates whether the current lookup is terminal; that is, the current NAPTR record is the last NAPTR record for the lookup. It also provides information about the next step in the lookup process. The flags that are currently used are:

U: Indicates that the output maps to a URI (Uniform Record Identifier).
S: Indicates that the output is a domain name that has at least one SRV record. The DNS client must then send a query for the SRV record of the resulting domain name.
A: Indicates that the output is a domain name that has at least one A or AAAA record. The DNS client must then send a query for the A or AAAA record of the resulting domain name.
P: Indicates that the protocol specified in the Service field defines the next step or phase.

- If the Flag field is blank, this indicates that the client must use the resulting domain name to look up other NAPTR records.
- The Service field specifies the service and protocol that are used to communicate with the host at the domain name. In the example, the service field specifies that SIP (Session Initiation Protocol) is used to contact the telephone service.
- The regular expression specifies the substitution expression that is applied to the original string of the client. In the example, the regular expression !^.*$!sip:jdoe@corpxyz.com! specifies that the domain name 7.6.5.4.3.2.1.5.5.5.1.e164.arpa is replaced with sip:jdoe@corpxyz.com.
  The regular expression in a NAPTR record is always applied to the original string of the client. It must not be applied to a domain name that resulted from a previous NAPTR rewrite.
- The Replacement field specifies the FQDN for the next lookup, if it was not specified in the regular expression.

Note

If a NAPTR record with the domain name in its native characters is added to the Infoblox Grid through DDNS updates, the **Domain** and **Replacement** fields display the domain name in UTF-8 encoded format. For example, a NAPTR record with the domain name 电脑 .test.com added through DDNS updates displays \231\148\181\232\132\145.test.com in the **Domain** and **Replacement** fields.

Adding NAPTR Records

To add a NAPTR record, perform the following steps:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **Add NAPTR Record**.
2. In the *Add NAPTR Record* wizard, complete the following fields:
   - **Domain**: If Grid Manager displays a zone name, enter the domain name to which this resource record refers. The displayed zone name can either be the last selected zone or the zone from which you are adding the NAPTR record. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click a zone name in the dialog box, and then enter a domain name for the record. The name you enter is prefixed to the DNS zone name that is displayed, and the complete name becomes the FQDN (fully qualified domain name) of the record. For example, if the zone name displayed is corpxyz.com and you enter admin, then the FQDN becomes admin.corpxyz.com. This field is not displayed when you configure a NAPTR record for a DTC server.
   - **DNS View**: Displays the DNS view of the selected zone.
   - **Service**: Specifies the service and protocol used to reach the domain name that results from applying the regular expression or replacement. You can enter a service or select a service from the list.
   - **Flags**: The flag indicates whether the resulting domain name is the endpoint URI or if it points to another record. Select one of the following:
     U: Indicates that the output maps to a URI.
     S: Indicates that the resulting domain name has at least one SRV record.
     A: Indicates that the resulting domain name has at least one A or AAAA record.
     P: Indicates that this record contains information specific to another application.
     Leave this blank to indicate that the DNS client must use the resulting domain name to look up other NAPTR records. You can use the NAPTR records as a series of rules that are used to construct a URI or domain name.
   - **Order**: Select an Integer from 10 to 100, or enter a value from 0 to 65535. This value indicates the order in which the NAPTR records must be processed. The record with the lowest value is processed first.

- **Preference**: Select an Integer from 10 to 100, or enter a value from 0 to 65535. Similar to the Preference field in MX records, this value indicates which NAPTR record should be processed first when the records have the same Order value. The record with the lowest value is processed first.
- **REGEX:** The regular expression that is used to rewrite the original string from the client into a domain name. RFC 2915 specifies the syntax of the regular expression. Note that the appliance validates the regular expression syntax between the first and second delimiter against the Python re module, which is not 100% compatible with POSIX Extended Regular Expression as specified in the RFC. For information about the Python re module, refer to *http://docs.python.org/release/2.5.1/lib/module-re.html*.
- **Replacement**: This specifies the domain name for the next lookup. The default is a dot (.), which indicates that the regular expression in the **REGEX** field provides the replacement value. Alternatively, you can enter the replacement value in FQDN format.
- **Comment:** Optionally, enter a descriptive comment for this record.
- **Disable:** Clear the checkbox to enable the record. Select the checkbox to disable it.

3. Click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*. This is not applicable when you configure a NAPTR record for a DTC server.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing LBDN Records

When your Grid has a DNS Traffic Control license, you can add LBDN (Load Balanced Domain Name) records to authoritative or delegated zones. You can add an LBDN even if the zone is DNSSEC signed but some restrictions apply. To add an LBDN record when in the DNS records list view:

- On the **Zones** or **Members/Servers** tab, click the arrow next to the Add icon and select **Record** -> **DTC LBDN**. For more information, see *Configuring DNS Traffic Control LBDNs*.

You can also add an LDBN when in the Traffic Control tab. For more information, see the previously referenced section.

Managing Unknown Records

An unknown record is a resource record for which the record type is unknown to NIOS. You can create an unknown record and assign a type to it. NIOS converts the unknown record to the type you assign. You can assign a type listed at *https://www.iana.org/assignments/dns-parameters/dns-parameters.xhtml*. For information about types that you cannot assign, see the *Guidelines for Creating Unknown Records* section.

Adding Unknown Records

To add a record of Unknown type, perform the following steps:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Add** -> **Record** -> **Unknown Record**.
2. In the *Add Unknown Record* wizard, complete the following fields:
   - **Domain Name**: Click **Select Zone** to select a zone. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click **Clear** to clear the zone that you have entered.
   - **DNS View**: The DNS view associated with the selected DNS zone is displayed.
   - **Type**: Enter the type that the unknown record belongs to. You can either enter the type in the textual mnemonic format or in the "TYPE*nnn*" format where "nnn" indicates the numeric type value. For example, for a record of type RP, you can either enter "RP" or "TYPE17".
3. Click the + icon to specify the details for the record you are creating:
   - **Field Type**: Select the field type that the record data must assume. Field types can be of the following:
     - **Base64-encoded Data**: BASE64 encoded binary data
     - **Hexadecimal Sequence**: Hexadecimal encoded binary data
     - **8-bit unsigned integer**: Unsigned 8-bit integer
     - **16-bit unsigned integer**: Unsigned 16-bit integer
     - **32-bit unsigned integer**: Unsigned 32-bit integer
     - **IPv4 Address**: IPv4 address in numerical form. For example, 192.0.1.1
     - **IPv6 Address**: IPv6 address in numerical form. For example, 2001:db8::abcd
     - **ASCII String**: ASCII text

        - **Domain Name**: Domain name
        - **Presentation**: Standard textual form of record data, as shown in a standard master zone file. This type is specifically intended to be used for standard types of records that cannot easily be represented as a sequence of fields of the other types. Such record types include LOC and APL. If you choose this field type, it must be the only field to represent the record
    - **Value**: Value of the field data. Before entering a value, see the *Guidelines for Creating Unknown Records* section.
    - **Length**: Format in which to specify the length of the field value. The length can only be **None** for fields of 8-bit unsigned integer, 16-bit unsigned integer, 32-bit unsigned integer, IPv4 Address, IPv6 Address, Domain Name, and Presentation types. For fields of type Base64-encoded Data, ASCII String, and Hexadecimal Sequence, the value of the **Length** field can be either **None** or **8 bits** or **16 bits** depending on the requirement of the corresponding record type.
      Irrespective of the field type you select, there is an implementation-specific limitation on the length of the record data. Specifically, the data is internally converted to a textual form that appears in a standard DNS master file, and it is rejected if the converted text exceeds 8192 bytes. Although unlikely, some extremely large data can be rejected because of this limitation.
4. Click **Add**. The record details are added to the table below.
5. In the **Comment** field, optionally enter a descriptive comment for the record.
6. Clear the **Disable** checkbox to enable the record. Select the checkbox to disable it.
7. Save the configuration or click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.
8. Click **Save & Close**.

Guidelines for Creating Unknown Records

Make note of the following guidelines when you create an unknown record:

- You cannot enter a record type that already exists in NIOS. For example, A, AAAA, ANY, CAA, CNAME, DHCID, DNAME, DNSKEY, DS, MX, NAPTR, NS, NSEC, NSEC3, NSEC3PARAM, PTR, RRSIG, SOA, SRV, TLSA, TXT.
- If the record contains an ASCII String field type and you include double quotes, you must escape it with a backslash. For example, to obtain a value of "a"b", specify the string as \"a\"b\".
- Ensure that you use the correct syntax when entering the value of the record.
- If you want to modify the field type of an unknown record, you have to delete the field type and then add it again.
- If you create an unknown record of a specific type and later on the record type is supported by NIOS, the record continues to exist as an unknown record. You will need to migrate the record to the newly supported type.
- If you add an unknown record that is not supported by the Microsoft server to the zone, you may encounter issues with the MS server synchronization.
- You cannot create records of type MD and MF.

Modifying and Deleting Unknown Records

When you modify an unknown record, you can change the information you previously entered in the **General** tab. You can also enter or edit information in the **TTL**, **Extensible Attributes** and **Permissions** tabs. For information on modifying and deleting resource records, see Modifying, Disabling, and Deleting Host and Resource Records below.

Prohibited Records

The following record types are prohibited as part of a zone, irrespective of whether or not they are defined as Unknown records:

- Type 0: Do not allocate it for ordinary use.
- Type 41 (OPT): Pseudo type
- Types 128-255: Meta type
- Types 55555, 55556, 55557, 65432, 65433: Used internally in NIOS
- Type 65533: Private use
- Type 3 (MD) and 4 (MF): Obsolete type

Viewing Resource Records

You can view the configured resource records by navigating to the **Data Management** tab -> **DNS** tab -> **Zones** tab -> *zone* -> **Records** tab. Grid Manager displays the following information for each resource record in the zone:

- **Name**: The name of the record, if applicable. For host records, this field displays the canonical name of the host. For PTR record, this displays the PTR record name without the zone name.
- **Type**: The resource record type.
- **Data**: Data that the record contains. For host records, this field displays the IP address of the host. For PTR records, this displays the domain names.
- **Active users**: The number of active users for the selected resource record.
- **Comment**: Comments that were entered for the resource record.
- **Site**: Values that were entered for this pre-defined attribute.
  Note that the DNS record that is obscured by an LBDN record is indicated by a strikethrough, for example, an obscured A record appears as A Record in Grid Manager.

You can also display the following columns:

- **MS Delegation Addresses**: This column appears only if the primary server of the zone is a Microsoft server. It displays the IP addresses that are associated with an NS record.
- **TTL**: The TTL (time-to-live) value of the record.
- **Address**: The IPv4 or IPv6 address associated with the owner domain name in a reverse-mapping zone.
- **Shared**: Displays true for shared resource records. Otherwise, displays false.
- **Shared Record Group**: Displays the shared record group name of a shared record.
- **Disabled**: Indicates if the record is disabled.

You can perform the following steps:

- Modify some of the data in the table. Double click a row and either modify the data in the field or select an item from a drop-down list. Click **Save** to save the changes. Note that some fields are read only.
- Add new DNS records by clicking the arrow next to the Add icon and selecting **Host**, **Record**, **Shared Record**, and then selecting the required record type.
- View the DNS Traffic Control structure for an LBDN.
  - Select the LBDN record and click the Open Visualization icon. For more information, see *Visualization for DNS Traffic Control Objects*.
- Create a DTC server based on an existing A, AAAA, or host record by selecting a record in the table and clicking **Create DTC Server** in the Toolbar or in the record's Action menu. For more information, see *Configuring DNS Traffic Control Servers*.
- Edit the properties of a resource record.
  - Select the resource record, and then click the Edit icon.
- Delete a resource record.
  - Select the resource record, and then click the Delete icon.
- Export the list of resource records to a .csv file.
  - Click the Export icon.
- Print the list of resource records.
  - Click the Print icon.
- Use filters and the **Goto** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Goto** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria:
  a. In the filter section, click **Show Filter** and define filter criteria for the quick filter.
  b. Click **Save** and complete the configuration In the Save Quick Filter dialog box.
  The appliance adds the quick filter to the quick filter drop-down list in the panel. Note that global filters are prefixed with [G], local filters with [L], and system filters with [S].

Modifying, Disabling, and Deleting Host and Resource Records

You can modify, disable, or delete an existing host or DNS resource record. When physical repair or relocation of a network device occurs, you can disable a record instead of deleting it. When you disable a record, the NIOS appliance does not answer queries for it, nor does it include disabled records in zone transfers and zone imports. This avoids having to delete and then add the record again. When the changes to the physical device are complete, you can simply

enable the host or resource record.
To modify or disable a host or resource record, perform the following steps:

1. Use one of the following methods to retrieve the host or resource record:
   - Perform a global search.
   - Select it from a Smart Folder.
   - From the **Data Management** tab, select the **DNS** tab - > **Zones** tab -> *dns_view* -> *zone* -> *host_record* or *resource_record*.
2. Select the record you want to modify and click the Modify icon.
3. In the host or resource record editor, you can do the following:
   - In the **General** tab, you can change most of the information, except for the read-only fields, such as the **DNS View** and **Host Name Policy**. You can select the **Disable** checkbox to disable the record.
   - In the **TTL** tab, you can modify the TTL setting. The NIOS appliance also allows you to specify TTL settings for each record. If you do not specify a TTL for a record, the appliance applies the default TTL value of the zone to each record. For information, see *About Time To Live Settings*.
   - In the **Extensible Attributes** tab, you can modify the attributes. For information, see *Using Extensible Attributes*.
   - The **Permissions** tab displays if you logged in as a superuser. For information, see *About Administrative Permissions*.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

When you delete host and resource records, Grid Manager moves them to the Recycle Bin. You can use the Recycle Bin to store deleted DNS configuration objects and selectively restore objects to the active configuration at a later time. You can also permanently remove the objects from the Recycle Bin.

> ⚠ Note
>
> You cannot delete automatically-generated records, such as NS records and SOA records.

To delete host and resource record, perform the following steps:

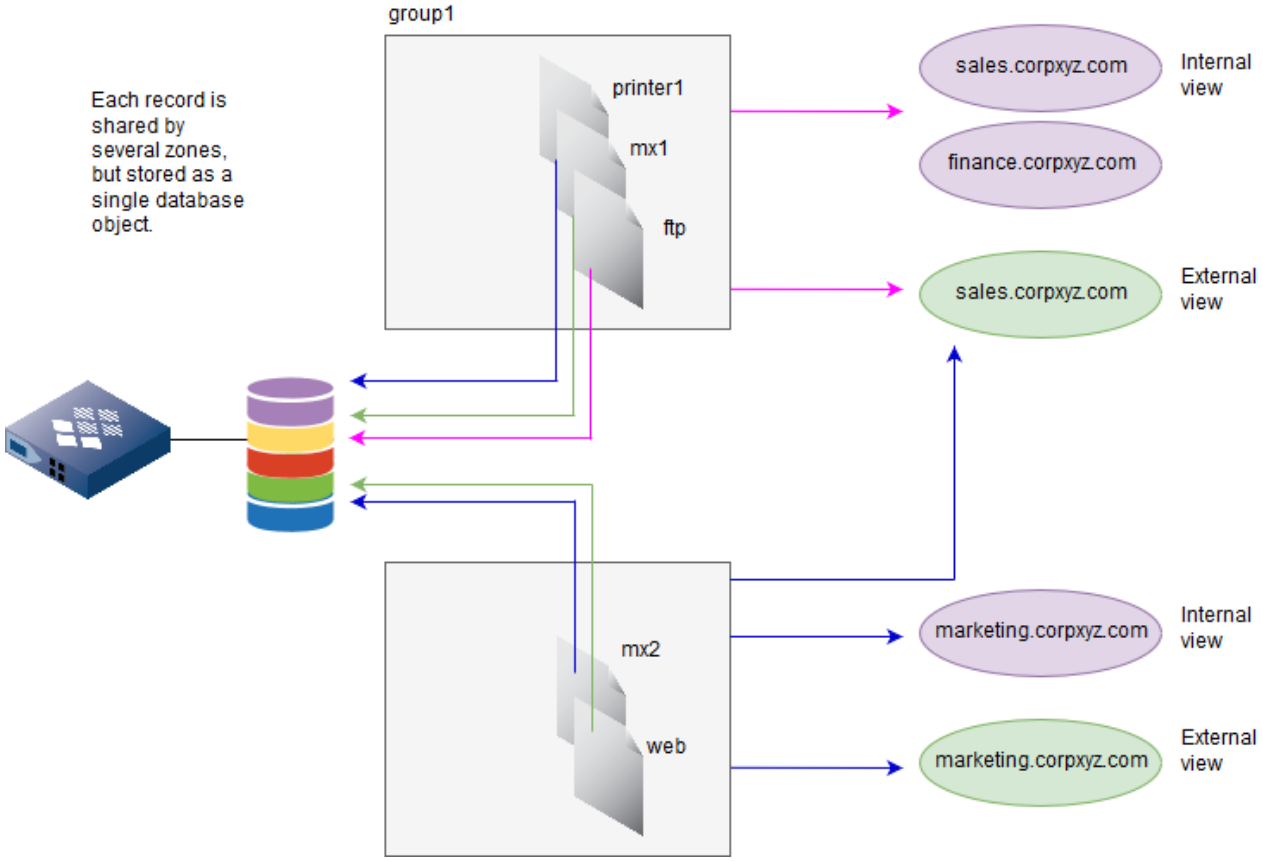
1. Perform a global search to retrieve the record you want to delete.
   Or
   From the **Data Management** tab, select the **DNS** tab, click the **Zones** tab-> *dns_view* -> *zone* -> *host_record* or *resource_record*.
2. Select the record and click the Delete icon.
3. In the *Delete Confirmation* dialog box, select **Yes** to delete or **No** to cancel.
4. Optionally, if the **Enable PTR record removal for A/AAAA records** option is selected and if you try to delete an A or AAAA record, the appliance displays the *Delete Confirmation (A or AAAA Record)* dialog box to confirm whether you want to remove the corresponding PTR record that was automatically generated while creating the A or AAAA record. In the *Delete Confirmation* dialog box, select the **Remove associated PTR resource record(s)** checkbox and click **Yes** to delete the associated PTR record or click **No** to cancel. For information about enabling this option, see *Deleting PTR Records associated with A or AAAA Records*.
   Or
   You can also schedule the deletion for a later time. Click **Schedule Deletion** and in the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Deletions*.

Configuring Shared Record Groups

A shared record group is a set of resource records that you can add to multiple zones. You can create resource records in a group and share the group among multiple zones. The zones handle the shared resource records as any other resource record. You can include the following types of DNS resource records in a shared record group: A, SRV, MX, AAAA, CNAME, and TXT.
Using shared record groups simplifies and expedites the administration of resource records. When you create or update a shared record, the appliance automatically updates it in all associated zones. In addition, shared resource records reduce the object count in the NIOS database; instead of the creating the same record in multiple zones, you can use only one shared record. For example, for 10 zones and 500 records per zone, the object count decreases from 5278

objects to 781 objects.
The figure Creating Shared Records below shows an example of how to create and use shared records.
In this example, there are two shared record groups. One group—group1— contains the A records ftp and printer1 and the MX record mx1, and the other group—group2—contains the A record web and the MX record mx2. The resource records in group1 are shared with the internal view zones sales.corpxyz.com and finance.corpxyz.com and the external view zone sales.corpxyz.com. The resource records in group2 are shared with the internal view zone marketing.corpxyz.com and the external view zones sales.corpxyz.com and marketing.corpxyz.com.

Creating Shared Records



Shared Records Guidelines

The following are guidelines for using shared records:

- You can include multiple shared A, AAAA, CNAME, SRV, MX and TXT resource records in a group. You cannot include NS, DNAME, PTR, host and bulk host records.
- You can add shared records to authoritative zones only. You cannot add shared records to forward zones, stub zones, or reverse mapping zones.
- Zones that contain shared records can also contain regular DNS records (not shared).
- When you change or delete a shared resource record, it changes the canonical source of the shared record and impacts all the zones that contain the record.
- You cannot copy shared records from a zone.
- You do not need to restart the appliance when you create, delete, or modify shared records.

Configuring Shared Record Groups

Before you can create shared resource records, you must first create the group to which they belong. The shared record group serves as a container for the shared resource records. The following are the tasks to configure a shared record group:

1. Create a shared record group and associate it with the appropriate zones. See Creating a Shared Record Group below.
2. Create shared A, CNAME, SRV, MX, AAAA, and TXT resource records, and add them into the shared record group. See Managing Shared Resource Records below.

Creating a Shared Record Group

When you create a shared record group, the only requirement is that you give it a name. You can associate it with one or multiple zones when you first create the group or at a later time, by editing the shared record group. You can associate a shared record group with authoritative zones only. Associating the shared record group with a zone adds the shared records to the zone. The zone handles the shared records like any other resource records.
To create a shared record group:

1. From the **Data Management** tab, select the **DNS** tab -> **Shared Record Groups** tab, and then click the Add icon.
2. In the *Shared Record Group* wizard, specify the following:
    - **Name:** Enter the name of the shared record group. It can be up to 64 characters long and can contain any combination of printable characters. You can change the shared record group name even after you create the group. It does not impact the shared records in the group.
    - **Hostname Policy:** Click **Override** to supersede the hostname restriction policy set at the zone level or click **Inherit** to use the zone policy. This sets the hostname policy for the shared records in the group. See *Specifying Hostname Policies*.
    - **Comment:** Optionally, enter additional information about the shared record group.
3. Click **Next** to associate the shared record group with at least one zone.
4. Click the Add icon in the Associated Zones panel.
5. In the *Zone Selector* dialog box, select a zone by clicking the zone name. You can add multiple zones.
6. Click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.
7. Save the configuration.

Viewing Shared Record Groups

You can view the configured shared record groups by navigating to the **Data Management** tab -> **DNS** tab -> **Shared Record Groups** tab. Grid Manager displays the following information about each shared record group:

- **Name:** The shared record group name.
- Comment: Comments that were entered for the shared record group.
- Site: Values that were entered for this pre-defined attribute.

You can do the following:

- List the shared resource records and associated zones in a shared record group.
- Click a shared record group name.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- Edit the properties of a shared record group.
    - Click the checkbox beside a shared record group, and then click the Edit icon.
- Delete a shared record group.
    - Click the checkbox beside a shared record group, and then click the Delete icon. Note that you must remove the zone associations in a shared record group before you delete it.
- Export the list of shared record groups to a .csv file.
    - Click the Export icon.
- Print the list of shared record groups.
    - Click the Print icon.

Modifying a Shared Record Group

When you edit a shared record group, you can do the following:

1. Perform a global search to retrieve the shared record group you want to modify.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Shared Record Groups** tab -> *shared_record _group* checkbox, and then click the Edit icon.
2. The *Shared Record Group* editor contains the following tabs from which you can modify information:
   - **General**: You can change any of the information you entered when you created it, including its name.Changing the shared record group name does not impact the shared resource records in it.
   - **Extensible Attributes**: You can modify the attributes. For information, see *Using Extensible Attributes.*
   - **Permissions**: This tab is displayed if you logged in as a superuser. For information, see *About Administrative Permissions*.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Deleting Shared Record Groups

Before you delete a shared record group, you must remove the zone associations in the group; otherwise, an error message appears when you delete. For information, see Deleting Associated Zones below.
To delete a shared record group:

1. Perform a global search to retrieve the shared record group you want to modify.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Shared Record Groups** tab -> *shared_record _group* checkbox, and then click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes**.

Grid Manager moves the shared record group to the Recycle Bin, if enabled. Use the Recycle Bin feature to recover a deleted shared record group and retrieve the deleted zones. For information, see *Using the Recycle Bin*.

Managing Shared Resource Records

You can create shared A, AAAA, CNAME, MX, SRV and TXT records. These resource records are similar to the non-shared resource records. The DNS server uses them to respond to queries in the same way as any other resource record. A shared resource record can belong to only one shared record group. This section describes how to add shared resource records to a group and how to modify and delete them. It includes the following sections:

- Creating Shared Records
- Viewing Shared Records
- Modifying Shared Records
- Deleting Shared Records

NIOS allows superusers to add shared A and AAAA records with a blank name. Limited-access users must have read/write permission to **Adding a blank A/AAAA record** to add shared A and AAAA records with a blank name. You can assign global permission for specific admin groups and roles to allow limited-access users to add shared A and AAAA records with a blank name. For more information, see *Administrative Permissions for Adding Blank A or AAAA Records.*

Creating Shared Records

After you create a shared record group, you can create its resource records. To create a shared A, AAAA, CNAME, MX, SRV or TXT record and add it to a group:

1. From the **Data Management** tab, select the **DNS** tab. Expand the Toolbar and click **Add** -> **Shared Record**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Shared Record Groups** tab -> *shared_record _group* .
   Expand the **Shared Records** tab and click the Add icon**.**
2. Select one of the following:
   - **Shared A Record**

- **Shared AAAA Record**
- **Shared CNAME Record**
- **Shared MX Record**
- **Shared SRV Record**
- **Shared TXT Record**

3. Enter information in the *Shared Record* wizard. See the online Help or the following for information about each resource record:
    - For information about A records, see *Managing A Records*.
    - For information about AAAA records, see *Managing AAAA Records*.
    - For information about CNAME records, see *Managing CNAME Records*.
    - For information about MX records, see *Managing MX Records*.
    - For information about SRV records, see *Managing SRV Records*.
    - For information about TXT records, see *Managing TXT Records*.
4. Save the configuration, or click **Next** to define extensible attributes for the shared record. For information, see *Using Extensible Attributes*.
5. Click **Restart** if it appears at the top of the screen.

Viewing Shared Records

You can view the shared records in a group and in a zone. To edit the shared record properties, click the shared record name and select the Edit icon.
To view the shared records in a group:

- From the **Data Management** tab, select the **DNS** tab -> **Shared Record Groups** tab -> *shared_record _group* -> **Shared Records** tab.

To view the shared records in a zone:

- From the **Data Management** tab, select the **DNS** tab -> **Zones** tab and select a zone. Grid Manager lists the following information about each shared record by default:
- **Name:** The shared record name.
- **Type:** Indicates the type of resource record, such as A, AAAA, CNAME, MX, SRV or TXT records. Shared records are identified as **(Shared)**.
- **Data:** The data the shared resource record provides.
- **Comment:** Comments that were entered in the resource record.
- **Site:** Displays values that were entered for this pre-defined attribute.

You can display the following additional columns:

- **TTL**: The TTL value of the shared resource record.
- **Disabled:** Indicates whether the record is disabled.

You can do the following:

- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- Edit the properties of a shared resource record.
    - Select the shared resource record, and then click the Edit icon.
- Delete a shared resource record.
    - Select the shared resource record, and then click the Delete icon.
- Export the list of shared resource records to a .csv file.
    - Click the Export icon.
- Print the list of shared resource records.
    - Click the Print icon.

Modifying Shared Records

You can modify, disable, or delete any shared record. When physical repair or relocation of a network device occurs, you can disable a record instead of deleting it. This alleviates having to delete, and then add the shared record again. When the changes to the physical device are complete, you can simply enable the shared record.
To modify or disable a shared record:

1. Perform a global search to retrieve the host or resource record you want to modify.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Shared Record Groups** tab -> *shared_record_group* -> **Shared Records** tab.
2. Select the shared record you want to modify and click the Edit icon.
3. The *Shared Records* editor contains the following tabs from which you can modify information:
   - **General**: You can change most of the information, except for the read-only fields, such as the Host Name Policy. You can also select the **Disable** checkbox to disable the record.
   - **TTL**: You can modify the TTL setting. For information, see *About Time To Live Settings*.
   - **Extensible Attributes**: You can modify the attributes. For information, see *Using Extensible Attributes*.
   - **Permissions**: This tab displays if you logged in as a superuser. For information, see *About Administrative Permissions*.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Deleting Shared Records

To delete shared resource records:

1. Perform a global search to retrieve the record you want to delete.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Shared Record Groups** tab -> *shared_record_group* -> **Shared Records** tab.
2. Select the shared record you want to delete and click the Delete icon.
3. When the confirmation dialog box displays, select **Yes**.

Grid Manager moves the shared records to the Recycle Bin, from which you can restore or permanently delete the records.

Managing Associated Zones

Typically, you associate a zone with a shared record group when you create the group. You can also add an associated zone to a shared record group after you create the group.

Creating Associated Zones

To associate a zone with a share record group:

1. From the **Data Management** tab, select the **DNS** tab -> **Shared Record Groups** tab -> *shared_record _group* -> **Associated Zones** tab, and then click the Add icon.
2. In the *Zone Selector* dialog box, select a zone by clicking the zone name.

The appliance adds the zone to the **Associated Zones** tab.

Viewing Associated Zones

To view the associated zones in a shared record group:

- From the **Data Management** tab, select the **DNS** tab -> **Shared Record Groups** tab -> *shared_record _group* -> **Associated Zones** tab.

Grid Manager lists the following information about each associated zone by default:

- **Zone**: The zone associated with the shared record group.

- **DNS View**: The DNS view to which the zones belong.
- **Network View**: The network view associated with the DNS view.
- **Comment**: Comments that were entered for the shared record group. You can do the following:
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Associate another zone with the shared record group.
    - Click the Add icon and select a zone.
- Delete an associated zone.
    - Select the zone, and then click the Delete icon.
- Export the list of associated zones to a .csv file.
    - Click the Export icon.
- Print the list of shared associated zones.
    - Click the Print icon.

Deleting Associated Zones

To delete an associated zone:

1. From the **Data Management** tab, select the **DNS** tab -> **Shared Record Groups** tab -> *shared_record_group* -> **Associated Zones** tab.
2. Select the associated zone and click the Delete icon.
3. When the confirmation dialog box displays, select **Yes**.

Grid Manager removes the zone from the shared record group.

Configuration Example: Configuring Shared Records

The following example shows you how to configure shared records. In this example, you do the following:

- Create a shared record group: **group1**.
- Associate it with three zones: **eng.com**, **sales.com**, and **marketing.com**.
- Create an A record **www** and an MX record **mx1**.

1. Create a shared record group called **group1** and associate it with **eng.com**, **sales.com**, and **marketing.com**.
    a. From the **Data Management** tab, select the **DNS** tab -> **Shared Record Groups** tab, and then click the Add icon.
    b. In the first step of the *Shared Record Group* wizard, specify the following **Name:** Enter **group1**.
    c. Click **Next**.
    d. Click the Add icon in the Associated Zones panel.
    e. Select **eng.com** from the list of zones and click the select icon. Do the same for the **sales.com**, and **marketing.com** zones.
    f. Save the configuration and click **Restart** if it appears at the top of the screen.
2. Add an A record **www** to **group1**.
    a. Expand the Toolbar and click **Add** -> **Shared Record** > **Shared A Record.**
    b. In the *Shared A Record* wizard, specify the following:
    Name: Enter **www**.
    Shared Record Group: Select **group1** from the drop-down list.
    IP Address: Enter the IP address **10.9.1.1**.
    c. Save the configuration and click **Restart** if it appears at the top of the screen.
3. Add an MX record **mx1** into **group1**.
    a. Expand the Toolbar and click **Add** -> **Shared Record** > **Shared MX Record.**
    b. In the *Shared MX Record* wizard, specify the following:
    Mail Destination: Enter **mx1**.
    Shared Record Group: Select **group1** from the drop-down list.
    Mail Exchanger: Enter **www.infoblox.com**.
    Preference: Enter **10**.
    Comment: Enter **mail exchanger record for shared record group1**.
    c. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring DDNS Updates

DDNS (Dynamic DNS) is a method to update DNS data (A, TXT, and PTR records) from sources such as DHCP servers and other systems that support DDNS updates, such as Microsoft Windows servers 2000, 2003, 2008, 2008 R2, 2012, 2012 R2, and 2016.

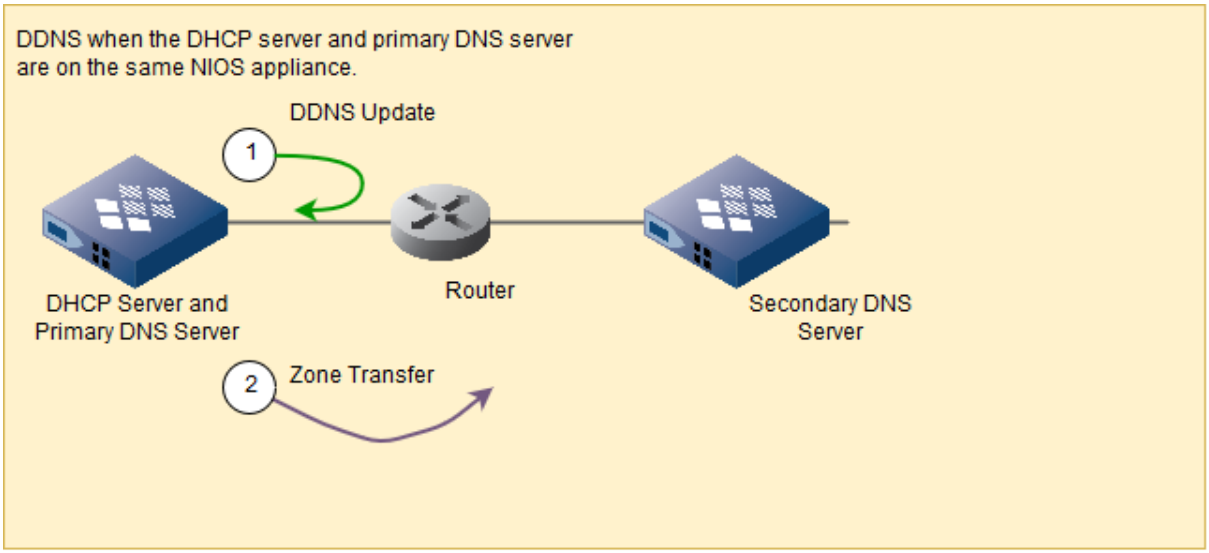
This section provides conceptual information about DDNS and explains how to configure NIOS appliances running DHCP, DHCPv6 and DNS to support DDNS updates. It contains the following main topics:

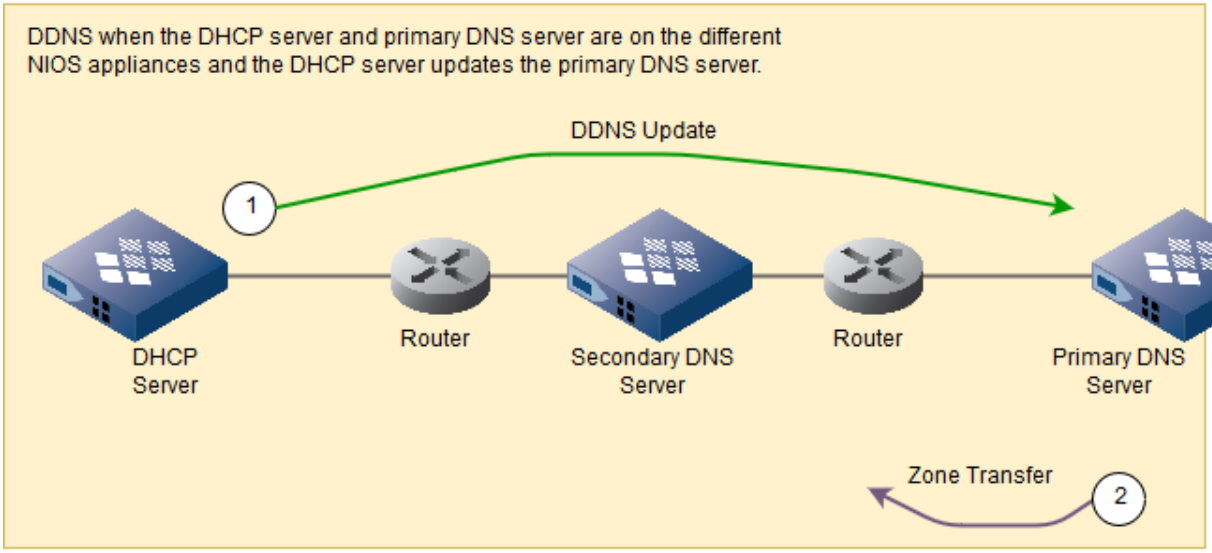
Understanding DDNS Updates from DHCP

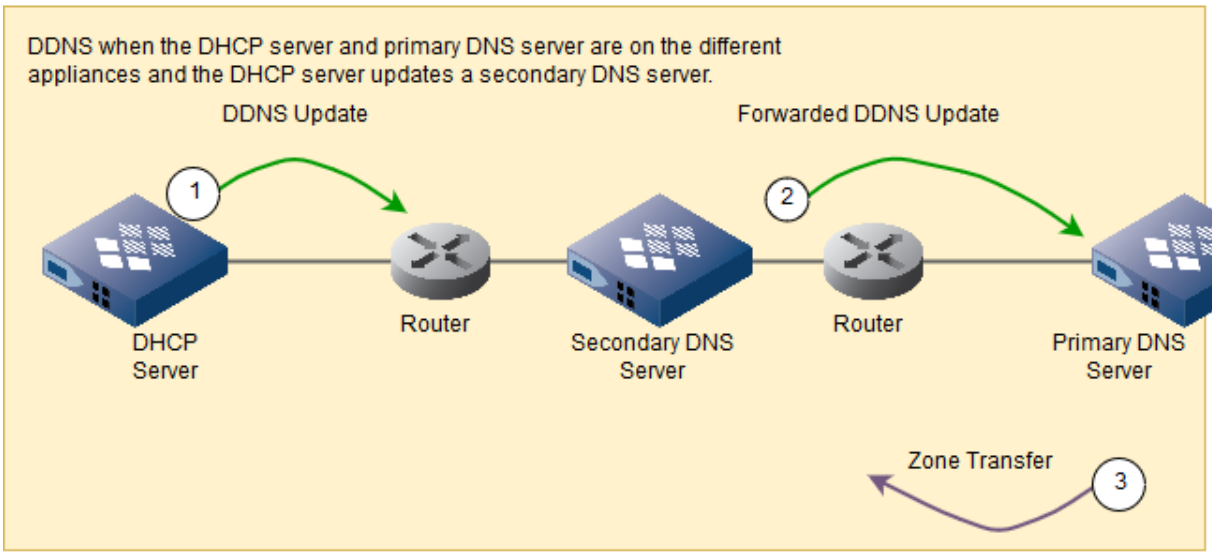
DHCP supports several DNS-related options (such as options 12, 15, and 81 for IPv4, and options 23, 24, and 39 for IPv6). With DDNS (Dynamic DNS) updates, a DHCP server or client can use the information in these options to inform a DNS server of dynamic domain name-to-IP address assignments.

> ⚠ Note
>
> DDNS updates is not supported by IPv6-only appliances.

To set up one or more NIOS appliances for DDNS updates originating from DHCP, you must configure at least one DHCP server and one DNS server. These servers might be on the same appliance or on separate appliances. Three possible arrangements for a DHCP server to update a DNS server are shown in the figure below.
Relationship of DHCP and DNS Servers for DDNS Updates





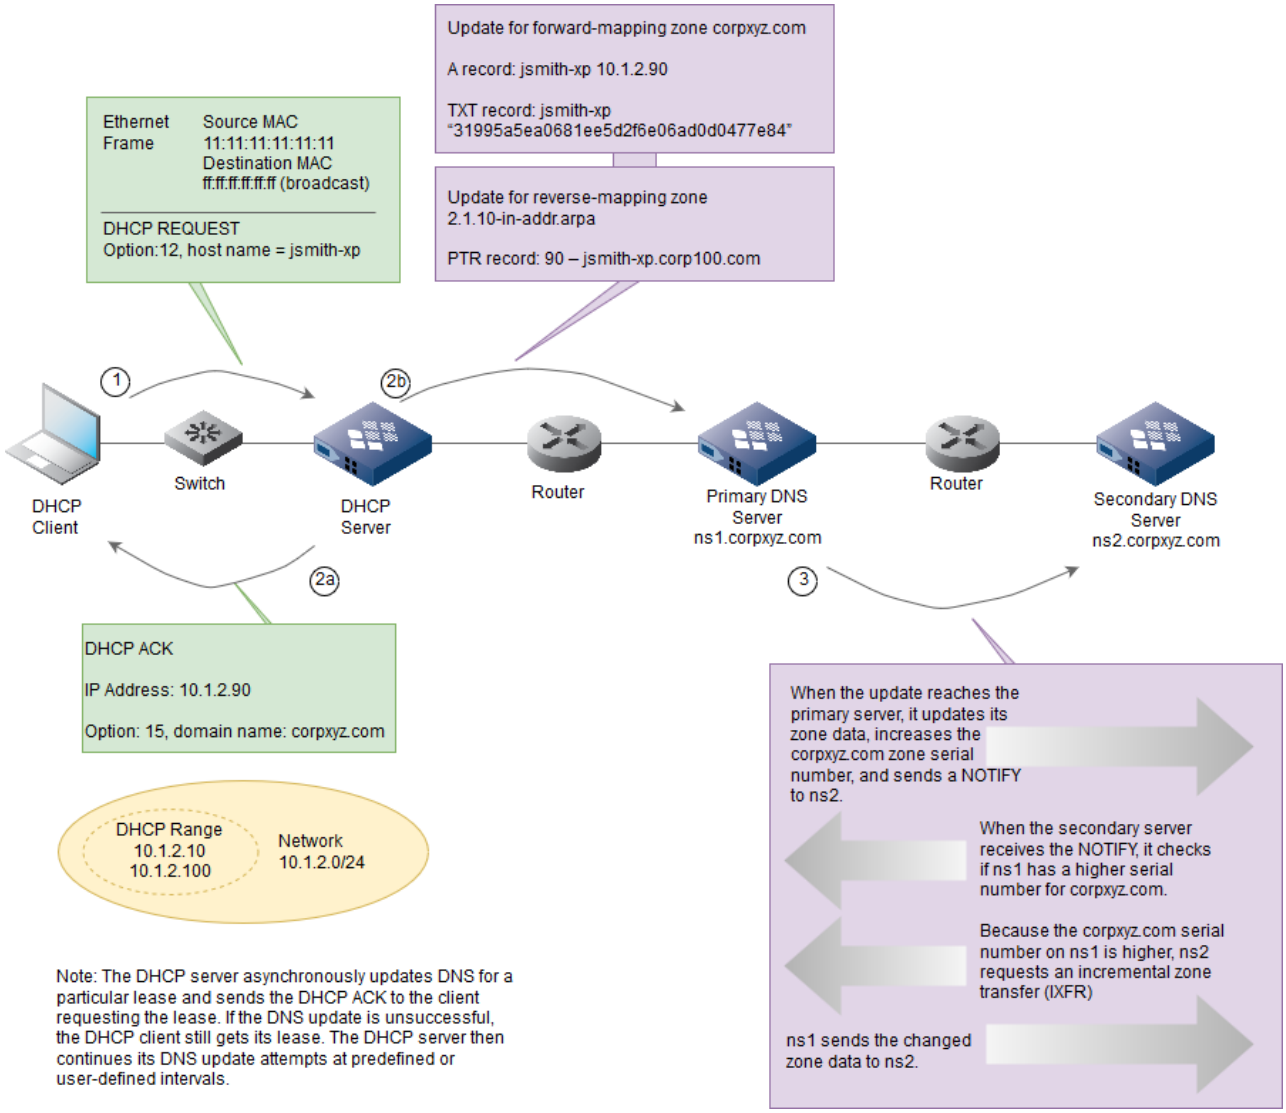


Here is a closer look at one setup for performing DDNS updates from a DHCP server (the steps relate to figure DDNS Update from a DHCP Server below).

1. When an IPv4 DHCP client requests an IP address, the client sends its host name (DHCP option 12). The client also includes its MAC address in the ethernet frame header.
2. a. When the DHCP server responds with an IP address, it usually provides a domain name (DHCP option 15). The combined host name (from the client) and domain name (from the server) form an FQDN (fully qualified domain name), which the NIOS appliance associates with the IP address in the DHCP lease.
   b. The DHCP server sends the A, TXT, and PTR records of the DHCP client to the primary DNS server to update its resource records with the dynamically associated FQDN + IP address.
3. The primary DNS server notifies its secondary servers of a change. The secondary servers confirm the need for a zone transfer, and the primary server sends the updated zone data to the secondary server, completing the update.

> ⚠ Note
>
> For information about zone transfers, see *Enabling Zone Transfers*.

DDNS Update from a DHCP Server



To enable a DHCP server to send DDNS updates to a DNS server, you must configure both servers to support the updates. First, configure the DHCP server to do the following:

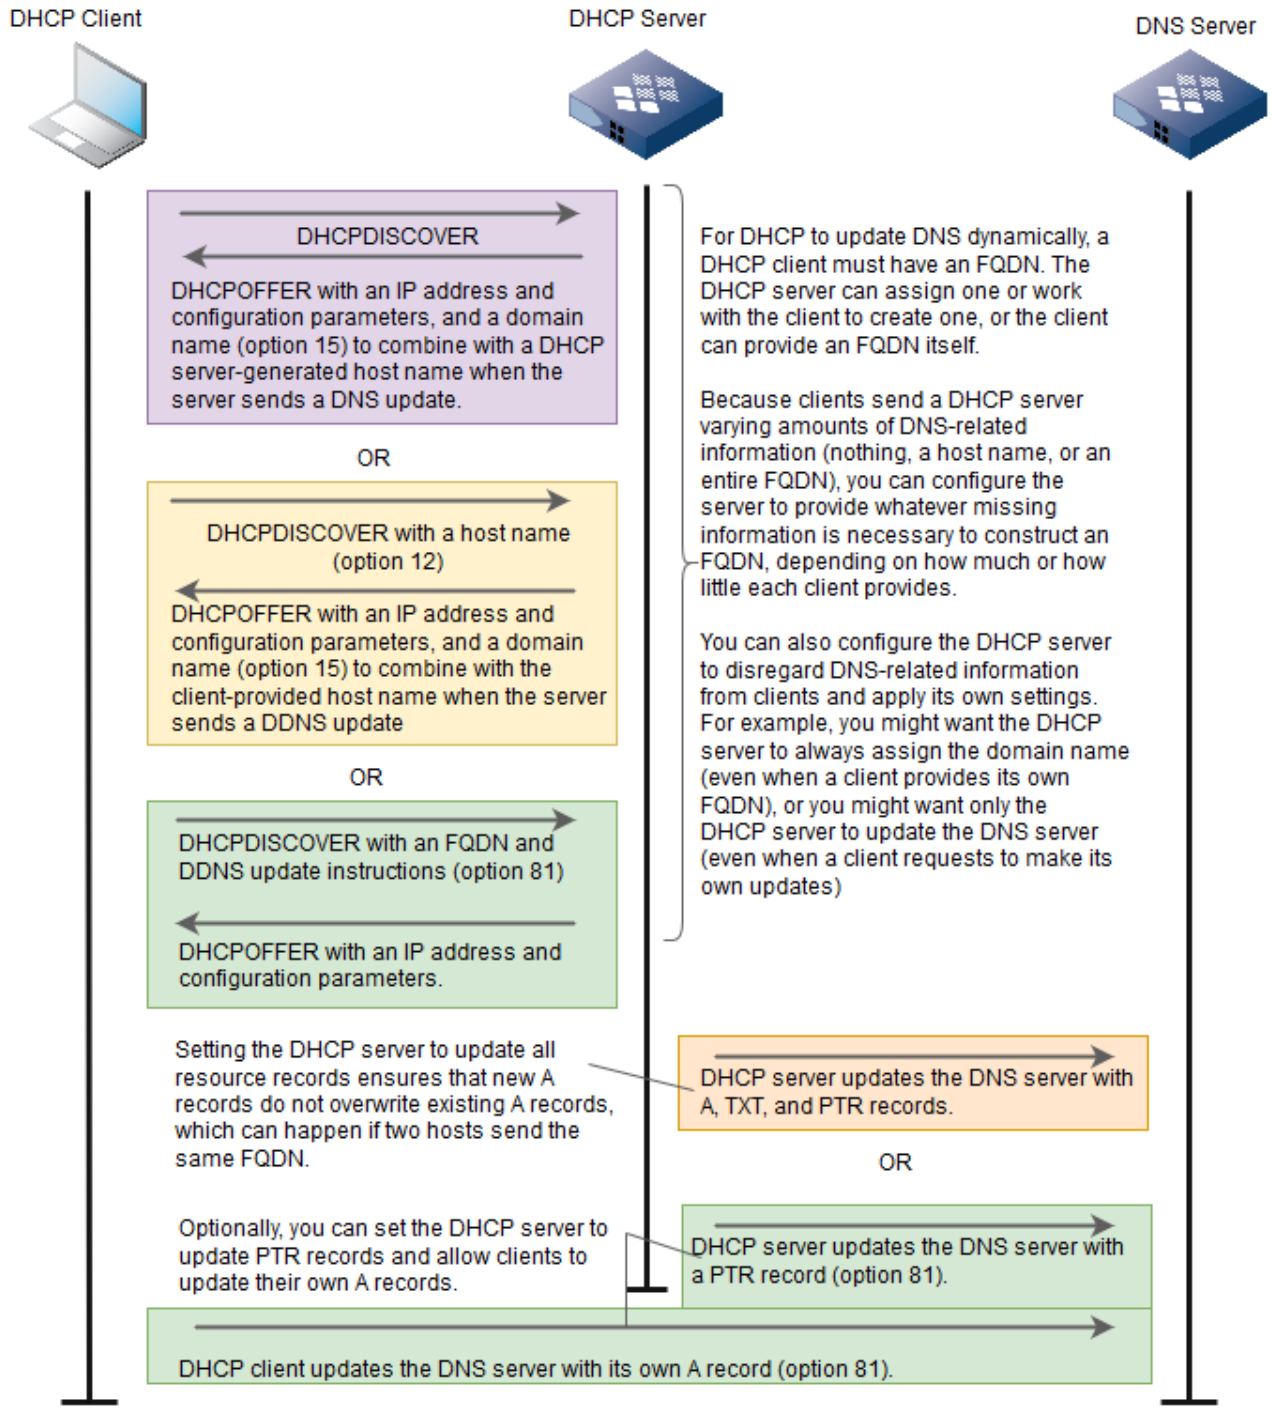
- Provide what is needed to create an FQDN: add a server-generated host name to a server-provided domain name, add a server-provided domain name to a client-supplied host name, or permit the client to provide its own FQDN
- Send updates to a DNS server

Then, configure the following on the DNS server:

- Accept updates from the DHCP server, a secondary DNS server, or a DHCP client
- If the DHCP server sends updates to a secondary DNS server, configure the secondary server to forward updates to the primary DNS server

When setting up DDNS, you can determine the amount of information that DHCP clients provide to a DHCP server — and vice versa — and where the DDNS updates originate. A summary of these options for IPv4 is shown in the following figure. It is similar for IPv6, except that the DHCP client and server exchange Request and Reply messages, AAAA records are updated instead of A records, and the FQDN option is option 39.

DHCP Clients and Server Providing DNS Information and Updates



You can configure the DHCP and DNS settings for DDNS at the Grid level, member level, and network and zone level. By applying the inheritance model in the NIOS appliance, settings made at the Grid level apply to all members in the Grid. Settings you make at the member level apply to all networks and zones configured on that member. Settings made at the network and zone level apply specifically to just that network and zone. When configuring independent appliances (that is, appliances that are not in a Grid), do not use the member-level settings. Instead, configure DDNS updates at the Grid level to apply to all zones and, if necessary, override the Grid-level settings on a per zone basis.

Configuring DHCP for DDNS

Before a DHCP server can update DNS, the DHCP server needs to have an FQDN-to-IP address mapping. When a DHCP IPv4 client requests an IP address, it typically includes its host name in option 12 of the DHCPDISCOVER packet, and an IPv6 client includes its hostname in the Request packet. You can configure the NIOS appliance to include a domain name in option 15 of the IPv4 DHCPOFFER packet or in the IPv6 Reply packet. You specify this domain name in the **IPv4 DHCP Options** -> **Basic and IPv6 DHCP Options** -> **Basic** tabs of the *Grid DHCP Properties* editor, *Member DHCP Configuration* editor, and the *Network* editor. For IPv4 clients you can also specify a domain name in the *DHCP Range* and *Fixed Address* editors.

Then, you can enable the DHCP server to send DDNS updates for IPv4 and IPv6 clients, as described in Enabling DDNS for IPv4 and IPv6 DHCP Clients below. After you enable the DHCP server to send DDNS updates, you can do the following:

- Configure the DHCP server to send DDNS updates to DNS servers in the Grid. For information, see Sending Updates to DNS Servers in the Grid below.
- Configure the DHCP server to send DDNS updates to external DNS servers. For information, see *Configuring DDNS Features*.
- Configure certain DDNS features. For information, see *Configuring DDNS Features*.
- Enable support for the FQDN option for IPv4 and IPv6 clients, and configure how the DHCP server updates DNS. For information, see *Enabling FQDN Option Support*.

> ⚠ Note
>
> Whether you deploy NIOS appliance in a Grid or independently, they send updates to UDP port 53. Grid members do not send updates through a VPN tunnel; however, Grid members do authenticate updates between each other using TSIG (transaction signatures) based on an internal TSIG key.

Enabling DDNS for IPv4 and IPv6 DHCP Clients

You can enable the DHCP server to send DDNS updates for IPv4 clients at the Grid, member, shared network, network, address range, DHCP template, fixed address, and roaming host levels, and for IPv6 clients at the Grid, member, network, shared network, network template and roaming host levels.
You can specify a different domain name that the appliance uses specifically for DDNS updates. The appliance combines the hostname from the client and the domain name you specify to create the FQDN that it uses to update DNS. For IPv4 clients, you can specify the DDNS domain name at the network, network template, range, and range template levels. For IPv6 clients, you can specify the DDNS domain name at the Grid, member, network, shared network, and network template levels. You can also use the name of a roaming host record as the name of the client for DDNS updates, as described in *Setting Properties for Roaming Hosts*.
To enable DDNS and specify a DDNS domain name:

1. **Grid:** From the **DataManagement** tab, select the **DHCP** tab, expand the Toolbar and click **GridDHCPProperties**.
   Member: From the **DataManagement** tab, select the **DHCP** tab and click the **Members** tab -> **Members** -> *member* checkbox -> Edit icon.
   Network: From the **DataManagement** tab, select the **DHCP** tab and click the **Networks** tab -> **Networks** -> *network* checkbox -> Edit icon.
   NetworkContainer: From the **DataManagement** tab, select the **IPAM** tab -> *network_container* checkbox, and then click the Edit icon.
   NetworkTemplate: From the **DataManagement** tab, select the **DHCP** tab and click the **Templates** tab -> *DHCP_template* checkbox -> Edit icon.
   RoamingHost: From the **DataManagement** tab, select the **DHCP** tab and click the **Networks** tab -> **RoamingHosts** -> *roaming_host* -> Edit icon.
   For IPv4 clients only:**IPv4AddressRange**: From the **DataManagement** tab, select the **DHCP** tab and click the **Networks** tab -> **Networks** -> *network* -> *addr_range* checkbox -> Edit icon.
   IPv4FixedAddress: From the **DataManagement** tab, select the **DHCP** tab and click the **Networks** tab -> **Networks** -> *network* -> *ip_addr* checkbox -> Edit icon.

IPv4AddressRange/**FixedAddressTemplate**: From the **DataManagement** tab, select the **DHCP** tab and click the **Templates** tab -> *DHCP_template* checkbox -> Edit icon.
To override an inherited property, click **Override** next to it and complete the appropriate fields.

2. In the **IPv4DDNS** -> **Basic** tab or the **IPv6DDNS** -> **Basic** tab, complete the following:
   - **Enable DDNS Updates**: Select this checkbox to enable DDNS updates.
     When setting properties for DHCP objects other than the Grid, you must click **Override** and select **Enable DDNS updates** for the DDNS settings to take effect. When turning on DDNS updates, first verify if *Option 81* has been enabled and whether DNS is being updated. If DNS is being updated, even if the DNS zone targets are not in the Grid, select Option 81 support and the correct sub option. For more information, see *Enabling FQDN Option Support*.
     When the **Enable DDNS Updates** checkbox is not selected, the default behaviour is to allow the client to update DNS.
     When the **Enable DDNS Updates** checkbox is selected, the default behaviour is to prevent DDNS updates from the client.
     In a dual mode Grid, if IPv6 DDNS updates is enabled at the Grid level, then when you join an IPv6 Grid member to the Grid, IPv6 DDNS updates is automatically disabled for the Grid member.
   - **DDNS domain name**: Specify the domain name of the network that the appliance uses to update DNS. For IPv4 clients, you can specify this at the network, network template, range, and range template levels. For IPv6 clients, you can specify this at the Grid, member, network, shared network, and network template levels.
   - **DDNS Update TTL**: You can set the TTL used for A or AAAA and PTR records updated by the DHCP server. The default is shown as zero. If you do not enter a value here, the appliance by default sets the TTL to half of the DHCP lease time with a maximum of 3600 seconds. For example, a lease time of 1800 seconds results in a TTL of 900 seconds, and a lease time of 86400 seconds results in a TTL of 3600 seconds. For information about how to set the lease time, see *Defining Lease Times*.
   - **DDNS Update Method**: Select the method used by the DHCP server to send DDNS updates. You can select either **Interim** or **Standard** from the drop-down list. The default is **Interim**. When you select **Interim**, TXT record will be created for DDNS updates and when you select **Standard**, DHCID record will be created for DDNS updates. But in the **IPv4 DDNS** -> **Advanced** tab or the **IPv6 DDNS** -> **Advanced** tab, if you have selected **No TXT Record** mode for the DHCP server to use when handling DNS updates, then TXT record or DHCID record is not created for DDNS updates.
     If you change the DDNS update method from **Interim** to **Standard** or vice versa, then the DHCP server changes the DHCID type used from TXT record to DHCID record or vice versa as the leases are renewed.
     This is supported for clients that acquire both IPv4 and IPv6 leases. Infoblox recommends you to configure different DDNS update method for IPV4 leases and IPv6 leases, **Interim** for IPv4 lease and **Standard** for IPv6 lease.
   - **Update DNS on DHCP Lease Renewal**: Select this checkbox to enable the appliance to update DNS when a DHCP lease is renewed.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Sending Updates to DNS Servers

The DHCP server can send DDNS updates to DNS servers in the same Grid and to external DNS servers. When you enable the appliance to send updates to Grid members, you must specify the DNS view to be updated. If a network view has multiple DNS views, you can select only one DNS view for DDNS updates. For information about DNS views, see *About DNS Views*.
When you enable DDNS updates for a Grid, member, shared network, network, address range, DHCP template, fixed address, or roaming host, the DHCP server sends updates to authoritative zones using the domain name (as DHCP option 15) you define in the DHCP properties. You can also define forward-mapping zones that receive DDNS updates for DHCP clients that use option 81 to define the domain name. For information, see *About the Client FQDN Option*.
To allow DDNS updates for clients using option 81, you must first enable the support for option 81. For information, see *Configuring DDNS Features*.

For DNS zones that have multiple primary servers, you can define a primary name server to be used as the default primary server when performing DDNS updates from the appliance. Note that you cannot configure an external primary as the default primary. For more information, see Defining the Default Primary for DDNS Updates to Zones with Multiple Primaries below.

Sending Updates to DNS Servers in the Grid

You must specify the DNS view to be updated for each network view.
To configure the DHCP server to send updates to DNS servers in the same Grid:

1. If there are multiple network views in the Grid, select a network view.
2. From the **Data Management** tab, select the **DHCP** tab, and then click **Configure DDNS** from the Toolbar.
3. In the *DDNS Properties* editor, complete the following:
    - **DNS View**: If a network view has more than one DNS view, this field lists the associated DNS views. From the drop-down list, select the DNS view to which the DHCP server sends DDNS updates. Otherwise, the appliance uses the default DNS view.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

The appliance sends DDNS updates to the appropriate zones in the selected DNS view. Note that you cannot delete a DNS view that has been selected for DDNS updates. By default, the DHCP server sends DDNS updates to zones using the domain name that you define for DHCP objects, such as networks and DHCP ranges.

Sending Updates for Zones on an External Name Server

The DHCP server can send dynamic updates to an external name server that you specify. For each network view, you can specify the zone to be updated and the IP address of the primary name server for that zone. You can add information for a forward and reverse zone. The DHCP server updates the A record in the forward zone and the PTR record in the reverse zone.
You can also use TSIG (transaction signatures) or GSS-TSIG to secure communications between the servers. TSIG uses the MD5 (Message Digest 5) algorithm and a shared secret key to create an HMAC (hashed message authentication code)—sometimes called a digital fingerprint—of each update. Both the DHCP server sending the update and the DNS server receiving it must share the same secret key. Also, it is important that the time stamps on the TSIG-authenticated updates and update responses be synchronized, or the participants reject them. Therefore, use an NTP server to set the time on all systems involved in TSIG authentication operations.
Note that only a superuser can configure DDNS. To configure DDNS, a limited-access admin must contact a superuser.

To send updates to a DNS server that is external to your Grid:

1. If there are multiple network views in the Grid, select a network view.
2. From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **Configure DDNS**.
3. In the **DDNS Updates to External Zones** section of the *DDNS Properties* editor, click the Add icon. Complete the following fields in the Add External DDNS Zone panel, and then click **Add**:
    - **Zone Name:** Enter the FQDN of a valid forward-mapping or reverse-mapping zone to which the DHCP server sends the updates. Do not enter the zone name in CIDR format. To specify a zone name in IDN, manually convert IDN to punycode and use the punycode representation.
    - **DNS Server Address:** Enter the IP address of the primary name server for that zone.
    - **Security:** Select one of the following security methods:
        - **None:** Select this to use unsecured DDNS updates. This is the default.
        - **TSIG:** Select this to use the standards-based TSIG key that uses the one-way hash function MD5 to secure transfers between name servers. You can either specify an existing key or generate a new key.
          To specify an existing key, complete the following:
          Key Name: Enter the TSIG key name. The key name entered here must match the TSIG key name on the external name server.
          Key Algorithm: Select either **HMAC-MD5** or **HMAC-SHA256.**
          Key Data: To use an existing TSIG key, type or paste the key in the **Key Data** field. Alternatively, you can select the key algorithm, select the key length from the **GenerateKeyData** drop down list, and then click **Generate Key Data** to create a new key.
        - **GSS-TSIG:** For information about using GSS-TSIG, see *About GSS-TSIG*.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Defining the Default Primary for DDNS Updates to Zones with Multiple Primaries

If you have configured multiple primary servers for an authoritative zone, you can define the default primary that the appliance uses to perform DDNS updates for the zone. Note that you can configure a Grid primary, but not an external primary, as the default primary. If you do not configure a default primary, the Grid Master becomes the default primary for the zones that it serves. Otherwise, the appliance selects a primary server that serves the zone as the default primary. For external zones that have multiple primaries, the first external primary server becomes the default primary.

Configuring a default primary for DDNS updates is useful when you have DHCP members that span across different locations. Performing DDNS updates becomes more efficient when you configure a default primary that is close in proximity to the DHCP member. For example, zone corpxyz.com has two primaries (usa.corpxyz.com and japan.corpxyz.com) serving two locations (USA and Japan). Service performance is faster when you select usa.corpxyz.com as the default primary for DDNS updates in the USA region and japan.corpxyz.com as the default primary for the Japan region.

When you configure a preferred or default primary server for DDNS updates to a zone that has multiple primaries, ensure that the following are in place:

- The zone that you select contains multiple primary servers.
- The primary server has DNS service enabled and is authoritative for the zone.
- The appliance has DHCP service enabled.

> ⚠ Note
> You can define the default primary for the Grid and override the setting at the member level, and you must restart service for the configuration to take effect. Primary selection is performed at service restart, not at runtime.

To define the default primary:

1. **Grid:** From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **Configure DDNS**. In the DDNS Properties editor, scroll down to the **Master Preferences for DDNS Updates to Multi-master DNS Zones** section.
   Member: From the **Data Management** tab, select the **DHCP** tab and click the **Members** tab -> *member* checkbox -> Edit icon. In the *Member DHCP Properties* editor, select the **Multi-master DDNS** tab.
2. In the **Master Preferences for DDNS Updates to Multi-master DNS Zones** section, click the Add icon and select one of the following from the list:
   - **Grid Zone**: In the Add Grid Zone panel, complete the following:
     - **Zone**: Click **Select Zone** to select the zone that has multiple primaries. Note that when configuring for the Grid, only zones that belong to the selected DNS view are displayed in the *Zone Selector* dialog box. For a Grid member however, if it is associated with a network view or if you have defined a DNS view for DDNS updates for that network view, only zones that belong to the DNS view configured for the associated network view are displayed.
     - **DNS View**: Displays the DNS view to which this zone belongs.
     - **DNS Primary**: From the drop-down list, select the primary name server you want the appliance to use when performing DDNS updates. Note that the list displays only primary servers that are defined for the selected zone.
   - **Default Primary**: In the Add Default Primary panel, complete the following:
     - **DNS Primary**: Click **Select** to select a primary name server from the *Member Selector* dialog. When you select a default primary, the appliance uses this name server for DDNS updates to all zones.
3. Click **Add** to add the zone and primary name server to the table, which displays the following information:
   - **DNS View**: The DNS view to which the zone belongs.
   - **Zone**: The selected zone that has multiple primaries. All zones added to the table belong to the same DNS view.
   - **DNS Primary**: The primary server to be used when performing DDNS updates from a NIOS DHCP server to the selected zone. If you have configured more than one Grid DNS primary server for DDNS updates for multi-master zones, DHCP servers use the first available DNS primary server that is configured. If the first DNS primary server is not reachable or is offline, then the DHCP servers reach for the next DNS

primary server in the preferred multi-domain DDNS list and so on. You can add upto a maximum of three DNS primary nameservers for each zone.

4. **Concatenated with the following rules defined at the Grid level**: This section appears only in the *Member DHCP Properties* editor. This table displays rules that are defined for zones with multiple primaries at the Grid level. Rules configured at the member level automatically override those configured for the Grid. Note that all rules configured for both the Grid and the member apply.

Configuring DDNS Features

You can enable the DHCP server to support certain DDNS features for IPv4 and IPv6 clients. These features affect the behavior of the DHCP server and how it handles DDNS updates. The following sections describe the different features you can set.

Resending DDNS Updates

You can enable the DHCP server to make repeated attempts to send DDNS updates to a DNS server. The DHCP server asynchronously updates DNS for a particular lease and sends the DHCP ACK to the client requesting the lease. If the update fails, the DHCP server still provides the lease and sends the DHCP ACK to the client. The DHCP server then continues to send the updates until it is successful or the lease of the client expires. You can change the default retry interval, which is five minutes.
You can enable this feature for the Grid and for individual Grid members.

Generating Host Names for DDNS Updates

Some IPv4 and IPv6 clients do not send a host name with their DHCP requests. When the DHCP server receives such a request, its default behavior is to provide a lease but not update DNS. You can configure the DHCP server to generate a host name and update DNS with this host name when it receives a DHCP request that does not include a host name. It generates a name in the following format: dhcp-*ip_address*, where *ip_address* is the IP address of the lease. For example, if this feature is enabled and the DHCP server receives a DHCP REQUEST from an IPv4 DHCP client with IP address 10.1.1.1 and no host name, the DHCP server generates the name dhcp-10-1-1-1 and appends the domain name, if specified, for the DDNS update. Likewise, if an IPv6 client with IP address 2001:db8:a23:0:0:0:0:d sends a request, the DHCP server generates the name dhcp-2001-db8-a23-0-0-0-0-d and appends the domain name, if specified, for the DDNS update.

Updating DNS for IPv4 Clients with Fixed Addresses

By default, the DHCP server does not update DNS when it allocates an IPv4 or IPv6 fixed address to a client. You can configure the DHCP server to update the A and PTR record of IPv4 clients with a fixed address. When you enable this feature and the DHCP server adds A and PTR records for a fixed address, the DHCP server never discards the records. When the lease of the client terminates, you must delete the records manually. Note that the DHCP server does not send DDNS updates for IPv6 fixed addresses and hosts. You can define fixed address settings for the Grid, Grid members, IPv4 networks, and IPv4 shared networks.

Configuring DDNS Features

You can configure DDNS features for a Grid, its member, IPv4 and IPv6 networks and shared networks, and IPv4 DHCP address ranges. You cannot set DDNS features for IPv6 DHCP ranges. To configure DDNS features:

1. **Grid:** From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **Grid DHCP Properties**.
   Member: From the **Data Management** tab, select the **DHCP** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   Network: From the **Data Management** tab, select the **DHCP** tab and click the **Networks** tab -> **Networks** -> *network* checkbox -> Edit icon.
   Shared Network: From the **Data Management** tab, select the **DHCP** tab and click the **Networks** tab -> **Shared Networks** -> *shared_network* checkbox -> Edit icon.

DHCP Range: From the **Data Management** tab, select the **DHCP** tab and click the **Networks** tab -> **Networks** -> *network* -> *addr_range* checkbox -> Edit icon.
To override an inherited property, click **Override** next to it and complete the appropriate fields.

2. In the **DDNS** -> **Advanced** tab for the Grid and member, or the **DDNS** -> **Basic** tab for the network, do the following:
    - **Update Retry:** You can set this for a Grid and its members only.
        - **Retry Updates When Server Becomes Available:** Select this checkbox.
        - **Retry interval (Minutes):** You can optionally set the retry interval. The default is five minutes.
    - **Generate Hostname**
        - **Generate Hostname if not Sent by Client:** Select this checkbox to enable the DHCP server to generate a hostname and update DNS with this hostname, when the DHCP request of a client does not include a hostname.
    - **Fixed Address Updates:** You can set this for IPv4 fixed addresses only. This option is available in the **IPv4 DDNS Advanced** tab of the *Grid DHCP Properties* and *Member DHCP Properties* editors, and in the **IPv4 DDNS Basic** tab of the IPv4 *DHCP Network* and *Shared Network* editors.
        - **Update Fixed Addresses:** Select this checkbox to allow he DHCP server to send updates to DNS forIPv4 fixed addresses.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

When a lease expires, the DHCP server removes the A, AAAA, and PTR records that it updated. It does not remove any records that the client updated.

Replacing Host Names for DDNS Updates

In situations where you need to restrict the use of specific characters in a host name for DDNS updates, you can configure a hostname rewrite policy. Such policy accepts certain characters and replaces others in host names specified in IPv4 DHCP requests. When you create a hostname rewrite policy, you enter a list of valid characters that the appliance accepts in the host name. You also specify a character that the appliance uses to replace invalid characters. You can create multiple hostname rewrite policies on the appliance, but you can only enable one policy at any given time. The appliance provides a default policy that includes **a-z0-9_** as valid characters and dash (**-**) as the replacement character. You cannot modify or delete the default policy.
When you enable a hostname rewrite policy, the appliance replaces host names with the newly translated host name when it issues DHCP leases and sends DDNS updates for IPv4 DHCP clients. For information about how to add and enable a hostname rewrite policy, see Adding and Enabling a Hostname Rewrite Policy below.
Before you enable a hostname rewrite policy, consider the following:

- You must enable DDNS updates before the hostname rewrite policy can take effect.
- You can use a hostname rewrite policy only if MS code pages are disabled.
- The policy supports only IPv4 DHCP clients.
- If DHCP option 81 support is enabled and updating DDNS is in the request, the appliance sends updates for A records directly to the DNS server and DHCP only updates the PTR record. When this happens, there can be a mismatch in the host name between the A and PTR records.
- Changes made to a hostname rewrite policy apply only to subsequent DDNS updates.

When an IPv4 DHCP client requests an IP address, it includes its host name in DHCP option 12. If you enable a hostname rewrite policy, the appliance uses the newly translated host name when it issues a lease to the client.
The client can also include a FQDN in option 81, in which it instructs the server whether to perform DDNS updates. If the client sends a FQDN in option 81, the appliance replaces the entire FQDN based on the policy. For example, if the FQDN in option 81 is dev.bldg12.corpxyz.com, the appliance replaces invalid characters in the entire FQDN even though the host name can be dev or dev.bldg12. For example, if your hostname rewrite policy specifies valid characters as **a-z** and the replacement character is -, the newly translated FQDN is dev.bldg--.corp---.com. For information about client FQDN in option 81, see *About the Client FQDN Option*.
Note that when multiple IPv4 DHCP clients specify host names that map to the same translated host name, the appliance allocates leases to all clients, but it only sends DDNS updates to the first client request. When it tries to update DNS for subsequent clients, the updates fail.
You can add and enable a hostname rewrite policy for the entire Grid. You can also override the policy at a member level, as described in Overriding a Grid Hostname Rewrite Policy below.

Adding and Enabling a Hostname Rewrite Policy

To add and enable a hostname rewrite policy, complete the following:

1. From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **Grid DHCP Properties**.
2. In the *Grid DHCP Properties* editor, click **Toggle Advanced Mode**.
3. In the **IPv4 DDNS** -> **Advanced** tab, click the Add icon in the **Hostname Rewrite Policy** section:
    - **Policy Name**: Enter the policy name. Each policy name must be unique.
    - **Valid Characters**: Enter a list of valid characters you want to keep in the host name. Ensure that you consider the following rules:
        - You can include only printable ASCII characters and space.
        - The appliance includes period (**.**) as a valid character by default. You do not need to specify it.
        - You can also use shortcuts for a series or range of characters. For example, when you enter **a-d**, the appliance includes the following: A, B, C, D, a, b, c, and d. When you enter **0-5**, the appliance includes the following: 0, 1, 2, 3, 4, and 5. In a character range, ensure that the start character is less than the end character.
        - If you want to use dash (**-**) as a character, ensure that you put it in front of the valid character pattern. Otherwise, the appliance treats the string as a range of characters.
        - You can build a POSIX regular expression based on the string you enter here, but you cannot enter an empty string.
        - You cannot use the meta character (**^**) as a start or end character in a range. For example, **a-^** is invalid. You also cannot use duplicate characters as character sets. For example, **aa** is invalid.
    - **Replace Invalid Characters with**: Enter a character the appliance uses to replace invalid characters. Only enter one printable ASCII character. You cannot enter multiple characters or use space as the replacement character.

    To test the hostname policy before adding it to the system, enter a sample hostname in the **Sample Host Name** field, and then click **Test**. The appliance displays the translated hostname. You can change the policy and test it again until you get the desired result.Click the Add icon to add the new hostname rewrite policy to the table. The appliance comes with a default policy that includes **a-z0-9_** as valid characters and dash (**-**) as the replacement character. Grid Manager displays the following for each policy:
    - **Policy Name**: The name of the hostname rewrite policy.
    - **Valid Characters**: Valid characters for the host name.
    - **Replace Invalid Characters with**: The character used to replace invalid characters in the host name. You can also select a hostname policy and click the Edit icon to modify it, or click the Delete icon to delete it. You cannot modify or delete the default policy. For information about how to modify a policy, see Modifying a Hostname Rewrite Policy below.
4. Complete the following to enable the hostname rewrite policy:
    - **Enable hostname rewrite policy**: Select this checkbox to use a hostname rewrite policy for DHCP leases and DDNS updates for IPv4 DHCP clients. From the drop-down list, select the hostname policy you want to use.
5. Save the configuration.

Modifying a Hostname Rewrite Policy

To modify a hostname rewrite policy, complete the following:

1. From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **Grid DHCP Properties**.
2. In the *Grid DHCP Properties* editor, click **Toggle Advanced Mode**.
3. In the **IPv4 DDNS** -> **Advanced** tab, do the following in the **Hostname Rewrite Policy** section:
    - Select a policy from the table, and then click the Edit icon.
    - In the Edit Hostname Rewrite Policy section, modify and test the policy as described in Adding and Enabling a Hostname Rewrite Policy above.
      Note that if you enable the policy at the Grid level, you can modify all information, including the policy name. If you enable the policy at the member level, you can modify any information, except for the policy name.
4. Click **Save**. The appliance updates the policy in the table.
5. Save the configuration.

Overriding a Grid Hostname Rewrite Policy

You can override a Grid hostname rewrite policy at the member level. To override a Grid policy, complete the following:

1. From the **Data Management** tab, select the **DHCP** tab and click the **Members** tab -> *member* checkbox -> *Edit* icon.
2. In the *Member DHCP Properties* editor, click **Toggle Advanced Mode**.
3. In the **IPv4 DDNS** -> **Advanced** tab, click **Override** in the **Hostname Rewrite Policy** section, and then complete the following:
    - **Enable hostname rewrite policy**: Select this checkbox to use a hostname rewrite policy, or deselect the checkbox to disable the policy.
    - When you enable this feature, select a policy that you want to use from the drop-down list. Grid Manager displays all hostname rewrite policies that you have configured on the appliance in the drop-down list. After you select a policy, Grid Manager displays the policy name, valid characters, and the replacement character.
4. Save the configuration.

About the Client FQDN Option

When an IPv4 DHCP client sends DHCP DISCOVER and DHCP REQUEST messages, it can include option 81, the Client FQDN option. An IPv6 DHCP client can include option 39, the Client FQDN option, when it sends Solicit and Request messages.
The Client FQDN option contains the FQDN (fully qualified domain name) of the client and instructions on whether the client or the server performs DDNS updates. You can configure the appliance to replace the FQDN in the option by defining a hostname rewrite policy. For information about adding and enabling a hostname rewrite policy, see *Replacing Host Names for DDNS Updates*.
The DHCP server can support option 81 for IPv4 and IPv6 clients, and use the host name or FQDN that the client provides for the update. It can also allow or deny the client's request to update DNS, according to the administrative policies of your organization. The DHCP server indicates its response in the DHCP OFFER message it sends back to an IPv4 client, and in the Reply message it sends back to an IPv6 client.

Sending Updates with the FQDN Option Enabled

When you enable the DHCP server to support the FQDN option, it uses the information provided by the IPv4 or IPv6 client to update DNS as follows:

- When an IPv4 or IPv6 DHCP client sends a DHCP request with the FQDN option, it can include either its FQDN or only its host name.
    - If the request includes the FQDN, the DHCP server uses this FQDN to update DNS. You can specify a list of forward-mapping zones to be updated for IPv4 and IPv6 clients using the FQDN option. For information, see Sending Updates for DHCP Clients Using the FQDN Option below.
    - If the request includes the host name, the DHCP server provides the domain name. It combines the host name of the client and the domain name to create an FQDN for the client. It then updates DNS with the FQDN it created. (You can enter the domain name in the General page of the DHCP Properties window. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
- When a DHCP client sends a DHCP request with its hostname, the DHCP server adds the domain name you specified to create an FQDN for the client. It then updates DNS with the FQDN it created. For information about entering the domain name, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
- When a DHCP client does not send a host name, the DHCP server provides a lease but does not update DNS. You can configure the DHCP server to generate a host name and update DNS as described in *Generating Host Names for DDNS Updates*.
- If multiple DHCP clients specify the same FQDN or host name, the DHCP server allocates leases to the clients, but updates DNS only for the client that first sent the request. When it tries to update DNS for the succeeding clients, the update fails.

Sending Updates from DHCP Clients or a DHCP Server

When you enable the DHCP server to support the FQDN option, you must decide if you want the DHCP server to allow clients to update DNS. If you allow the client to update DNS, then the client updates its A or AAAA record only. The DHCP server always updates the PTR records. You can configure the DHCP server as follows:

- The DHCP server can allow clients to update DNS when they send the request in the FQDN option. This is useful for small sites where security is not an issue or in sites where clients move from one administrative domain to another and want to maintain the same FQDN regardless of administrative domain.
  If you configure the DHCP server to allow clients to perform DDNS updates, you must also configure the DNS server to accept these updates from clients. Note that multiple clients can use the same name, resulting in multiple PTR records for one client name.
  When a lease expires, the DHCP server does not delete the A or AAAA record, if it was added by the client.
- The DHCP server can refuse the DHCP client's request to update DNS and always perform the updates itself. When the DHCP server updates DNS, it uses the FQDN provided by the DHCP client. Select this option if your organization requires tighter control over your network and does not allow clients to update their own records.

If you do not enable support for the FQDN option and a client includes it in a DHCP request with its FQDN, the DHCP server does not use the FQDN of the client. Instead, it creates the FQDN by combining the host name from the client with the domain name specified in the Grid or Member DHCP Configuration editor.
Do the following to configure support for the FQDN option for both IPv4and IPv6 clients:

- Enable support for the option and specify who performs the DDNS update. For more information, see Enabling FQDN Option Support velow.
- Specify the DNS zones and DNS view for the updates. For more information, see Sending Updates for DHCP Clients Using the FQDN Option below.

Enabling FQDN Option Support

You can configure support for the FQDN option for IPv4 and IPv6 clients at the Grid, member, network and shared network levels.
To configure support for the FQDN Option (option 81) for IPv4 and (Option 39) for IPv6:

1. **Grid:** From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **Grid DHCP Properties**.
   Member: From the **Data Management** tab, select the **DHCP** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   Network: From the **Data Management** tab, select the **DHCP** tab and click the **Networks** tab -> **Networks** -> *network* checkbox -> Edit icon.
   Shared Network: From the **Data Management** tab, select the **DHCP** tab and click the **Networks** tab -> **Shared Networks** -> *shared_network* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the **IPv4 DDNS** -> **Advanced** tab for the Grid and member, or the **IPv4 DDNS** -> **Basic** tab for the network, do the following:
   - **Option 81 Support**
     - **Enable Option 81 Support:** Select this to enable the support for option 81.
     - **DHCP server always updates DNS:** Select this to allow the DHCP server to update DNS, regardless of the requests from DHCP clients.
     - **DHCP server updates DNS if requested by client:** Select this to allow the DHCP server to update DNS only when requested by DHCP clients.
3. In the **IPv6 DDNS** -> **Advanced** tab for the Grid and member, or the **IPv6 DDNS** -> **Basic** tab for the network, do the following:
   - **FQDN Support:** Select **Enable FQDN Support** and select one of the following to indicate whether the DHCP server or the client performs the DDNS update.
     - DHCP always updates DNS
     - DHCP updates DNS if requested by client
4. Save the configuration and click **Restart** if it appears at the top of the screen.

When a lease expires, the DHCP server removes the A or AAAA records and PTR records that it updated. It does not remove any records that the client updated.

Sending Updates for DHCP Clients Using the FQDN Option

You must specify the DNS view to be updated for each network view.
To send updates to zones for DHCP IPv4 and IPv6 clients using the FQDN option:

1. If there are multiple network views in the Grid, select a network view.
2. From the **Data Management** tab, select the **DHCP** tab, and then click **Configure DDNS** from the Toolbar.
3. In the *DDNS Properties* editor, complete the following:
    - **DNS View:** If a network view has more than one DNS view, this field lists the associated DNS views. From the drop-down list, select the DNS view to which the DHCP server sends DDNS updates. Otherwise, the appliance uses the default DNS view.
    - **Zones to Update for Hosts Using DHCP FQDN Option:** In this section, you can define forward-mapping zones to which the DHCP server sends DDNS updates for IPv4 and IPv6 DHCP clients that use the FQDN option. You must first enable support for the FQDN option before the DHCP server can send DDNS updates to these zones. By default, the DHCP server sends DDNS updates to zones using the domain name that you define for DHCP objects, such as networks and DHCP ranges. For clients using this option, the DHCP server uses the domain name defined in the option.
      Click the Add icon to specify a forward-mapping zone. Note that the Forward-mapping Zone Selector dialog box displays only the DNS zones that are associated with the selected DNS view. The zones you select here are written to the dhcpd.conf file and the dhcpdv6.conf file as "zone" statements with the matching TSIG key of the DNS view, so the updates are sent to the correct DNS view.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring DDNS Update Verification

The DHCP server can handle DDNS updates differently, depending on how stringently you configure record handling. You can configure the DHCP server to update records only after passing verification. You can adjust the way DHCP handles updates so the DHCP server updates records after passing less stringent verification requirements, or without any type of verification.
To provide a measure of protection against unintentional changes of DNS data, NIOS appliances support the generation and use of TXT records, as described in IETF draft, *draft-ietf-dhc-dhcp-dns-12.txt* and by the ISC (Internet Systems Consortium). When DHCP updates or deletes an A or AAAA record, the corresponding TXT record is checked first to verify the authenticity of the update. The TXT record is based on a hash of the DHCID which is unique to each client, usually based in part on the MAC address or the DUID. If the client requests an update to DNS, the DHCP server first checks the TXT record to verify that it matches the client that originally inserted the record. This process provides assurance that the updates are from the same client. These security checks are based upon inserting a cryptographic hash of the DHCID (DHCP Client Identifier) into a DNS TXT RR and then verifying that value before updating. For example, a sample client update adds the following records in DNS:

oxcart.lo0.net.	21600	IN A 172.31.1.20
oxcart.lo0.net.	21600	IN TXT "313ce164780d34b91486b7c489ed7467e6"
20.1.31.172.in-addr.arpa.	21600	IN PTR oxcart.lo0.net.

However, your DNS configuration might require that the NIOS appliance handle DNS record updates differently than described in draft-ietf-dhc-dhcp-dns-12.txt. Your specific requirements might benefit from less-stringent verification of the DHCID, or might require skipping verification entirely. Verification checks might cause complications in some specific cases described below:

- **Mobility:** The TXT record is based on the DHCID unique to each client and is usually based on the MAC address or DUID of the interface. Devices such as laptops that connect to both wired and wireless networks have different MAC addresses or DUIDs and different DHCID values for each interface. In this scenario, after either one of the

network interfaces inserts a DNS record, updates are allowed from that interface only. This results in a disruption of service for DDNS updates when roaming between wired and wireless networks.

- **Migration:** The second problem occurs during a migration from non-ISC based systems to ISC systems. For example, if the user is migrating from a Microsoft-based system, the clients have A or AAAA and PTR records in the DDNS updates but no TXT records. As a result, new DDNS updates fail after the migration.
- **Mixed Environments:** The final problem occurs in mixed ISC and non-ISC environments. For example, assume that both Microsoft and ISC DHCP servers update DNS records on the appliance. In a mixed environment, since the Microsoft DHCP server does not insert the TXT records, DDNS updates from ISC-based systems fail while updates from the Microsoft DHCP server are committed into the database. This behavior is applicable only when you select **Standard ISC** and **Check TXT only** DDNS update verification modes.

The NIOS appliance offers four modes to handle DDNS updates as described in the DDNS Update Verification Mode table :

DDNS Update Verification Mode

Mode	If a Record at Lease Grant	Then TXT Record at Lease Grant	Lease Grant Action	Lease Expire Action
Standard ISC	Exists	Must match	Delete A or AAAA, TXT if exists Add A or AAAA Add PTR	Delete PTR Delete A or AAAA, TXT if TXT matches and no other A or AAAA RRs
	No A or AAAA record	No check	Add A or AAAA, TXT Add PTR	
Check TXT only	Exists	Must exist	Delete A or AAAA, TXT Add A or AAAA, TXT Add PTR	Delete PTR Delete A or AAAA if TXT exists and no other A or AAAA RRs
	No A or AAAA record	No check	Add A or AAAA, TXT Add PTR	
ISC Transitional	Exists	No check	Delete A or AAAA, TXT if exists Add A or AAAA, TXT Add PTR	Delete PTR Delete A or AAAA, TXT if TXT matches and no other A or AAAA RRs
	No A or AAAA record	No check	Add A or AAAA, TXT Add PTR	
No TXT record	Exists	No check	Delete A or AAAA Add A or AAAA Add PTR	Delete PTR, A or AAAA
	No A or AAAA record	No check	Add A or AAAA Add PTR	

Depending on your expected usage, you must carefully consider the various options for update verification. The following section illustrates recommendations for each verification option:

- **Standard ISC:** This method is the most stringent option for verification of updates. This is the default.
- **ISC Transitional:** This method is useful during migrations from systems that do not support the TXT record to systems that are ISC-based.
- **Check TXT only:** This method is useful for the roaming laptop scenario. The NIOS appliance checks that a TXT record exists, but does not check the value of the TXT record.
- **No TXT record:** This method should be used with caution because anyone can send DDNS updates and overwrite records. This method is useful when both ISC and non-ISC-based DHCP servers and clients are updating the same zone. Infoblox recommends that you allocate a DNS zone for this authentication method, as a precaution.

Note that in certain situations, when a DHCP lease expires, the DHCP server might remove the TXT record even if there is no A or AAAA record.

You can enable this feature at the Grid level. To configure TXT record handling on the DHCP server:

1. From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **Grid DHCP Properties**.
2. In the **IPv4 DDNS** -> **Advanced** tab or the **IPv6 DDNS** -> **Advanced** tab, select one of the following from the **TXT (DHCID) Record Handling** drop-down list:
   - **Check Only:** Select this checkbox to enable minimal checking of DDNS updates. Specifically, A or AAAA records are modified only if a TXT record exists. The NIOS appliance checks that a TXT record exists, but does not check its value.
   - **ISC:** Select this checkbox to enable standard ISC (Internet Systems Consortium) handling for DDNS updates. Specifically, A or AAAA records are modified or deleted only if the TXT records match. This option is the default setting on the appliance.
   - **ISC Transitional:** Select this checkbox to enable less stringent handling of DDNS updates. Specifically, the NIOS appliance enables you to add or modify A or AAAA records whether or not TXT records exist. It checks whether a TXT record exists and then processes the update. If the appliance does not find a TXT record, it adds the record.
   - **No TXT Record:** Select this checkbox to disable TXT record checking. Specifically, A or AAAA records are added, modified, or deleted whether or not the TXT records match. No TXT records are added, and existing TXT records are ignored.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring DNS Servers for DDNS

For security reasons, an Infoblox DNS server does not accept DDNS updates by default. You must specify the sources from which you want to allow the DNS server to receive updates. You can configure the Infoblox DNS server to receive updates from specified DHCP clients, as described in Enabling DNS Servers to Accept DDNS Updates below, and to accept forwarded updates from another DNS server, as described in Forwarding Updates below.
For protection against spoofed IP addresses, you can use TSIG (transaction signatures) to authenticate and verify updates.
TSIG uses the MD5 (Message Digest 5) algorithm and a shared secret key to create an HMAC (hashed message authentication code) — sometimes called a *digital fingerprint* — of each update. Both the DHCP server sending the update and the DNS server receiving it must share the same secret key. Also, it is important that the time stamps on the TSIG-authenticated updates and update responses be synchronized, or the participants reject them. Therefore, use an NTP server to set the time on all systems involved in TSIG authentication operations.
The TSIG key that you use can come from several places:

- You can use the key generation tool described in this section to create a new TSIG key to authenticate updates from the DHCP server.
- You can enter (copy and paste) a TSIG key that you previously generated for another purpose, such as for zone transfers.
- If the DHCP server is on a separate appliance and a TSIG key was previously generated on that appliance, you can enter (copy and paste) that TSIG key onto the local DNS server.

The TSIG key name and value that the DHCP and DNS servers use must be the same.

> ⚠ Note
>
> Whether you deploy NIOS appliances in a Grid or independently, they send updates to UDP port 53. Grid members do not send updates through a VPN tunnel. Grid members do, however, authenticate updates between them using TSIG (transaction signatures) based on an internal TSIG key.

Enabling DNS Servers to Accept DDNS Updates

You can configure the Infoblox DNS server to receive updates from specified DHCP clients only. You can set this for the Grid so that the Grid members receive DDNS updates only from the specified sources. Note that you specify the IP

addresses of the sources of the updates and not the actual IP addresses in the DNS records being updated.
To configure the DNS server to accept updates from the specified sources complete the following steps:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   Zones: From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab-> *dns_view* -> *zone* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the editor, click **Toggle Advanced Mode**, select the **Updates** tab.
   Ensure that you understand how the appliance handles match lists before you specify the list of IP sources for DDNS updates, as described in *You can use the following OpenStack cloud-init template to configure an IB-V815 as a Grid Master.*
3. In the *Allow updates from* section, select one of the following:
   - **None**: Select this to deny DDNS updates from any DHCP clients. This is selected by default.
   - **Named ACL**: Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this option, the appliance receives DDNS updates from the sources that have the **Allow** permission in the named ACL. You can click **Clear** to remove the selected named ACL.
   - **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows:
     - **IPv4 Address** and **IPv6 Address**: Select this to add an IPv4 address or IPv6 address. Click the **Value** field and enter the IP address. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
     - **IPv4 Network**: In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address**: Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
       - **Permission**: Select **Allow** or **Deny** from the drop-down list.
     - **IPv6 Network**: In the **Add IPv6 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address**: Enter an IPv6 network address and select the netmask from the drop-down list.
       - **Permission**: Select **Allow** or **Deny** from the drop-down list.
     - **TSIG Key**: In the **Add TSIG Key** panel, complete the following, and then click **Add** to add the TSIG key to the list:
       - **Key name**: Enter a meaningful name for the key, such as a zone name or the name of a remote name server. This name must match the name of the same TSIG key on other name servers.
       - **Key Algorithm**: Select either **HMAC-MD5** or **HMAC-SHA256.**
       - **Key Data**: To use an existing TSIG key, type or paste the key in the **Key Data** field. Alternatively, you can select the key algorithm, select the key length from the **Generate Key Data** drop-down list, and then click **Generate Key Data** to create a new key.
         You must enable GSS-TSIG signed updates to receive DDNS updates from TSIG key based ACEs. For information about how to enable this, see *Accepting GSS-TSIG Updates*.
     - **Any Address/Network:** Select this to receive DDNS updates from any IP addresses.
     After you have added access control entries, you can do the following:
       - Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
       - Reorder the list of ACEs using the up and down arrows next to the table.
       - Select an ACE and click the Edit icon to modify the entry.
       - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.

- **Allow GSS-TSIG signed updates**: This checkbox is selected only if you have enabled GSS-TSIG signed updates.

4. Optionally, you can:
   - Modify an item on the list by selecting it and clicking the Edit icon.
   - Remove an item from the list by selecting it and clicking the Delete icon.
   - Move an item up or down the list. Select it and drag it to its new position, or click the up or down arrow. The appliance applies permissions to items in the order they are listed.
5. Save the configuration.

Forwarding Updates

When a secondary DNS server receives DDNS updates, it must forward the updates to the primary server because it cannot update zone data itself. In such situations, you must enable the secondary server to receive updates from the DHCP server, and then forward them to the primary DNS server.
To configure the secondary server to accept and forward updates for all zones:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   Zones: From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab-> *dns_view* -> *zone* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. In the editor, click **Toggle Advanced Mode**.
3. When the additional tabs appear, click the **Advanced** subtab of the **Updates** tab, and then complete the following:
   - **Allow secondary name servers to forward updates**: Select this checkbox.
   - **Forward updates from**: This is available only for authoritative zones. Click **Add**. Depending on the item that you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows:
   - **None**: Select this to deny DDNS updates from any clients. This is selected by default.
   - **Named ACL:** Select this and click **Select Named ACL** to select a named ACL. Grid Manager displays the *Named ACLs* Selector. Select the named ACL you want to use. If you have only one named ACL, Grid Manager automatically displays the named ACL. When you select this option, the appliance receives DDNS updates from the sources that have the **Allow** permission in the named ACL. You can click **Clear** to remove the selected named ACL.
   - **Set of ACEs**: Select this to configure individual ACEs. Click the Add icon and select one of the following from the drop-down list. Depending on the item you select, Grid Manager either adds a row for the selected item or expands the panel so you can specify additional information about the item you are adding, as follows.
     - **IPv4 Address** and **IPv6 Address**: Select this to add an IPv4 address or IPv6 address. Click the **Value** field and enter the IP address. The **Permission** column displays **Allow** by default. You can change it to **Deny** by clicking the field and selecting **Deny** from the drop-down list.
     - **IPv4 Network**: In the **Add IPv4 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address**: Enter an IPv4 network address and either type a netmask or move the slider to the desired netmask.
       - **Permission**: Select **Allow** or **Deny** from the drop-down list.
     - **IPv6 Network**: In the **Add IPv6 Network** panel, complete the following, and then click **Add** to add the network to the list:
       - **Address**: Enter an IPv6 network address and select the netmask from the drop-down list.
       - **Permission**: Select **Allow** or **Deny** from the drop-down list.
     - **TSIG Key**: In the **Add TSIG Key** panel, complete the following, and then click **Add** to add the TSIG key to the list:
       - **Key name**: Enter a meaningful name for the key, such as a zone name or the name of a remote name server. This name must match the name of the same TSIG key on other name servers.
       - **Key Algorithm**: Select either **HMAC-MD5** or **HMAC-SHA256**.
       - **Key Data**: To use an existing TSIG key, type or paste the key in the **Key Data** field. Alternatively, you can select the key algorithm, select the key length from the **Generate Key Data** drop-down list, and then click **Generate Key Data** to create a new key.

You must enable GSS-TSIG signed updates to receive DDNS updates from TSIG key based ACEs. For information about how to enable this, see *Accepting GSS-TSIG Updates*.

- **Any Address/Network:** Select to allow or disallow the appliance to receive DDNS updates from any IP address.

After you have added access control entries, you can do the following:

- Select the ACEs that you want to consolidate and put into a new named ACL. Click the Create new named ACL icon and enter a name in the *Convert to NamedACL* dialog box. The appliance creates a new named ACL and adds it to the **Named ACL** panel. Note that the ACEs you configure for this operation stay intact.
- Reorder the list of ACEs using the up and down arrows next to the table.
- Select an ACE and click the Edit icon to modify the entry.
- Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.

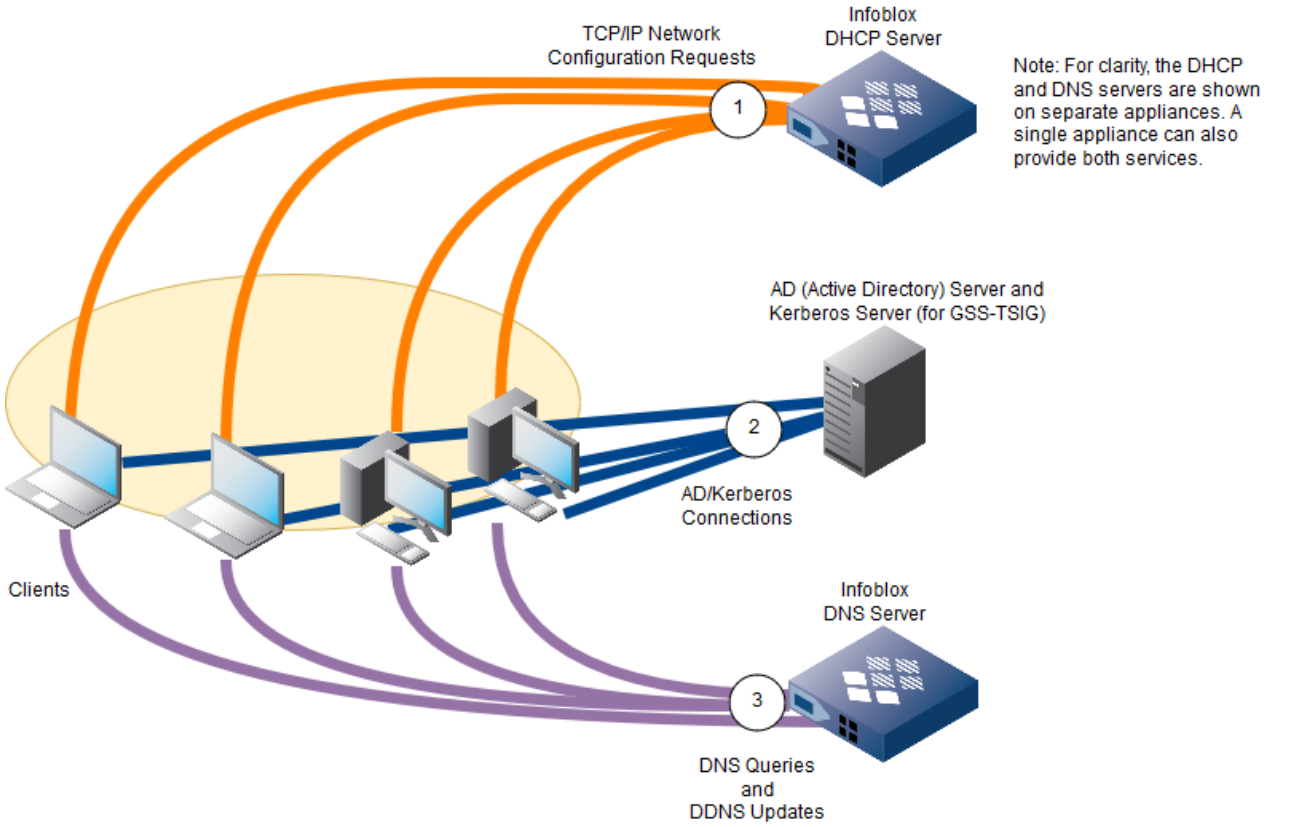
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Supporting Active Directory

Active Directory™ (AD) is a distributed directory service that authenticates network users and — by working with DHCP and DNS — provides the location of and authorizes access to services running on devices in a Windows® network. You can integrate a NIOS appliance providing DHCP and DNS services with servers running Windows 2000 Server, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, or Windows Server 2016 with the Active Directory service installed. Assuming that you already have AD set up and it is currently in use, you can migrate DHCP and DNS services away from internal operations on the AD domain controller or from other third party DHCP and DNS systems to NIOS appliances that serve DHCP and DNS.

A NIOS appliance providing DHCP and DNS services to an AD environment can send and receive DDNS updates. In addition, a NIOS appliance can use GSS-TSIG (Generic Security Service-Transaction Signatures) authentication for DDNS updates. The basic DHCP, AD, and DNS services are shown in the following DHCP, Active Directory, and DNS figure.

DHCP, Active Directory, and DNS



Sending DDNS Updates to a DNS Server

You can configure an Infoblox DHCP server to send unauthenticated or GSS-TSIG-authenticated DDNS updates to a DNS server in an AD domain. There are no special configurations to consider when configuring a NIOS appliance to send unauthenticated DDNS updates to the DNS server. (For information about configuring DHCP, see *Configuring DHCP Properties*, and for information on configuring the DHCP server to send DDNS updates, see *Configuring DHCP for DDNS*.) For information about configuring a DHCP server to send GSS-TSIG authenticated updates, see *About GSS-TSIG*.

About GSS-TSIG

GSS-TSIG (Generic Security Service Algorithm for Secret Key Transaction) is used to authenticate DDNS updates. It is a modified form of TSIG authentication that uses the Kerberos v5 authentication system.

GSS-TSIG involves a set of client/server negotiations to establish a "security context." It makes use of a Kerberos server (running on the AD domain controller) that functions as the KDC (Kerberos Key Distribution Center) and provides session tickets and temporary session keys to users and computers within an Active Directory domain. The client and server collaboratively create and mutually verify transaction signatures on messages that they exchange. Windows 2000 server, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, Windows Server 2016 and Windows Server 2019 all support DDNS updates using GSS-TSIG.

You can configure the appliance to accept GSS-TSIG signed DDNS updates from a single client or multiple clients that belong to different AD domains in which each domain has a unique GSS-TSIG key. You can also configure the appliance to support one or multiple GSS-TSIG keys for each Grid member. For information about how to configure GSS-TSIG for DHCP and DNS, see *Configuring GSS-TSIG keys*. This feature also supports HA pairs and is compatible with DNS zones that have multiple primary servers configured. For more information about HA pairs and DNS zones with multiple primary servers, see *About HA Pairs* and *Assigning Zone Authority to Name Servers* respectively.

You can upload keytab files that contain one or multiple GSS-TSIG keys and manage the keys globally. NIOS supports up to 256 GSS-TSIG keys for each member in the Grid. NIOS logs administrative changes to GSS-TSIG keys in the audit

log and failures in parsing or loading the keytab files in the syslog. Note that this feature is enabled only when you have installed the DNS license.

> **Note**
>
> For information about GSS-TSIG,
> see *RFC 3645, Generic Security Service Algorithm for Secret Key Transaction Authentication for DNS (GSS-TSIG)*.

A NIOS appliance can use GSS-TSIG authentication for DDNS updates for either one of the following:

- A NIOS appliance serving DHCP can send GSS-TSIG authenticated DDNS updates to a DNS server in an AD domain or multiple AD domains whose domain controller is running Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, Windows Server 2016 or Windows Server 2019. The DNS server can be in the same AD domain as the DHCP server or in a different domain.
  - For information about sending secure DDNS updates to a DNS server in the same domain, see Sending Secure DDNS Updates to a DNS Server in the Same Domain below.
  - For information about sending secure DDNS updates to a DNS server in a different domain, see Sending Secure DDNS Updates to a DNS Server in Another Domain below.
- A NIOS appliance serving DNS can accept GSS-TSIG authenticated DDNS updates from DHCP clients and servers in an AD domain or multiple AD domains whose domain controller is running Windows 2000 Server, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, Windows Server 2016 or Windows Server 2019.
  - For information, see *Accepting GSS-TSIG-Authenticated Updates*.
    Note that a NIOS appliance cannot support both of these features at the same time.

Kerberos Authentication for GSS-TSIG

A keytab file contains pairs of Kerberos principal names and their corresponding encryption keys. It can contain keys for a single realm or multiple realms. It is possible to infer the KDC from the principal because Windows uses uppercase AD domain names for Kerberos realm names. You must provide the principal name. The principal name may contain Kerberos realm, and the DNS servers for the domain are available for DNS name resolution. Therefore, resolving SRV _kerberos._tcp.REALM. will return the appropriate KDC. New TGTs cannot be acquired when the KDC that issues the TGT fails. If the appliance has successfully authenticated before the KDC failure, the secure updates will continue until the session key and TGT expire. The default expiration on Windows is 10 hours. If the appliance restarts or reboots, secure updates are deferred until the KDC becomes available.

Infoblox recommends restarting the DHCP service on NIOS to avoid any update failures, if the encryption key type is changed on the Microsoft server.
The following provides information about the traffic flow between the appliance and the KDC:

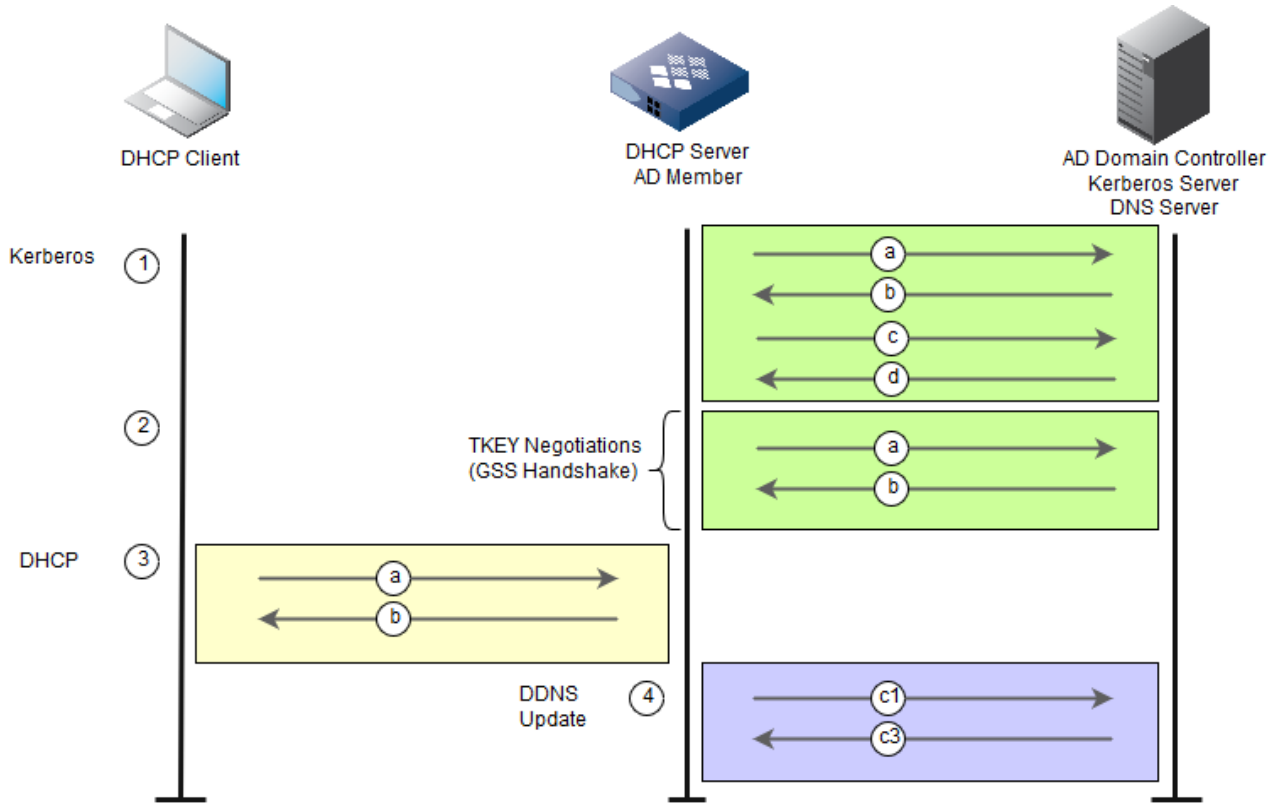
- Client uses keytab to get TGT for principal from KDC (AS-REQ/AS-REP).
- Client uses TGT to get session ticket from KDC (TGS-REQ/TGS-REP).
- Client uses session ticket to acquire TKEY from DNS server (TKEY/TKEY).
- Client uses TKEY to sign DNS updates (DNS-TSIG/DNS-TSIG).

The DNS server authenticates into the domain when the keytab file is generated on the KDC and its SPN (Service Principal Name) is mapped to an account. The server's private key is known to itself and to the KDC. The KDC generates the ticket and the DNS server allows the update.
Note the following when you upload multiple keytab files on the appliance:

- NIOS displays an error message and discards the keytab file if the file does not have a recognizable key, SPN, version or encryption type, and it saves the error message in the syslog.
- NIOS considers duplicate keys as invalid keys if the keys have the same SPN, version, and encryption type.
- If NIOS encounters an invalid key during an upload, it will not upload the other keys in the keytab and the operation fails. NIOS saves the warning and error message in the syslog and in Grid Manager.

Sending Secure DDNS Updates to a DNS Server in the Same Domain

An Infoblox DHCP server can send GSS-TSIG authenticated DDNS updates to a DNS server in an AD domain whose domain controller is running Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, Windows Server 2016 or Windows Server 2019. The DHCP server, DNS server, and domain controller are all in the same AD domain. The process by which an Infoblox DHCP server dynamically updates resource records on a DNS server using GSS-TSIG authentication is shown in the below figure. In the illustration, the Kerberos Key Distribution Center (KDC) is running on an AD domain controller, which also provides DNS service.
An Infoblox DHCP Server Sends GSS-TSIG Updates to a DNS Server



After you enable the NIOS appliance to send GSS-TSIG authenticated updates to a DNS server, the following process occurs:

1. Kerberos – Login, and TGT and Service Ticket Assignments
    a. The Infoblox appliance automatically logs in to the AD/Kerberos server.
    b. The Kerberos server sends the appliance a TGT (ticket-granting ticket).
    c. Using the TGT, the appliance requests a service ticket for the DNS server.
    d. The Kerberos server replies with a service ticket for that server.
2. TKEY negotiations (GSS Handshake):
    a. The appliance sends the DNS server a TKEY (transaction key) request. A Transaction Key record establishes shared secret keys for use with the TSIG resource record. For more information, see *RFC 2930, Secret Key Establishment for DNS (TKEY RR)*.
    The request includes the service ticket. The service ticket includes the appliance's principal and proposed TSIG (transaction signature) key, along with other items such as a ticket lifetime and a timestamp.
    b. The DNS server responds with a DNS server-signed TSIG, which is a "meta-record" that is never cached and never appears in zone data. A TSIG record is a signature of the update using an HMAC-MD5 hash that provides transaction-level authentication. For more information, see *RFC 2845, Secret Key Transaction Authentication for DNS (TSIG)*.

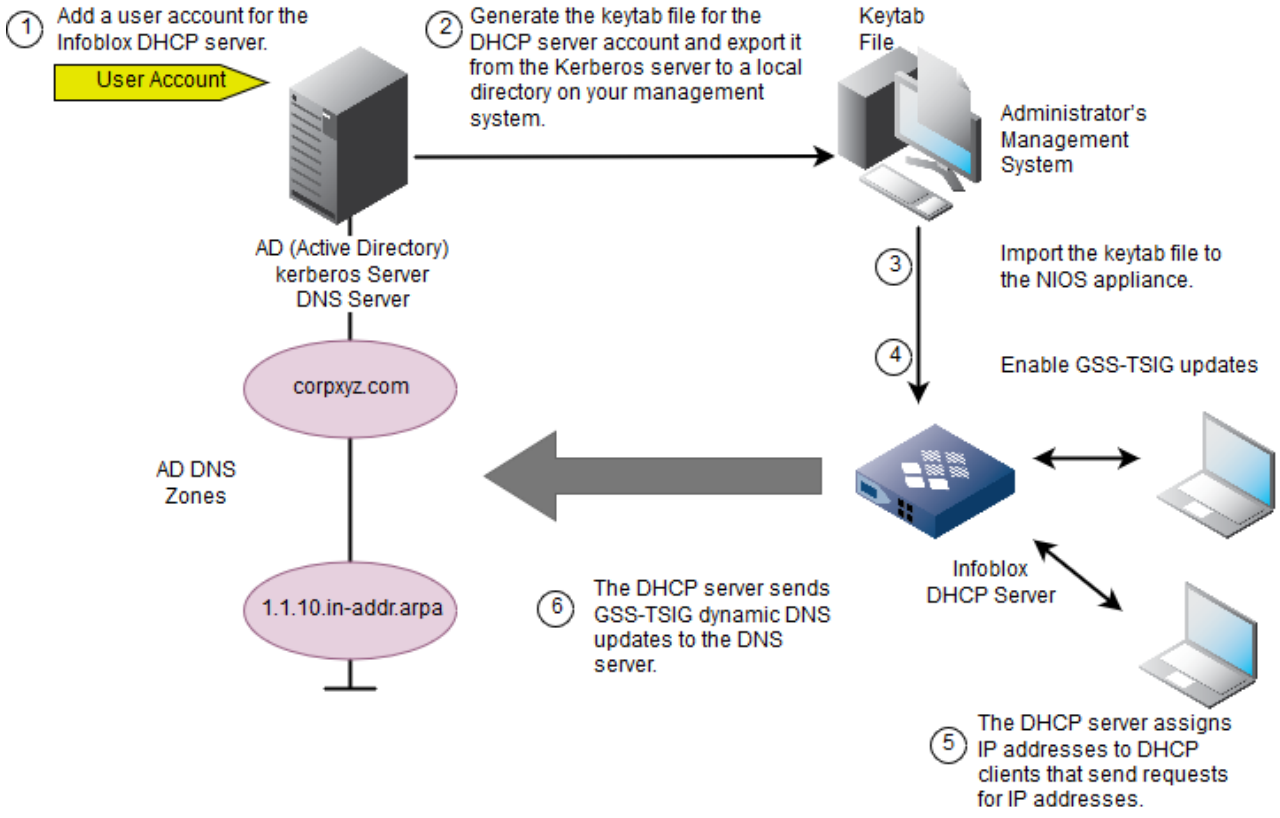
The two participants have established a security context.
When a DHCP client sends a request for an IP address to the DHCP server, the following occurs:

3. DHCP – IP Address and Network Parameters Assignment
    a. The DHCP client requests an IP address.
    b. The DHCP server assigns an IP address, subnet mask, gateway address, DNS server address, and a domain name.
    After the appliance assigns an IP address to the DHCP client, it sends the DDNS update to the DNS server as follows:
4. DDNS – Dynamic Update of the Client's Resource Records
    a. GSS-TSIG-Authenticated DDNS Update
        i. The appliance sends an authenticated DDNS update, which may include the following resource records:
            - A or AAAA – Address record
              or
              PTR – Pointer record
            - TKEY – Transaction Key record
            - TSIG – TSIG record
        ii. The DNS server verifies the DDNS update and allows it to complete.
        iii. The DNS server sends a GSS-TSIG-authenticated response to the appliance, confirming the update.

Configuring DHCP to Send GSS-TSIG Updates in the Same Domain

Before configuring an Infoblox DHCP server to support GSS-TSIG, you must create a user account on the Kerberos server for the appliance. Then you must export the corresponding keytab file from the Kerberos server and import it onto the NIOS appliance. The below figure illustrates the initial configuration tasks.

Adding an Infoblox DHCP Server to an AD Environment with GSS-TSIG Support



The Infoblox DHCP server can send GSS-TSIG-signed DDNS updates to a DNS server for one domain only, though multiple Infoblox DHCP servers can update that domain. If you want more than one Infoblox DHCP server to update a DNS domain, you can either import the same keytab file to the other Infoblox DHCP servers or generate and import a different keytab file. In a Grid, each member can update a different domain.

> **Note**
>
> For GSS-TSIG authentication to work properly, the system clock times of the Infoblox DHCP server, AD domain controller and DNS server must be synchronized. One approach is to use NTP and synchronize all three devices with the same NTP servers.

To use an AD domain controller as a Kerberos Key Distribution Center, complete the following tasks on an AD/Kerberos server:

1. Add a user account for the NIOS appliance to the AD domain controller. For information, see Creating an AD User Account below.
2. Generate the keytab file for the NIOS appliance account and export it from the AD domain controller to a local directory on your management system. For information, see Generating and Exporting the Keytab File below.

To configure a NIOS appliance to support AD and send GSS-TSIG secure DDNS updates to a DNS server, complete the following tasks on a NIOS appliance:

1. Import the keytab file from your management system to the appliance and enable GSS-TSIG dynamic updates at the Grid or member level. For information, see *Enabling GSS-TSIG Authentication for DHCP*.
2. Configure the appliance to send GSS-TSIG dynamic updates to forward-mapping and optionally, reverse-mapping zones on the DNS server. For information, see *Managing GSS-TSIG keys*.

Creating an AD User Account

Connect to the AD domain controller and create a user account for the NIOS appliance.

> **Note**
> The name that you enter in the User logon name is the name that you later use when exporting the keytab file. This is also the principal name. The text in the First name, Initials, Last name, and Full name fields is irrelevant to this task.

The AD domain controller automatically creates a Kerberos account for this user. Note the following:

- If you define an expiration date for the user account and you later create a new account when the first one expires, the keytab for the corresponding Kerberos account changes. At that point, you must update the keytab file on the NIOS appliance (see Generating and Exporting the Keytab File below and *Enabling GSS-TSIG Authentication for DHCP*). Optionally, if your security policy allows it, you can set the user account for the NIOS appliance so that it never expires.
- If the AD domain controller is running Windows Server 2003, the user account must have the DES encryption type enabled. You can enable this either in the Account tab of the AD domain controller when you create the user account or by specifying **+DesOnly** when you use the Ktpass tool to generate the keytab file. For instructions, see the next section, Generating and Exporting the Keytab File below.
- The newly created AD user account must be a member of the DnsUpdateProxy group or an account that allows it to update records that have potentially been added by another DHCP server, such as DNS Admins.

Generating and Exporting the Keytab File

You can use the Ktpass tool to generate and export the keytab file for the Kerberos account. Note that the version of the Ktpass tool that you use must match the Windows version of the domain controller. For example, if you are using a domain controller running Windows Server 2008 or Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, Windows Server 2016 or Windows Server 2019, you must use the Ktpass tool for Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, Windows Server 2016 or Windows Server

2019.
You enter different commands for generating and exporting the keytab file, depending on whether you are generating the keytab file from a server running Microsoft Windows 2000, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2010, Windows Server 2012, Windows Server 2012 R2, Windows Server 2016 or Windows Server 2019.
A Windows Server 2003 domain controller allows you to generate a keytab file with only one key for a principal. A Windows Server 2008, Windows Server 2008 R2 domain controller, Windows Server 2012, Windows Server 2012 R2, Windows Server 2016 or Windows Server 2019 allows you to generate a keytab file with multiple keys for one principal. This is useful when the KDC has principals with multiple encryption types. When the NIOS DHCP server uses a keytab with multiple keys, it negotiates a key based on those in the configured keytab file.

> ⚠ Note
> The keytab file contains highly sensitive data for the NIOS appliance account. Ensure that you store and transport its contents securely.

Infoblox strongly recommends the following encryption types for compatibility purposes:

Microsoft Windows Server	Export keytab
Microsoft Windows 2000	Specify **/crypto DES-CBC-MD5** as the export keytab.
Microsoft Windows 2003	Specify **/crypto RC4-HMAC-NT** as the export keytab. • Infoblox recommends that you do not use DES, but it is supported if you need it for compatibility with non-Windows systems.
Microsoft Windows 2008 and higher	Specify **/crypto RC4-HMAC-NT** as the export keytab. • You can also use AES, but RC4 is set by default for Windows 2008 servers. • Infoblox recommends that you do not use DES, but it is supported if you need it for compatibility with non-Windows systems.

Generating the Keytab on Windows 2000 Servers

To export the keytab file using a Microsoft Windows 2000 Resource Kit:

1. Start a command prompt.
2. Enter the following command to export the keytab file for the NIOS appliance user account:

```
C:> ktpass -princ service_name/FQDN_instance@REALM -mapuser AD_username -pass password -out filename.keytab
```

Note that the values are case-sensitive.
where:
- *service_name/instance*: The AD user name for the NIOS appliance and a character string. The AD user name must match the user logon name on the AD domain controller.
- *REALM*: The Kerberos realm in uppercase. It must match the realm (or domain name) specified in the **–mapuser** option.

For example:

```
C:> ktpass -princ DNS/ns1.corpxyz.com@corpxyz.COM -mapuser ns1@corpxyz.com -pass
37Le37
-out ns1.keytab
```

Generating the Keytab on Windows Servers 2003

The Ktpass tool is included in the Windows Server 2003 Support Tools. To export the keytab file using a Microsoft Windows 2003 Resource Kit:

1. Start a command prompt.
2. Enter the following command to generate the keytab file for the NIOS appliance user account:
   ktpass -princ *service_name/FQDN_instance@REALM* **-mapuser** *AD_username@REALM* **-pass** *password* **-out** *filename*.ktb **-ptype** KRB5_NT_PRINCIPAL **-crypto RC4-HMAC-NT**
   Note that the values are case-sensitive.

The following are some examples of keytab file:

```
ktpass -princ HOST/ns1.corpxyz.com@GSS.LOCAL -mapuser gssuser@GSS.LOCAL -pass 37Le37
-out ns1.keytab -ptype krb5_nt_principal -crypto all
ktpass -princ gssuser@GSS.LOCAL -mapuser gssuser@GSS.LOCAL -pass 37Le37 -out
gssuser.keytab -ptype krb5_nt_principal -crypto all
ktpass -princ DNS/ns1.corpxyz.com@GSS.LOCAL -mapuser jsmith@GSS.LOCAL -pass 37Le37
-out ns1.ktb -ptype KRB5_NT_PRINCIPAL -crypto des-cbc-md5 +DesOnly
```

where
-princ = Kerberos principal. Note that this parameter is case sensitive. Specifies the principal name for the host or service in this format: DNS/ns1.corpxyz.com@GSS.LOCAL

- DNS = Service name in uppercase format.
- ns1.corpxyz.com = Instance in FQDN (fully-qualified domain name) format; this is the same as the DNS name of the NIOS appliance.
- GSS.LOCAL = The Kerberos realm in uppercase format. This must be the same as the AD domain name.

-mapuser = Maps the Kerberos principal name to the AD user account. If you omit the account name, mapping is deleted from the specified principal. You can use ksetup without any parameters or arguments to see the current mapped settings and the default realm. Example: ksetup /mapuser <Principal> <Account>. To create an AD user account, see Creating an AD User Account above.

- jsmith = The AD user name for the NIOS appliance.
- GSS.LOCAL = The Kerberos realm in uppercase. The realm (or domain name) must be the same as that specified in the **-princ** option.

-pass = The AD user account password. The Ktpass command changes the account password to the specified value, thus incrementing the version number of the user account and the resulting keytab file.

- 37Le37 = The password of the user account for the NIOS appliance.

-out = The name of the keytab file that is generated.

- ns1.ktb = The name of the keytab file

-ptype = Sets the principal type. This must be **krb5_nt_principal**.
-crypto = Specifies the encryption type. You can use the following encryption types:

- DES-CBC-CRC = Specifies DES encryption for the account. This encryption type is used for compatibility.
- DES-CBC-MD5 = Specifies DES encryption for the account. This encryption type adheres to the MIT implementation and is used for compatibility.
- RC4-HMAC-NT = Specifies 128-bit RC4-HMAC encryption for the account. This is enabled by default.

+DesOnly = Specifies DES encryption for the account.

> **Note**
> Windows Server 2003 does not support AES encryption.

After you execute the command to generate the keytab file, the AD domain controller displays a series of messages similar to the following to confirm that it successfully generated the keytab file:

```
Targeting domain controller: ibtest-xu5nxd56.corpxyz.local

Using legacy password setting method

Successfully mapped dns/anywhere to dns.

Key created.

Output keytab to dns.ktb:

Keytab version: 0x502

keysize 56 dns/anywhere@GSS.LOCAL ptype 1 (KRB5_NT_PRINCIPAL) vno 5 etype 0x3 (DES-
CBC-MD5)

keylength 8 (0xbae610f11552c80b)
```

Generating the Keytab on Windows Servers 2008 or Windows Servers 2008 R2

To generate the keytab file using the Ktpass tool:

1. Start a command prompt.
2. Enter the following command to generate the keytab file for the NIOS appliance user account:

```
ktpass -princ username@REALM -mapuser logon_name@REALM -pass password -out
my.tab -ptype krb5_nt_principal -crypto encryption
```

Example:

```
ktpass -princ DNS/ns1.corpxyz.com@GSS.LOCAL -mapuser jsmith@GSS.LOCAL -pass 37Le37
-out ns1.keytab -ptype krb5_nt_principal -crypto RC4-HMAC-NT
```

where:
-princ = Kerberos principal. Note that this parameter is case sensitive. Specifies the principal name for the host or service in this format: DNS/ns1.corpxyz.com@GSS.LOCAL

- DNS = Service name in uppercase format.
- ns1.corpxyz.com = Instance in FQDN (fully-qualified domain name) format; this is the same as the DNS name of the NIOS appliance.
- GSS.LOCAL = The Kerberos realm in uppercase format. This must be the same as the AD domain name.

-mapuser = Maps the Kerberos principal name to the AD user account. If you omit the account name, mapping is deleted from the specified principal. You can use ksetup without any parameters or arguments to see the current mapped

settings and the default realm. Example: ksetup /mapuser <Principal> <Account>. To create an AD user account, see Creating an AD User Account above.

- jsmith = The AD user name for the NIOS appliance.
- GSS.LOCAL = The Kerberos realm in uppercase. The realm (or domain name) must be the same as that specified in the **-princ** option.

-pass = The AD user account password. The Ktpass command changes the account password to the specified value, thus incrementing the version number of the user account and the resulting keytab file.

- 37Le37 = The password of the user account for the NIOS appliance.

-out = The name of the keytab file that is generated.

- ns1.ktb = The name of the keytab file

-ptype = Sets the principal type. This must be **krb5_nt_principal**.
-crypto = Specifies the encryption type. Note that the **RC4-HMAC-NT** encryption type is enabled by default. You can also use the following:

- **DES-CBC-CRC** = Specifies DES encryption for the account. This encryption type is used for compatibility.
- **DES-CBC-MD5** = Specifies DES encryption for the account. This encryption type adheres to the MIT implementation and is used for compatibility.
- **RC4-HMAC-NT** = Specifies 128-bit RC4-HMAC encryption for the account. This is enabled by default.
- **AES256-SHA1** = Specifies 256-bit AES encryption for the account.
- **AES128-SHA1** = Specifies 128-bit AES encryption for the account.
- **ALL** = Specifies all of the above encryption types. Do not use this option if DES support is disabled.

You can optionally specify the following:
+DesOnly = Specifies DES encryption for the account. You must use this only when you use DES-CBC-MD5 for compatibility. Note that Windows 7 and Windows Server 2008 R2 do not support DES by default. However, you can enable DES on the Windows 2008 server. Include this option if you did not enable DES encryption for the account. For more information, refer to the information available in a third-party portal at: *http://weblogic-wonders.com/weblogic/2010/11/30/windows-7-des-encryption-support-for-kerberos-authentication/*

> ⚠ Note
> You must not use +Desonly with /crypto all or other non-DES encryption types.

- **+setpass** = Sets a new AD user account password. This is required if the **+DesOnly** option is specified. When you use this encryption type, you must change the user's password. Otherwise, the ticket issued for the principal becomes unusable.

After you execute the command to generate the keytab file, the AD domain controller displays a series of messages similar to the following to confirm that it successfully generated the keytab file:

```
Targeting domain controller: qacert.test.local

Using legacy password setting method

Successfully mapped DNS/ns1.corpxyz.com to ns1.

Key created.

Output keytab to ns1.ktb: Keytab version: 0x502

keysize 80 DNS/ns1.corpxyz.com@GSS.LOCAL ptype 1 (KRB5_NT_PRINCIPAL) vno 3 etype 0x12
 (AES256-SHA1)

keylength 32 (0xea8675d7abf13fd760a744088642fb917ceb6c9d267f5c54e595597846f06407)
```

Generating the Keytab on Windows Servers 2012 or Windows Server 2012 R2

To generate the keytab file using the Ktpass tool:

- Start a command prompt.
- ```
  Enter the following command to generate the keytab file for the NIOS appliance
  user account:
  ktpass -princ username@REALM -mapuser logon_name@REALM -pass password -out
  my.tab -ptype krb5_nt_principal -crypto encryption
  ```

  ```
  Example:
  ktpass -princ DNS/ns1.corpxyz.com@GSS.LOCAL -mapuser jsmith@GSS.LOCAL -pass
  37Le37 -out ns1.keytab -ptype krb5_nt_principal -crypto RC4-HMAC-NT
  ```

  where:
  -princ = Kerberos principal. Note that this parameter is case sensitive. Specifies the principal name for the host or service in this format: DNS/ns1.corpxyz.com@GSS.LOCAL
  - DNS = Service name in uppercase format.
  - ns1.corpxyz.com = Instance in FQDN (fully-qualified domain name) format; this is the same as the DNS name of the NIOS appliance.
  - GSS.LOCAL = The Kerberos realm in uppercase format. This must be the same as the AD domain name.

-mapuser = Maps the Kerberos principal name to the AD user account. If you omit the account name, mapping is deleted from the specified principal. You can use ksetup without any parameters or arguments to see the current mapped settings and the default realm. Example: ksetup /mapuser <Principal> <Account>. To create an AD user account, see Creating an AD User Account above.

- jsmith = The AD user name for the NIOS appliance.
- GSS.LOCAL = The Kerberos realm in uppercase. The realm (or domain name) must be the same as that specified in the **-princ** option.

-pass = The AD user account password. The Ktpass command changes the account password to the specified value, thus incrementing the version number of the user account and the resulting keytab file.

- 37Le37 = The password of the user account for the NIOS appliance.

-out = The name of the keytab file that is generated.

- ns1.ktb = The name of the keytab file
  ```

-ptype = Sets the principal type. This must be **krb5_nt_principal**.
-crypto = Specifies the encryption type. You can specify the following encryption types:

- **DES-CBC-CRC** = Specifies DES encryption for the account. This encryption type is used for compatibility.
- **DES-CBC-MD5** = Specifies DES encryption for the account. This encryption type adheres to the MIT implementation and is used for compatibility.
- **RC4-HMAC-NT** = Specifies 128-bit RC4-HMAC encryption for the account. This is enabled by default.
- **AES256-SHA1** = Specifies 256-bit AES encryption for the account.
- **AES128-SHA1** = Specifies 128-bit AES encryption for the account.
- **ALL** = Specifies all of the above encryption types. Do not use this option if DES support is disabled.

After you execute the command to generate the keytab file, the AD domain controller displays a series of messages similar to the following to confirm that it successfully generated the keytab file:

```
Targeting domain controller: qacert.test.local

Using legacy password setting method

Successfully mapped DNS/ns1.corpxyz.com to ns1.

Key created.

Output keytab to ns1.keytab: Keytab version: 0x502

keysize 80 DNS/ns1.corpxyz.com@GSS.LOCAL ptype 1 (KRB5_NT_PRINCIPAL) vno 3 etype 0x12
 (AES256-SHA1)

keylength 32 (0xea8675d7abf13fd760a744088642fb917ceb6c9d267f5c54e595597846f06407)
```

Generating the Keytab on Windows Servers 2016 or Windows Servers 2019

To generate the keytab file using the Ktpass tool:

1. Start a command prompt.
2. Enter the following command to generate the keytab file for the NIOS appliance user account:

   ktpass -princ *username@REALM* **-mapuser** *logon_name@REALM* **-pass** *password* **-out** *my.tab* **-ptype krb5_nt_principal -crypto** *encryption*
   Example:
   `ktpass -princ DNS/ns1.corpxyz.com@GSS.LOCAL -mapuser jsmith@GSS.LOCAL -pass 37Le37 -out ns1.keytab -ptype krb5_nt_principal -crypto RC4-HMAC-NT`
   where:
   -princ = Kerberos principal. Note that this parameter is case sensitive. Specifies the principal name for the host or service in this format: `DNS/ns1.corpxyz.com@GSS.LOCAL`

   - DNS = This is an example of the service name in uppercase format.
   - ns1.corpxyz.com = This is an example of the instance in FQDN (fully-qualified domain name) format; this is the same as the DNS name of the NIOS appliance.
   - GSS.LOCAL = This is an example of the Kerberos realm in uppercase format. This must be the same as the AD domain name.

   -mapuser = Maps the Kerberos principal name to the AD user account. If you omit the account name, mapping is deleted from the specified principal. You can use ksetup without any parameters or arguments to see the current settings and the default realm. Example: `ksetup /mapuser <Principal> <Account>`. To create an AD user account, see Creating an AD User Account above.

- jsmith = This is an example of the AD user name for the NIOS appliance.
- GSS.LOCAL = This is an example of the Kerberos realm in uppercase. The realm (or domain name) must be the same as that specified in the **-princ** option.

-pass = The AD user account password. The Ktpass command changes the account password to the specified value, thus incrementing the version number of the user account and the resulting keytab file.

- 37Le37 = This is an example of the password of the user account for the NIOS appliance.

-out = The name of the keytab file that is generated.

- ns1.ktb = This is an example of the name of the keytab file.

-ptype = Sets the principal type. This must be **krb5_nt_principal**.
-crypto = Specifies the encryption type. You can specify the following encryption types:

- **DES-CBC-CRC** = Specifies DES encryption for the account. This encryption type is used for compatibility purposes.
- **DES-CBC-MD5** = Specifies DES encryption for the account. This encryption type adheres to the MIT implementation and is used for compatibility purposes.
- **RC4-HMAC-NT** = Specifies 128-bit RC4-HMAC encryption for the account. This is enabled by default.
- **AES256-SHA1** = Specifies 256-bit AES encryption for the account.
- **AES128-SHA1** = Specifies 128-bit AES encryption for the account.
- **ALL** = Specifies all of the above encryption types. Do not use this option if DES support is disabled.

After you execute the command to generate the keytab file, the AD domain controller displays a series of messages similar to the following to confirm that it successfully generated the keytab file:

```
Targeting domain controller: qacert.test.local

Using legacy password setting method

Successfully mapped DNS/ns1.corpxyz.com to ns1.

Key created.

Output keytab to ns1.keytab:

Keytab version: 0x502

keysize 80 DNS/ns1.corpxyz.com@GSS.LOCAL ptype 1 (KRB5_NT_PRINCIPAL) vno 3 etype 0x12
 (AES256-SHA1)

keylength 32 (0xea8675d7abf13fd760a744088642fb917ceb6c9d267f5c54e595597846f06407)
```

Creating an External Zone for GSS-TSIG Updates

For each network view, specify the zone to be updated, the IP address of the primary DNS server for that zone, and the security method, GSS-TSIG. The zone must be in the same Active Directory domain as the member that is sending the updates.
You can add information for a forward and reverse zone. The DHCP server updates the A record in the forward zone and the PTR record in the reverse zone.
To enable the NIOS appliance to send dynamic updates to a DNS server using GSS-TSIG for authentication:

1. If there are multiple network views in the Grid, select a network view.
2. On the **Data Management** tab, select the **DHCP** tab, expand the Toolbar, and then click **Configure DDNS**.
3. In the *DNS Updates to External Zones* table of the *DDNS Properties* editor, click the Add icon and complete the following fields in the *Add External DDNS Zone* panel:

- **Zone Name:** Enter the name of the zone that receives the updates. You can specify both forward-mapping and reverse-mapping zones.
- **DNS Server Address:** Enter the IP address of the primary name server for that zone.
- **Security:** Choose **GSS-TSIG** from the drop-down list, complete the following, and then click **Add**:
  - **Active Directory Domain:** Choose the Active Directory domain associated with the keytab file.
  - **DNS Principal:** The name and domain of the DNS server receiving the DDNS updates. Note that this value is not the same as the Kerberos principal you specified when you generated the keytab file.
    Use the following format when you complete this field: **DNS/***dns_server_fqdn***@***ad_domain*
    dns_server_fqdn: This is the FQDN of the DNS server. You can use the "dig" command to perform a DNS lookup to obtain the FQDN of the DNS server as it appears on the SOA record.
    ad_domain: This is the Active Directory domain of the DNS server.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Verifying the Configuration

After you configure the AD domain controller and the Infoblox DHCP server, you can view the syslog of the Infoblox DHCP server to verify if it successfully established a security context with the AD domain controller. The DHCP server displays a series of messages similar to the following:

```
dhcpd: Enabled GSS-TSIG for zone corpxyz. using principal jdoe/anywhere@corpxyz.LOCAL
.

dhcpd: GSS-TSIG security thread has started.

dhcpd: GSS-TSIG security update starting at 1222389338.

dhcpd: Acquiring GSS-TSIG credential for jdoe/anywhere@corpxyz.LOCAL.

dhcpd: Acquired GSS-TSIG credential for jdoe/anywhere@corpxyz.LOCAL(good for 3568s).

dhcpd: Security context established with server 10.34.123.4 for principal[ jdoe/
anywhere@corpxyz.LOCAL|mailto:jdoe/anywhere@corpxyz.LOCAL] (good for 568s).

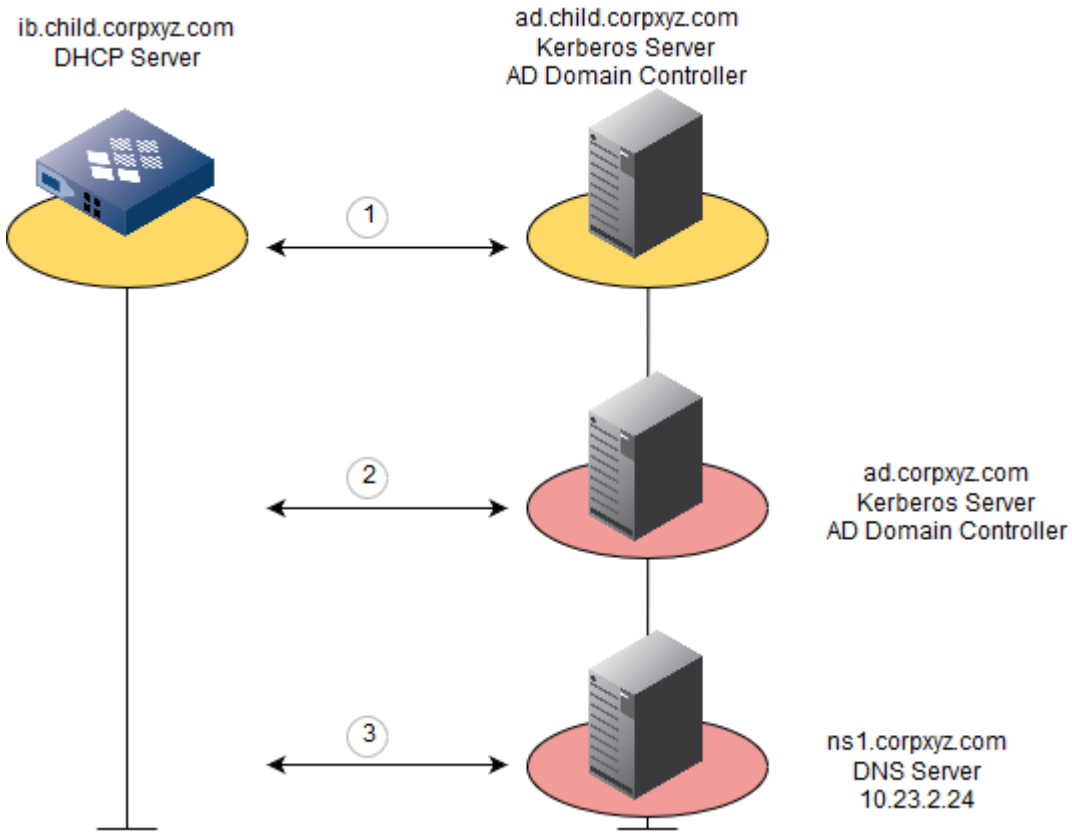
dhcpd: GSS-TSIG security update complete at 1222389338. Next update in 360s.
```

In addition, you can log in to the Infoblox CLI and use the show dhcp_gss_tsig CLI command to troubleshoot your configuration. For information about this command, refer to the *Infoblox CLI Guide*.

Sending Secure DDNS Updates to a DNS Server in Another Domain

Domain and forest trust relationships provide clients authenticated access to resources in other domains. Some trusts are automatically created, such as the two-way, direct trust between parent and child domains in a forest. Other trusts must be created manually. Refer to the Microsoft Active Directory documentation for information on establishing trusts between domains.
Once a direct trust exists between two AD domains, a KDC from one domain can grant a referral to the KDC of the other domain. The Infoblox DHCP server can then use the referral to request access to services in the other domain.
In the following figure the Infoblox DHCP server in the child.corpxyz.com domain needs to send GSS-TSIG authenticated DDNS updates to the DNS server in its parent domain, corpxyz.com domain. There is an automatic two-way trust between the domains because corpxyz.com domain is the parent of child.corpxyz.com domain.

Sending Secure DDNS Updates to a DNS Server in Another Domain



After you configure the Infoblox DHCP server and AD domain controller, the following occurs:

1. Kerberos – In Same Domain
   The Infoblox DHCP server uses the TGT (ticket-granting ticket) from the AD/Kerberos server, ad.child.corpxyz.com, to request a service ticket for DNS/ns1.corpxyz.com@corpxyz.COM. The Kerberos server replies with a referral ticket for the Kerberos server in the corpxyz.com domain, ad.corpxyz.com.
2. Kerberos — In the Other Domain
   The Infoblox DHCP server uses the referral ticket and requests a service ticket from ad.corpxyz.com for DNS/ns1.corpxyz.com@corpxyz.COM. The Kerberos server replies with a service ticket for DNS/ns1.corpxyz.com@corpxyz.COM.
3. TKEY Negotiations (GSS Handshake)
   The Infoblox DHCP server sends the DNS server ns1.corpxyz.com a TKEY (transaction key) request, which includes the service ticket. The DNS server replies with a TKEY response that includes a TSIG (transaction signature). The Infoblox appliance and the DNS server have established a security context, enabling the DHCP server to send DDNS updates to the DNS server.

Configuring DHCP to Send GSS-TSIG Updates to Another Domain

Before the DHCP server can send secure DDNS updates to a DNS server in a different domain, you must ensure that a direct trust relationship exists between the domain of the DHCP server and that of the DNS server. (For information, refer to the Active Directory documentation.)
Following are the tasks to configure the AD domain controller and the Infoblox DHCP server for secure updates to another domain. All the configuration is done on the AD domain controller for the domain of the DHCP server and on the Infoblox DHCP server.:

1. Complete the following tasks on the AD domain controller for the domain of the DHCP server:
   a. Add a user account for the Infoblox DHCP server. In the configuration example, the user account is ibdhcp. For information, see Creating an AD User Account above.

b. Generate the keytab file for the Infoblox DHCP server and export it from the AD domain controller to a local directory on your management system. For the DHCP server in the Sending Secure DDNS Updates to a DNS Server in Another Domain, the principal is ibdhcp/ib.child.corpxyz.com@CHILD.corpxyz.COM. For information, see Generating and Exporting the Keytab File above.

2. Complete the following tasks on the Infoblox DHCP server:
   a. Import the keytab file from your management system to the appliance and enable GSS-TSIG dynamic updates at the Grid or member level. For information, see *Enabling GSS-TSIG Authentication for DHCP.*
   b. Configure the external forward-mapping zone for the DDNS updates. Note that the DNS principal uses the domain of the DNS server, regardless of the domain of the DHCP server. For the DNS server in the figure Sending Secure DDNS Updates to a DNS Server in Another Domain above, the DNS principal is DNS/ns1.corpxyz.com@corpxyz.COM. For information, see *Managing GSS-TSIG keys.*

Configuration Example

Following are the steps to configure the example shown in the figure Sending Secure DDNS Updates to a DNS Server in Another Domain above:

On the Active Directory domain controller:

1. Create a user account for the Infoblox DHCP server. The user account is **ibdhcp**.
2.
```
Generate the keytab file and export it to your management system. If the domain
controller is running Windows Server 2003:
ktpass -princ ibdhcp/ib.child.corpxyz.com@CHILD.corpxyz.COM -mapuser ibdhcp@CHI
LD.corpxyz.COM -pass infoblox -out ibdhcp.ktb -ptype krb5_nt_principal -crypto
des-cbc-md5 +desonly
```

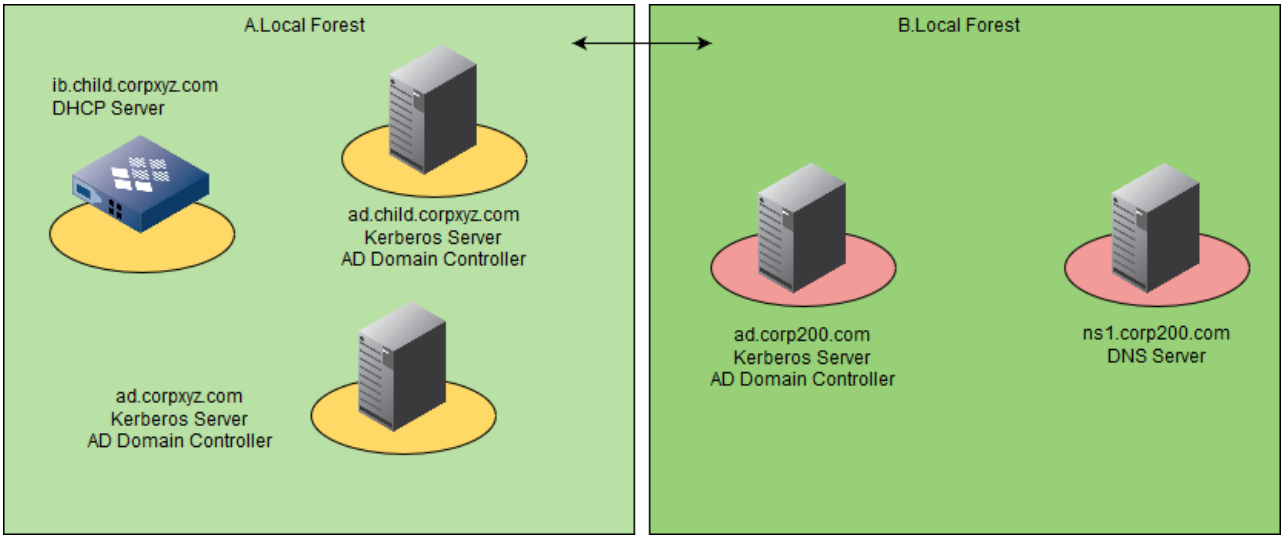
On the Infoblox DHCP server:

1. Enable GSS-TSIG at the member level.
2. From the **DHCP** tab, click the **Members** tab -> *member* checkbox -> Edit icon.
3. On the **DDNS** -> **Basic** tab of the editor, complete the following:
   - **Override**: Select this checkbox.
   - **DDNS Updates**: Select the **Enable DDNS Updates** checkbox.
   - **GSS-TSIG:** Select **Override**, and then complete the following:
     - **Enable GSS-TSIG Updates**: Select this checkbox.
     - **Domain Controller (KDC)**: Enter **ad.child.corpxyz.com**. This is the KDC in the domain of the DHCP server.
     - **Manage Key tab Files**: Click **Manage Key tab Files**. In the *Manage GSS-TSIG Keys* dialog box, click the Add icon. Click **Select**, navigate to the keytab file, select the keytab file that you just uploaded, **ibdhcp/ib.child.corpxyz.com@CHILD.corpxyz.COM**, and then click **Upload**. Click **Close**.
4. Save the configuration and click **Restart** if it appears at the top of the screen.
5. Configure the external forward mapping zone, corpxyz.com:
   a. On the **DHCP** tab, expand the Toolbar, and then click **Configure DDNS**.
   b. In the *DNS Updates to External Zones* table of the *DDNS Properties* editor, click the Add icon and complete the following fields in the *Add External DDNS Zone* panel:
      - **Zone Name**: Enter **corpxyz.com**.
      - **DNS Server Address**: Enter the IP address of the primary DNS server to which the Infoblox DHCP server sends DDNS updates. In the example, the DNS server is ns.corpxyz.com. Therefore, enter its IP address, which is **10.23.2.24**.
      - **Security:** Choose **GSS-TSIG** from the drop-down list, complete the following, and then click **Add**:
        - **Active Directory Domain:** Choose **child.corpxyz.com**.
        - **DNS Principal:** Enter **DNS/ns1.corpxyz.com@corpxyz.COM**.
6. Save the configuration and click **Restart** if it appears at the top of the screen.

Sending GSS-TSIG Updates to a DNS Server in Another Forest

The Infoblox DHCP server can also send secure DDNS updates to a DNS server that belongs to a domain in another forest, as long as a forest trust exists. Refer to the Microsoft Active Directory documentation for information on establishing forest trusts.
Similar to the authentication process between domains, the authentication process between forests also uses referrals. The appliance follows the referral chain until it reaches the domain controller of the domain in which the service is located. Note that forest trusts are not transitive. For example, if the DHCP server is in forest A and the DNS server is in forest C, a direct trust must exist between forest A and forest C for the DDNS updates to succeed. Having a trust between forest A and B, and between forest B and C is not sufficient.
In the below figure, a trust exists between the A.Local forest and the B.Local forest. The Infoblox DHCP server in the A.Local forest needs to dynamically update the DNS server in the B.Local forest.

Sending Secure DDNS Updates to a DNS Server in Another Forest



The following authentication process occurs:

1. Kerberos – In Same Domain
   The Infoblox appliance uses the TGT (ticket-granting ticket) from the AD/Kerberos server, ad.child.corpxyz.com, to request a service ticket for DNS/ns1.corp200.com@CORP200.COM. The Kerberos server does not find the principal name in its domain database and after consulting the global catalog, it replies with a referral ticket for its parent domain.
2. Kerberos — Referral Chain
   The appliance contacts a domain controller in corpxyz.com and requests a referral to a domain controller in the corp200.com domain in B.Local Forest.
   When it receives the referral, the DHCP server contacts the domain controller and requests a service ticket for the DNS server, ns1.corp200.com. The domain controller replies with a service ticket for[DNS/ ns1.corp200.com@CORP200.COM.|mailto:DNS/ns1.corp200.com@CORP200.COM]
3. TKEY Negotiations (GSS Handshake)
   The Infoblox appliance sends the DNS server ns1.corp200.com a TKEY (transaction key) request, which includes the service ticket. The DNS server replies with a TKEY response that includes a TSIG (transaction signature). The Infoblox appliance and the DNS server have established a security context.

Configuring DHCP to Send GSS-TSIG Updates to a Different Forest

Configuring the Infoblox DHCP server for dynamic updates to a DNS server in another forest is similar to the configuration used to send dynamic updates to another domain in the same forest. For information, see Configuring DHCP to Send GSS-TSIG Updates to Another Domain section.

Configuring GSS-TSIG keys

You can upload keytab files that contain a single GSS-TSIG key or multiple GSS-TSIG keys on a single NIOS appliance. For each member in the Grid, you can upload up to 256 GSS-TSIG keys in a single keytab file. Trust relationships between AD domains and AD forests are not required. You can upload GSS-TSIG keys through Grid Manager or the Infoblox API.
Note that only superusers can manage all GSS-TSIG keys globally on a given member through Grid Manager or the Infoblox API. Using this feature, superusers can determine the keys that belong to a particular member. You can assign multiple GSS-TSIG keys to a member and all these keys are saved in the Grid. The uploaded keys will be available in the member DNS, Grid DNS, member DHCP or Grid DHCP properties. NIOS supports the following GSS-TSIG encryption types:

- des-cbc-crc
- des-cbc-md5
- arcfour-hmac-md5
- aes128-cts-hmac-sha1-96
- aes256-cts-hmac-sha1-96

NIOS displays a warning message in Grid Manager and in the syslog if you upload a key that does not belong to the GSS-TSIG encryption types. For more information, see Logging Messages below.

Limitations when Using Multiple GSS-TSIG keys

- You can assign SPNs belonging to different domains to a DNS member, but you cannot assign SPNs belonging to different domains to a DHCP member, although two DHCP members can update the same DNS member.
- You must ensure that the domains assigned to a DNS member are unique.
- The GSS-TSIG domain for a remote forward or remote reverse zone is single-valued. For example, if DHCP clients ABC and XYZ from Grid 1 want to send DDNS updates to Grid 2, either client ABC or XYZ will succeed.

Scheduled Upgrade

A scheduled upgrade with one or more keys in the keytab files that you have uploaded will operate the same as prior to upgrade. NIOS will parse and extract keys from the uploaded keytab file. NIOS automatically assigns these keys to the DNS member, DHCP member, Grid DHCP or Grid DNS to which the keytab file was uploaded before the upgrade. You can assign these keys to Grid members after the upgrade is complete.
NIOS does not display an error message if the keys do not have an SPN with the DNS prefix, but it will record a warning message in the syslog.

Admin Permissions for Configuring GSS-TSIG keys

You can assign a key to a Grid member only if you have read permission for the kerberos key and read/write permission for the member. You can upload keys only if you have read/write permissions for kerberos keys. To remove a key that is assigned to a member, you must have read/write permission for the respective member.
Note that in the **Administration** -> **Administrators** -> **Permissions** tab, NIOS displays **All Kerberos Keys** and **Kerberos Key** in the **Resource** and **Resource Type** columns respectively for **DHCP Admin** and **DNS Admin** roles with default read/write permissions.

Enabling GSS-TSIG Authentication for DHCP

You can enable GSS-TSIG authentication at the Grid or member level and associate it with one or more keys of the same SPN or realm. When you enable GSS-TSIG authentication, make sure that you upload the keytab file from the Kerberos account for the Infoblox DHCP server. You can import keytab files with multiple keys to the Grid or to individual members. You can assign the uploaded keys to member DHCP or Grid DHCP. The appliance displays a warning message if you assign a GSS-TSIG key with service class "DNS" in its SPN to a DHCP member.
The appliance displays an error message in the following cases:

- if you assign keys of different realms to a DHCP member or Grid DHCP.

- when you try to enable GSS-TSIG without a valid key.

The AD domain controller stores the keytab file in the directory in which you generated the keytab file. You can copy this file to a management system that connects to the NIOS appliance or launch the NIOS Grid Manager on the AD domain controller and import the keytab file to the NIOS appliance.
To enable GSS-TSIG authentication for DHCP and import keytab files:

1. **Grid:** From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **Grid DHCP Properties**. **Member**: From the **Data Management** tab, select the **DHCP** tab and click the **Members** tab -> *member* checkbox -> Edit icon. To override an inherited property, click **Override** next to it and complete the appropriate fields. **Standalone DHCP:** From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **System DHCP Properties**.
2. In the **IPv4 DDNS** -> **Basic** tab or the **IPv6 DDNS** -> **Basic** tab of the editor, complete the following:
    - **DDNS Updates:** Select **Enable DDNS Updates** to enable the DHCP servers in the Grid to send DDNS updates.
    - **DDNS Domain Name**: Specify the domain name of the network that the appliance uses to update DNS. For IPv4 clients, you can specify this at the network, network template, range, and range template levels. For IPv6 clients, you can specify this at the Grid, member, network, shared network, and network template levels.
    - **DDNS Update TTL**: You can set the TTL used for A record and PTR records updated by the DHCP server. The default is shown as zero. If you do not enter a value here, the appliance by default sets the TTL to half of the DHCP lease time with a maximum of 3600 seconds. For example, a lease time of 1800 seconds results in a TTL of 900 seconds, and a lease time of 86400 seconds results in a TTL of 3600 seconds.
    - **DDNS Update Method**: Select the method used by the DHCP server to send DDNS updates. You can select either **Interim** or **Standard** from the drop-down list. The default is **Interim**. When you select **Interim**, TXT record will be created for DDNS updates and when you select **Standard**, DHCID record will be created for DDNS updates. But in the **IPv4 DDNS** -> **Advanced** tab or the **IPv6 DDNS** -> **Advanced** tab, if you have selected **No TXT Record** mode for the DHCP server to use when handling DNS updates, then TXT record or DHCID record is not created for DDNS updates.
      If you change the DDNS update method from **Interim** to **Standard** or vice versa, then the DHCP server changes the DHCID type used from TXT record to DHCID record or vice versa as the leases are renewed.
      This is supported for clients that acquire both IPv4 and IPv6 leases. Infoblox recommends you to configure different DDNS update method for IPV4 leases and IPv6 leases, **Interim** for IPv4 lease and **Standard** for IPv6 lease.
    - **GSS-TSIG**: Complete the following:
        - **Enable GSS-TSIG Updates:** Select this to enable the DHCP server to send GSS-TSIG authenticated DDNS updates. The DHCP server uses the KDC server configured in the member properties. Therefore. the **Enable GSS-TSIG Updates** field must be overridden in the *Member DHCP Properties* dialog box to use the KDC configured in the *Member DHCP Properties* dialog box.
        - **Manage Keytab Files**: To upload a keytab file, click **Manage GSS-TSIG keys**. In the *Manage GSS-TSIG Keys* dialog box, click the Add icon. In the *Upload* dialog box, click **Select**, navigate to the keytab file, select it, and then click **Upload**. You can also delete individual keys. For more information about managing GSS-TSIG keys, see Managing GSS-TSIG keys below.
        - **Domain Controller:** Enter the resolvable host name or IP address of the AD domain controller that hosts the KDC for the domain.
        - **Principal**: The principal member of the key. For GSS-TSIG based DDNS updates, the SPN of the key used to carry out the update does not require the server class 'DHCP.' You can either specify an FQDN or an IP address for the <host> of an SPN.
        - **GSS-TSIG Key:** Select the name of the GSS-TSIG key from the drop-down list that you want the Grid to use. This is only available if you have uploaded a keytab file. Click the arrow beside the Add icon to either assign keys or upload and assign keys. You can either select **Assign Keys** or **Upload & Assign Keys** from the drop-down list.
            - **Assign Keys**: Select **Assign Keys** to select a GSS-TSIG key from the *GSS-TSIG Key Selector*. Click **Principal**, which is displayed as a hyperlink, to select it. For more information about the **GSS_TSIG Key Selector**, see Selecting Keys in the GSS-TSIG Key Selector below.

        - **Upload & Assign Keys**: Select **Upload & Assign Keys** to upload and assign keys. In the *Upload* dialog box, select the file and navigate to the file you want to upload. Click **Upload**. The appliance assigns the keys contained in the selected keytab file.
      - The following are displayed in the table:
        - **Version**: The version of the key.
        - **Encryption type**: The encryption type of the key.
        - **Last update**: The timestamp when the key was uploaded.
    - **Zones this member can update securely**: Click **Display** to list the external zones to which the Grid member can send secured DDNS updates.
    - **Lease Renewal Update**: Select **Update DNS on DHCP Lease Renewal** to enable the DHCP server to update DNS when a DHCP lease is renewed.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Deleting GSS-TSIG keys associated with DHCP Objects

You can delete individual keys if it is not in use by the Grid or any member. To delete a key that is assigned to a member, you must have Read/Write permission for the member. To delete individual keys:

1. **Grid:** From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **Grid DHCP Properties**.
   Member: From the **Data Management** tab, select the **DHCP** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   Standalone DHCP: From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **System DHCP Properties**.
2. In the **IPv4 DDNS** tab or the **IPv6 DDNS** -> **Basic** tab of the editor, select keys from the list under **GSS-TSIG Keys** and click the Delete icon to delete keys.

Enabling GSS-TSIG Authentication for DNS

For GSS-TSIG based DDNS updates, the SPN of the key used to carry out the update must have 'DNS' in its service class. You can upload a keytab file to the Grid with multiple keys in which each key has an SPN in this format: DNS/<host>@<realm>. You can associate a DNS member or a Grid DNS with one or more keys of the same SPN or realm or of different SPN or realms. You can assign the uploaded keys to member DNS or Grid DNS, but NIOS displays an error when you try to enable GSS-TSIG without a valid key if the assigned key does not have the service class 'DNS' in its SPN.
To enable GSS-TSIG authentication for DNS and import keytab files:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon. To override an inherited property, click **Override** next to it and complete the appropriate fields.
   Standalone DNS: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **System DNS Properties**.
2. In the **GSS-TSIG** -> **Basic** tab of the editor, complete the following:
   - **GSS-TSIG:** Select **Enable GSS-TSIG authentication of clients** to accept GSS-TSIG signed DDNS updates from clients that belong to different AD domains in which each domain has an unique GSS-TSIG key.
   - **Manage Keytab Files**: To upload a keytab file, click **Manage GSS-TSIG keys**. In the *Manage GSS-TSIG Keys* dialog box, click the Add icon. In the *Upload* dialog box, click **Select**, navigate to the keytab file, select it, and then click **Upload**. You can also delete individual keys. For more information, see Managing GSS-TSIG keys below.
   - **GSS-TSIG Keys**: Click the arrow beside the Add icon to either assign keys or upload and assign keys. You can either select **Assign Keys** or **Upload & Assign Keys** from the drop-down list.
     - **Assign Keys**: Select **Assign Keys** to select a GSS-TSIG key from the *GSS-TSIG Key Selector*. Click **Principal**, which is displayed as a hyperlink, to select it. For more information about the **GSS_TSIG Key Selector**, see Selecting Keys in the GSS-TSIG Key Selector below.
     - **Upload & Assign Keys**: Select **Upload & Assign Keys** to upload and assign keys. In the *Upload* dialog box, select the file and navigate to the file you want to upload. Click **Upload**. The appliance assigns keys in the uploaded file.
       The following are displayed:
     - **Principal**: The principal member of the key. For GSS-TSIG based DDNS updates, the SPN of the key used to carry out the update must have DNS in its service class. It is of the following form:

```
DNS/<host>@<realm>
```

You can either specify an FQDN or an IP address for the <host> of an SPN.

- **Domain**: The domain name assigned to the DNS member.
- **Version**: The version of the key.
- **Encryption type**: The encryption type of the key.
- **Last update**: The timestamp when the key was uploaded.

3. Save the configuration.

NIOS sorts the data in the table based on the last updated timestamp, by default. Note that sometimes GSS-TSIG updates might stop working after you restart the DNS service because the appliance discards the GSS-TSIG keys, when you restart the DNS service. If this happens, wait several minutes until the Microsoft server performs another handshake using the new key.

Deleting GSS-TSIG keys associated with the DNS Objects

You can delete individual keys if it is not in use by the Grid or any member. To delete a key that is assigned to a member, you must have Read/Write permission for the member. To delete individual keys:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties.**
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
   Standalone DNS: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **System DNS Properties**.
2. In the **GSS-TSIG** -> **Basic** tab of the editor, select keys from the list under **GSS-TSIG Keys**.
3. Click the Delete icon to delete.

Logging Messages

The appliance saves the audit log entries for insert and delete operations. If you upload keys with encryption types other than the ones that NIOS supports, the appliance displays a warning message in Grid Manager and in the syslog and also it displays the encryption type as *other* in Grid Manager and in the syslog. For more information about the syslog, see *Using a Syslog Server*.

The appliance generates an audit log when you upload a key, assign the key to a member, remove the key associated with a member or delete a key. The audit log entries are based on each key that you have uploaded. For example, NIOS saves the following in the audit log when you upload a key:

```
2014-02-14 18:17:30.531Z \[admin\]: imported DNS Kerberos key for

principal='DNS/infoblox.localdomain@abc.com', version=5, enctype=des-cbc-crc
```

For more information about audit logs, see *Using the Audit Log*. You can search Kerberos keys using the realm (domain), principal name or an encryption type.

The appliance generates a comment in the option section of the DNS configuration file for each Kerberos principal that is associated with the Grid member. These comments are for information only and it indicates the principals, their versions and encryption types that are used by the appliance.

Managing GSS-TSIG keys

You can upload a keytab file that contains one or multiple GSS-TSIG keys and delete multiple keys through the *Manage GSS-TSIG Keys* wizard. To manage multiple GSS-TSIG keys, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, expand the Toolbar and click **Manage GSS-TSIG Keys.**
2. In the *Manage GSS-TSIG Keys* wizard, the following are displayed:

- **Principal**: The principal name that is mapped to the keytab file.
- **Domain**: The name of the domain that is mapped to the keytab file.
- **Version**: The version of the keytab file.
- **In use:** Indicates whether the keytab file is in use or not.
- **Members**: The members associated with the keytab file. Click the hyperlink and the *Members* dialog box is displayed. It displays the list of members that are associated with the keytab file.
- **Encryption type**: The encryption type of the key.
- **Last update**: The timestamp when the key was last uploaded.

3. Click the Upload Keytab File icon to upload a new keytab file. In the *Upload* dialog box, click **Select** and navigate to the keytab file. Click **Upload** to upload the file.

To delete a GSS-TSIG key, select the appropriate key and click the Delete icon.

Selecting Keys in the GSS-TSIG Key Selector

NIOS displays the keys that you have uploaded using the keytab files. You can choose a filter and an operator to view specific keys that you have uploaded. The *GSS-TSIG Key Selector* wizard is displayed only when you select **Assign Keys** in the *Properties* editor. For more information about how to assign keys to DNS and DHCP objects, see Enabling GSS-TSIG Authentication for DNS and Enabling GSS-TSIG Authentication for DHCP above respectively.
To select a key from the *GSS-TSIG Key Selector*, complete the following:

1. Click **Show Filter** to filter the values:
   - Select a value from the drop-down list to filter your values: **Domain**, **Encryption type**, **In use**, **Last update**, **Principal**, and **Version**.
   - Select one of these operators from the drop-down list: **equals**, **does not equal**, **begins with**, and **does not begin with**.
   - Enter the value that you want to search in the text box.
     Click **Hide Filter** to hide the filter. Alternatively, you can enter a value in the text box for **Find** and click **Go** to search specific keys from the keytab files.
2. The following details are displayed in the table:
   - **Principal**: The principal name that is mapped to the keytab file. Click **Principal** to assign the key to the DNS or DHCP object.
   - **Domain**: The name of the domain that is mapped to the keytab file.
   - **Version**: The version of the keytab file.
   - **In use:** Indicates whether the keytab file is in use or not.
   - **Members**: The members associated with the keytab file.
   - **Encryption type**: The encryption type of the key.
   - **Last update**: The timestamp when the key was last uploaded.

Accepting DDNS Updates from DHCP Clients

A NIOS appliance serving DNS can support Active Directory and accept both unauthenticated and GSS-TSIG authenticated updates from DHCP clients, DHCP servers, and AD domain controllers. The appliance supports servers running Windows 2000 Server, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, or Windows Server 2016 with the Active Directory service installed.
When adding a NIOS appliance that serves DNS to an AD environment, you must configure the AD/Kerberos server and NIOS appliance as follows—based on whether or not you want the DNS server to support DDNS updates using GSS-TSIG authentication:

- AD/Kerberos Server

1. Enable zone transfers to the NIOS appliance.
2. (For GSS-TSIG) Create a user account for the NIOS appliance that it can use for authentication.
3. (For GSS-TSIG) Generate the keytab file of the DNS server and save it to your management system.

- NIOS Appliance

4. (GSS-TSIG) Enable GSS-TSIG support.

5. (GSS-TSIG) Import the keytab file of the DNS server from your management system to the NIOS appliance.

6. (GSS-TSIG) Enable GSS-TSIG authentication.

7. Add a forward-mapping zone and give it a name matching the AD DNS zone whose resource records you want to import.

8. Specify the domain controller from which the appliance can receive DDNS updates. An AD domain controller replicates its data among other domain controllers within its AD domain and among domain controllers in other domains.

9. Import zone data from the specified domain controller.

10. Enable the acceptance of DDNS updates from the AD domain controller and from the DHCP clients and servers whose addresses the DHCP server assigns. You can set this at the Grid, member, and zone levels.

11. (For GSS-TSIG) Enable acceptance of GSS-TSIG DDNS updates from the AD domain controller and from the addresses that the DHCP server assigns. You can set this at the Grid, member, and zone levels.

As you can see from the above task list, adding a NIOS appliance that serves DNS to an AD environment without GSS-TSIG support involves four simple steps. To include GSS-TSIG support, there are several additional steps.

Supporting Active Directory and Unauthenticated DDNS Updates

Before configuring the NIOS appliance, configure the AD domain controller to permit zone transfers to the IP address of the appliance. Then on the appliance, you can do the following to configure a forward-mapping zone to support AD (Active Directory) and receive unauthenticated DDNS updates from DHCP clients, DHCP servers, and AD domain controllers.

- Create a forward-mapping zone, as described in *Creating an Authoritative Forward-Mapping Zone*. Give it a name that matches the AD DNS zone whose resource records you want to import.
- Specify the domain controllers from which the appliance can receive updates, as described in Configuring AD Support below.
- Import the zone date from the domain controller. For information, see *Importing Data into Zones*.
- Enable the appliance to accept DDNS updates from the DHCP clients and servers whose addresses the DHCP server assigns. You can set this at the Grid, member, and zone levels. For information, see *Enabling DNS Servers to Accept DDNS Updates*.

Configuring AD Support

You can configure a forward-mapping zone to support AD from the *Active Directory* wizard or from the **Active Directory** tab of the *Authoritative Zone* editor. This section describes both methods.
To configure AD support using the *Active Directory* wizard:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Configure Active Directory**. Note that from the **Zones** tab, you must select a zone before you click **Configure Active Directory**.
2. In the *Active Directory* wizard, complete the following, and then click **Next**:
    - **Select Zone**: Click this and select a zone. The name of the zone must match the name in the AD domain controller so the zone transfer from the AD domain controller to the NIOS appliance can succeed.
    - **Allow unsigned updates from Domain Controllers**: Select this option.
      If you have configured DNS resolvers in the Grid, the appliance sends DNS queries for the names and addresses of the AD domain's domain controllers. Since the name of the zone that you selected is the same as the AD domain name on the domain controller, the appliance can then send a DNS query for the SRV records attached to the domain name. It also sends a DNS query for the A record of each domain controller to determine its IP address. The query results are listed in the next panel.
3. You can edit the list of domain controllers, if necessary. Click **Next** to proceed to the next step.
    - To add a domain controller, click the Add icon and specify the IP address.
    - To delete a domain controller from the list, select it and click the Delete icon.
4. Complete the following:
    - **Do you want to create underscore zones to hold the records added by the Domain Controllers?**

This option allows the appliance to create the following subzones that the DNS server must have to answer AD-related DNS queries:
_msdcs.*zone*
_sites.*zone*
_tcp.*zone*
_udp.*zone*
domaindnszones.*zone*
forestdnszones.*zone*
Note that these zones are automatically generated. You cannot edit these zones or import data into them. They cannot be modified, thus providing protection against forged updates.

5. Save the configuration and click **Restart** if it appears at the top of the screen.

To configure AD support using the *Authoritative Zone* editor:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox -> Edit icon.
2. In the *Authoritative Zone* editor, select the **Active Directory** tab and do the following:
   - **Allow unsigned updates from these Domain Controllers:** Select this checkbox and specify the AD domain controllers from which the appliance can receive DDNS updates.
   - **Automatically create underscore zones:** Select this checkbox to automatically create the subzones.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

You can then import zone data, as described in *Importing Data into Zones*.

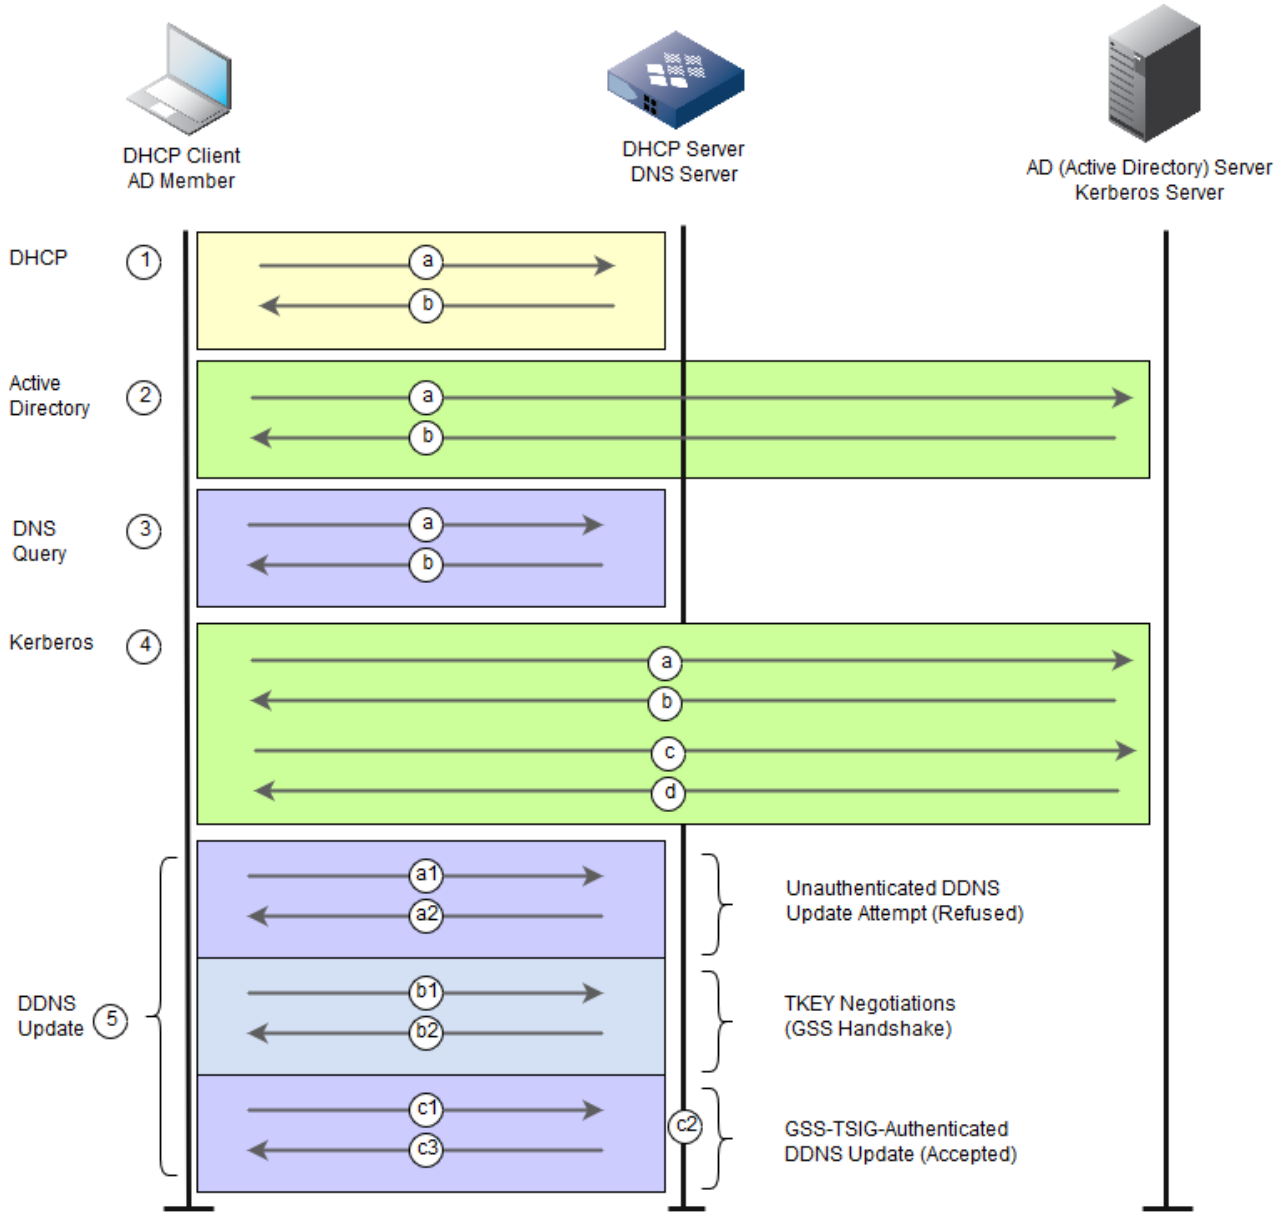
Accepting GSS-TSIG-Authenticated Updates

A NIOS appliance can support Active Directory and process secure GSS-TSIG-authenticated DDNS updates from DHCP clients, DHCP servers, and AD domain controllers. The appliance supports servers running Windows 2000 Server, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, or Windows Server 2016 with the Active Directory service installed. The process in which a DHCP client dynamically updates its resource records on a DNS server using GSS-TSIG authentication is shown in *Figure 21.10* below. The illustration also shows the relationship of the clients, the DHCP server, the DNS server, and the Kerberos server (running on the AD domain controller).

Note

For explanations of the alphanumerically notated steps in *Figure 21.10 below*, see the section following the illustration.

Figure 21.10 Authenticating DDNS Updates with GSS-TSIG



1. DHCP – IP Address and Network Parameters Assignment
    a. The DHCP client requests an IP address.
    b. The DHCP server assigns an IP address, subnet mask, gateway address, and a DNS server address.
2. Active Directory – Computer and User Logins
    a. The computer sends a DNS request to locate the AD domain controller, and then logs in to the domain controller.
    Note that the computer accounts have passwords that the AD domain controller and computer maintain automatically. There are two passwords for each computer: a computer account password and a private key password. By default, both passwords are automatically changed every 30 days.
    b. The user manually logs in to a domain.
3. DNS – Query for the Kerberos Server
    a. The computer (or *client*) automatically sends a query for *kerberos._udp.dc_msdcs.*dom_name_ to the DNS server whose IP address it received through DHCP.
    b. The NIOS appliance replies with the name of the Kerberos server.
4. Kerberos – Login, and TGT and Service Ticket Assignments
    a. The client automatically logs in to the Kerberos server.
    b. The Kerberos server sends the client a TGT (ticket-granting ticket).

c. Using the TGT, the AD member requests a service ticket for the DNS server.
d. The Kerberos server replies with a service ticket for that server.

5. DDNS – Dynamic Update of the Client's Resource Records
   a. Unauthenticated DDNS Update Attempt (Refused)
      i. The client sends an unauthenticated DDNS update.
      ii. The DNS server refuses the update.
   b. TKEY negotiations (GSS Handshake):
      i. The client sends the DNS server a TKEY (transaction key) request. A Transaction Key record estab- lishes shared secret keys for use with the TSIG resource record. For more information, see *RFC 2930,Secret Key Establishment for DNS (TKEYRR)*.
      The request includes the service ticket. The service ticket includes the appliance's principal and proposed TSIG (transaction signature) key, along with other items such as a ticket lifetime and a timestamp.
      ii. The DNS server responds with a DNS server-signed TSIG, which is a "meta-record" that is never cached and never appears in zone data. A TSIG record is a signature of the update using an HMAC-MD5 hash that provides transaction-level authentication. For more information, see *RFC 2845,Secret Key Transaction Authentication for DNS (TSIG)*.
      The two participants have established a security context.
   c. GSS-TSIG-Authenticated DDNS Update (Accepted).
      i. The client sends an authenticated DDNS update, which includes the following resource records:
         - A – Address record
           or
           PTR – Pointer record
         - TKEY – Transaction Key record
         - TSIG – TSIG record
      ii. The DNS server authenticates the DDNS update and processes it.
      iii. The DNS server sends a GSS-TSIG-authenticated response to the AD member, confirming the update.

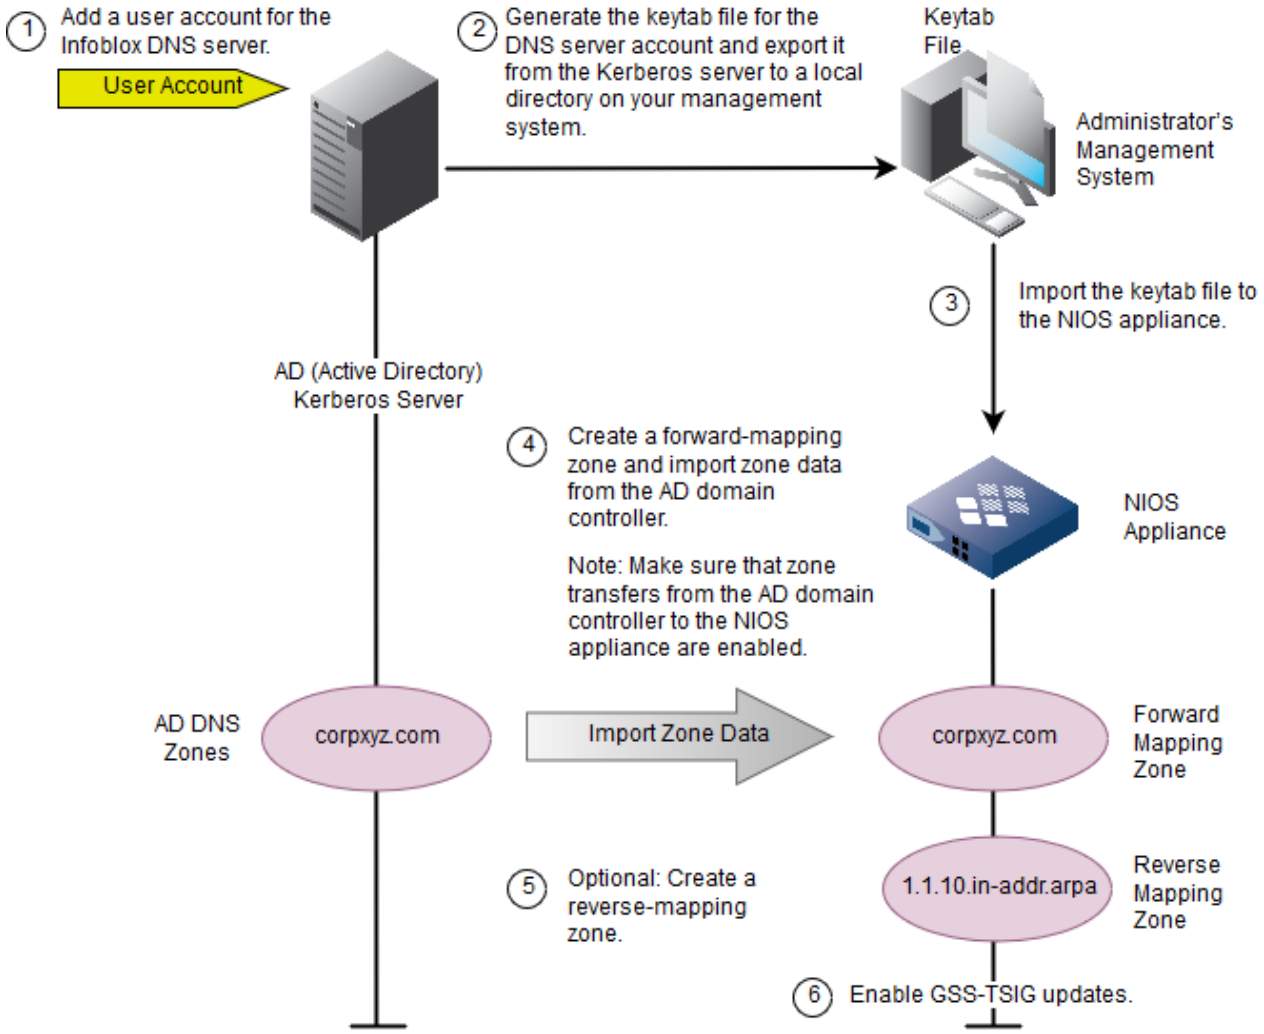
Note

For GSS-TSIG authentication to work properly, the system clock times of the Infoblox DHCP server, AD domain controller and DNS server must be synchronized. One approach is to use NTP and synchronize all three devices with the same NTP servers.

Configuring DNS to Receive GSS-TSIG Updates

You can configure an appliance to support Active Directory and accept secure DDNS updates from clients using GSS-TSIG. The initial configuration tasks are shown in *Figure 21.11*. The appliance supports servers running Windows 2000 Server, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, or Windows Server 2016 with the Active Directory service installed.

Figure 21.11 Adding a NIOS Appliance to an AD Environment with GSS-TSIG Support



On an already functioning AD domain controller:

1. Enable zone transfers to the NIOS appliance.
2. Add a user account for the NIOS appliance serving DNS. A corresponding account on the Kerberos server is automatically created. For information, see Creating an AD User Account below.
3. Export the keytab file for the NIOS appliance account from the Kerberos server to a local directory on your management system. For information, see Generating and Exporting the Keytab File below.

On an Infoblox appliance:

1. Import the keytab file from your management system to the Infoblox appliance and enable GSS-TSIG authentication on the appliance. For information, see Importing the Keytab File and Enabling GSS-TSIG Authentication below.
2. Configure a forward-mapping zone with the same name as the AD zone. For information, see *Creating an Authoritative Forward-Mapping Zone*.
3. (Optional) Create a reverse-mapping zone for the network address space that corresponds to the domain name space in the forward-mapping zone. For information, see *Creating an Authoritative Reverse-Mapping Zone.*
4. Import the zone data from the AD domain controller. For information, see *Importing Zone Data*.
5. Enable the acceptance of GSS-TSIG-signed updates from the AD controller and from the DHCP clients and servers whose addresses the DHCP server assigns. For information, see Accepting GSS-TSIG Updates below.

Creating an AD User Account

Connect to the AD domain controller and create a user account for the NIOS appliance.

> ⚠ Note
> The name you enter in the User logon name is the name that you later use when exporting the keytab file. This is also the principal name. The text in the First name, Initials, Last name, and Full name fields is irrelevant to this task.

The AD domain controller automatically creates a Kerberos account for this user with an accompanying keytab. Note the following:

- If you define an expiration date for the user account and you later create a new account when the first one expires, the keytab for the corresponding Kerberos account changes. At that point, you must update the keytab file on the NIOS appliance (see Generating and Exporting the Keytab File and Importing the Keytab File and Enabling GSS-TSIG Authentication below). Optionally, if your security policy allows it, you can set the user account for the NIOS appliance so that it never expires.
- If the AD domain controller is running Windows Server 2003, the user account must have the DES encryption type enabled. You can enable this either in the Account tab when you create the user account or by specifying **+DesOnly** when you use the Ktpass tool to generate the keytab file.
- The newly created AD user account must be a member of the DnsUpdateProxy group or an account that allows it to update records that have potentially been added by another DHCP server, such as DNS Admins.

Generating and Exporting the Keytab File

You can generate and export the keytab file for the Kerberos account by using the Ktpass tool. Note that the version of the Ktpass tool that you use must match the Windows version of the domain controller. For example, if you are using a domain controller running Windows Server 2008 or Windows Server 2008 R2, you must use the Ktpass tool for Windows Server 2008 or Windows Server 2008 R2.
You enter different commands for generating and exporting the keytab file, depending on whether you are generating the keytab file from a server running Microsoft Windows 2000, Windows Server 2003, Windows Server 2008, or Windows Server 2008 R2.

Generating the Keytab on Windows 2000

To export the keytab file using a Microsoft Windows 2000 Resource Kit:

1. Start a command prompt.
2. Enter the following command to export the keytab file for the NIOS appliance user account:

```
C:> ktpass -princ service_name/FQDN_instance@REALM -mapuser AD_username -pass
password -out
filename.keytab
```

For example:

```
C:> ktpass -princ DNS/ns1.corpxyz.com@corpxyz.COM -mapuser ns1@corpxyz.com -pass
37Le37
-out ns1.keytab
```

Generating the Keytab on Windows Server 2003

The Ktpass tool is included in the Windows Server 2003 Support Tools. To export the keytab file using a Microsoft Windows 2003 Resource Kit:

1. Start a command prompt.
2. Enter the following command to export the keytab file for the NIOS appliance user account:

```
ktpass -princ DNS/FQDN_instance@REALM -mapuser AD_username -pass password -out
filename.keytab
-ptype KRB5_NT_PRINCIPAL -crypto des-cbc-md5 +DesOnly
```

For example:

```
ktpass -princ DNS/ns1.corpxyz.com@corpxyz.COM -mapuser ns1@corpxyz.com -pass 37Le37
-out ns1.keytab -ptype KRB5_NT_PRINCIPAL -crypto des-cbc-md5 +DesOnly
```

where:
-princ = Kerberos principal

- DNS = Service name in uppercase format
- ns1.corpxyz.com = Instance in FQDN (fully-qualified domain name) format; this is the same as the DNS name of the NIOS appliance
- corpxyz.COM = The Kerberos realm in uppercase format; this must be the same as the AD domain name

-mapuser = Maps the Kerberos principal name to the AD user account

- ns1@corpxyz.com = The AD user name for the NIOS appliance

-pass = The AD user account password

- 37Le37 = The password of the user account for the NIOS appliance

-out = Exports the keytab file

- ns1.keytab = The name of the keytab file

-ptype = Sets the principal type. This must be **krb5_nt_principal**.
-crypto = Specifies the encryption type. This must be **des-cbc-md5**.
+DesOnly = Specifies DES encryption for the account. Include this if you did not enable DES encryption for the account.

Generating the Keytab on Windows Server 2008/Windows Server 2008 R2

A Windows Server 2008 or Windows Server 2008 R2 domain controller allows you to generate a keytab file with multiple keys for one principal. The Infoblox DNS server accepts GSS-TSIG updates from DHCP clients that provide a Kerberos ticket for any of the keys in its configured keytab. To generate the keytab file using the Ktpass tool:

1. Start a command prompt.
2. Enter the following command to export the keytab file for the NIOS appliance user account:

```
ktpass -princ DNS/FQDN_instance@REALM -mapuser AD_username -pass password -out
filename.keytab
-ptype krb5_nt_principal -crypto encryption
```

For example:

```
ktpass-princDNS/ns1.corpxyz.com@corpxyz.COM-mapuserns1@corpxyz.com-pass37Le37-
outns1.keytab-ptype krb5_nt_principal-cryptoAES256-SHA1
```

where:
-princ = Kerberos principal

- DNS = Service name in uppercase format
- ns1.corpxyz.com = Instance in FQDN format; this is the same as the DNS name of the NIOS appliance
- corpxyz.COM = The Kerberos realm in uppercase; this must be the same as the AD domain name

-mapuser = Maps the Kerberos principal name to the AD user account

- ns1@corpxyz.com = The AD user name for the NIOS appliance

-pass = The AD user account password

- 37Le37 = The password of the user account for the NIOS appliance

-out = Exports the keytab file

- ns1.keytab = The name of the keytab file

-ptype = Sets the principal type. This must be **krb5_nt_principal**.
-crypto = Specifies the encryption type.
After you execute the command to generate the keytab file, the AD domain controller displays a series of messages similar to the following to confirm that it successfully generated the keytab file:

```
Targeting domain controller: qacert.test.local Using legacy password setting method

Successfully mapped DNS/ns1.corpxyz.com to ns1.

Key created.

Output keytab to ns1.keytab:

Keytab version: 0x502

keysize 80 DNS/ns1.corpxyz.com@corpxyz.COM ptype 1 (KRB5_NT_PRINCIPAL) vno 3 etype
0x12 (AES256-SHA1)

keylength 32 (0xea8675d7abf13fd760a744088642fb917ceb6c9d267f5c54e595597846f06407)
```

> **Note**
> The keytab file contains highly sensitive data for the NIOS appliance account. Ensure that you store and transport its contents securely.

Modifying an AD User Account

To change any AD user account information (login, password, etc):

1. Remove the previous user account from AD.
2. Create a new user for GSS-TSIG mapping.
3. Generate a new keytab file.
4. Import the keytab file to the DNS server.

Importing the Keytab File and Enabling GSS-TSIG Authentication

Before you can enable GSS-TSIG authentication, you must import the keytab file from the Kerberos account for the NIOS appliance. To import the keytab file:

1. From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Member DNS Properties* editor, click **Toggle Expert Mode**.
3. When the additional tabs appear, click **GSS-TSIG** and do the following:
   If a principal name and version number are listed, there is a keytab file loaded on the appliance. Compare this information with that for the NIOS appliance account on the Kerberos server to make sure that they match. If there is no keytab file on the NIOS appliance or if the loaded keytab file does not match that on the Kerberos server, you must load the correct keytab file.
   - Click **Upload**, click **Browse** to navigate to the keytab file, and then click **Upload**.
   - **Enable GSS-TSIG authentication of clients**: Select this checkbox.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Each time you export a keytab file from a Kerberos server running on Windows Server 2003, the version number of the keytab file increases incrementally. Because the version number on the keytab file that you import to the NIOS appliance must match the version that is in use on the Kerberos server, you should select the last keytab file that is exported from the Kerberos server if you have exported multiple keytab files. (A Kerberos server running on Windows 2000 does not increase the version number of keytab files with each export.)

Accepting GSS-TSIG Updates

You can allow a Grid or specific members or zones to accept GSS-TSIG signed updates from domain controllers and DHCP clients and servers, as follows:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon.
   Zone: From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox -> Edit icon.
   To override an inherited property, click **Override** next to it and complete the appropriate fields.
2. Select the **Updates** tab and do the following in the **Basic** subtab:
   - **Allow GSS-TSIG signed updates:** Select this option.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

You can then use the *Active Directory* wizard or navigate to the **Active Directory** tab of the *Authoritative Zone* editor to enable the appliance to create underscore zones for the records hosted by domain controllers and to allow GSS-TSIG signed updates to the underscore zones.
To use the *Active Directory* wizard:

1. From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Configure Active Directory**.
2. In the *Configure Active Directory* wizard, complete the following, and then click **Next**:
   - **Select Zone**: Click this and select a zone. The name of the zone must match the name in the AD domain controller so the zone transfer from the AD domain controller to the NIOS appliance can succeed.
   - **Allow GSS-TSIG-signed (secure) updates from Domain Controllers:** Select this option.
3. Complete the following:
   - **Do you want to create underscore zones to hold the records added by the Domain Controllers?**
     This option allows the appliance to create the following subzones that the DNS server must have to answer AD-related DNS queries:
     _msdcs.*zone*
     _sites.*zone*
     _tcp.*zone*
     _udp.*zone*
     domaindnszones.*zone*
     forestdnszones.*zone*
     Note that these zones are automatically generated. You cannot edit these zones or import data into them.
   - **Allow GSS-TSIG-signed updates to underscore zones:** Select this checkbox to allow underscore zones to accept GSS-TSIG signed updates.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

To use the *Authoritative Zone* editor:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox -> Edit icon.
2. In the *Authoritative Zone* editor, select the **Active Directory** tab and do the following:
    - **Allow unsigned updates from these Domain Controllers:** Clear this checkbox.
    - **Automatically create underscore zones:** (select)
      This option automatically creates the following subzones that the DNS server must have to answer AD-related DNS queries:
      _msdcs.*zone*
      _sites.*zone*
      _tcp.*zone*
      _udp.*zone*
      domaindnszones.*zone*
      forestdnszones.*zone*
      Note that these zones are automatically generated and cannot be manually edited.
    - **Allow GSS-TSIG-signed updates to underscore zones:** Select this checkbox to allow underscore zones to accept GSS-TSIG signed updates.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Secure Dynamic Updates

The secure dynamic updates feature provides several methods to restrict dynamic DNS updates to certain records. This includes:

- Restrictions for updates to statics records. For more information, see Restricting Updates to Static Records below.
- Restrictions for updates to records marked as protected. For more information, see Restricting Updates to Protected Records below.
- Restrictions based on GSS-TSIG principal authentication. For more information, see Restricting Updates Based on GSS-TSIG Principal Authentication below.
- Restrictions based on FQDN patterns. For more information, see Restricting Updates Based on FQDN Patterns below.

Only static and dynamic record source type support secure dynamic updates. You can see the record source type in the Resource Record Viewer. The following table shows which type of secure dynamic updates is applicable to different record source types.
Secure Dynamic Update Types

Secure Dynamic Update Type	Record Source Type
Restrictions for updates to statics records	Static
Restrictions for updates to protected records	Static, dynamic
Restrictions based on GSS-TSIG principal authentication	Dynamic
Restrictions based on FQDN patterns	Static, dynamic

Sometimes when the updating record has the same data as the existing record, you may need to initialize the record creation timestamp to avoid unwanted DNS record scavenging. For more information, see Forcing Creation Timestamp Initialization for Unchanged Records below.

Failed attempts to dynamically update secured records are recorded in the NIOS syslog. You can view it, as described in *Viewing the Syslog* and *Searching in the Syslog*.
You can use Smart Folders to organize data by record source, principal, or protection state. For more information, see *Smart Folders*.

In addition, you can use Global Search to search for records by principal name. For more information, see *Using Global Search*.

> ⚠ Note
>
> To use the secure dynamic updates feature, you must have a DNS license installed in the Grid Manager.

Restricting Updates to Static Records

This method prevents updates to all RRsets containing static records at once in the Grid, DNS view, or zone. To prevent updates to specific static records, see Restricting Updates to Protected Records below.

> ⚠ Note
>
> When you upgrade from a previous NIOS version to NIOS 7.3 or later, all dynamic updated records are labelled as static records if you enable the Secure Dynamic Updates feature. Infoblox suggests that you enable this feature only after all records are changed to Dynamic. NIOS tags the RRsets that are not auto-generated as static records.

To restrict updates to all static records in the Grid, DNS view, or zone:

1. In the Grid DNS, view, or zone properties, click **Updates** -> **Advanced**.
2. To override the inherited properties, click **Override**.
3. Under **Secure Dynamic Updates**, select **Prevent dynamic updates to RRsets containing static records**.
4. Click **Save & Close**.

Restricting Updates to Protected Records

You can restrict updates to the records of your choice, by marking them as protected. You can do this for both static and dynamic records. The Resource Record Viewer displays the protection status of the records in the Protected column: Yes or No.
You can protect the following record types:

- A record
- AAAA record
- CNAME record
- DNAME record
- MX record
- NAPTR record
- PTR record
- SRV record
- TXT record
- Host record

For all the above mentioned records except the host record, you can change the type from static to dynamic and back, if required.
To restrict updates to protected records:

1. In the DNS Resource Records viewer, select a record or multiple records.
2. In the Toolbar, select **Protect Records** -> **Enable Protection**.
   Or
   In the properties dialog for a record, click **Updates**, select the **Protected** checkbox, and then click **Save & Close**.
3. Enable updates prevention at the corresponding level:
   a. In the Grid DNS, view, or zone properties, click **Updates** -> **Advanced**.
   b. If necessary, click **Override** to override the inherited properties.

c. Select **Prevent dynamic updates to RRsets containing protected records**.
d. Click **Save & Close**.

Restricting Updates Based on GSS-TSIG Principal Authentication

This method implies tracking the Kerberos GSS-TSIG principal that created a record and restricting DDNS updates attempted by a different GSS-TSIG principal on this record.
The Resource Record Viewer displays the GSS-TSIG authentication information in the Principal column: it displays the principal name if the client that created the record is authenticated and the principal is tracked.
The tracked principal is also displayed in the record properties. You can change the principal associated to a record by clicking **Select Principal** in the record properties and specifying the required principal.
Additionally, you can use dynamic update groups to manage the allowed principals. For more information, see About Dynamic Update Groups below.
To restrict updates based on GSS-TSIG principal authentication:

1. In the Grid DNS, view, or zone properties, click **Updates** -> **Advanced**.
2. To override the inherited properties, click **Override**.
3. Under **Secure Dynamic Updates**, select **Track the GSS-TSIG principals that create dynamic records**.
   Note that for this option to work, ensure that you have selected **Enable GSS-TSIG authentication of clients** in the GSS-TSIG properties of the Grid or the corresponding zone or view.
4. Select **Require the appropriate GSS-TSIG principal to update RRsets that track principals**.
5. Optionally, specify an active dynamic update group.
6. Click **Save & Close**.

About Dynamic Update Groups

In some cases, for example, in DHCP failover associations, you need to allow different GSS-TSIG principals to update each other's records. To that end, you can join multiple principals into clusters, where all principals are considered as equivalent and therefore can update affected records without being their originators. You can join multiple clusters into a dynamic update group. The clusters within a group, however, are not considered equivalent and cannot update each other's records.
When you have several dynamic update groups defined, you can assign different groups to be active for the Grid, a DNS view, or a zone as described in Restricting Updates Based on GSS-TSIG Principal Authentication below. If no group is assigned, then no principals are considered to be equivalent.
For information on how to add dynamic update groups and clusters, see Managing Dynamic Update Groups and Clusters below.

> ⚠ Note
> Viewing and modifying the configuration of a dynamic update group requires Grid DNS permissions. Selecting a group as active for the Grid, a view, or a zone requires read permission on the Grid DNS, as well as write permission on the object being modified.

Managing Dynamic Update Groups and Clusters

To add a dynamic update group:

1. In **Data Management** -> **DNS**, expand the Toolbar and click **Manage Dynamic Update Groups**.
2. Click the Add icon.
3. Select **Add Dynamic Update Group**.
4. Specify the group name.
5. Optionally, provide a comment.
6. Click **Save and Close**. Proceed to adding clusters to the group as described below.

To add a cluster:

1. In the *Manage Dynamic Update Groups* window, click the Add icon.
2. Select **Add Cluster**.
3. Select the dynamic update group in which you want to include the cluster.

4. Specify the cluster name.
5. Optionally, provide a comment.
6. Click **Save and Close**.
7. To add principals to the cluster, select the cluster in the *Manage Dynamic Update Groups* window and click the Add icon. A principal can appear in multiple clusters.
8. Select one of the following:
    - **Add Principal**: This adds a new row in the table. Specify the principal name in the row.
    - **Select Principal**: This opens the *Principal Selector* dialog. Select the required principal from the list.
9. Click **Close**.

To edit or delete a group, cluster, or principal, select it in the *Manage Dynamic Update Groups* window, and click the corresponding icon.
You can also export data about dynamic update groups, their clusters, and principals in the Infoblox CSV Import format by clicking the Export icon in the *Manage Dynamic Update Groups* window. For more information, see *Exporting Data to Files*.

Restricting Updates Based on FQDN Patterns

This implies defining FQDN patterns for domain names which prevents DDNS updates to matching FQDNs. To restrict updates based on FQDN patterns:

1. In the Grid DNS, view, or zone properties, click **Updates** -> **Advanced**.
2. To override the inherited properties, click **Override**.
3. Under **Dynamic Update Patterns**, select **Prevent dynamic updates to FQDNs matching these patterns** and specify patterns:
    - To add an FQDN pattern, click the Add icon and specify a pattern in the new table row.
      Not that to use the DNS Traffic Control LBDN wild cards to specify FQDN patterns. For more information, see *Configuring LBDN Patterns*.
    - To delete an FQDN pattern, select the checkbox next to the pattern and click the Delete icon.
4. Click **Save & Close**.

Forcing Creation Timestamp Initialization for Unchanged Records

If the attributes of a resource record do not change in the result of a DDNS update, Grid Manager ignores the update and the record's creation timestamp remains the same. This may cause valid records with outdated timestamp to be removed during DNS scavenging. To avoid this, you can set the record creation time to be modified even when the record data do not change at DDNS update. You can do this for the whole Grid, or for a specific DNS view or authoritative zone.

To force the creation timestamp initialization for unchanged resource records:

1. Open the *Grid DNS Properties*, *DNS View Properties*, or *Authoritative Zone Properties* editor.
2. For a DNS view or authoritative zone, click **Override**.
3. Select **Modify creation time even when resource record data is unchanged**.
4. Click **Restart** in the Grid Manager's system messages banner for the setting to take effect.

For information about DNS scavenging, see *DNS Record Scavenging*.

Configuring DNSSEC

This section provides general information about DNSSEC. The topics in this section include:

- *DNSSEC*
- *DNSSEC Resource Records*
- *DNSKEY Resource Records*
- *RRSIG Resource Records*
- *NSEC/NSEC3 Resource Records*
- *NSEC3PARAM Resource Records*
- *DS Resource Records*

- *Configuring DNSSEC on a Grid*
- *Enabling DNSSEC*
- *Setting DNSSEC Parameters*
- *Signing a Zone*
- *About HSM Signing*
- *Configuring Grid Members to Support DNSSEC as Secondary Servers*
- *Configuring Recursion and Validation for Signed Zones*
- *Applying Policies and Rules to DNS Queries that Request DNSSEC Data*

DNSSEC

DNSSEC (DNS Security Extensions) provides mechanisms for authenticating the source of DNS data and ensuring its integrity. It protects DNS data from certain attacks, such as man-in the middle attacks and cache poisoning. A man-in-the middle attack occurs when an attacker intercepts responses to queries and inserts false records. Cache poisoning can occur when a client accepts maliciously created data. DNSSEC helps you avoid such attacks on your networks.
DNSSEC provides changes to the DNS protocol and additional resource records (RRs) as described in the following RFCs:

- *RFC 4033, DNS Security Introduction and Requirements*
- *RFC 4034, Resource Records for the DNS Security Extensions*
- *RFC 4035, DNSSEC Protocol Modifications*
- *RFC 4641, DNSSEC Operational Practices*
- *RFC 4956, DNS Security (DNSSEC) Opt-In*
- *RFC 4986, Requirements Related to DNS Security (DNSSEC) Trust Anchor Rollover*
- *RFC 5155, DNS Security (DNSSEC) Hashed Authenticated Denial of Existence*
- *RFC 5702, Use of SHA-2 Algorithms with RSA in DNSKEY and RRSIG Resource Records for DNSSEC*

DNSSEC uses public key cryptography to authenticate the source of DNS responses and to ensure that DNS responses were not modified during transit. Public key cryptography uses an asymmetric key algorithm. With asymmetric keys, one key is used to decrypt data that was encrypted using the other key.
In DNSSEC, the primary name server of a zone generates at least one public/private key pair. It "signs" each data set in the zone by running it through a one-way hash, and then encrypting the hash value with the private key. The public key is stored in an RR type introduced by DNSSEC, the DNSKEY RR. Resolvers use the DNSKEY record to decrypt the hash value. If the hash values match, then the resolver is assured of the authenticity of the message.
In addition to the DNSKEY record, DNSSEC also introduces new RRs which DNS servers can use to authenticate the non-existence of servers, zones, or resource records. For information about the DNSSEC resource records, see *DNSSEC Resource Records*.
DNSSEC uses the EDNS0 message extension. Resolvers include the EDNS OPT pseudo-RR with the DO (DNSSEC OK) bit set to indicate that they are requesting DNSSEC records. A DNS client or resolver sets the EDNS DO bit when it sends a query for data in a signed zone. When the DNS server receives such a query, it includes the additional DNSSEC records in its response, according to the DNSSEC standard rules. In addition, because DNSSEC messages are often large, the EDNS0 message extension also provides mechanisms for handling larger DNS UDP messages. For information about EDNS0, refer to *RFC 2671, Extension Mechanisms for DNS (EDNS0)*. For information about the DO bit, refer to *RFC 3225, Indicating Resolver Support of DNSSEC.*

Warning

When you disable EDNS0 on the appliance, all outgoing DNSSEC queries to zones within trusted anchors will fail even if DNSSEC validation is enabled. To ensure that DNSSEC functions properly, do not disable EDNS0 on the appliance. For more information, see Using Extension Mechanisms for DNS (EDNS0).

DNSSEC also supports new data in the packet header, the CD (Checking Disabled) bit and the AD (Authenticated Data) bit. The CD bit is used by resolvers in their DNS queries and the AD bit is used by recursive name servers in their responses to queries.
A resolver can set the CD bit in its query to indicate that the name server should not validate the DNS response and that the resolver takes responsibility for validating the DNS data it receives.
A name server that has successfully validated the data in a DNS response sets the AD (Authenticated Data) bit in the message header to indicate that all resource records in its response have been validated and are authentic. Note that unless the connection between the DNS server and client has been secured, such as through TSIG, the client cannot rely on the AD bit to indicate valid data. The data could have been changed in transit between the server and client. Resolvers can trust a response with the AD bit set only if their communication channel is secure.
You can also configure the NIOS appliance to always apply RPZ policies, DNS blacklists, or NXDOMAIN rules to DNS responses, regardless of whether the queries request DNSSEC data. For more information about how to configure this, see *Applying Policies and Rules to DNS Queries that Request DNSSEC Data*. For information about RPZ policies, DNS blacklists, and NXDOMAIN rules, see their respective sections in this guide.

Configuring DNSSEC

DNSSEC Resource Records

Following are the DNSSEC RR types:

- DNS Public Key (DNSKEY) resource records — For information, see *DNSKEY Resource Records*.
- Resource Record Signature (RRSIG) records — For information, see *RRSIG Resource Records*.
- Next Secure (NSEC/NSEC3) records — For information, see *NSEC/NSEC3 Resource Records*.
- NSEC3PARAM records — For information, see *NSEC3PARAM Resource Records*.
- Delegation Signer (DS) resource records — For information, see *DS Resource Records*.

For detailed information about each RR, refer to *RFC 4034, Resource Records for the DNS Security Extensions* and *RFC 5155, DNS Security (DNSSEC) Hashed Authenticated Denial of Existence.*

Note

The appliance supports IDNs for DNSKEY records, DS records, NSEC records, NSEC3PARAM records, and RRSIG records.

DNSKEY Resource Records

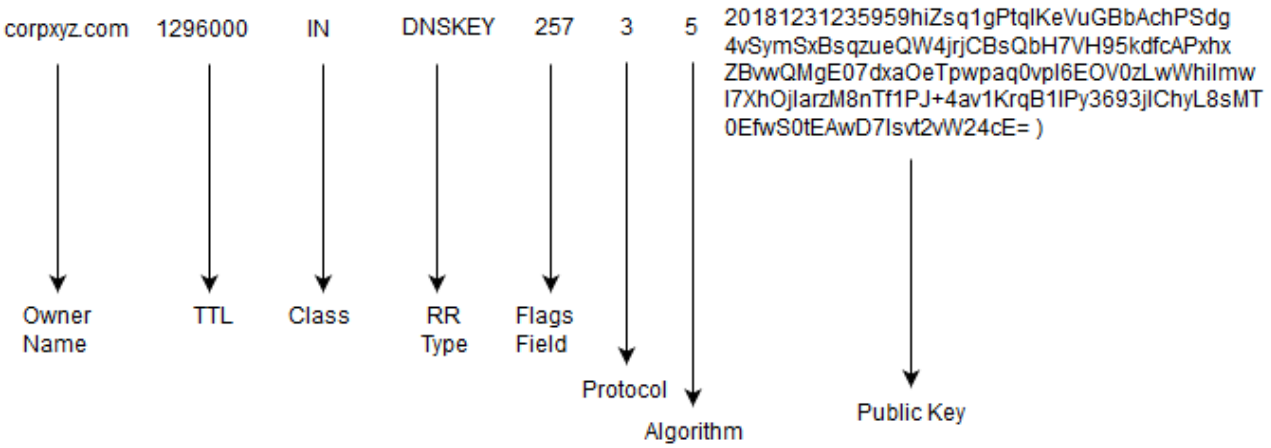
When an authoritative name server digitally signs a zone, it typically generates two key pairs, a zone-signing key (ZSK) pair and a key-signing key (KSK) pair. The name server uses the private key of the ZSK pair to sign each RRset in a zone (an RRset is a group of resource records that are of the same owner, class, and type.). It stores the public key of the ZSK pair in a DNSKEY record. The name server then uses the private key of the KSK pair to sign all DNSKEY records, including its own, and stores the corresponding public key in another DNSKEY record. As a result, a zone typically has two DNSKEY records; a DNSKEY record that holds the public key of the ZSK pair, and another DNSKEY record for the public key of the KSK pair.

Note

For the remainder of this chapter, the DNSKEY record that holds the public key of the ZSK pair is referred to as the ZSK and the DNSKEY record that holds the public key of the KSK pair is referred to as the KSK.

The purpose of the KSK is two-fold. First, it is referenced in the Delegation Signer (DS) RR that is stored in a parent zone. The DS record is used to authenticate the KSK of the child zone, so a resolver can establish a chain of trust from the parent zone to its child zone. For more information about the DS RR, see *DS Resource Records*.
Second, if a zone does not have a chain of trust from a parent zone, security aware resolvers can configure the KSK as a trust anchor; that is, the starting point from which it can build a chain of trust from that zone to its child zones.
Note that though the two key pairs, KSK and ZSK, are used in most DNSSEC environments, their use is not required by the RFCs. A zone administrator can use a single private/public key pair to sign all zone data. (Note that Infoblox appliances require two key pairs.)

Following is an example of a DNSKEY RR:



The first four fields specify the domain name of the zone that owns the key, the resource record TTL, class, and RR type. The succeeding fields are:

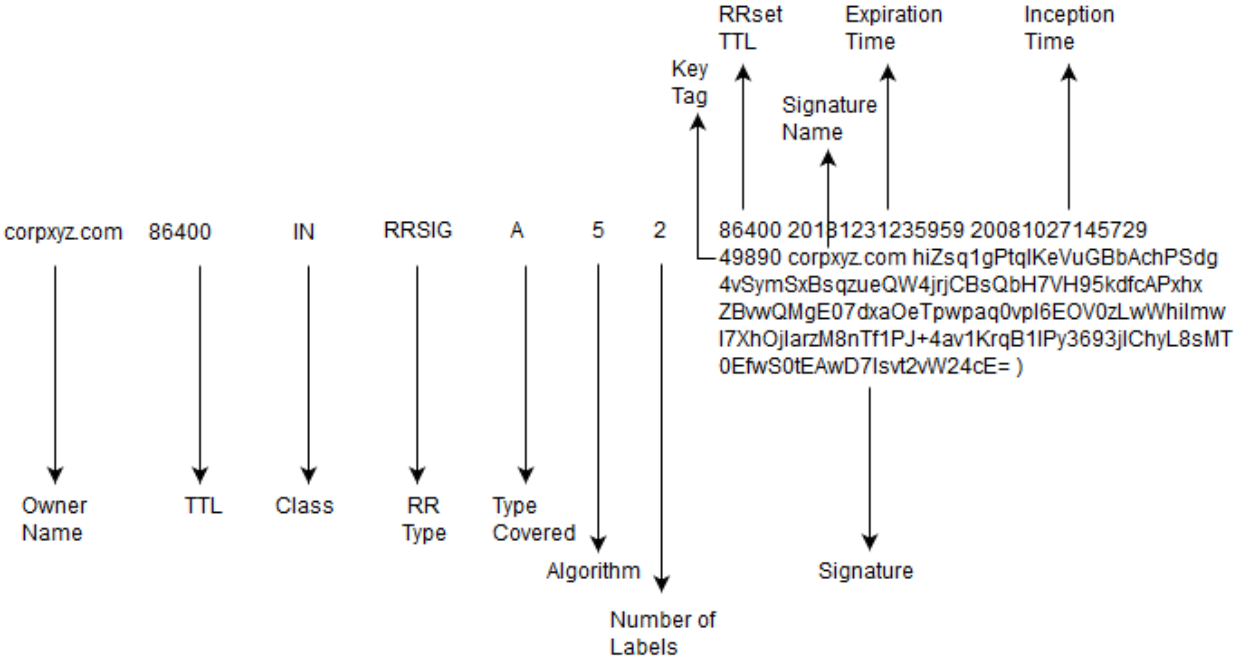
- Flags Field: In its wire format, this field is two bytes long. (The wire format is used in DNS queries and responses.) Bits 0 through 6 and 8 through 14 are reserved, and have a value of 0. Bit 7 indicates if the record holds a DNS zone key. Bit 15 is the Secure Entry Point (SEP) flag, which serves as a hint that indicates whether the DNSKEY record contains a ZSK or a KSK, as described in *RFC 3757, DNSKEY RR SEP Flag*. Zone administrators typically set the SEP flag of a DNSKEY record of a zone when it contains the KSK, to indicate that it can be used as a trust anchor. However, a DNSKEY record that does not have the SEP flag set can also be used as a trust anchor.

  Given the currently defined flags, in its text format, the flags field is represented as an unsigned decimal integer with the possible values of 0, 256 and 257. A value of 256 indicates that the DNSKEY record holds the ZSK and a value of 257 indicates that it contains the KSK. In general, this field contains an odd number when the DNSKEY record holds the KSK.
- Protocol: This always has a value of 3, for DNSSEC.
- Algorithm: Identifies the cryptographic algorithm of the public key. The available types are:
  - 1 = RSA/MD5
  - 2 = Diffie-Hellman (This is not supported by BIND and Infoblox appliances.)
  - 3 = DSA
  - 4 = Reserved
  - 5 = RSA/SHA1
  - 6 = DSA/SHA1/NSEC3
  - 7 = RSA/SHA1/NSEC3
  - 8 = RSA/SHA-256
  - 10 = RSA/SHA-512
  - 13 = ECDSAP/SHA-256
  - 14 = ECDSAP/SHA-384
- Public Key: The public key encoded in Base64.

RRSIG Resource Records

A signed zone has multiple RRsets, one for each record type and owner name. (The owner is the Fully Qualified Domain Name of the RRset.) When an authoritative name server uses the private key of the ZSK pair to sign each RRset in a zone, the digital signature on each RRset is stored in an RRSIG record. Therefore, a signed zone contains an RRSIG record for each RRset.

Following is an example of an RRSIG record:

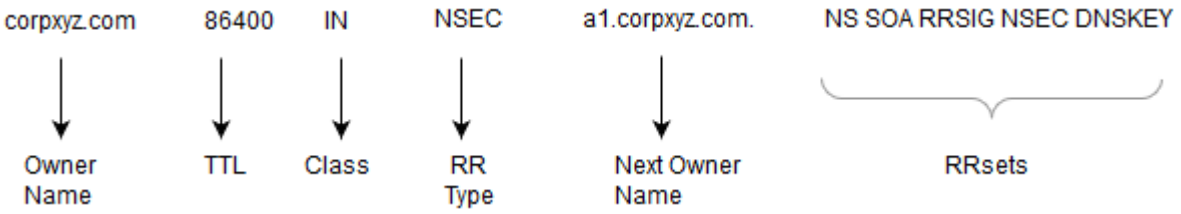


The first four fields specify the owner name, TTL, class, and RR type. The succeeding fields are:

- Type Covered: The RR type covered by the RRSIG record. The RRSIG record in the example covers the A records for corpxyz.com.
- Algorithm: The cryptographic algorithm that was used to create the signature. It uses the same algorithm types as the DNSKEY record indicated in the Key Tag field.
- Number of Labels: Indicates the number of labels in the owner name of the signed records. There are two labels in the example, corpxyz and com.
- RRset TTL: The TTL value of the RRset covered by the RRSIG record.
- Expiration Time: The signature expiration time in UTC format.
- Inception Time: The signature inception time in UTC format.
- Key Tag: The key tag value of the DNSKEY RR that validates the signature.
- Signature Name: The zone name of the RRset.
- Public Key: The Base64 encoding of the signature.

NSEC/NSEC3 Resource Records

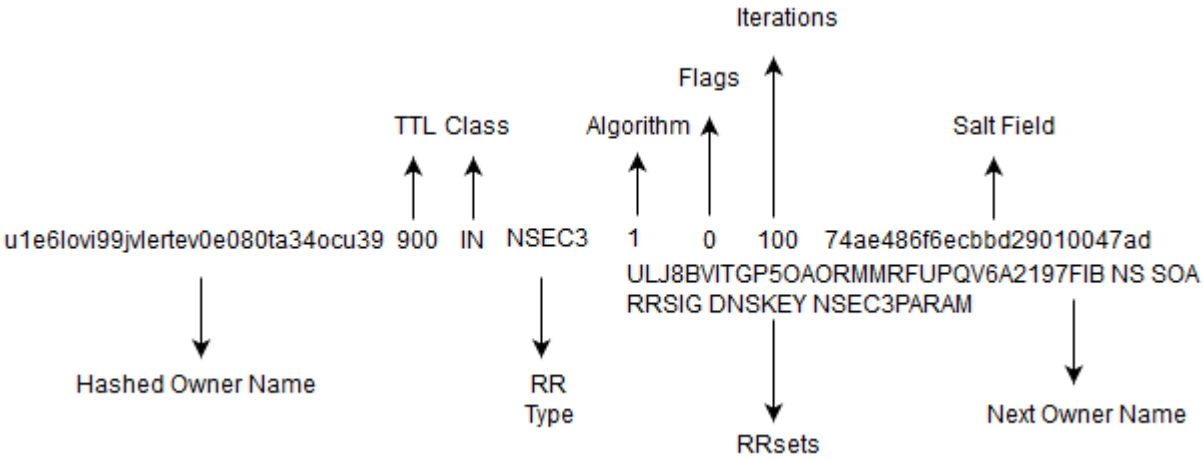
When a name server receives a request for a domain name that does not exist in a zone, the name server sends an authenticated negative response in the form of an NSEC or NSEC3 RR. NSEC and NSEC3 records contain the next secure domain name in a zone and list the RR types present at the NSEC or NSEC3 RR's owner name. The difference between an NSEC and NSEC3 RRs is that the owner name in an NSEC3 RR is a cryptographic hash of the original owner name prepended to the name of the zone. NSEC3 RRs protect against zone enumeration.
Following is an example of an NSEC record:



The first four fields specify the owner name, TT, class and RR type. The succeeding fields are:

- Next Owner Name: In the canonical order of the zone, the next owner name that has authoritative data or that contains a delegation point NS record.
- RRsets: The RRsets that exist at the owner name of the NSEC record, which are NS, SOA, RRSIG, NSEC, and DNSKEY in the example.

Following is an example of an NSEC3 RR:



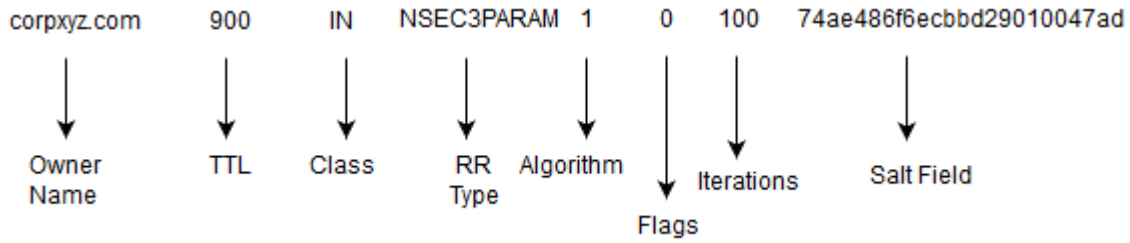
The first field contains the hashed owner name. It is followed by the TTL ,class and RR type. The fields after the RR type are:

- Algorithm: The hash algorithm that was used. The currently supported algorithm is SHA-1, which is represented by a value of 1.
- Flags Field: Contains 8 one-bit flags, of which only one flag, the Opt-Out flag, is defined by RFC 5155. The Opt-Out flag indicates whether the NSEC3 record covers unsigned delegations.
- Iterations: The number of times the hash function was performed.
- Salt Field: A series of case-insensitive hexadecimal digits. It is appended to the original owner name as protection against pre-calculated dictionary attacks.
- Next Owner Name: Displays the next hashed owner name.
- RRsets: The RR types that are at the owner name.

NSEC3PARAM Resource Records

An authoritative DNS server uses NSEC3PARAM RRs to determine which NSEC3 records it includes in its negative responses. An NSEC3PARAM RR contains the parameters that an authoritative server needs to calculate hashed owner names. As stated in RFC 5155, the presence of an NSEC3PARAM RR at a zone apex indicates that the specified parameters may be used by authoritative servers to choose an appropriate set of NSEC3 RRs for negative responses.

Following is an example of an NSEC3PARAM record:

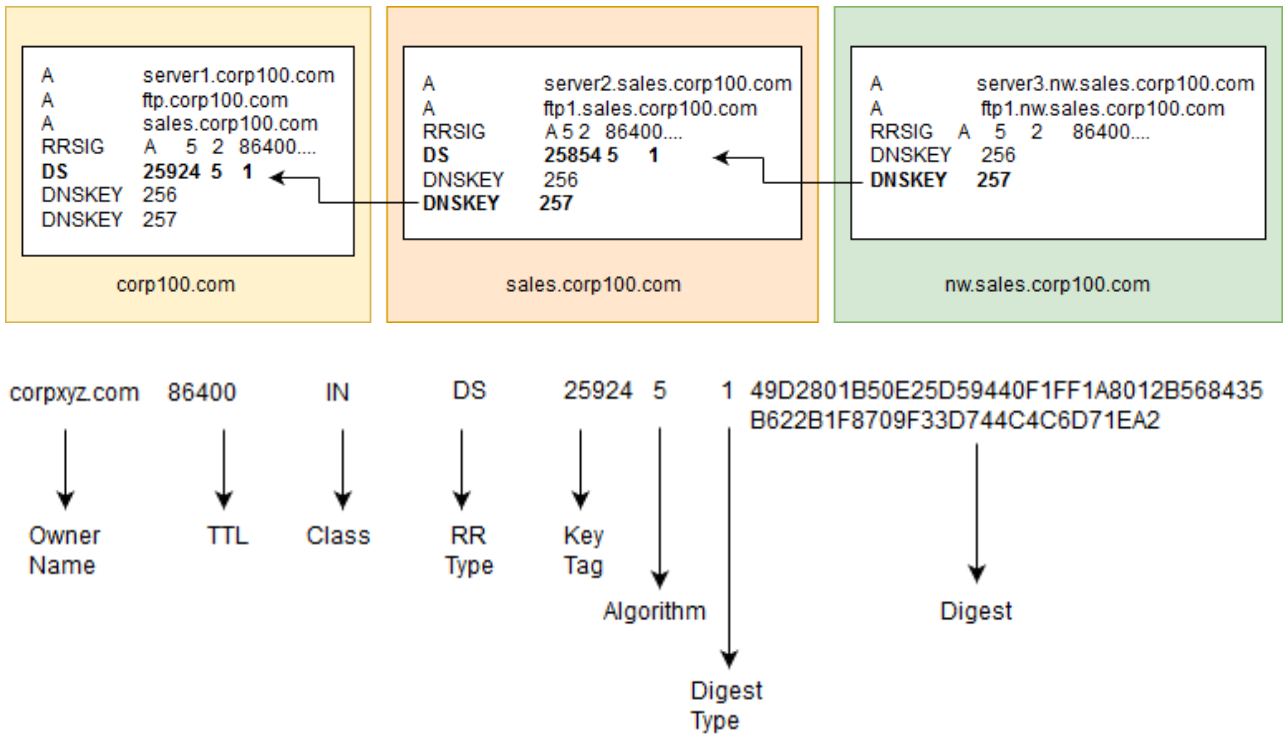


The first four fields specify the owner name, TTL, class and RR type. The succeeding fields are:

- Algorithm: The hash algorithm that was used. The currently supported algorithm is SHA-1, which is represented by a value of 1.
- Flags Field: Contains 8 one-bit flags, of which only one flag, the Opt-Out flag, is defined by RFC 5155. The Opt-Out flag indicates whether the NSEC3 record covers unsigned delegations.
- Iterations: The number of times the hash function was performed. The number of NSEC3 iterations is set to 10.
- Salt Field: A series of case-insensitive hexadecimal digits. It is appended to the original owner name as protection against pre-calculated dictionary attacks. New salt value is generated when the ZSK rolls over, for which the user can control the period. For random salt, the selected length is between one and 15 octets.

DS Resource Records

A DS RR contains a hash of a child zone's KSK and can be used as a trust anchor in some security-aware resolvers and to create a secure delegation point for a signed subzone in DNS servers. As illustrated in the figure below, the DS RR in the parent zone corpxyz.com contains a hash of the KSK of the child zone sales.corpxyz.com, which in turn has a DS record that contains a hash of the KSK of its child zone, nw.sales.corpxyz.com.
Figure 22.1



The first four fields specify the owner name, TTL, class and RR type. The succeeding fields are as follows:

- Key Tag: The key tag value that is used to determine which key to use to verify signatures.
- Algorithm: Identifies the algorithm of the DNSKEY RR to which this DS RR refers. It uses the same algorithm values and types as the corresponding DNSKEY RR.
- Digest Type: Identifies the algorithm used to construct the digest. The supported algorithms are:
    - 1 = SHA-1
    - 2 = SHA-256
- Digest: If SHA-1 is the digest type, this field contains a 20 octet digest. If SHA-256 is the digest type, this field contains a 32 octet digest.

Configuring DNSSEC on a Grid

You can configure the name servers in a Grid to support DNSSEC. You can configure the Grid Master as the primary server for a signed zone and the Grid members as secondary servers. (For more information, see *Configuring Grid Members to Support DNSSEC as Secondary Servers*.) Note that only the Grid Master can serve as the primary server for a signed zone. Only the Grid Master can re-sign DNSSEC keys, and it must be primary for signed zones (as well as for signed zones with DNS Traffic Control records). That is, the Grid Master must serve the whole part of the configuration in which DNSSEC is used. Therefore, a running DNS service, DNS and DNS Traffic Control licenses are required on the Grid Master to use DNSSEC.

You can enable the Grid Master to sign zones and manage the DNSSEC keys, or you can configure the Grid Master as a client to a third-party, network-attached Hardware Security Module (HSM) that performs the key generation, zone signing, and key safekeeping. You must use either the Grid Master or HSM for zone signing and key management; you cannot use both. Note that each method may have different performance implications, depending on the hardware platform, number of zones and other factors. For information about using HSMs, see *About HSM Signing*.
Any authoritative forward-mapping or reverse-mapping zone can be signed according to the following criteria:

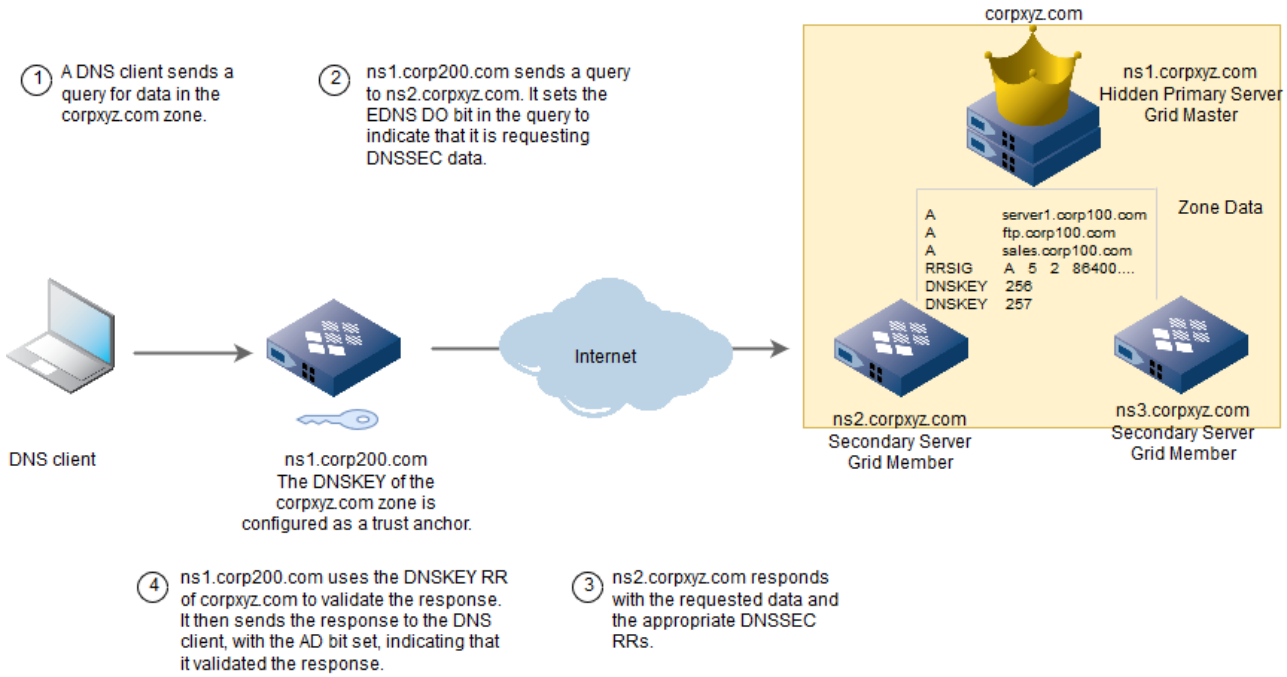
- The zone does not contain any bulk host records.
- DNSSEC is enabled on the Grid Master.
- The primary server of the zone must be a Grid member. If the zone is assigned to an NS group, the primary server in the group must be a Grid member that has DNSSEC enabled.

Note that you can use DNS views to separate internal and external zone data, to manage your zones more efficiently and reduce the size of the zones that require signing. For information about DNS views, see *About DNS Views*.

Grid Master as Primary Server

When you sign a zone whose primary server is a Grid member, that member becomes a secondary server and the Grid Master becomes the hidden primary server. If the zone is assigned to an NS group, the Grid Master removes the association with the NS group. The previous primary server becomes a secondary server for the zone.
If a Master Candidate is promoted to Grid Master and the previous Grid Master was the primary server for signed zones, the new Grid Master becomes the hidden primary server for all signed zones. The previous Grid Master, which was the primary server for the zone, becomes a secondary server for the zone.
As the primary server, the Grid Master sends zone data to the secondary servers through zone transfers; or, if the secondary servers are Grid members, the Grid Master transfers data to all Grid members through the database replication process, by default. The Grid Master transfers all records in that zone, including all NSEC/NSEC3, RRSIG, DNSKEY and DS records with owner names that belong to that zone. The RRSIG RRs are included in zone transfers of the zone in which they are authoritative data. The Grid Master also performs incremental zone transfers to secondary servers as a result of incremental zone signings.
In addition, the Grid Master automatically performs an incremental signing of the zone data sets when their contents change. Incremental signing refers to signing just those parts of a zone that change when RRs are added, modified, or deleted. The Grid Master uses the private key of the ZSK when it incrementally signs a zone. In addition, the Grid Master adds, modifies or deletes the corresponding RRSIG records and the appropriate NSEC/NSEC3 records.
For example, the following Figure shows a Grid Master as the primary server of a signed zone and its Grid members as secondary servers. The Grid Master, ns1.corpxyz.com, is the hidden primary DNS server for the corpxyz.com zone. As the hidden primary name server for corpxyz.com, the Grid Master does not respond to queries from other name servers. Instead, it provides data to its secondary servers, ns2.corpxyz.com and ns3.corpxyz.com, which use this data to respond to DNS queries. Because the secondary servers are Grid members, they receive zone data from the Grid Master through the Grid database replication process.
The name server ns1.corp200.com is a recursive name server. It has configured the DNSKEY of the corpxyz.com zone

as a trust anchor. Therefore, it is able to validate the data it receives when it sends a query for the corpxyz.com zone.



Following are the tasks to configure the Grid Master to sign zones:

1. Create the zones. For information, see *Configuring Authoritative Zones*.
    - Specify the Grid Master as the primary server.
2. Enable DNSSEC, as described in *Enabling DNSSEC*.
3. Optionally, change the default DNSSEC settings. For information, see *Setting DNSSEC Parameters*.
4. Sign the zone. The appliance automatically generates the DNSSEC RRs when you sign a zone. For information, see *Signing a Zone*.

Enabling DNSSEC

You can enable DNSSEC on a Grid, individual members, and DNS views. Because only Grid Masters can serve as primary servers for signed zones, you must enable DNSSEC on the Grid Master before you can sign zones. You must also enable DNSSEC on any Grid member that serves as a secondary server for signed zones.
When you enable DNSSEC on a Grid, you can set certain parameters that control the DNSSEC RRs, as described in *Setting DNSSEC Parameters*.
When you enable DNSSEC on a Grid member or DNS view, you can set parameters that affect its operations as a secondary server, as described in *Configuring Grid Members to Support DNSSEC as Secondary Servers*.
To enable DNSSEC on a Grid, member or DNS view:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab. Expand the Toolbar and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **Members** tab -> *member* checkbox and click the Edit icon.
   DNS View: From the **Data Management** tab, select the **Zones** tab -> *dns_view* checkbox and click the Edit icon.
2. In the editor, click **Toggle Expert Mode**.
3. When the additional tabs appear, click **DNSSEC**.
4. In the **DNSSEC** tab, select **Enable DNSSEC**.
   Note when you disable EDNS0, all outgoing DNSSEC queries to zones within trusted anchors will fail even if DNSSEC validation is enabled. This is due to the restriction of the UDP packet length when you disable EDNS0. For information about EDNS0, see *Using Extension Mechanisms for DNS (EDNS0)*.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Setting DNSSEC Parameters

The Grid Master uses certain default parameters when it signs a zone and generates the DNSSEC RRs. If you want to use different parameters for certain zones, you can change these defaults for the entire Grid or for individual zones. The following sections describe the different parameters that you can set:

- *About the DNSKEY Algorithm*
- *About Key Rollovers*
    - *Zone-Signing Key Rollover*
    - *Key-Signing Key Rollover*
    - *About Key Rollovers and DNS TTLs*
- *RRSIG Signatures*
- *Configuring DNSSEC Parameters*
- *Applying the Algorithm Changes*
- *Deleting the DNSSEC Keys Associated with a Zone*

For information on setting these parameters, see Configuring DNSSEC Parameters below.

About the DNSKEY Algorithm

You can add multiple cryptographic algorithms that the Grid Master uses when it generates the KSK and ZSK. You can also add multiple algorithms at the Grid level and override them at the zone level. By default, the appliance uses RSA/SHA1 for both KSK and ZSK. You can add DSA, RSA/MD5, RSA/SHA1, RSA/SHA-256, RSA/SHA-512, ECDSAP/SHA-256, or ECDSAP/SHA-384 algorithms. However, you cannot add RSA/MD5 if the zone is signed with NSEC3 records. Note that a zone can contain either NSEC or NSEC3 records, but not both. You can add same or different set of algorithms with possibly different key sizes for both KSK and ZSK.
You can assign the DNSKey algorithm for HSMs. Entrust nShield HSMs don't support DSA. All other parameters are not used by HSMs.

About Key Rollovers

To reduce the probability of being compromised, ZSKs and KSKs must be periodically changed. The time within which a key pair is effective is its rollover period. The rollover period starts as soon as a zone is signed. After a rollover period starts, you cannot interrupt or restart it unless you unsign the zone. During the key rollover, all the algorithms are rolled over at the same time and the rollover is performed on a per-zone basis.

Zone-Signing Key Rollover

You can configure automatic ZSK rollovers on the Grid Master by using the double-signature rollover method or the pre-publish method. For more information, see Configuring DNSSEC Parameters below. The appliance initiates the ZSK rollover of signed zones when they are due. You can also perform a manual rollover of ZSKs. For more information about rolling zone-signing keys, see *Signing a Zone*.
The double signature method provides a grace period, which is half of the rollover period. The default ZSK rollover period is 30 days; thus, the default grace period is 15 days.
At the end of a rollover period of a ZSK, the Grid Master generates a new ZSK key pair. It signs the zone with the private key of the new ZSK key pair, and consequently generates new RRSIG RRs with the new signatures. However, the Grid Master also retains the old ZSK key pair and RRSIG RRs. Thus, during the grace period, the data in the zone is signed by the private keys of both the old and new ZSKs. Their corresponding public keys (stored in DNSSEC RRs) can be used to verify both the old and new RRSIGs.
The grace period also allows the data that exists in remote caches to expire and during this time, the updated zone data can be propagated to all authoritative name servers. The Grid Master removes the old ZSK and its RRSIGs when the rollover grace period elapses. When a scheduled DNSSEC operation exists for a zone, the appliance does not lock it against other administrative changes and the administrator can still operate on a given zone even if there is a pending DNSSEC operation scheduled for it.
The appliance sets pre-publish method described in RFC 4641 as the default zone-signing key rollover method for NIOS 6.11.0 or later releases. In the pre-publish rollover method, the new key is published in the keyset before the actual

rollover. After the key propagates to all client caches, Grid Master removes the old signatures and creates new signatures with the new keys. The pre-publish rollover method uses the current key to sign the zone.

Key-Signing Key Rollover

You can configure automatic KSK rollovers on the Grid Master or perform a manual KSK rollover. The default KSK rollover period is one year. The Grid Master also uses the double signature rollover method described in RFC 4641 for KSK rollovers. To configure automatic KSK rollovers, see as described in *Configuring Automatic KSK Rollovers and Notifications*. For information about performing a manual KSK rollover, see *Rolling Zone-Signing Keys*.
When the KSK rollover is overdue or is due within seven days, the Grid Master displays a warning when admins log in. In addition, you can also check which KSKs are due for a rollover as described in *Checking Key-Signing Keys*.
When a user initiates a KSK rollover, the Grid Master sets the grace period to half the KSK rollover period. It generates a new KSK, and signs the DNSKEY records with the new KSK. Thus, during the grace period, the DNSKEY records are signed by the private keys of both the old and new KSKs. Both the old and the new KSKs can be used to validate the zone. The grace period allows the old keys in remote caches to expire. In addition, the admin should also export the new KSK and send it to the recursive name servers that use the KSK as trust anchors.
If the KSK rollover is for a child zone and the primary server of the parent zone is a Grid member, the Grid Master also inserts a DS record in the parent zone for the new DNSKEY in the child zone. If the primary server of the parent zone is external to the Grid, the admin must export either the DS record or the new KSK to the admin of the parent zone. For information about exporting a KSK, see as described in *Exporting Trust Anchors*.
The Grid Master then removes the old KSK and its RRSIG records when the grace period for the KSK rollover ends.

About Key Rollovers and DNS TTLs

Note that the KSK and ZSK rollover intervals affect TTLs used by RRs in signed zones.
A grace period is half of the key rollover interval. For example, if the KSK rollover interval is 1 year (365 days), then the grace period is 182.5 days; if the ZSK rollover interval is 30 days, then the grace period is 15 days.

The DNSKEY RRset in the zone is assigned a TTL, which is half of the signature validity interval. The default signature validity interval is set to 4 days, so DNSKEY RRset TTL is set to 2 days (172800 seconds).
All other RRs in the signed zone is limited to a “zone maximum TTL,” which is the grace period of the ZSK. In the example, this is also 15 days.
When the zone is initially signed, if the TTL of an RR exceeds the zone maximum TTL, the Grid Master reduces the TTL to the zone maximum TTL. Additionally, the TTL settings for the signed zone are set to override; the values are inherited from the Grid DNS properties at that time, and the default TTL setting is reduced to the zone maximum TTL if the Grid property exceeds it. If the zone is later unsigned, the zone DNS properties remain at their overridden settings.

RRSIG Signatures

As shown in the sample RRSIG record in *RRSIG Resource Records*, the signatures have an inception and an expiration time. The default validity period of signatures in RRSIG records on the Grid Master is four days. You can change this default as long as it is not less than one day or more than 3660 days. The Grid Master automatically renews signatures before their expiration date.

Configuring DNSSEC Parameters

The guidelines for choosing the DNSSEC parameters are as follows:

- RSA/SHA1 is the most widely used cryptographic algorithm for generating KSK and ZSK. However, it is recommended to use RSA/SHA-256 and RSA/SHA-512 for better interoperability.
- The usage of DSA cryptographic algorithm is optional. As stated in RFC 6944, it may not be supported by many systems.
- It is not recommended to use RSA/MD5 cryptographic algorithm as it is not very secure. As stated in RFC 6944, there are known defects in MD5.
- The key size of KSK algorithm is recommended to be equal to or greater than the key size of ZSK algorithm.

To set parameters at the Grid or zone level, complete the following steps:

1. **Grid**: On the **Data Management** tab, select the **DNS** tab. Expand the Toolbar and click **Grid DNS Properties**.
   Zone: On the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and then click the Edit icon. Click **Override** to override the parameters.
   Standalone appliance: On the **Data Management** tab, select the **DNS** tab. Expand the Toolbar and click **System DNS Properties**.
2. In the editor, click **Toggle Advanced Mode**.
3. When the additional tabs appear, click **DNSSEC**.
4. On the **DNSSEC** tab, click the **Basic** tab and complete the following:
   - **Resource Record Type for Nonexistent Proof**: Select the resource record type (**NSEC** or **NSEC3**) you want to use for handling non-existent names in DNS. The default is **NSEC3**. The algorithms used by the KSK and ZSK can generate the same type of NSEC record. Note that a zone cannot contain both NSEC and NSEC3 resource records.
   - **Key-signing Key**: Click the Add icon to add the cryptographic algorithm that the Grid Master or HSM uses when it generates the KSK. You can add multiple algorithms, but you cannot add the same algorithm more than once. Grid Manager adds a row to the table each time you click the Add icon. Select the row and the algorithm from the drop-down list and enter the key size for the algorithm. The default is **RSA/SHA1** with the key size as **2048**.
     Following are the valid values for each algorithm:
     DSA: The minimum is 512 bits and the maximum is 1024 bits, which is also the default. The key length must be a multiple of 64. Note that Entrust nShield HSMs do not support DSA.
     RSA/MD5: The minimum is 512 bits, the maximum is 4096 bits, and the default is 2048 bits. You can configure this for NSEC only.
     RSA/SHA1: The minimum is 512 bits, the maximum is 4096 bits, and the default is 2048 bits.
     RSA/SHA-256: The minimum is 512 bits, the maximum is 4096 bits, and the default is 2048 bits.
     RSA/SHA-512: The minimum is 1024 bits, the maximum is 4096 bits, and the default is 2048 bits.
     ECDSAP/SHA-256: The minimum is 160 bits, the maximum is 256 bits.
     ECDSAP/SHA-384: The minimum is 160 bits, the maximum is 384 bits.
     You can delete an algorithm by selecting it and clicking the Delete icon.
   - **Key-signing Key Rollover Interval**: Specify the key signing key rollover interval for all the algorithms. The minimum value is one day and the maximum is the time remaining to January 2038. The default is one year.
   - **Zone-signing Key**: Click the Add icon to add the cryptographic algorithm that the Grid Master or HSM uses when it generates the ZSK. You can add multiple algorithms, but you cannot add the same algorithm more than once. Grid Manager adds a row to the table each time you click the Add icon. Select the row and the algorithm from the drop-down list and enter the key size for the algorithm. The default is **RSA/SHA1** with the key size **1024**.
     Following are the valid values for each algorithm:
     DSA: The key length must be a multiple of 64. The minimum is 512 bits and the maximum is 1024 bits. The default is 1024 bits. Note that Entrust nShield HSMs do not support DSA.
     RSA/MD5: The minimum is 512 bits, the maximum is 4096 bits, and the default is 1024 bits. You can configure this for NSEC only.
     RSA/SHA1: The minimum is 512 bits, the maximum is 4096 bits, and the default is 1024 bits.
     RSA/SHA-256: The minimum is 512 bits, the maximum is 4096 bits, and the default is 1024 bits.
     RSA/SHA-512: The minimum is 1024 bits, the maximum is 4096 bits, and the default is 1024 bits.
     ECDSAP/SHA-256: The minimum is 160 bits, the maximum is 256 bits.
     ECDSAP/SHA-384: The minimum is 160 bits, the maximum is 384 bits.
     You can delete an algorithm by selecting it and clicking the Delete icon.
   - **Zone-signing Key Rollover Interval**: Specify the zone signing key rollover interval for all the algorithms. The minimum value is one day and the maximum is the time remaining to January 2038. The default is 30 days.
   - **Signature Validity:** Specify the signature validity period for RRSIG RRs. The minimum is one day and the maximum is 3660 days. The default signature validity interval is four days.
   - **Zone-signing Key rollover method**: You can use either of these methods to sign all the RRsets in a zone:
     i. **Pre-publish**: Select this if you want to use the pre-publish signature scheme to sign all the RRsets in a zone while performing the ZSK rollover. When you select this option, the record sets are signed using a single key. The appliance sets this option as the default zone-signing key method for NIOS 6.11.0 and later releases.

ii. **Double Sign**: Select this if you want to use the double signature scheme to sign all the RRsets in a zone while performing the ZSK rollover. The non-DNSKEY RRset are signed twice, which increases the size of the zone files.
Note that you can select the **Zone-signing Key rollover method** only after you enable DNSSEC.

5. Save the configuration and click **Restart** if it appears at the top of the screen.

When you modify the algorithms for a signed zone, you can apply the algorithm changes to the zone, as described later or you can unsign the zone and sign it again. For an unsigned zone however, you can apply the algorithm changes by signing the zone. For information about signing a zone, see *Signing a Zone*.
When you re-sign a zone after adding an algorithm, the DNSKEY key pairs of the old algorithms are rolled over and all the old RRSIG records are removed. The zone is re-signed with the new DNSKEY key pairs. When you re-sign a zone after removing an algorithm, the DNSKEY key pairs of the remaining algorithms are rolled over and the DNSKEY key pairs of the removed algorithm is removed. All old RRSIG records are removed and the zone is re-signed with the new DNSKEY key pairs.

> ⚠ Note
> If you add or remove a KSK algorithm from a zone, you must update the DS RRsets at the parent zone when the parent zone is managed by a non-Infoblox DNS server or by an Infoblox server that is part of a different Grid. For information, see *Importing a Keyset*.

Applying the Algorithm Changes

You can apply the algorithm changes to a zone whenever the KSK or ZSK algorithms are modified. You can apply the algorithm changes only to a signed zone.
To apply the algorithm changes to a signed zone, complete the following steps:

1. On the **Data Management** tab, select the **DNS** tab.
2. Expand the Toolbar and click **DNSSEC** -> **Apply Algorithm Changes**.
3. In the *Apply Algorithm Changes* dialog box, click the Add icon to select a zone. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. The appliance displays signed zones only. Select a zone. To add multiple zones, click the Add icon and select a zone.
   To remove a zone from the list, select the checkbox adjacent to the respective zone and click the Delete icon.
   You can click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, either select **Now** or select **Later** and enter a date, time, and time zone.
4. After you have selected the zones, click **Apply Algorithm Changes.**
5. When the confirmation dialog appears, click **Yes**.

Deleting the DNSSEC Keys Associated with a Zone

You can view the status of KSKs and ZSKs or delete the existing keys. Note that you can only delete keys that are either published or rolled over. You cannot delete keys that are active.
To delete keys, complete the following steps:

1. On the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and click the Edit icon.
2. In the *Authoritative Zone* editor, click the **DNSSEC** tab, and the following fields are displayed in the **Advanced** tab:
   - **Key ID**: The appliance generates a separate ID for each key. Select the checkbox adjacent to the **Key ID**. To delete a KSK, select the checkbox in the **Key-signing Keys** table. Select the checkbox in the **Zone-signing Keys** table to delete a ZSK.
   - **Status**: The **Status** column displays the status of the respective key. It can be one of the following: **Active**, **Published**, or **Rolled**.
   - **Public Key**: This column displays the public key that is associated with the respective KSK or ZSK.
   - **Algorithm**: This column displays the algorithm that is associated with the respective KSK or ZSK.
   - **Time until next event**: This column displays the time that is left to perform the next action for a key that is associated with the respective ZSK. This column helps you decide whether to roll over manually or wait for a zone to resign automatically. The time is displayed in months, days, hours format. For example, 2m 3d 13h implies time left to perform the next action is 2 months, 3 days and 13 hours.
     - **Active Key**: Indicates the time when the active key is rolled and zone is signed with the published key.

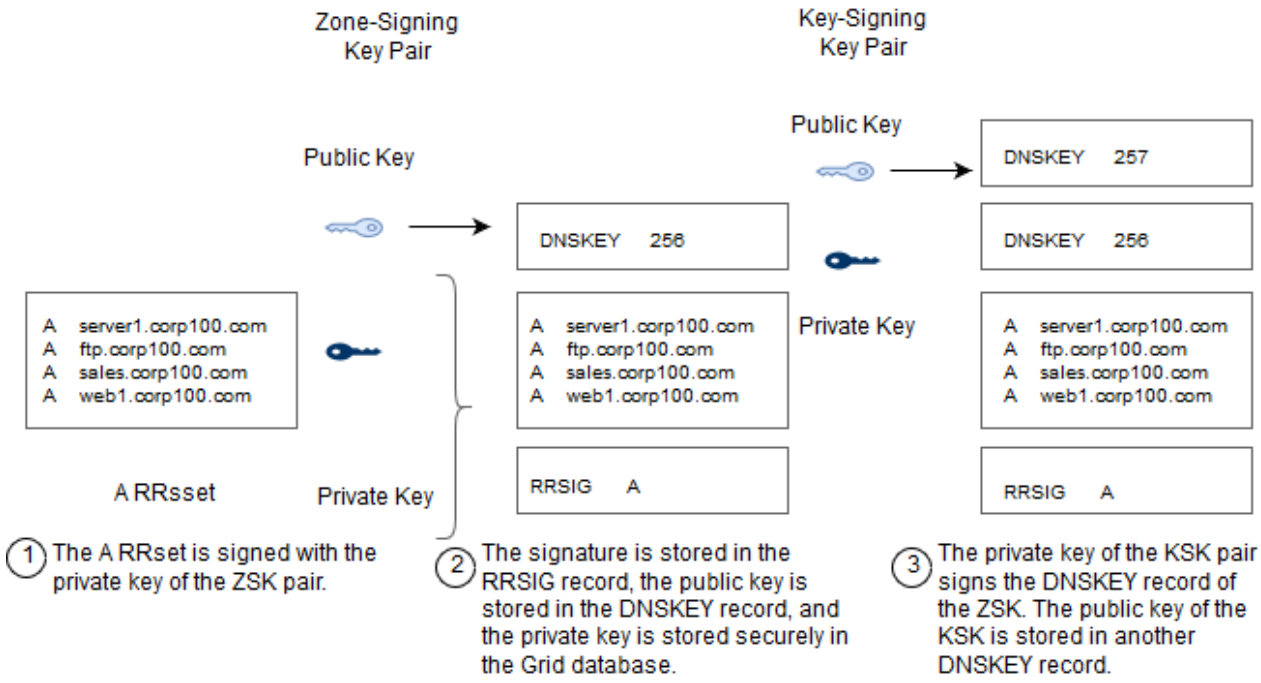
- **Published Key**: Indicates the time when the published key is used to resign a zone.
- **Rolled Key**: Indicates the time when a rolled key is deleted. Rolled keys are stored for quite a long period of time and are not used. You can manually cleanup the rolled keys.

3. Click the Delete icon.

Signing a Zone

When it signs a zone, the Grid Master generates new DNSKEY key pairs. As shown in the below figure, it uses the private key of the ZSK to sign the authoritative RRsets in the zone, and stores the corresponding public key in a DNSKEY record. It then uses the private key of the KSK to sign the DNSKEY records and stores the corresponding public key in another DNSKEY record. It stores the private keys in the Grid database and stores the public keys in the DNSKEY records in the database.

Zone Signing Process



The Grid Master also does the following:

- It inserts NSEC or NSEC3 records. The use of NSEC or NSEC3 records depends on the NSEC type you selected for the Grid or the zone. When you select NSEC3, the Grid Master uses NSEC3 records in signed zones.
- It increments the SOA serial number and notifies the secondary servers that there is a change to its zone data. When the secondary servers check the serial number and see that it has been incremented, the secondary servers request a zone transfer.
- If the TTL of an RR in the zone exceeds the ZSK grace period, the Grid Master reduces the TTL to the ZSK grace period. (For information about the grace period, see *About Key Rollovers*.) Setting a TTL value that exceeds half of the rollover period is not allowed.
- If the KSK rollover period is less than the ZSK rollover period, the Grid Master sets the TTL of the DNSKEY RR to the KSK rollover period.
- The appliance sets the Grid Master as the primary server for zones, enables DNSSEC on the Grid Master, and starts DNS service on the Grid Master.

When it signs a subzone, the Grid Master automatically inserts DS records for parent zones that are hosted by Grid members. The appliance allows you to sign a single zone or multiple zones simultaneously. For example, if you have multiple zones that are due for rollover at the same time, you can select all such zones and sign them at once. Note that each operation is independent of the other. For example, if you want to sign five zones at the same time, and if one of the zones fails during this time, NIOS signs the remaining four zones. Note that the selected zones must have an associated

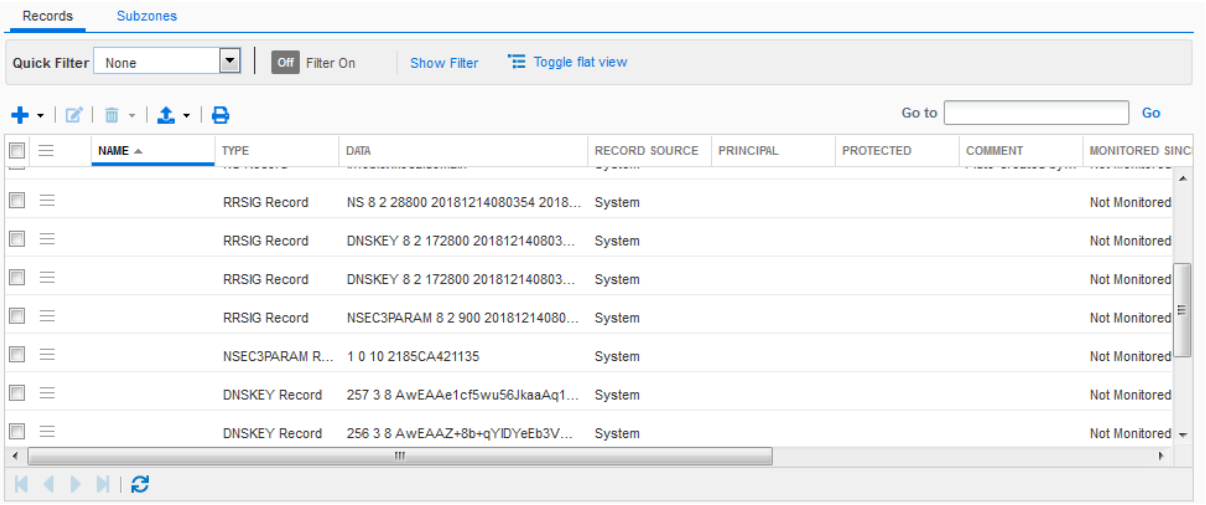
primary server. The appliance displays an error message if the zone does not have a primary server. When the sign operation fails, the appliance displays the zone names, associated DNS views, and the error message indicating the reason for failure.
To sign a zone:

1. From the **Data Management** tab, select the **DNS** tab.
2. Expand the Toolbar and click **DNSSEC** -> **Sign Zones**.
3. In the *Sign Zones* dialog box, the displayed zone name can either be the last selected zone or the zone from which you are signing. If no zone name is displayed or if you want to select a different zone, click the Add icon. The appliance displays unsigned zones only. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Select a zone. To add multiple zones, click the Add icon and select a zone.
   You can click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, either select **Now** or select **Later** and enter a date, time, and time zone. For information, see *Scheduling Tasks.*
4. After you have selected the zones, click **Sign Zones**.
5. When the confirmation dialog displays, click **Yes**.

When you sign multiple zones, the appliance displays generic error messages for the following cases:

- The value to which the resource record TTL is reduced is not displayed.
- The appliance displays a message about name server group disassociation if at least one zone is associated with a name server group. It will not list the affected zones.
- When you sign a zone or multiple zones, the appliance displays a warning message indicating that the operation might take a longer time.
- The appliance displays an error message if the number of characters in the zone name, which you want to sign, exceeds 180 characters. You can sign a zone only when the name of the zone is less than 180 characters in size.

To remove a zone from the list, select the checkbox adjacent to the respective zone and click the Delete icon. To view the records of the signed zone, from the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone*. Expand the Records section to list the RRs of the zone, as shown in the below figure.



Managing Signed Zones

After you sign a zone, you can do the following:

- You can add a DS RR at the delegation point for a signed subzone when the subzone is hosted on a non-Infoblox DNS server or an Infoblox server that is part of a different Grid. For information, see Importing a Keyset below.
- Trust anchors can be specified as DNSKEY RRs, DS RRs, and as a BIND trusted-keys statement. You can export any of these as trust anchors. For information, see Exporting Trust Anchors below.
- You must change the KSK periodically, to ensure its security. For information, see Checking Key-Signing Keys and Rolling Key-Signing Keys below.
- You can initiate ZSK rollovers manually. For information, see Rolling Zone-Signing Keys below.

- If, for any reason, the security of the keys are compromised, you can delete a key and perform a manual rollover. For information, see Configuring Emergency KSK Rollover below.
  Note that when you re-sign a zone, the Grid Master generates new ZSK and KSK pairs. You must send the new DNSKEY of the KSK to resolvers that use it as a trust anchor and generate new DS records and send them to the parent zones.
- You can move a signed zone to the Recycle Bin, from where you can delete it permanently or restore it. For information, see Deleting and Restoring Signed Zones below.

In addition, signed zones can accept dynamic DNS updates. For information about configuring zones to accept dynamic DNS updates, see *Configuring DNS Servers for DDNS*.

Importing a Keyset

A keyset is a DS RRset, or a DNSKEY RRset which is used as input to generate the DS RRset. To import a keyset:

1. From the **Data Management** tab, select the **DNS** tab.
2. Expand the Toolbar and click **DNSSEC** -> **Import Keyset**.
3. In the *Import Keyset* dialog box, the displayed zone name can either be the last selected zone or the zone from which you are importing the keyset. If no zone name is displayed or if you want to select a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box from which you can select a zone.
4. Paste the KSK or DS record being imported. It must be a KSK or DS record, and must belong to an immediate subzone of the zone to which the record is being imported.
5. Click **Import**.

If you imported a DNSKEY RRset, the Grid Master uses the SHA-1 algorithm to generate the DS RRset, which it adds to the parent zone. If you imported a DS RRset, the Grid Master adds it to the parent zone. The Grid Master incrementally signs the DS RRset.

Exporting Trust Anchors

A trust anchor is a DNSSEC public key which is used by security-aware resolvers as the starting point for establishing authentication chains. A trust anchor can be specified as a DNSKEY RR or a DS RR, which contains the hash of a DNSKEY RR and can also be used to create a secure delegation point for a signed subzone in DNS servers.
In BIND, trust anchors are configured using the trusted-keys directive. A trusted key is a DNSKEY RR without the TTL, class and RR type. You can export the trust anchors for the selected zone in a format that can be used in a BIND trusted-keys directive. Exporting trust anchors supports multiple algorithms, which means you can export all the algorithms in a key.
To export trust anchors:

1. From the **Data Management** tab, select the **DNS** tab.
2. Expand the Toolbar and click **DNSSEC** -> **Export Trust Anchors**.
3. In the *Export Trust Anchors* dialog box, do the following:
   - The displayed zone name can either be the last selected zone or the zone from which you are exporting trust anchors. If no zone name is displayed or if you want to select a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box from which you can select one.
   - Select one of the following: **DNSKEY records**, **DS records**, or **BIND trusted-keys statement**.
4. Click **Export**.
5. Specify the location of the exported file and click **OK**.

If you exported DS records, the exported file contains DS records that use the SHA-1 and SHA-256 algorithms.

Checking Key-Signing Keys

To check which key-signing keys are overdue for a rollover or are due to roll over within a week:

1. From the **Data Management** tab, select the **DNS** tab.
2. Expand the Toolbar and click **DNSSEC** -> **Check KSK Rollover Due**.

3. The *KSK Rollover Due* dialog box lists the key-signing keys that are due to rollover. It includes the domain name of the zone, DNS view (if there are multiple DNS views), and the number of days until the rollover.
4. You can click the Schedule icon at the top of the wizard to schedule a KSK rollover for one or more zones at a given date and time. In the *Schedule Change* panel, either select **Now** or select **Later** and enter a date, time, and time zone. For information, see *Scheduling Tasks*.
5. Click **Close**.

Rolling Key-Signing Keys

You can initiate a rollover before or after a rollover period, or when you need to replace the KSK for security reasons. You can initiate a KSK rollover several times simultaneously, but note that the number of keys will increase each time you perform a rollover. You can schedule the KSK rollover to occur at a later date and time.
To roll over key-signing keys:

1. From the **Data Management** tab, select the **DNS** tab.
2. Expand the Toolbar and click **DNSSEC** -> **Roll Over Key-Signing Key**.
3. In the *Roll Over Key-Signing Key* dialog box, the displayed zone name can either be the last selected zone or the zone from which you are rolling over key-signing keys. If no zone name is displayed or if you want to select a different zone, click the Add icon. The appliance displays signed zones only. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. To add multiple zones, click the Add icon and select a zone. You can click the Schedule icon at the top of the wizard to schedule a KSK rollover for one or more zones at a given date and time. In the *Schedule Change* panel, either select **Now** or select **Later** and enter a date, time, and time zone. For information, see *Scheduling Tasks.* Note that you cannot schedule the KSK rollover on a recurring basis.
4. Click **Roll Over**.

You can export the new KSK and send it to the security-aware resolvers that use it as a trust anchor. To remove a zone from the list, select the checkbox adjacent to the respective zone and click the Delete icon.

Rolling Zone-Signing Keys

Only an administrator can initiate ZSK rollovers either before or after a rollover period, or when you want to replace the ZSK for security reasons. You can initiate a ZSK rollover several times simultaneously, but note that the number of keys will increase each time you perform a rollover.
To roll over zone-signing keys:

1. From the **Data Management** tab, select the **DNS** tab.
2. Expand the Toolbar and click **DNSSEC** -> **Roll Over Zone-Signing Key**.
3. In the *Roll Over Zone-Signing Key* dialog box, the displayed zone name can either be the last selected zone or the zone from which you are rolling over zone-signing keys. If no zone name is displayed or if you want to select a different zone, click the Add icon. The appliance displays unsigned zones only. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. To add multiple zones, click the Add icon and select a zone. You can click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, either select **Now** or select **Later** and enter a date, time, and time zone. For information, see *Scheduling Tasks.*
4. Click **Roll Over**.

To remove a zone from the list, select the checkbox adjacent to the respective zone and click the Delete icon. The appliance displays warning messages when the changes take effect on the first zone or when the rollover occurs. You cannot change the zone-signing key rollover method while the previous change is still in progress. The previous change will be completed only when the zone active key, which is active when the rollover method is changing, expires and is deleted.

Best Practices for Configuring Zone Signing Keys

Infoblox recommends that you use the pre-publish option for zone signing key method for the following reasons:

- The double-signature ZSK rollover doubles the number of signatures in your zone when a rollover is in progress. The size of the zone increases due to the duplicate signature records. This is not recommended if the size of your

zones are large. When you select this option, the appliance creates a new set of signatures for all the resource records. This also increases the database usage.

- When you select to pre-publish key rollover, the rollover uses a single key to sign the records at a given time and it does not sign the zone data twice. The appliance publishes the new key in the keyset even before the actual rollover. This reduces the database usage.

Unsigning a Zone

When you unsign a zone, the Grid Master permanently removes all automatically generated DNSSEC records in the zone and parent zone. It does not remove any DS records associated with a child zone. You can unsign a single zone or multiple zones at the same time.
To unsign a zone:

1. From the **Data Management** tab, select the **DNS** tab.
2. Expand the Toolbar and click **DNSSEC** -> **Unsign Zones**.
3. In the *Unsign Zones* dialog box, the displayed zone name can either be the last selected zone or the zone from which you are unsigning. If no zone name is displayed or if you want to select a different zone, click the Add icon. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. The appliance displays signed zones only. Select a zone. To add multiple zones, click the Add icon and select a zone.
   You can click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, either select **Now** and click **Save** or select **Later** and enter a date, time, and time zone. For information, see *Scheduling Tasks.*
4. After you have selected the zones, click **Unsign Zones.**
5. When the confirmation dialog displays, click **Yes**.

To remove a zone from the list, select the checkbox adjacent to the respective zone and click the Delete icon.

Deleting and Restoring Signed Zones

When you delete a signed zone, the Grid Master unsigns the zone before moving it to the Recycle Bin. Unsigning the zone effectively deletes all auto-generated DNSSEC RRs; only user-defined DS records are retained and moved to the Recycle Bin as well. The Grid Master also retains the ZSK and KSK in its database, until you permanently delete the zone from the Recycle Bin.
When you restore a signed zone, the Grid Master restores it and re-signs its data sets with the original keys, which are also restored. You can also restore the user-defined DS records. The rollover period of the ZSK and KSK starts when the zone is signed after it is restored. Note that when you restore a zone that contains rolled keys, either KSK or ZSK, the appliance removes all these rolled keys.
Note that when you restore a deleted zone from recycle bin on the NIOS server, which is created and signed on the Microsoft Server 2012, then all the DNSSEC records will be deleted, except for the DNSKEY records. The DNSKEY records will only be resynchronized. The DNSSEC records are read-only and cannot be regenerated using NIOS. You must recreate the zone manually on the Microsoft Server. When you recreate the zone on the Microsoft Server, new keys will be generated. The signed zone, which is restored, and the DNSSEC keys are synced to Microsoft Server. This zone will be seen as an unsigned zone on the Microsoft Server, as NIOS does not trigger the signing zone request for the corresponding zone. For such zones, the 'DNSSEC' label is not displayed and the value for 'Signed' column is 'No'.
To delete a signed zone:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab.
2. Click the checkbox of the zone you want to delete.
3. Click the Delete icon.
4. Click **Yes** to confirm the deletion.

To restore a signed zone:

1. In the *Finder* panel, expand **Recycle Bin**.
2. Select the zone you want to restore.
3. Click the Restore icon.

Configuring Automatic KSK Rollovers and Notifications

You can configure automatic KSK rollovers at the Grid level and override the settings at the zone level. You can also configure notifications for KSK rollovers. The appliance sends one notification, SNMP, or email, or both based on the selection, for each event. For example, if the KSK of two zones are rolled over in the same batch, the appliance sends two notifications, one for each zone. Note that the appliance sends these notifications only once, and they are not recurring. Apart from the notifications that you receive, Grid Manager also displays a banner when you log in to the Grid indicating that the KSK rollover is due within the next seven days.
These notifications are not applicable to an ZSK, as the ZSK rollover is an automated process. The appliance generates numerous notifications.
To configure KSK rollover, complete the following:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab. Expand the Toolbar and click **Grid DNS Properties**.
   Zone: From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and click the Edit icon. Click **Override** to override the values at the zone level.
   Standalone appliance: From the **Data Management** tab, select the **DNS** tab. Expand the Toolbar and click **System DNS Properties**.
2. Select the **DNSSEC** tab and complete the following in the **Basic** tab:
   - KSK Notification Configuration: You can choose to receive notifications for KSK rollover events.
     - **No Notifications**: Select this if you do not want to receive any notifications for KSK rollover events.
     - **Notifications for all KSK rollover events**: Select this if you want to receive notifications for all KSK rollover events. The appliance sends notifications after the rollover.
     - **Notifications only for KSK rollover events requiring manual DS update to parent zone**: Select this if you want to receive notifications only for KSK rollover events that require manual DS updates to parent zone. This is selected by default.
     - **Enable KSK Email Notification**: Select this to receive email notifications about DNSSEC keys.
     - **Enable KSK SNMP Notification**: Select this to receive SNMP trap alerts about DNSSEC keys.
3. **Enable automatic KSK rollover:** This is selected by default. When you select this option, the appliance will automatically roll over KSKs when they are due. The appliance starts the rollover process at most six hours after the due date. The appliance logs the messages in the syslog.
   Note that the appliance enables notifications and automatic KSK rollover by default for NIOS 6.11.0 and later releases.
   These are not available for earlier releases. Similar to automatic ZSK rollover, the appliance automatically restarts the DNS service after a KSK is rolled over.
4. Save the configuration.

Configuring NSEC3 Salt Length and Hashing Iterations

The salt is a random string, which is appended to the domain name before it gets hashed. The number of iterations indicates the number of additional times the hashing occurs. These serve as a protection against dictionary attacks. The appliance generates a new salt for initial signing and changes it every time a ZSK rollover occurs. Note that when you use a longer salt and higher number of iterations, DNS is more secure and the chances of dictionary attacks on NSEC3 are reduced.
You can choose the minimum and the maximum salt length at the Grid level and override them at the zone level. Note that the length of the salt has an impact on the size of the NSEC3 record, but it does not have an impact on the performance of the appliance.
When the number of iterations increases, the DNS client has to validate a additional data and the cost of the DNS server to serve the zone increases. This might also reduce the performance of the system with regards to DNSSEC operations.
To define salt length and hashing iterations, complete the following:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab. Expand the Toolbar and click **Grid DNS Properties**.
   Zone: From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and click the Edit icon. Click **Override** to override the parameters.
   Standalone appliance: From the **Data Management** tab, select the **DNS** tab. Expand the Toolbar and click **System DNS Properties**.
2. Select the **DNSSEC** tab and complete the following in the **Basic** tab:

- **Zone-signing Key Settings**

- **NSEC3 Salt Length**: Specify a minimum and maximum length for NSEC3 salt. The minimum length is one octet and the maximum length is 255 octets. The appliance sets the following default values for minimum and maximum lengths respectively: one and 15 octets.
- **Number of NSEC3 hashing iterations**: The appliance uses the default value, ten, for hashing iterations. The minimum value is ten and the maximum value depends on the smallest key size, as defined in RFC 5155 as follows:
    - 150 if the key size is equal or less than 1024 bits.
    - 500 if the key size is equal or less than 2048 bits.
    - 2,500 if the key size is equal or less than 4096 bits.

> ⚠ Note
> The above fields are displayed only when you select NSEC3 record type.

Deleting Server Keys

The appliance retains the key until the expiration of the grace period. For example, if the validity period of a KSK is two years, you can delete the rolled key after publishing the DS record to the parent zone and waiting for a period greater than its TTL.
The following rules are valid for KSK and ZSK signing using the double-signature scheme:

- You cannot delete an active key.
- When you delete a rolled key, the appliance displays a warning message indicating that it might break validation on clients.

The following rules are valid for ZSK signing using the pre-publish scheme:

- You cannot delete an active key.
- When you delete a pre-published key, the appliance generates a new pre-published key.
- You can delete a rolled key. The appliance deletes this key as it is no longer used.

When you use an HSM, the appliance does not delete the key from HSM. For more information, see *About HSM Signing*.

Configuring Emergency KSK Rollover

The appliance supports emergency rollover that can be used when the keys are compromised. In an emergency operation, you must delete the compromised key and the associated compromised data from the zone. The ability to perform emergency rollovers enable administrators to react quickly when a zone is compromised. To initiate an emergency rollover, you must first perform a manual rollover. For information about rolling over a KSK manually, see Rolling Key-Signing Keys below. After the rollover, you must delete the compromised key. For information about deleting the compromised key, see Deleting Server Keys below.
An emergency KSK rollover involves the following:

- The administrator of the compromised zone, which is hosted on the Infoblox appliance, must initiate the emergency KSK rollover and later export the corresponding DS record.
- The administrator of the parent zone, which is hosted on an external server, must import the DS record of the child zone. This is required to maintain the chain of trust.

During this emergency procedure, the chain of trust is temporarily broken. As stated in RFC 6781, the effect depends on the order of the operations:

- You must perform the KSK rollover first. The chain of trust is broken until the administrator of the parent zone replaces the DS record. In the meantime, the zone appears bogus to a validating client.
- You must remove the compromised DS record first. The chain of trust is broken until the NIOS administrator performs the KSK rollover, communicates the new DS record to the administrator of the parent zone who then adds it. In the meantime, the zone appears insecure to validating resolvers.

Handling Error and Warning Messages for DNSSEC Operations

Grid Manager consolidates warnings from one or more DNSSEC long running operations and displays them in a single dialog box. For more information about long running tasks, see *About Long Running Tasks*. When the long running operations are completed with warnings, the appliance displays the message using a yellow banner at the top of Grid Manager. Click **Show Warnings** to view the warnings that are generated by the server for DNSSEC operations. Click **Close** to close the warning dialog box.
The appliance also displays a warning icon in the **Execution Status** column of the **Task Manager.** For more information about the task manager, see *Viewing Tasks*. When you click the icon, the appliance displays a dialog box indicating that the task is complete with warnings. Click the **show task details** hyperlink to view detailed information about the error or warning message. The appliance displays *Scheduled Task Details* wizard in which you can view the task details and error or warning messages, if any. For more information, see *Viewing Scheduled Tasks*. The appliance clears the warning messages from the cache when you close the dialog box.
When a DNSSEC operation fails, NIOS saves the messages in the syslog. For more information about the syslog, see *Using a Syslog Server*.

Viewing Scheduled Tasks

You can view the status of operations that are scheduled. The appliance also displays error or warning messages, if any. For example, if you schedule the **Sign Zones** operation for multiple zones, there is a possibility that some operations may fail, some may succeed with warnings, and some are completed successfully. You can also view the error or warning messages that are generated for certain affected zones. To view the status:

1. From the **Administration** tab, select the **Workflow** tab -> **Task Manager** tab.
2. Grid Manager displays the DNSSEC operations that are scheduled. To view the details you can either click the Action icon

   next to the task ID and select **View** from the menu or select the checkbox adjacent to the Action icon and then click **View** from the Toolbar.
3. The **General** tab of the *Scheduled Task Details* wizard displays the following details:
   - **Task ID**: The ID associated with the task. The appliance assigns an ID to a task in chronological order. By default, the appliance sorts tasks by **Task ID**.
   - **Action Type**: The operation the appliance performs in this task.
   - **Submitter**: The username of the admin who scheduled or submitted the task.
   - **Submitted Time**: The date, time, and time zone when the task was submitted.
   - **Ticket Number**: For an approval workflow, this number may be entered by the submitter to associate the task with a help desk ticket number or a reference number.
   - **Approver**: The username of the admin who has approved this task.
   - **Approver Comments**: Comments entered by the approver.
   - **Executed on Member**: The Grid member on which the task is executed.
   - **Execution Status**: The execution status of the task. Possible values are **Completed**, **Failed**, **Pending**, and **Executing**.
   - **Execution Time**: The date, time, and time zone when the task was executed.
   - **Affected Objects**: The name of the object and object type.
4. The **Warnings/Errors** tab of the *Scheduled Task Details* wizard displays error or warning messages related to tasks. It also displays object execution details. This table is blank if there are no error messages or warnings. You can view the error message and the name of the zone with which the error or warning message is associated.
5. Click **Close** to close the dialog box.

About HSM Signing

You can integrate a Grid with third-party, network-attached Hardware Security Modules (HSMs) for secure private key storage and generation, and zone-signing off-loading. Infoblox appliances support integration with either Thales Luna HSMs or Entrust nShield HSMs. When using a network-attached HSM, you can provide tight physical access control, allowing only selected security personnel to physically access the HSM that stores the DNSSEC keys. When you enable this feature, the HSM performs DNSSEC zone signing, key generation, and key safe keeping.
Note that if you migrate from using the Grid Master to HSMs, HSM signing starts at the next key rollover. Only a superuser can configure this feature. To configure HSM signing in a Grid, do the following:

1. Create the HSM group and add HSMs to the group. You can create either a Thales Luna HSM group or an Entrust nShield HSM group. You can use only one group at a time. After you add the HSM group, the Add icon and Add button in the Toolbar are greyed out.
    - For information on adding a Thales Luna HSM group, see Configuring a Thales Luna HSM Device below.
    - For information on adding an Entrust nShield HSM group, see Adding and Managing an Entrust nShield HSM Group below.

Note that if you delete an HSM or an HSM group, it is permanently deleted. It is not stored in the Recycle Bin.

2. Enable HSM signing. For information, see Enabling HSM Signing below.

After you enable this feature, you can monitor the HSM group, as described in Monitoring the HSM Group below. In addition, the Grid sends SNMP traps when zone signing succeeds or fails. For information about these traps, see *Processing and Software Failure Traps*.
Note that NIOS does not provide key life cycle management functions; these are handled by the HSM and must be configured via the HSM's administrative interface to adhere to corporate policies on key management. The keys (ZSK and KSK) used for DNSSEC are stored securely on the HSM and are not deleted by NIOS when the key is no longer required by the DNSSEC function. However, references to the keys are removed from the appliance.

Configuring a Thales Luna HSM Device

You can integrate a Grid with a Thales Luna HSM group. The Thales Luna HSM group can contain either Thales Luna 4, Luna 5, or Luna 6 devices in standalone or HA mode; the group cannot contain a mix of both models. You must first configure each HSM device, and then create the group and add the devices to the group, as described in Adding a Thales Luna HSM Group below.

Configuring a Thales Luna HSM Device

Do the following for each Thales Luna HSM device that you are adding to the group:

1. On the Grid, generate a client certificate for the Grid Master and Grid Master Candidate. For information, see *About Client Certificates*. If you are upgrading the Thales Luna HSM from Luna 5 or 6 to Luna 7 CPL, you must generate a new client certificate.
2. On the Thales Luna HSM, do the following:
    - Assign the Grid Master and Grid Master Candidate to a partition on the HSM to avoid any service interruptions, in case the Grid Master Candidate is promoted to Grid Master.
    - Upload the certificates of the Grid Master and Grid Master Candidate to the HSM and register the certificates in the HSM's list of clients. The certificates of the Grid Master and Grid Master Candidate are linked to their IP addresses. Therefore, if any of their IP addresses change, you must generate a new client certificate and register it with the HSM.
      Note that if the HSM is configured and you replace an appliance that was a Grid Master or Grid Master Candidate and you backed up the database of the old appliance and restored it on the replacement appliance, the certificates remain intact. Therefore, you do not need to regenerate a new certificate for the replacement, as long as the IP address does not change.
    - If you are upgrading from a previous version of Thales Luna HSM to a later version, such as from Luna 6 to Luna 7 CPL, you must complete the following before adding the new Luna configuration to NIOS:
        - Remove the previous certificate registration from the HSM server and then re-register the Grid Master and Grid Master Candidate certificates.
        - Generate a new HSM certificate if you want to retain the current IP settings for the Grid Master.
    - Download the HSM certificate.

⚠ Note
- Make sure that the common name used in the certificates is distinct when you configure HSM servers in HA mode.
- To configure Thales Luna on an HA pair, add a static route with the virtual IP address of the Grid to the HSM server.

For additional information, refer to your Thales Luna HSM documentation.

Adding a Thales Luna HSM Group

When you configure a Thales Luna HSM group, add the Thales Luna HSM devices to the group and upload their certificates to the Grid. You can add only one HSM group. To add a Thales Luna HSM Group:

1. From the **Grid** tab, select the **HSM Group** tab.
2. Click the Add drop-down list and select **Thales Luna Group**.
3. In the *Add Thales Luna Group* wizard, complete the following and click **Next**:
    - **Name:** Enter a name for the HSM group.
    - **Partition Password:** Enter the partition password, and re-enter it in the **Confirm Partition Password** field.
    - **Version:** Select the Thales Luna HSM version, which is either **Luna 4**, **Luna 5**, **Luna 6**, or **Luna 7 CPL**.
    - **Comment:** You can enter additional information about the HSM.
4. Click the Add icon to add a Thales Luna HSM device, and complete the following:
    - **Name or IP Address:** Enter the hostname or IP address of the HSM device.
    - **Partition SN:** Enter the partition serial number (PSN) of the HSM. The **Partition ID** field automatically displays the ID after the configuration is saved and the appliance has successfully connected to the device.
    - **Disabled:** Select this checkbox to disable use of this HSM.
    - **Server Certificate:** Upload the certificate of the Thales Luna HSM.
5. Save the configuration.

After you add the HSM group, the Add icon and Add button in the Toolbar are greyed out. Note that if the HSM is configured in FIPS 140-2 compliant mode, certain key algorithms and key sizes are disallowed. Requests for those key algorithms or key sizes result in an error. The following algorithms are FIPS 140-2 compliant: DSA, DSA/NSEC3, RSA/SHA1, RSA/SHA1/NSEC3, RSA/SHA-256, and RSA/SHA-512. For additional information about selecting key algorithms, see *About the DNSKEY Algorithm*.
You can verify whether the Grid Master Candidate is properly registered with the HSM by navigating to the **Grid** -> **Grid Manager** -> **Members** page. It's Status icon is yellow if it is not registered with the HSM.
If DNS service is enabled, you can also verify whether the Grid Master was able to contact the Thales Luna HSMs by navigating to the **Data Management** > **DNS** > **Members** page. If the Grid Master status is yellow, check the status of the HSMs in the **Grid** > **HSM Group** page. (For more information, see Monitoring the HSM Group below.) If the status is not green, check the configuration of the HSMs and restart the DNS service.

Adding and Managing an Entrust nShield HSM Group

On the Entrust nShield HSM, configure the Grid Master and Grid Master Candidate as HSM clients. Enroll the IP addresses of both the Grid Master and Grid Master Candidate to avoid any service interruptions, in case the Grid Master Candidate is promoted to Grid Master. If the Grid Master and Grid Master Candidates are HA pairs, you must enroll their VIPs.

> ⚠ Note
> In the unlikely event that the Grid Master Candidate was registered with the Entrust nShield HSM after the Grid Master promotion, you must restart the DNS service on the newly promoted Grid Master.

In addition, you must also set up client cooperation to allow both the Grid Master and Grid Master Candidate access to the Remote File Server (RFS). Note that anytime you add a new Grid Master Candidate, you must enroll its IP address and set up a client cooperation to allow it access to the RFS. For more information on these procedures, refer to your HSM documentation.
Note that DSA cannot be used as the DNSSEC cryptographic algorithm for Entrust nShield HSMs. Therefore, migrating to Entrust nShield HSMs is not allowed if the Grid Master uses DSA as the DNSSEC cryptographic algorithm.
You can create one Entrust nShield HSM group in the Grid, and then add HSMs to the group. The appliance tries to connect to each of the HSMs in the order that they are listed.
To add an Entrust nShield HSM group:

1. From the **Grid** tab, select the **HSM Group** tab and click the Add icon.
2. In the **Add HSM Group** wizard complete the following, and then click **Next**:
    - **Name:** Enter a name for the HSM group.
    - **Protection:** Select the level of protection that the HSM group uses for the DNSSEC key data.

        - **Module:** Select this if the HSM group uses a module-protected key. You do not have to enter a password phrase for this type of key.
        - **Softcard:** Select this if the HSM group uses a softcard-protected key. You must then specify the card name and password.
    - **Card Name:** Enter a name for the softcard.
    - **Password Phrase:** Enter the password and re-enter it in the **Confirm Password Phrase** field.
    - **RFS IP Address:** Enter the remote file server (RFS) IP address. Note that you must ensure that you enter a valid RFS IP address for the Security World. Validation is limited to IP address checking. Infoblox recommends that you use **Test HSM Group** to check the HSM group configuration before proceeding.
    - **RFS Port:** Specify the port of the RFS.
    - **Comment:** Optionally, enter additional information about the group.
3. To add modules to the group, click the Add icon and complete the following:
    - **Remote IP:** Enter the IP address of the HSM.
    - **Remote Port:** Specify the destination port on the HSM. The firewall must be configured to allow connection to this port.
    - **Disabled:** Select this checkbox to disable use of this HSM.
    - **Keyhash:** Enter the keyhash, which is displayed on the console of the HSM. It can be obtained through an out of band mechanism from the HSM administrator. Note that the appliance validates the keyhash. If the entry is correct, the appliance displays the Electronic Serial Number (ESN) of the HSM when the editor is next launched. If the keyhash is incorrect, the appliance does not connect to the HSM.
    - **ESN:** This is a read-only field that displays the ESN of the HSM after you save the configuration and relaunch the editor. Infoblox strongly recommends that you verify the ESN displayed by the appliance with the one obtained from the HSM administrator to ensure that the appliance is communicating with the correct HSM.
4. Save the configuration.

Monitoring the HSM Group

You can monitor the status of the HSM group and of individual modules in the group by navigating to the **Grid** tab > **HSM Group** panel. To view the status of each HSM, click the arrow beside the group name. This panel displays the following information:

- **Name:** The name of the HSM group or module.
- **Status:** The HSM group status displays the status for all the HSMs in the group. The status icon can be one of the following:
  Green: All the HSMs in the group are functioning properly.
  Yellow: At least one HSM in the group is not functioning properly.
  Red: All the HSMs in the group are not functioning properly.
  Black: The status of the HSM devices is unknown.

  The status icon for each HSM can be one of the following:
  Green: The HSM is functioning properly. For Thales Luna 5 or 6 devices, the status icon can also display ***x*%used** which refers to the storage capacity of the HSM partition that is assigned to the Grid. Note that when the capacity reaches 100%, new zone signings and key rollovers for existing zones cannot be performed.
  Red: The HSM is not functioning properly. For a Thales Luna HSM, this indicates that the Grid Master was able to connect to the HSM, but no partition was assigned to the Grid Master.
  Black: The status of the HSM device is unknown.
- **FIPS:** This applies to a Thales Luna HSM only. It indicates if the HSM is in FIPS compliant mode.
- **Comment:** Any comments that were entered about the HSM group.

You can also do the following in this tab:

- Sort the data in ascending or descending order by column.
- Print and export the data in this tab.

Enabling HSM Signing

When you enable HSM signing, the HSM starts generating the DNSSEC keys at the next key rollover. For information about key rollovers, see *About Key Rollovers*. You can enable this feature at the Grid level only.
To enable HSM signing:

1. From the **Data Management** tab -> **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
2. In the *Grid DNS Properties* editor, Click **Toggle Advanced Mode**, if the editor is in Basic mode, and then select the **DNSSEC** tab.
3. In the **DNSSEC** tab, select the **Enable DNSSEC** checkbox, if it is not selected, and then select the **Enable HSM Signing** checkbox.
4. Complete the other fields described in *Configuring DNSSEC Parameters*. Note that Entrust nShield HSMs do not support DSA.
5. Save the configuration.

Testing the HSM Group

After you configure the HSM group, you can test the HSM signing functionality of the group. Click **Test HSM Group** in the Toolbar, and then click **Yes** when the confirmation dialog displays. The appliance then executes the command to perform a signing test. The feedback panel displays the status of the test in the Grid Manager feedback panel.

Synchronizing the HSM Group

You can click **Resync HSM Group** in the Toolbar to do any of the following:

- For an Entrust nShield HSM group, if the RFS security settings change use this function to have the appliance perform an RFS synchronization.
- For a Thales Luna HSM group, use this function to synchronize the keys of the HSM members in the group.

Configuring Grid Members to Support DNSSEC as Secondary Servers

Any Infoblox Grid member can function as a secondary server for DNSSEC signed zones. It can receive transfers of signed zones from the Grid Master or an external primary server, and from other secondary servers. It can also respond to queries for DNS data in DNSSEC signed zones for which it is a secondary server.

Configuring a Secondary Server for Signed Zones

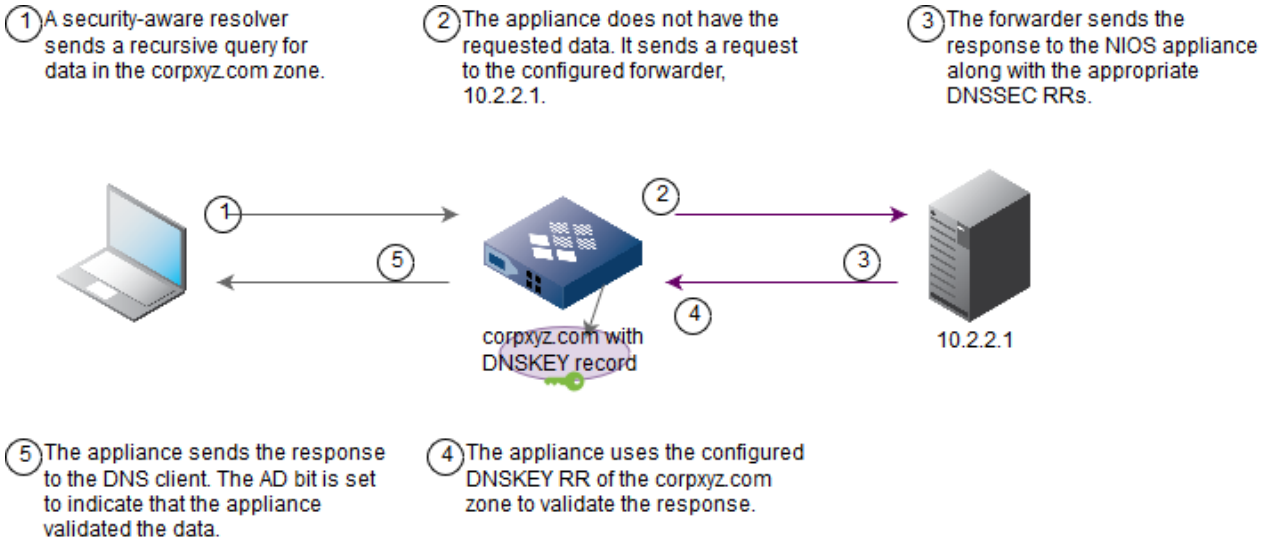
The following are the tasks to configure an appliance as a secondary server for signed zones:

1. Enable DNSSEC on the appliance. For information, see *Enabling DNSSEC*.
2. Configure the appliance as a secondary server for the zone. For information, see *Specifying Secondary Servers*.If the primary server for the signed zone is external, then you must allow zone transfers to the secondary server.
3. For information, see *Enabling Zone Transfers.* If the primary server is the Grid Master, then the secondary server receives data through the Grid replication process by default.

Configuring Recursion and Validation for Signed Zones

When you enable recursion on a Grid member and it receives a recursive query for DNS data it does not have, it queries remote name servers that you specified in the *Grid DNS Properties* or *Member DNS Properties* editor. It then includes the DNSSEC data it retrieved through recursion in its responses to clients that requested DNSSEC RRs. You can enable the appliance to validate the responses of these servers for certain zones. On the appliance, you specify the zones to validate and configure their DNSKEY records as trust anchors. When the appliance validates a response for a zone configured with a trust anchor or for any of its child zones, the appliance starts with the DNSKEY that you configured and proceeds recursively down the DNS tree.
In the example shown in the below figure, the following was configured on the NIOS appliance:

- Forwarder with the following IP address: 10.2.2.1
- Recursion was enabled
- DNSSEC and validation were enabled
- The corpxyz.com zone and its DNSKEY record were configured



Enabling Recursion and Validation for Signed Zones

The following are the tasks to enable recursion and validate recursively derived data:

1. Enable DNSSEC on the appliance. For information, see *Enabling DNSSEC*.
2. Enable validation and configure the trust anchor of each signed zone. For information, see Enabling DNSSEC Validation below. You must configure at least one trusted DNSKEY RR.
3. Enable recursion on the appliance. For information, see *Enabling Recursive Queries*.
4. Complete any of the following:
   - Configure the forward, delegated, stub or root zones for the signed zones. For information, see *Configuring Delegated, Forward, and Stub Zones* and *Creating a Root Zone*.
   - Configure global forwarders and custom root name servers, if needed. For information, see *Using Forwarders* and *About Root Name Servers*.

Enabling DNSSEC Validation

To configure trust anchors and enable Infoblox name servers to validate responses:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab. Expand the Toolbar and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **Members** tab -> *member* checkbox and click the Edit icon.
   DNS View: From the **Data Management** tab, select the **Zones** tab -> *dns_view* checkbox and click the Edit icon.
   To override an inherited property, click **Override** next to the property to enable the configuration.
2. In the editor, click **Toggle Expert Mode**.
3. When the additional tabs appear, click **DNSSEC**.
4. In the **DNSSEC** tab, complete the following:
   - **Enable DNSSEC validation**: If you allow the appliance to respond to recursive queries, you can select this checkbox to enable the appliance to validate responses to recursive queries for domains that you specify. You must configure the DNSKEY RR of each domain that you specify.
   - **Accept expired signatures**: Click this checkbox to enable the appliance to accept responses with signatures that have expired. Though enabling this feature might be necessary to work temporarily with zones that have not had their signatures updated in a timely fashion, note that it could also increase the vulnerability of your network to replay attacks.
   - **Trust Anchors**: Configure the DNSKEY record that holds the KSK as a trust anchor for each zone for which the Grid member returns validated data. Click the Add icon and complete the following:

- **Zone:** Enter the FQDN of the domain for which the member validates responses to recursive queries.
- **Secure Entry Point (SEP)**: This checkbox is enabled by default to indicate that you are configuring a KSK.
- **Responses must be secure**: Enable this checkbox to make all responses to domains configured with a trust anchor to be DNSSEC secure and valid. When you enable this checkbox, the appliance returns SERVFAIL responses for the domains that are not DNSSEC secure. Note that for each anchor, the current setting of **Responses must be secure** will be preserved when NIOS is upgraded.
- **Algorithm**: Select the algorithm of the DNSKEY record: **RSA/SHA1(5)**, **DSA (3)**, **DSA/NSEC3 (6)**, **RSA/MD5 (1)**, **RSA/SHA1/NSEC3 (7)**, **RSA/SHA-256 (8)**, **RSA-SHA-512 (10)**, **ECDSAP/SHA-256 (13)**, **or ECDSAP/SHA-384 (14)**. This must be the same algorithm that was used to generate the keys that were used to sign the zones.
- **Public Key**: Paste the key into this text box. You can use either of the following commands to retrieve the key:
  - `dig . dnskey +multiline`
    The above command retrieves root zone keys and is the only public key you require for full chain of trust validation.
  - `dig \[@server_address\] <zone> dnskey +multiline +dnssec`
    The above command retrieves public keys from the zone you specify on the server and can be used if the parent zone is not signed.
    Note that the aforementioned command provides you with a key you need to cross validate against other servers to ensure you have an identical key.
    As an alternative, you can use *http://data.iana.org/root-anchors/* to retrieve signed public keys. You can find the trust anchors in formats like XML and CSR. For more information, refer to *http://data.iana.org/root-anchors/*.
- **Negative Trust Anchors**: Configure negative trust anchors to suppress DNSSEC validation for certain domains. Click the Add icon to add the domain name to the list. You can define negative trust anchors at the Grid level and override them at the member and DNS view levels. For more information about negative trust anchors, see Defining Negative Trust Anchors below.
  To delete a negative trust anchor, select the checkbox adjacent to the **Zone** column and click the Delete icon.

5. Save the configuration and click **Restart** if it appears at the top of the screen.

Defining Negative Trust Anchors

A DNSSEC misconfiguration is not uncommon, and it can lead to failures in validating clients for particular domains. You can use negative trust anchors to enhance the deployment of DNSSEC validation even with misconfigured domains, as the administrator can enable DNSSEC validation without worrying about resolution failure for misconfigured signed domains that succeeds without DNSSEC validation.
A negative trust anchor is a domain name for which DNSSEC validation must be suppressed even if the domain name is listed under a trust anchor.
You can define a negative trust anchor at the Grid level and override it at the member and DNS view levels. You can define negative trust anchors within a view or at the Grid level. If you define it at both levels, only the configuration with the view will be effective for the respective view.
For any specific domain name, negative trust anchors are mutually exclusive of trusted anchors; if a negative trust anchor is specified for a domain name, you cannot configure a trust anchor using the same name. Likewise, if a trust anchor is configured for a domain name, you cannot configure negative trust anchor using the same name.
Note that if there is a trust anchor for a specific name under a negative trust anchor, that trust anchor will re-enable DNSSEC validation for query names covered by the trust anchor. For example, if you configure trust anchors for "." and "example.com," and "com" is in the negative trust anchor list, queries for "www.example.com" are subject to DNSSEC validation, while DNSSEC validation will be suppressed for www.insecure.com, even if "." is listed in the trust anchor.
The appliance does not support automatic cleanup of negative trust anchors, nor does it provide any information about their expiration. Administrators must manually keep track of the status of domains listed as a negative trust anchor, and must remove them from the list as soon as the domains become DNSSEC signed correctly. Infoblox recommends that you do not use negative trust anchors, and rather disable DNSSEC validation, if the administrator is not familiar with negative trust anchors or is not able to maintain the negative trust anchors properly; careless use of negative trust

anchors would rather hinder the deployment of DNSSEC, which is the opposite to the purpose of negative trust anchors. For more information about general technical details of negative trust anchors, refer to *http://tools.ietf.org/html/draft-livingood-negative-trust-anchors*.
Note the following about negative trust anchors:

- You must restart the DNS service when you modify the list of negative trust anchors.
- The appliance displays an error message if an entry is present in both the trust anchors and the negative trust anchors list for the same FQDN.
- The appliance displays an error message if the same FQDN is present multiple times in a negative trust anchor.
- When DNSSEC validation is suppressed due to a negative trust anchor, the corresponding response from the validating resolver does not include the AD bit.

Applying Policies and Rules to DNS Queries that Request DNSSEC Data

You can configure the NIOS appliance to always apply RPZ policies, DNS blacklists, or NXDOMAIN rules to DNS queries, regardless of whether the queries request DNSSEC data. You can also configure the appliance to generate synthesized AAAA records for DNS queries that request DNSSEC data.

> Warning
>
> *When you enable this feature, NIOS applies the selected policies and rules even when it responds to DNS clients that support DNSSEC.*
> *Note that responses to these clients may result in resolution failure. Infoblox recommends that you use caution when enabling this feature and DNSSEC validation at the same time.*

To enable this feature, complete the following:

1. **Grid:** From the **Data Management** tab, select the **DNS** tab. Expand the Toolbar and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox and click the Edit icon.
   DNS View: From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *default dns_view* and click the Edit icon.
2. In the editor, click **Toggle Expert Mode**, if the editor is in Basic mode, and then select the **DNSSEC** tab.
3. In the **Apply the selected policies/rules to queries requesting DNSSEC records** section, complete the following:
   - **Response Policy Zones (RPZ) policies**: Select this to apply RPZ policies to DNS queries that request DNSSEC data. You must install the RPZ license to view this checkbox. For more information, see *About Infoblox DNS Firewall*.
   - **Blacklist rules**: Select this to apply blacklist rules to DNS queries that request DNSSEC data. For more information, see *About Blacklists*.
   - **NXDOMAIN rules**: Select this to apply NXDOMAIN rules to DNS queries that request DNSSEC data. This checkbox is visible only if you install the Query Redirection license. For more information, see *About NXDOMAIN Redirection*.
   - **DNS64 Groups**: Select this to generate synthesized AAAA records for DNS queries that request DNSSEC data. For more information, see *Enabling DNS64 Service*.
     The member and the DNS views inherit settings from the Grid, by default. To override the settings, click **Override**. You can override settings at the member and DNS view levels. To retain the same settings as the Grid, click **Inherit** at the member and DNS view level.
4. Save the configuration.

Managing DNS Traffic Control

This section describes the Infoblox DNS Traffic Control solution. It provides guidelines about how to adjust DNS responses based on DNS query source IP, server availability, and network topology. It also describes the required objects in this process such as DTC (DNS Traffic Control) servers, pools, and LBDNs (Load Balanced Domain Names), and how to configure them to achieve the best load balancing results.

It includes the following topics:

About DNS Traffic Control

Infoblox DNS Traffic Control (DTC) provides a load balancing solution by creating DNS responses based on DNS query source IP, server availability, and network topology. Through DTC, you can set up multiple global sites and configure supported objects and load balancing methods to direct DNS clients to the best available servers. For detailed information about how DNS Traffic Control handles DNS queries and responses, see DNS Traffic Control Querying Process below.

To use the DTC feature and bypass the standard DNS querying process, you must install the DNS Traffic Control license on designated Grid members. For information about license and admin requirements, see *License Requirements and Admin Permissions*. Members that are not authoritative for zones or members that do not have the DTC license installed will not process DNS queries through DTC. However, the appliance can process DNS queries through DNS Traffic Control for secondary servers in the Grid using the data replication method.

DNS Traffic Control utilizes a load balancing mechanism to create DNS responses. It returns tailored DNS responses based on settings you configure for associated objects such as DTC servers, pools, and LBDNs. For more information about these objects, see Supported DNS Traffic Control Objects below and *Managing DNS Traffic Control Objects*.

You can configure load balancing methods for pools and LBDNs based on the source IP address and other criteria. For more information, see *Load Balancing Methods for DNS Traffic Control*.

To ensure that DTC servers are reachable and can process DNS queries, you can configure health monitors that help you determine the availability of these servers. For more information, see *Using DNS Traffic Control Health Monitors*.

After you have set up DNS Traffic Control for specific DTC objects, you can monitor their status as described in the section *Viewing DNS Traffic Control Objects*. You can also view a visualization of the hierarchy of DNS Traffic Control objects that you configured. For more information, see *Visualization for DNS Traffic Control Objects*.

You can enable or disable logging for DNS Traffic Control load balancing and health monitors. The appliance logs this information to the syslog. For more information, see *Setting DNS Logging Categories*.

You can configure the DNS Traffic Control properties for the Grid and Grid members. For more information, see *Configuring DNS Traffic Control Properties*.

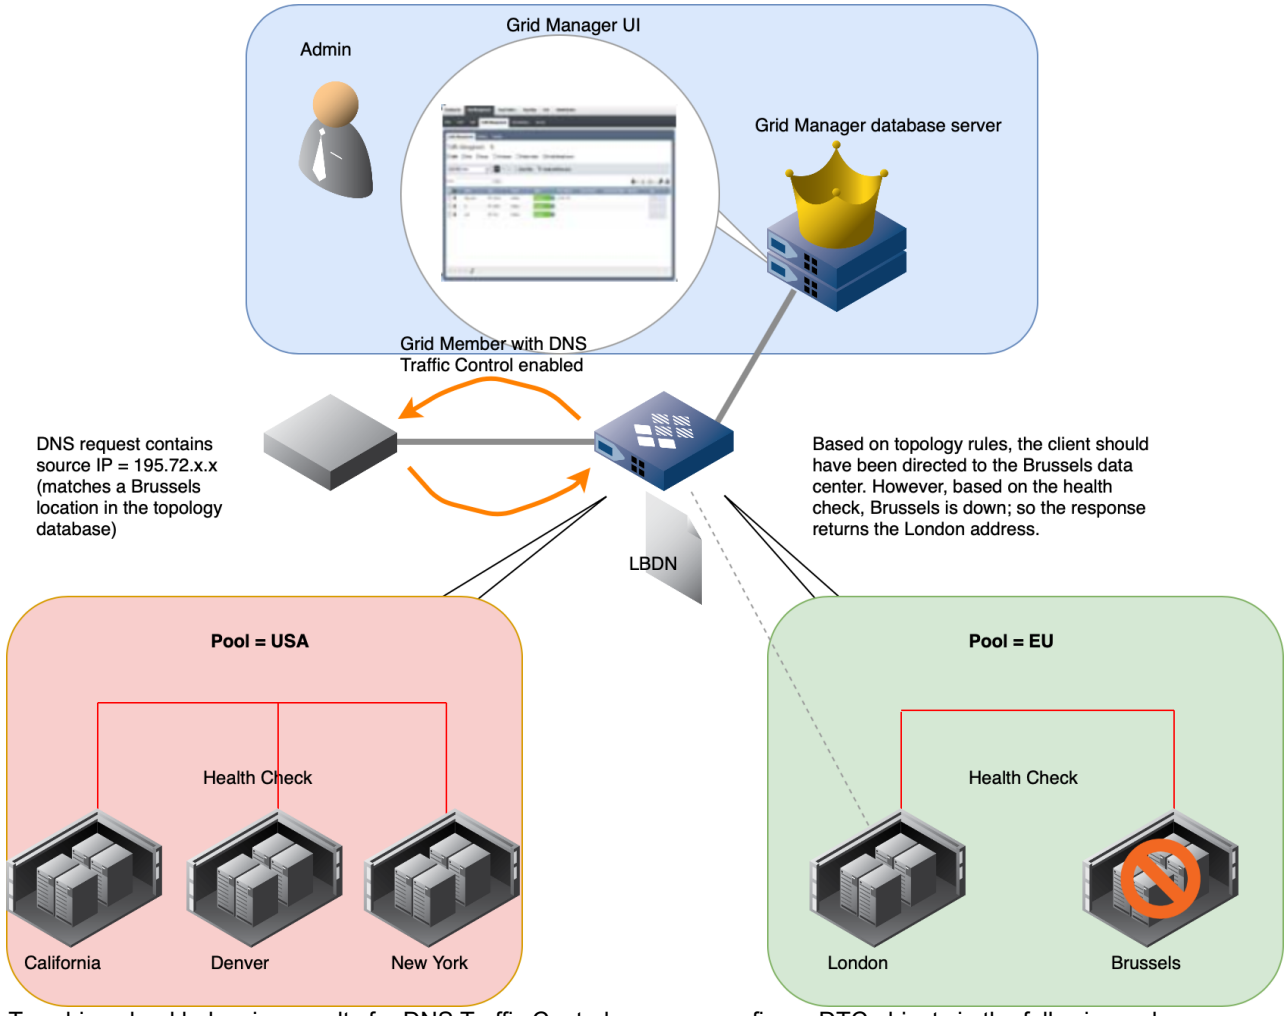
DNS Traffic Control Configuration Example

The *DNS Traffic Control Example* figure below illustrates the basic concept of DNS Traffic Control and how you can use it to direct DNS clients to the best available server using the Topology load balancing method. In the illustration, consider your company manages five data centers: California, Denver, New York, London, and Brussels. Each data center offers the same services and applications your users need. To optimize server utilization and minimize response time, you use DNS Traffic Control to provide DNS responses based on the source IP address and the geographic locations of your data centers. You define your data centers as DTC server objects, and then add them to a pool based on their locations. Data centers in California, Denver, and New York go into Pool USA while London and Brussels go into Pool EU. You also create a topology ruleset containing geography rules that is used when you configure Topology as the load balancing method for your LBDN and pools. To ensure that your data centers are available, you also configure health monitors so that your pools can check the health of its DTC servers.

In DNS Traffic Control, you complete the following to set up the above configuration:

1. Define a geography rule for the topology ruleset, as described in *Configuring Topology Rules and Rulesets.*
2. Configure each data center as a DTC server object, as described in *Configuring DNS Traffic Control Servers.*
3. Configure health monitors that NIOS will use to check the availability of DTC servers, as described in *Using DNS Traffic Control Health Monitors*.
4. Create two pools (USA and EU), which group your servers by geographical locations, configure health monitors that you created earlier, and then select Topology as the load balancing method. For information, see *Configuring DNS Traffic Control Pools*.
5. Define an LBDN and select Topology as the load balancing method and then associate it with a DNS zone. The appliance can then match the geography of the source IP addresses and direct the client to the best available server. For information, see *Configuring DNS Traffic Control LBDNs*.

DNS Traffic Control Example



To achieve load balancing results for DNS Traffic Control, you can configure DTC objects in the following order:

1. Create DNS Traffic Control servers for each data center or server you want to manage. For information, see *Configuring DNS Traffic Control Servers Configuring DNS Traffic Control Servers*.
2. Optionally, if you want to monitor server health, configure health monitors and add them to your pools when you create them. For information, see *Using DNS Traffic Control Health Monitors*.
3. Configure any topology rulesets that will be used by DTC pools. For information, see *Defining Topology Rulesets*.
4. Configure DTC pools, as described in *Configuring DNS Traffic Control Pools*.

5. Configure any topology rulesets that will be used with LBDNs, as described in *Configuring Topology Rules and Rulesets*.
6. Configure DTC LBDNs, as described in *Configuring DNS Traffic Control LBDNs*.

DNS Traffic Control Querying Process

DNS Traffic Control handles a DNS query if the query name belongs to a zone for which the appliance is authoritative and matches an LBDN that is linked to the respective zone. Otherwise, the appliance processes DNS queries normally using the standard DNS query processing.
If you have configured persistence for DTC LBDN and the DTC cache contains a previous response for the same client, then DTC returns the cached response to the respective client. Otherwise, the DNS Traffic Control querying process first selects an LBDN, a pool, and then a specific server from that pool. A DNS record is synthesized from the address of the selected server and returns only DTC LBDN records to the client. Note that the configured DNS records are obscured by the DTC LBDN records. The obscured records are indicated by a strikethrough. For example, an obscured A record appears as A Record in Grid Manager.
When all the pools associated with the LBDNs are unavailable, the appliance returns DNS data for the zone. For information about how to configure availability and topology rules, see *Configuring Topology Rules and Rulesets*.
Following is a brief description of the DNS Traffic Control querying process:

1. The DNS Traffic Control querying process first checks an LBDN's DTC cache to verify if a response is available for the same client, same query and if the server in the cached response is online. If these conditions match, it returns the cached response to the client and refreshes the cache expiry time.
2. If the response is not available in the DNS Traffic Control cache, the DNS Traffic Control querying process occurs as follows:
    - Based on the FQDN in the request, the DNS Traffic Control querying process selects a matching LBDN based on its associated zone and pattern.
    - Based on the selected LBDN load balancing method, the DNS Traffic Control querying process selects an available pool. It does not select pools that are not available or do not have online servers associated with it. If pools are not available for the selected LBDN, the DNS Traffic Control querying process fails to determine the result.
    - After selecting a pool, the DNS Traffic Control querying process selects a server from the pool, based on the load balancing method that you have selected for the respective pool. The DNS Traffic Control querying process uses the preferred load balancing method of the pool by default and the alternate method only if the preferred method fails to return a result.
    - If the DNS Traffic Control querying process fails to determine a result, then the DNS server responds to the client with the matching DNS records configured for the respective zone. If matching DNS records are not configured, it returns an empty result. You can enable or disable the DTC to DNS fall through in the Grid DNS properties.

Supported DNS Traffic Control Objects

You can configure the following DNS Traffic Control objects in the Grid:

- Server: DNS Traffic Control synthesizes DNS records for the servers. For information about how to add and modify servers, see *Configuring DNS Traffic Control Servers*.
- Pool: A pool is a collection of servers that you can put together as possible responses to queries. For information about how to add and modify load balancing pools, see *Configuring DNS Traffic Control Pools.*
- LBDN: A DTC LBDN is a load balanced domain name object that is used by DNS Traffic Control to process DNS queries for load balanced resources. For more information about how to add and modify LBDN objects, see *Configuring DNS Traffic Control LBDNs*.

License Requirements and Admin Permissions

The DNS Traffic Control works as an add-on feature for the DNS service in the NIOS appliance. In order to use it, install the DNS and DNS Traffic Control licenses on the appliance. You can add the DNS Traffic Control license only when you have installed the DNS license. After you add the license, the feature becomes available to you in **Data Management**-> **DNS** -> **Traffic Control**.
The DNS Traffic Control feature starts, stops, or restarts with the DNS service. You may need to restart the DNS service

after you make configuration changes. When you click **Restart** at the top of the screen, the DNS Traffic Control service takes some time to update the configuration and the status of LBDNs, pools and servers on the appliance. For more information about how to install licenses, see *Managing Licenses*.

The appliance creates a new role, **DTC Admin**, when you install the DNS Traffic Control license. For more information about how to define permissions, see *About Admin Roles*.

License Requirements for DNS Traffic Control

- If you are using HA for DNS, Infoblox best practice recommendation is that you apply the DNS Traffic Control license on both the active and passive nodes of the HA pair. If the DNS Traffic Control license is applied only on the active node but not the passive node, the DNS query that matches with LBDN will elicit a DNS Traffic Control response. However, if the DNS Traffic Control license is applied only on the passive node and not the active node, then the DNS query will not elicit a DNS Traffic Control response. You must pass the DNS query using only the virtual IP address.
- A DNS Traffic Control license is required for the name servers in a load balanced zone. If there is no DNS Traffic Control license, then that server will not take part in DNS Traffic Control.

Admin Permissions for DNS Traffic Control

- You can update, add, or delete LBDNs if you have read/write permission on **All DTC LBDNs**, but you need additional permissions to link them to a zone.
- You must have read/write permission on **All DTC LBDNs** to modify an LBDN if a configuration change results in a deletion of LBDN records.
- You must have read/write permission on both **All DTC LBDNs** and **All DTC LBDN Records** to modify LBDN patterns that might result in the creation of new LBDN records.
- Administrators who have access to set up zones have read/write access to their LBDN records. The LBDN records permission is similar to other zone record permissions.
- When you link an LBDN to a zone, you must have both read-only permission on **All DTC LBDNs** and read/write permission on the LBDN record of the zone.
- You must have read/write permission on **All DTC LBDNs** to disable an LBDN. This implicitly disables associated LBDN records from the associated zones and does not require an LBDN record permission.
- You must have read/write permission on **All Topology Databases** to upload a MaxMind GeoIP location database. To modify a rule in the topology ruleset, you must have read/write permission on **All DTC Topologies.**
- To create and modify DTC pools, you must have read/write permission on **All DTC Pools**.
- You must have read/write permission on **All DTC Servers** to create and modify DTC servers.
- You must have read/write permission on **All DTC Monitors**, **All DTC Certificates**, and **All DTC Topologies** to create and modify DTC monitors, certificates and topologies respectively.

For more information about defining global permissions, see *Defining Global Permissions*.

Limitations of DNS Traffic Control

- A member will return DNS Traffic Control results for a zone only if the member is a Grid primary, or a Grid secondary that is using database replication. DNS Traffic Control results are not produced for zones using AXFR, regardless of whether or not the primary member is in the Grid.
- The DNS Traffic Control querying process is not supported for recursive queries.
- The DNS Traffic Control does not support the Global application of an LBDN pattern against all queries. The appliance returns a result only if the query resolves to an authoritative zone to which an DNS Traffic Control LBDN is explicitly linked.
- You can use the **IDN converter** for conversion, but the appliance supports manually encoded puny code as an LBDN pattern.
- DNS Traffic Control health monitoring does not monitor servers if the server has IPv4 and/or IPv6 addresses and the health monitoring interface on the Grid member does not have the corresponding IP address type. The appliance sets the status as unknown for such IPv4 and IPv6 addresses. In addition, the appliance may return a timeout error while loading the Traffic Control tab in Grid Manager if you have configured health monitoring for a lot of DTC servers.

Load Balancing Methods for DNS Traffic Control

You can define the following load balancing methods:

Load Balancing Method	LBDN	Pool
All Available	-	+
Global Availability	+	+
Source IP Hash	+	+
Round Robin	+	+
Ratio: Fixed	+	+
Ratio: Dynamic (Round Trip Delay)	-	+
Ratio: Dynamic (SNMP)	-	+
Topology	+	+

Based on the load balancing method defined for an LBDN, the DNS Traffic Control selects an available pool. Based on the method selected for a pool, it selects an available server.

The following is a description of the load balancing methods with examples for pools or LBDNs:

- Using the **All Available** method, the appliance responds to the query with all the available servers in the DTC pool for the appropriate record type. The responses are returned in the same order in which the servers are listed in the DTC pool, eliminating the unavailable servers.
  Consider the following example for all available records load balancing method with an LBDN x.abc.com:
  Pool= Pool_1; load balancing method= all available records; health check= HTTPS
  10.10.1.1; Availability = up
  2001:db8:a22:a00::29; Availability = up
  10.10.2.2; Availability = down
  2001:db8:a22:a00::32; Availability = up
  10.10.3.3; Availability = up

  In this example, the appliance responds with 10.10.1.1, 10.10.3.3 for each A record query. For each AAAA record query, NIOS responds with 2001:db8:a22:a00::29, 2001:db8:a22:a00::32. The unavailable servers are eliminated. Note that the system considers only the order of the servers in the DTC pool and ignores the weight of available servers.

- Using the **Global Availability** method, the appliance creates the response to the query, so that the clients are directed to the first available pool and server.
  Consider the following example for global availability load balancing method with an LBDN x.abc.com:
  - Pool= Pool_1; load balancing method= global availability; health check= HTTPS 10.10.1.1
    10.10.2.2
    10.10.3.3
  - Pool= Pool_2; load balancing method = global availability; health check = HTTPS 10.10.4.4
    10.10.5.5
    10.10.5.5

  In this example, the appliance always responds with 10.10.1.1 (A record) for all x.abc.com queries assuming that all servers are available. The DNS Traffic Control LBDN determines which pool to use based on the health check

response and adjusts the response accordingly. The appliance responds with 10.10.4.4 from Pool_2 if health check for all servers associated with Pool_1 fails.

- Using the **Source IP Hash** method, NIOS matches an IP address from an incoming query with the health statuses of pools and servers to address the responses by the client. When multiple pools or servers are configured, NIOS uses the source IP hash load balancer method, a load-balancing pattern in which requests are distributed based on the hash value of an IP address from an incoming query and the health status of the pool or server. With the source IP hash load balancing method, clients have their own pool or server and are always associated with the same pool or server for the same query as long as the pool or server is green; if the health status of the pool or server turns red, NIOS switches the clients to the working pool or server and switches back when the health restores to green.
  Consider the following example for the source IP hash load balancing method. The DNS Traffic Control pool has two servers and uses the source IP hash load balancer. When the health statuses are green for both the servers, depending on the client IP address and DNS Traffic Control health status, the pool returns the DNS record from the first DNS Traffic Control server for the first client and returns the DNS record from the second DNS Traffic Control Server for the second client. This continues as long as the health statuses are green; if the health status turns red for a DNS Traffic Control server, the pool switches the client to the working server and switches it back when the health status restores to green.
  For information on the Limitations and Warnings of Source IP Hash Load Balancing Method, see the following section, Limitations of Source IP Hash Load Balancing Method.
- Using the **Ratio: Fixed** method, NIOS adjusts the response to the query so that the clients are directed to servers in a pool or among pools. When multiple pools or servers are configured, the appliance uses the weighted round robin method, a load-balancing pattern in which requests are distributed among several pools or servers based on a weight assigned to each pool or server. Note that the system considers the weight of available servers only. Consider the following example for ratio load balancing method with an LBDN x.abc.com, load balancing method = **Ratio** and two linked pools: Pool_1 with weight = 70 and Pool_2 with weight = 30.
  - Pool = Pool_1; load balancing method = ratio; health check = HTTPS 10.10.1.1; Weight = 50
    10.10.2.2; Weight = 2
    10.10.3.3; Weight = 25
  - Pool = Pool_2; load balancing method = ratio; health check = HTTPS 10.10.4.4; Weight = 50
    10.10.5.5; Weight = 25
    10.10.5.5; Weight = 25

  In this example, the appliance responds 70% of the time with a server associated with Pool_1. Within Pool_1, it responds with 10.10.1.1 address 50% of the time.

- Using the **Ratio: Dynamic** method, the appliance weights the DTC servers dynamically based on round trip delay or SNMP health monitor data. You can use one of the following options:
  - **Round trip delay**: Based on the round trip delay from the DTC member that received a client's DNS request, the system sends clients to the server with the minimal latency time, i.e. the closest one. You need a pre-configured health monitor for this load balancing method.
    For example:
    - Server A latency = 25 ms
    - Server C latency = 18 ms
    - Server D latency = 50 ms
      In this case, the traffic distribution is as follows:
    - Server A = 0%
    - Server C= 100%
    - Server D = 0%
- **SNMP**: Based on data from the SNMP monitor associated to the server, for example, CPU or memory utilization, the system sends clients to the server with the lowest load. For this load balancing method, you need a pre-configured SNMP health monitor with a required metric to be tracked. The metric is set through an object identifier (OID) in the monitor properties. This method supports only OIDs for which the server can return an integer value.
  The value of the monitored metric defines how the traffic is directed. By default, the servers with the highest metric values receive the client requests. There may be cases when your selected metric reflects server availability in the opposite way, that is, the lowest metric values indicate available servers. For such cases, you can invert the value of the OID, that is, of the monitored metric, and have the traffic directed to the lowest-rated servers.
  You can select to weight servers by either priority or ratio. In case of priority, traffic is directed towards the servers

that report the best metric values, other servers being bypassed. In case of ratio, traffic is distributed across all servers based on the values of the monitored metric for each of them. If a health check for a server is failed, the server is excluded from the load balancing.
Consider the following example where the CPU utilization metric is used for server monitoring:

- Server A CPU utilization = 90%
- Server C CPU utilization = 50%
- Server D CPU utilization = 10%
  With normal dynamic weights, the distribution is as follows:
- Server A 60% (calculated as 90 / (10 + 50 +90) = 90/150 = 0.6)
- Server C 33% (calculated as 50 / (10 + 50 +90) = 50/150 ~ 0.33)
- Server D 7% (calculated as 10 / (10 + 50 +90) = 10/150 ~ 0.066)
  This means that the most loaded server will receive most requests than the less loaded one. For this case, the metric should be inverted to reflect server availability appropriately:
- Server A 8% (calculated as 1/90 / (1/90 + 1/50 + 1/10) = 0.011/0.131 ~ 0.08)
- Server C 15% (calculated as /50 / (1/90 + 1/50 + 1/10) = 0.02/0.131 ~ 0.15)
- Server D 77% (calculated as 1/10 / (1/90 + 1/50 + 1/10) = 0.1/0.131 ~ 0.77)

Note

You can see traffic distribution percentage across members in pools and servers based on selected load balancing methods in the visualization panel. For information, see *Visualization for DNS Traffic Control Objects*.

- Using the **Round Robin** method, the appliance returns servers sequentially and cyclically. Consider the following example for round robin load balancing method with an LBDN x.abc.com:
  Pool = Pool_1; load balancing method = Round Robin; health check = HTTPS 10.10.1.1;
  10.10.2.2;
  10.10.3.3;

In this example, NIOS responds with a server associated with Pool_1. Within Pool_1, it responds sequentially:
Time 1: Response = 10.10.1.1
Time 2: Response = 10.10.2.2
Time 3: Response = 10.10.3.3
Time 4: Response = 10.10.1.1
Time 5: Response = 10.10.2.2
Time 6: Response = 10.10.3.3

- Using the **Topology** method, the appliance applies a predefined geographic mapping method and evaluates user-defined geography, subnet, or extensible attribute rules sequentially. Geographical locations for the geography rules are provided through an external topology database. The appliance supports the MaxMind GeoIP2 City or Country database and the MaxMind GeoLite2 City or Country database. For more information, see the following section, *Configuring Topology Rules and Rulesets*.

Limitations of Source IP Hash Load Balancing Method

- The source IP hash load balancing method does not balance clients evenly between DNS Traffic Control pools and DNS Traffic Control servers because the load is divided based on the IP addresses of the clients and the health statuses of the DNS Traffic Control servers.
- For the source IP hash load balancing method with the **Auto Consolidated Monitor** option enabled, when the health status of a DNS Traffic Control server changes and simultaneously two DNS Traffic Control Grid members receive the same DNS requests from a single client, the response from the Grid members may vary as the DNS Traffic Control consolidated monitors need a little time to share health results across DNS Traffic Control Grid members.

Warning

- If you use the source IP hash load balancing method without enabling the **Auto Consolidated Monitors** option, a warning message to enable the option is displayed to synchronize health statuses between all DNS Traffic Control Grid members. This synchronization helps in getting the same DNS replies for each DNS Traffic Control Grid member for one DNS request.
- NIOS cannot guarantee persistence in DNS responses for each DNS Traffic Control Grid member when a part of the DNS Traffic Control configuration with the source IP hash load balancing method has an active DNS Traffic Control DNS cache (LBDN persistence more than 0) even after enabling the **Auto Consolidated Monitors** option. DNS Traffic Control Grid members may respond with different DNS Traffic Control records for one DNS request because DNS Traffic Control caches can have differences between DNS Traffic Control Grid members for the same DNS request.
- When a part of the DNS Traffic Control configuration with the **Auto Consolidated Monitors** option enabled and the source IP hash load balancing method has a DNS Traffic Control server with health monitors assigned to it, a warning message asking you to manually switch the health monitors from the DNS Traffic Control server to a DNS Traffic Control pool is displayed.

Configuring Topology Rules and Rulesets

A topology rule maps a client IP address to a DNS Traffic Control (DTC) pool or server. To use Topology as the load balancing method for a pool or an LBDN, you must define a topology ruleset containing at least one rule. The rulesets are configured globally. When the DNS Traffic Control returns a response, it evaluates the list of rules in the topology ruleset in order and uses the first match with an available destination. The method fails if there are no matches.

You can define the following topology rules in a ruleset:

- Extensible Attribute rule
- Subnet rule
- Geography rule

In the DTC Topology ruleset for Subnet rule, Geographical rule, and Extensible Attribute topology (EA) rules there are options to choose the **NOERR/NODATA** response or the **NXDOMAIN** response. It will also allow you to set the **Destination** as **SERVER** or **POOL** for the subnet from the IPAM object. The destination for a topology ruleset is either a server or a pool. An LBDN can use only topology rulesets with a pool as the destination. A pool can use only topology rulesets with a server as the destination. You can also use CSV import to import rules into NIOS.

To use DTC topology with extensible attribute rules, you must select the extensible attributes that support DTC balancing in the *Grid DNS Properties* editor. You can select up to four extensible attributes and the order in which you select them is required for filling the extensible attributes topology rule. For example, if a ruleset is to have three extensible attributes in the order A, B, and C, while creating the extensible attributes topology rule, you must select the value of A first, then B, and finally the value of C in the *Grid DNS Properties* editor. For more information, see *Configuring Grid DNS Traffic Control Properties*.

The extensible attributes topology rules work based on the IPAM configuration. The rules are supported only on IPv4 and IPv6 networks, and are not supported on network containers and hosts. For a correct DTC load balancing based on IPAM networks, you must assign extensible attributes that are selected for DTC and have valid values for IPv4/IPv6 Networks. You can also configure extensible attributes to be inherited from parent IPv4/IPv6 network containers. For more information, see *Managing Extensible Attributes*.

DTC topology rulesets with extensible attribute rules use a separate database instance — DTC EA database that should be up to date to ensure correct navigation for the incoming DTC queries. Each time you make changes to extensible attributes in the IPAM object, or manage a set of extensible attributes for DTC in Grid Manager, a notification prompting you to rebuild the DTC EA database is displayed. If you choose to ignore the prompt, then all changes to DTC balancing behavior that require a database rebuild will not take effect. For more information about rebuilding the EA database, see Rebuilding EA Database below.

Note

- If the DNS service is already running, you must not restart the service after the rebuild of the EA database. Instead, wait until the DTC members finish making the new EA database build active.
- Once the DNS Traffic Control restores, you must manually rebuild the DNS Traffic Control EA database.

Limitations of Configuring Topology Rules and Rulesets

- Based on the destination type of the DTC Topology ruleset settings, you can set the **NOERR/NODATA** or the **NXDOMAIN** response for a new DTC Topology rule. However, you cannot choose the destination **DTC Pool** or the **DTC Server**.
- If the **Destination Type** is set as **SERVER**, then the topology rule set for DTC pool cannot have only **NOERR** and **NXDOMAIN** rules. This is because the NAMED does not process the queries in the IDNS if the incoming requests are matched to LBDN with no topology balance method. Also, the pools under this LBDN do not have active or existing servers. Hence a **NOERR** response is always received. To prevent this behavior, the grid must have at least one active server as the **Rule Destination** under any DTC pool in the LBDN to allow IDS processing for the current LBDN and Pool. The rule set must have at least one rule with the **REGULAR** Return Type.
- The **Disable for DHCP** checkbox must be not be selected to enable networks and to build the topology database. For more information about the checkbox, see *Configuring IPv4 Networks*.
- The topology ruleset must have a specific order for the following rules:
  a. REGULAR rules
  b. NOERR rules
  c. NXDOMAIN rules

  The ruleset cannot have rules with a **REGULAR** return type after the **NOERR** or **NXDOMAIN** rules are set in order. You will receive a warning message when you try to save the topology ruleset in any other order. However, the GRID automatically sorts the rules in the correct order, once you accept the warning message.

Note

During the WAPI call, if the rules are not in the correct order, they are automatically sorted as WAPI does not give any warnings.

Defining Topology Rulesets

A topology ruleset can contain multiple rules. The rules in a topology ruleset must use the same destination type. Multiple LBDNs or pools can reuse a topology ruleset.

Each server that you use as a destination in the topology must exist in every pool that is using the topology. When you select Topology as a load balancing method for a pool, you can select one of these rulesets for the topology rules. The ruleset can be a combination of extensible attribute, subnet, and/or geography rules.

Note the following about extensible attribute, subnet, and geography source matches:

- A rule with an extensible attribute source matches if a client query comes from the network that has the specified set of extensible attributes. In other words, extensible attributes you specify when you create a rule.
- A rule with a subnet source matches if the subnet contains the client IP address.
- A rule with a geography source label matches if the client IP address and geography source label match corresponding information in the MaxMind location database.

Note the following information about rules and rulesets:

- When you upload a new MaxMind location database or restore a backup, the appliance does not automatically remove rules that contain invalid labels. Instead, it marks the rules with labels that do not exist in the database as invalid. The appliance ignores these rules during the querying process, and you cannot save the configuration if it is modified, but you can use the existing configuration.

- The appliance checks specific combinations of labels when the rules use multiple conditions. For example, if you have a rule with the source types Country = Canada and City = Vancouver and you change the Country source type to Russia, the City source type is cleared and the selector resets to contain only known cities in Russia. This is applicable for both geography and extensible attribute rules.

The following is an example of valid source types:

Continent	Country	Subdivision	City
Any	Canada	Any	Vancouver
Any	Any	Any	Vancouver
North America	Any	Any	Vancouver
North America	USA	Washington	Vancouver

- When rules have multiple source conditions, the client must match all conditions for the rule to execute.
- A ruleset may have multiple subnet rules and the subnets may overlap. Similarly, a ruleset may have multiple geography rules and the matches may overlap. Similarly, a ruleset may have multiple extensible attribute rules and the matches may overlap. During the querying process, the rules in a topology ruleset are evaluated in order. For example, if you configure subnet rules where #1 is 10.10.0.0/16 and #2 is 10.0.0.0/8, both are considered valid in the appliance.

To define a ruleset, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Topology Rulesets** in the Toolbar.
2. In the *Topology Manager* window, click the Add icon.
3. In the *Ruleset* wizard that appears, complete the following:
    - **Name**: Enter a name for the ruleset.
    - **Destination Type**: Select a destination type, **Pool**, or **Server**. Rulesets with the Pool destination type can only be used by LBDNs. Rulesets with the Server destination type can only be used by pools. You cannot change the destination type if the ruleset contains any rules.
    - **Comment**: Enter additional information about the ruleset.
    - **Rules**: You can define multiple extensible attribute rules, subnet rules, and geography rules in the ruleset. Click the arrow next to the Add icon and select either **Extensible Attribute Rule**, **Subnet Rule**, or **Geography Rule**.
        - When you select **Extensible Attribute Rule**, the Grid Manager displays the following:
            - **Source Type**: Define up to four extensible attributes to use as the source type for the EA topology ruleset. The values for the IPAM object EAs are provided from the DNS Traffic Control EAs selected in the Grid DNS Properties editor. To define extensible attribute source types for the topology rules, see *Configuring Grid DNS Traffic Control Properties*.
              Note that "Any" matches any value. There must be at least one source type with a specific value (the value is not "Any").
              When a source type uses "does not equal" as the operator, it must be the lowest level source type (most specific). For example, with Continent/Country/Subdivision/City, City is the most specific source type.
            - **Destination/Response**:
                - **DTC Pool/Server**: Click **Select** to select a destination. The appliance displays the *DTC Pool Selector* dialog box when you have selected the Pool destination type, and displays *DTC Server Selector* dialog box when you have selected the Server destination type. Click a specific pool or server to select it. Note that if there is only one pool or server, no dialog box is displayed when selecting the destination.
                - **NOERROR/NODATA (Response)**: Select this option to provide a **NOERROR/NODATA** response for DTC queries.

- **NXDOMAIN (Response):** Select this option to provide an **NXDOMAIN** response for DTC queries.
  Click **Add** to add the source. The appliance displays the following information in the Rules table:
  - **Source**: The values of extensible attributes that you specified.
  - **Destination**: The destination that you selected.
  - **Valid Source**: After you save the ruleset, the value is set to **Yes** if the extensible attributes exist in the EA database.
    Note that the source must be valid when creating a ruleset. It can become invalid when a new topology database no longer contains the source.
  - **Order**: Displays the order of the rule in the ruleset.
  - **Return Type:** The response type that is selected.

- When you select **Subnet Rule**, the Grid Manager displays the following:
  - **Source Subnet**: Select a value from the drop-down list. You can either select **equals** or **does not equal,** and specify a subnet IP address or click **Select** and choose a network from the *Network Selector* dialog box.
    Note that "Any" matches any value. There must be at least one source subnet with a specific value (the value is not "Any").
    When a source subnet uses "does not equal" as the operator, it must be the lowest level source subnet (most specific).
  - **Destination/Response**:
    - **DTC Pool/Server**: Click **Select** to select a destination. The appliance displays the *DTC Pool Selector* dialog box when you have selected the Pool destination type and displays the *DTC Server Selector* dialog box when you have selected the Server destination type. Click a specific pool or server to select it. Note that if there is only one pool or server created, no dialog box is displayed when selecting the destination.
    - **NOERROR/NODATA (Response)**: Select this option to provide a **NOERROR/ NODATA** response for DTC queries.
    - **NXDOMAIN (Response)**: Select this option to provide an **NXDOMAIN** response for DTC queries.
      Click **Add** to add the source. The appliance displays the following information in the Rules table:
      - **Source**: The subnet address that you specified.
      - **Destination**: The destination that you selected.
      - **Valid Source**: For a subnet rule, the rule is always marked as valid after you save the ruleset.
      - **Order**: Displays the order of the rule in the ruleset.
      - **Return Type:** The response type that is selected.

- When you select **Geography Rule**, Grid Manager displays the following:
  - **Source Type**: Select a source type.
  - **Continent**: Select a continent from the drop-down list. You can also enter the first few characters of the continent to match an item in the database.
  - **Country**: Select a country from the drop-down list. You can also enter the first few characters of the country to match an item in the database.
  - **Subdivision**: Select a subdivision from the drop-down list. You can also enter the first few characters of the subdivision to match an item in the database.
  - **City**: Select a city from the drop-down list. You can also enter the first few characters of the city to match an item in the database. The drop-down list has paging controls to page through the available values.
  - **Destination/Response**:
    - **DTC Pool/Server**: Click **Select** to select a destination. The appliance displays the *DTC Pool Selector* dialog box when you have selected the Pool destination type and the displays *DTC Server Selector* dialog box when you have selected the Server destination type. Click a specific pool or server to select it. Note that if there is only one pool or server created, no dialog box is displayed when selecting the destination.
    - **NOERROR/NODATA (Response)**: Select this option to provide a **NOERROR/ NODATA** response for DTC queries.

- **NXDOMAIN (Response)**: Select this option to provide an **NXDOMAIN** response for DTC queries.
  Click **Add** to add the source. The appliance displays the following information in the Rules table:
  - **Source**: The subnet address that you specified.
  - **Destination**: The destination that you selected.
  - **Valid Source**: After you save the ruleset, the value is set to **Yes** if the labels exist in the MaxMind location database.
  - **Order**: Displays the order of the rule in the ruleset.
  - **Return Type:** The response type that is selected.
  - **Default destination if none of the above rules match (optional)**: Click **Select** to select the default destination if none of the above rules match. The appliance displays the *DTC Pool Selector* dialog box when you have selected the Pool destination type and displays the *DTC Server Selector* dialog box when you have selected the Server destination type. Click a specific pool or server to select it. You can click **Clear** to remove the selected pool or server. Note that you can select a default destination even if there are no rules defined in the Rules table.

4. If necessary, modify the order of rules in the table. You can do so by editing the value in the **Order** column or by using the arrows on the left-hand side of the table.
5. Click **Next**.
6. Define the extensible attributes. For information, see *Using Extensible Attributes*.
7. Click **Next** to schedule a change. In the *Schedule Change* panel, click **Now** to immediately execute this task. Or click **Later** to schedule this task, and then specify a date, time, and time zone.
8. Click **Save & Close**.

Note

After making changes to the extensible attributes, you may need to rebuild the topology EA database. For more information, see Rebuilding EA Database below.

Viewing Topology Rulesets

To view topology rulesets, navigate to the **Data Management** tab -> **DNS** tab -> **Traffic Control** tab, and then click **Manage Topology Rulesets** in the Toolbar. The Topology Manager lists the configured rulesets, their destination types, sites, and comments.

You can perform the following:

- Add new rulesets. To add a new ruleset, click the Add icon. For more information, see Defining Topology Rulesets above.
- To edit a ruleset, click the checkbox next to the ruleset name, and then click the Edit icon. You can modify the following in the *Ruleset* editor:
  - In the **General Basic** tab, you can perform the following:
    - Add new rules to the ruleset. Click the arrow next to the Add icon and select either **Extensible Attribute Rule**, **Subnet Rule**, or **Geography Rule**. For more information, see Defining Topology Rulesets above.
    - Modify rules in the ruleset. To edit an existing rule, select the checkbox of the required rule in the Rules table, and then click the Edit icon. When you are finished editing, click **Save** above the Rules table. For more information, see Defining Topology Rulesets above.
    - Delete existing rules from the ruleset. Select the checkbox of the required rule in the Rules table, and then click the Delete icon.
      You can modify the destination type only if there are no rules in the ruleset.
  - In the **Extensible Attributes** tab, you can add new or edit existing extensible attributes. For information, see *Using Extensible Attributes*.
- Delete a ruleset or schedule the deletion for a later time.

    - To delete a ruleset, select the checkbox next to its name and click the arrow next to the Delete icon. To delete the object immediately, select **Delete**.
    - To schedule the deletion, click **Schedule Delete**. For more information, see *Scheduling Deletions*.
- Export topology rulesets. To export the entire list of rulesets in a format that can be imported, click the Export icon and choose **Export data in Infoblox CSV Import format**. To export all data that is currently visible in the Topology Manager, click the Export icon and choose **Export visible data**.
- Print the data that is currently visible in the Topology Manager. Click the Print icon to print.

Importing a Topology Database

The DNS Traffic Control license includes a MaxMind location database that is deployed when you enable the DNS Traffic Control. Note that only a single MaxMind location database can be present on the Grid at a time. The MaxMind location database contains various geographic locations that can be used when you define a geography rule. NIOS supports both paid GeoIP2 and free GeoLite2 MaxMind location databases. The GeoLite2 MaxMind Country database is shipped with the NIOS appliance. The MaxMind location database is static over the lifetime of the querying process until you import a new database and restart services.

When you import a new MaxMind location database, the appliance replaces the existing database. You can import MaxMind location databases that are in MMDB or CSV format. To view the current version of the database, click **Current Version.**

You can import a ready-to-use MaxMind location database or create your own ZIP file containing multiple CSV files. To import a MaxMind location database or to view the current version of the database, complete the following:

1. From the **Data Management** tab, select the **DNS** tab, and then select the **Traffic Control** tab.
2. Click the arrow next to the **Topology Database**, and then select **Import GeoIP Database** from the drop-down list.
3. In the *Import Topology Database* wizard, complete the following:
    - **File**: Click **Select** and navigate to the MaxMind location database.
    - **Upload**: Click **Upload** to import the MaxMind location database.
4. In the Toolbar, click the arrow next to **Topology Database**, and select **Current Version** from the drop-down list to view the details of the imported MaxMind location databases. In the Geography section, the Grid Manager displays the database type, build date, build version, and the date and time when the database was deployed to the Grid Master.
   The latest database version may not be deployed on all DTC members. To view the current deployed versions, select **Data Management** -> **DNS** -> **Members**.

To create a custom database in a ZIP file, complete the following:

1. Create a directory with CSV files and name them using the following pattern:
   {Product}-{Content}-{Blocks-or-Locations}-{version-or-localization}.csv.
   Only the three CSV files matching these patterns are suitable for the import:
   {Product}-{Content}-Blocks-IPv4.csv
   {Product}-{Content}-Blocks-IPv6.csv
   {Product}-{Content}-Locations-en.csv
   For example:
   GeoLite2-City-Blocks-IPv4.csv
   GeoLite2-City-Blocks-IPv6.csv
   GeoLite2-City-Locations-ru.csv
   or
   GeoIP2-Country-Blocks-IPv4.csv
   GeoIP2-Country-Blocks-IPv6.csv
   GeoIP2-Country-Locations-en.csv
   where
   “GeoLite2” and “GeoIP2” correspond to {Product}
   “City” and “Country” correspond to {Content}
   “IPv4” and “IPv6” correspond to {version}
   “ru” and “en” correspond to {localization}
   Note that the locations file and at least one of the Blocks files must exist or the import fails. Also, all of these files

must have identical {Product}-{Content} pairs or the import fails. You can use a ready-to-use MaxMind location database as an example.

2. You can add multiple CSV files for different localizations to your ZIP file. Use the following naming pattern: {Product}-{Content}-Locations-{localization}.csv.
   For example:
   GeoLite2-City-Locations-ru.csv
   GeoIP2-City-Locations-de.csv
   GeoIP2-Country-Locations-en.csv
3. Add the directory with the CSV files to a ZIP file. The name of the ZIP file you upload and the name of the directory in the ZIP file are not significant. The ZIP file should contain only one directory and no subdirectories. Any files in the ZIP file with an extension different from .csv are ignored.
4. Import the ZIP file to Grid Manager as described above.

> ⚠ Note
>
> The Country database does not support 'subdivision' labels and importing it invalidates all existing rules that use 'subdivision' labels.

Rebuilding EA Database

Unlike the GeoIP database, the EA database is not imported externally but configured within the system. After making changes to extensible attributes, Grid Manager offers you to rebuild the DNS Traffic Control Topology Database. You can use the banner that appears at the top of the screen and then click **Rebuild** to rebuild the database immediately. Or, you can click **Ignore** to rebuild the database later in the **Traffic Control** tab. Clicking **Ignore** applies to all changes that require a rebuild of the EA database. The EA database rebuild is ignored for the duration of the user session.

To rebuild the EA database, complete the following:

1. From the **Data Management** tab, select the **DNS** tab, and then select the **Traffic Control** tab.
2. In the Toolbar, click the arrow next to the **Topology Database** and select **Rebuild EA Database** -> **Rebuild** or **Schedule Rebuild**.
3. In the *Rebuild EA Database* dialog box, select **Yes** to rebuild the database or **No** to discard the rebuild. To schedule the rebuild task, in the *Rebuild EA Database Schedule* dialog box, specify a date, time, and time zone.

To view the current version of the EA database, click **Topology Database** -> **Current Version** in the Toolbar. Grid Manager displays the database build date and its last rebuild status in the Extensible Attributes section.

> ⚠ Note
>
> The latest database version may not be deployed on all DTC members. To view the current deployed versions, select **Data Management** -> **DNS** -> **Members**.

Managing DNS Traffic Control Objects

You can configure multiple DNS Traffic Control servers, pools, or LBDNs on a NIOS appliance. For information on how to configure and manage the DNS Traffic Control Objects, see:

- *Managing DNS Traffic Control Pools*
- *Managing DNS Traffic Control LBDNs*
- *Managing DNS Traffic Control Servers*

Sections covered in the topic are:

- *Viewing DNS Traffic Control Objects*
- *Deleting DNS Traffic Control Objects*

Viewing DNS Traffic Control Objects

Grid Manager lists all DNS Traffic Control objects in the **Traffic Control** tab. You can view the objects that you have configured in the Grid from: **Data Management** tab -> **DNS** tab -> **Traffic Control** tab.

Based on the selected columns, Grid Manager displays the following information for each DNS Traffic Control object:

- **Name**: The name of the object.
- **Type**: The object type.
- **Status**: Displays information about the last update, connection status, load balancer methods, and servers and pools. Hover your mouse over the status value to view full information in a tooltip. For more information about the possible statuses, see as described in *Understanding DTC Object Status*.
- **IPv4 Address**: The IPv4 address of the object, if applicable.
- **IPv6 Address**: The IPv6 address of the object, if applicable.
- **Disabled**: **Yes** or **No**. Indicates whether the DNS Traffic Control object is disabled.
- **Comment**: Displays any comments that were entered for the object.
- **Last Status Update**: Displays the timestamp of the last status update.
- **Load Balancing Method**: Displays the load balancing methods defined for the object.
- **Topology Ruleset**: Displays the topology ruleset defined for the object if it uses the Topology load balancing method.
- Extensible attributes, if configured:
  - **Site**: Displays any values that were entered for the Site pre-defined attribute.
  - **IB Discovery Owned**: Displays any values that were entered for the IB Discovery Owned pre-defined extensible attribute.
  - **Building**: Displays any values that were entered for the Building pre-defined attribute.
  - **Country**: Displays any values that were entered for the Country pre-defined attribute.
  - **Region**: Displays any values that were entered for the Region pre-defined attribute.
  - **State**: Displays any values that were entered for the State pre-defined attribute.
  - **VLAN**: Displays any values that were entered for the VLAN pre-defined attribute.

> ⚠ Note
> You can perform inline editing in the **Name**, **Comment**, and **Site** columns by double-clicking the required line in the table and providing the value in the corresponding column.

You can perform the following in the **Traffic Control** tab:

- Select the checkbox to view specific objects only:
  - **LBDN**: Select the checkbox to view LBDN objects only. For more information, see *Configuring DNS Traffic Control LBDNs*.
  - **Pool**: Select the checkbox to view pools only. For more information, see *Configuring DNS Traffic Control Pools*.
  - **Server**: Select the checkbox to view servers only. For more information, see *Configuring DNS Traffic Control Servers*.
- Change the set of columns displayed in the DTC objects table and change their width. For more information, see *Customizing Tables*.
- Click the Add icon to add an object.
- Select an object and click the Edit icon to edit the configuration. You can also click the Action icon ☰ of the object and select **Edit** from the menu.

- Select an object and click the Delete icon to delete it. You can also click the Action icon of the object and select **Delete** from the menu. For more information, see the *Deleting DNS Traffic Control Objects* section.
- Click a DTC server name to open the list of DTC records associated with the server. For more information, see *Managing DTC Server Records*.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Click the Export icon to export the list of objects to a .csv file.
- Click the Print icon to print the list of objects.
- Add or delete extensible attributes for a DTC object by selecting the object in the table and clicking **Extensible Attributes** in the Toolbar. For information, see *Using Extensible Attributes*.
- Test a selected LBDN by clicking **Test LBDN** in the Toolbar. For more information, see *Testing DNS Traffic Control LBDNs*.
- Enable/disable one or more selected traffic control objects. For more information, see the *Enabling or Disabling Traffic Control Objects* section.
- View a visualization of the traffic control structure for an object by selecting the object in the table. The visualization is displayed by default. To hide the visualization, click **Hide Visualization** in the Toolbar. For more information, see *Visualization for DNS Traffic Control Objects.*
- Use the **IDN Converter** from the Toolbar to convert IDNs into punycodes. For more information, see *Decoding IDNs and Encoding Punycode*.

> ⚠ Note
> The Grid Master Candidate provides the health status of DNS Traffic Control objects such as servers, pools, and LBDNs through WAPI requests.

Deleting DNS Traffic Control Objects

You can delete DNS Traffic Control objects, such as servers, pools, or LBDNs. When you delete an LBDN, the appliance automatically dissociates it from the zones. To delete an LBDN, you must either have write permission on the LBDN record or the LBDN. For more information, see *License Requirements and Admin Permissions*.

You cannot delete a DNS Traffic Control pool when it is in use. To delete a pool, you must first delete it from the associated LBDNs. You cannot delete a DNS Traffic Control server when it is in use. You must first remove it from every pool and topology ruleset before deleting the server.

To delete an object:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, click the Action icon of the object name and select **Delete** from the menu or select an object and click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes** to delete the object or **No** to cancel the operation.

The *Delete Confirmation* dialog box displays information about associated objects and warns if the object cannot be deleted due to the associations.

To schedule an object deletion, click the Action icon of the object and select **Delete** -> **Schedule Delete**. Alternatively, you can select the object in the **Traffic Control** panel and then select the Delete icon -> **Schedule Delete**. In the *Schedule Deletion* panel, enter a date, time, and time zone. For information, see *Scheduling Deletions*.

> ⚠ Note
> If you remove a name server associated with a zone that comprises LBDN records and if the name server is configured as part of a *consolidated monitor list*, ensure that you remove the name server from the consolidated health monitor list in the DTC pool. For more information about health monitors, see *Using DNS Traffic Control Health Monitors* and *Configuring DTC Monitors for Health Check*.

Enabling or Disabling Traffic Control Objects

You can enable or disable a single or multiple DNS Traffic Control objects for a selected Grid member.

The Grid-level status of DNS Traffic Control objects can be viewed on the **Data Management** tab -> **DNS** tab -> **Traffic Control** tab and the member-level status in the visualization panel. For more information, see *Visualization for DNS Traffic Control Objects* and *Understanding DTC Object Status*. You will not be able to view the disabled configuration of an object in Grid Manager.

Disabling Traffic Control Objects

To disable a traffic control object:

> ⚠ Note
> Ensure that at least one health monitor is configured in a pool or a server object before you attempt to disable that DTC object.

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab.
2. In the *Traffic Control* panel, select the object that you want to disable.
3. Click the arrow beside the Enable/Disable icon or click the Action icon of the selected object, and select **Disable**.
4. Complete the following steps in the *Disable Traffic Management Objects* dialog:
    - **Disable health monitoring**: Select it if you want to disable the health monitoring when the selected DTC object is disabled.
    - **Disable options**: Select one of the following options:
        - **Disable until objects are enabled manually**: Select it to keep the object disabled until you enable the object manually.
        - **Disable until DNS service restarts**: Select it to keep the object disabled until the DNS service is restarted.
        - **Disable for specified time (seconds)**: Select it and specify a time interval in seconds until when the object must remain disabled. The object is enabled automatically after the specified interval elapses.
    - **Disable after (seconds)**: Select it and specify a time interval in seconds after which the object is disabled automatically.
    - In the **DTC grid members** section, select the Grid members on which the selected object must be disabled:
        i. Click a member in the **Enabled on** box to select it.
        ii. Click the right arrow to move the member to the **To disable on** box.
5. Click **Save & Close**.

Consider the following points when you have disabled DNS Traffic Control objects in a Grid:

- When you restore a Grid that had a DNS Traffic Control object disabled with the **Disable until DNS restarts** option, the object gets enabled as the restore operation causes all services including the DNS service to restart. You must disable the object once again.
- If you need to override or modify the configuration used to disable a DTC object, you must either wait until the object is enabled based on the setting you have defined, or manually enable the object.
- Disabling DNS Traffic Control objects does not impact the DTC backup or restore operation. A restore operation enables all objects in a Grid leaving them in Running state.
- When a Dig request is running, if you force restart the DNS service, the disabled DTC objects continue to send responses until all objects that were in the disabled state are reinstated to the disabled state after the restart. The time taken to reinstate the objects varies depending on the count of the disabled objects.
- When you modify the name server association of zones configured for an LBDN object, and then restart the DNS service, the DTC object disable settings (manual fail back events) configured for members associated with the LBDN, its pool, or server objects prior to the zone's name server modification, becomes stale, and the stale data is cleared at regular intervals.

Enabling Traffic Control Objects

In a DNS Traffic Control setup, you must have at least one server object enabled in a pool and at least one pool object enabled in an LBDN.

To enable a traffic control object:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab.
2. In the *Traffic Control* panel, select the object that you want to enable.
3. Click the arrow beside the Enable/Disable icon, or click the Action icon of the selected object, and select **Enable**.
4. In the *Enable Traffic Management Objects* dialog, select the Grid members on which the object must be enabled:
    a. In the **DTC grid members** section, click a member in the **Disabled on** box to select it.
    b. Click the right arrow to move the member to the **To enable on** box.
5. Click **Save & Close**.

Note
- To enable a disabled DNS Traffic Control server object, its pool must be enabled. If not, the status of the server object will remain disabled.
- In NIOS version 8.6.2 and later, to enable an object that was disabled in a prior version of NIOS, do not use the **Enable** option. Instead, complete the following steps:
    a. On the **Traffic Control** tab, click the Action icon of the disabled object and select **Edit**.
    b. In the editor, on the **General** tab, clear the selection in the **Disabled** checkbox.
    c. Click **Save & Close**.

Limitations and Warnings for Auto Consolidated Monitors

You can view the limitations and warnings of Auto Consolidated Monitors for the DNS Traffic Control, server, and LBDN objects listed in this section.

DNS Traffic Control

- The Auto Consolidated Monitors option uses DNS Traffic Control consolidated monitors that cannot share results of health monitors specified on DNS Traffic Control servers (server monitors). Therefore, DNS Traffic Control objects may have some differences in health statuses per Grid members when the Auto Consolidated Monitors option is enabled.
- If you disable the Auto Consolidated Monitors option for a DNS Traffic Control pool that is linked to an LBDN that has Auto Consolidated Monitors enabled, an error message is displayed. You cannot disable the Auto Consolidated Monitors option when this option is enabled in the linked LBDN.
- You cannot make any changes to the DNS Traffic Control consolidated monitors settings if the Auto Consolidated Monitors option is enabled.

Warning
- If you enable the Auto Consolidated Monitors option on the DNS Traffic Control pool, all existing DNS Traffic Control consolidated monitors are deleted.
- When there are no health monitors on the DNS Traffic Control pool and you enable the Auto Consolidated Monitors option, a warning message asking you to manually add health monitors to the DNS Traffic Control pool is displayed.

DNS Traffic Control LBDN

- Since the Auto Consolidated Monitors option uses DNS Traffic Control Consolidated Monitors which cannot share results of health monitors specified on DNS Traffic Control Servers (server monitors), DNS Traffic Control objects may have some differences in health statuses per Grid members even when the Auto Consolidated Monitors option is enabled.

Warning
- If you enable Auto Consolidated Monitors on the LBDN, all the existing DNS Traffic Control Consolidated Monitors on all linked DNS Traffic Control Pools are deleted.
- When Auto Consolidated Monitors is enabled on LBDN, all linked DNS Traffic Control Pools also have this option automatically enabled.
- When there are no health monitors assigned on the linked DNS Traffic Control Pool(s), and you enable Auto Consolidated Monitor on the LBDN, the warning message asking to manually add health monitors on DNS Traffic Control Pool is displayed.

DNS Traffic Control Servers

Warning
When you add health monitors to a DNS Traffic Control server that is a part of the DNS Traffic Control configuration with the source IP hash load balancing method selected and the Auto Consolidated Monitors option enabled, a warning message is displayed that these changes can cause differences in resolving queries among DNS Traffic Control Grid members for the same DNS request.

Managing DNS Traffic Control Pools

A pool contains load balanced servers. You can define multiple servers for a pool. Each LBDN must have at least one pool associated with it to be operational. For sites with a large volume of incoming traffic, you can configure DNS Traffic Control to distribute client requests to multiple servers using a load balancing pool. An individual server can belong to one or multiple load balancing pools, depending on how you want to manage your network traffic. You can also set the order of servers in the pool and define a ratio on a server basis.

Configuring DNS Traffic Control Pools

A pool can contain preferred and alternative load balancing methods. You can define permissions on these pools and associate extensible attributes with them. Each pool can contain one or more health monitors associated with it. You can define TTLs at the LBDN level. These TTLs are valid for dynamic RRsets that are created by the querying process for each query.

To configure a pool, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click the arrow next to the Add icon and select **Pool**.
2. In the *DTC Pool Wizard*, complete the following:
   - **Name**: Enter the name of the pool.
   - **Comment**: Enter additional information about the pool.
   - **Auto Consolidated Monitors**: Select this option to enable auto-managing of DNS Traffic Control Consolidated Monitors. This option locks all the DNS Traffic Control consolidated monitor settings and creates a DNS consolidated monitor for each health monitor in the pool with the following settings:
     - Availability – ALL
     - Full health communication – Yes
     - Listen To members - all DNS Traffic Control members that serve linked LBDN(s).

     Enabling the **Auto Consolidated Monitor** option also helps to synchronize the health statuses of DNS Traffic Control objects in the LBDN for each DNS Traffic Control Grid member, which means if one Grid member considers that the DNS Traffic Control Server is RED, this server will be RED for each Grid member performing the health check. For information on DNS consolidated monitors, see *Configuring DTC Monitors for Health Check*.

     For information on Limitations and Warnings of the **Auto Consolidated Monitors** option, see *Limitations For DNS Traffic Control*.
   - **Disabled**: Select this to disable the pool.
3. Click **Next** to associate health monitors with the pool:

- **Health Monitors**: Select the health monitor from the **Available** table, which you want to associate with the pool, and then click the right arrow to move the selected health monitor to the **Active** table. You can use SHIFT+click and CTRL+click to select multiple health monitors. To dissociate the health monitor from the pool, select it and click the left arrow to move it to the **Available** pane from the **Active** pane.
- **Availability Requirements**: Select from the following:
  - **All**: All active monitors must report the available status for the pool to be determined as available.
  - **Any**: Any number of active monitors must report the available status for the pool to be determined as available.
  - **At least**: The minimum number of active monitors that must report the available status for the pool to be determined as available.

4. Click **Next** and select the preferred load balancing method:
   - **All Available**
   - **Ratio: Dynamic (see details below in the procedure)**
   - **Global Availability**
   - **Source IP Hash**
   - **Ratio: Fixed**
   - **Round Robin**
   - **Topology (see details below in the procedure)**

   For more information, see *Load Balancing Methods for DNS Traffic Control*.
5. If you select Ratio: Dynamic as the preferred method, also select a dynamic ratio method from the following:
   - **Round Trip Delay**: Select this to enable load balancing based on the proximity of DTC servers determined through round trip delay. Specify the following:
     - **Monitor**: Select a pre-configured health monitor to use for monitoring the round trip delay.
   - **SNMP**: Select this to enable load balancing based on a server metric captured by an SNMP health monitor. Specify the following:
     - **Monitor**: Select a health monitor for which to track a server metric.
     - **OID**: Specify an object identifier that indicates the metric to track.
     - **Weighing**: Select to weigh DTC servers by priority or ratio.
     - **Inverse OID value**: Select this if you want to use the value of the monitored metric as inversed for convenience of determining the availability of the server.
6. If you select **Topology** as preferred method, also select a Topology Ruleset. Only topology rulesets with the Server destination type are displayed in the drop-down list.

   If you select Topology as the preferred method, you can also specify the alternate method which is used to select a server from the pool if the preferred one does not return any result. The preferred and alternate methods must be different.
7. If applicable, select the alternate load balancing method.
   - **All Available**
   - **Ratio: Dynamic**
   - **Global Availability**
   - **Source IP Hash**
   - **None**
   - **Ratio: Fixed**
   - **Round Robin**
   - **Topology**

   For details on each alternate method, see the description of the preferred method above.
8. Click **Next** to associate servers with the pool. Click the Add icon, select a server from the *DTC Server Selector* dialog box and click **OK**. You can use SHIFT+click and CTRL+click to associate multiple servers. The appliance displays the following information:
   - **Server Name**: The name of the DNS Traffic Control server.
   - **Host**: The host address of the server.
   - **Ratio**: You can modify the ratio value. The value must be greater than zero.
   - **Disabled**: Indicates whether the server is disabled.
   - **Order**: Displays the order of servers in the list.

   To dissociate a server from the pool, select the checkbox next to the server name and click the Delete icon.
9. Click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.

10. To schedule the change, click **Next** or **Schedule for Later**. In the *Schedule Change* panel, select **Now** to immediately execute this task. Or, select **Later** to schedule this task, and then specify a date, time, and time zone.
11. Save the configuration.

Modifying DNS Traffic Control Pools

To modify a pool, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, click the Action icon next to the pool name and select **Edit** from the menu.
2. The *DTC Pool* editor contains the following basic tabs from which you can modify data. For information about how to modify data, see Configuring DNS Traffic Control Pools above.
    - **General**: This tab displays the pool **Name** and **Comment**. You can edit the values and enable or disable the pool.
    - **TTL**: This tab displays the TTL value configured for the pool. The default value is inherited from the LBDNs which are using the pool. There can be multiple inheritance. Click **Override** to override the value.
    - **Health Monitors**: This tab displays health monitors that are associated with the pool. You can associate new health monitors or dissociate the health monitors that are already associated with the pool.
    - **Load Balancing**: This tab displays the load balancing methods that you have selected while configuring the pool. You can select a new preferred and alternate load balancing methods.
    - **Pool Members**: This tab displays the servers that are associated with the pool. You can add new servers or delete servers that are associated with the pool. You can also modify the ratio and order of servers.
    - **Extensible Attributes**: Add and delete extensible attributes that are associated with the pool. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.
3. To schedule this task, click the Schedule icon at the top of the wizard. In the *Schedule Change* panel, select **Later** and enter a date, time, and time zone. The Schedule icon is green when there is a pending scheduled task. For information, see *Scheduling Tasks*.
4. Save the configuration.

Managing DNS Traffic Control LBDNs

A DTC LBDN is a load balanced domain name object that is used by DNS Traffic Control to process DNS queries for load balanced resources. You can define multiple LBDNs on the NIOS appliance and associate extensible attributes to them. You can configure permissions for DTC LBDNs. For more information, see *License Requirements and Admin Permissions*.

Configuring DNS Traffic Control LBDNs

You can configure a load balancing method for each LBDN. You can assign multiple pools and a single load balancing method to an LBDN. You can associate or dissociate LBDNs with a zone. Note that zone transfers and incremental zone transfers ignore LBDNs. When you configure or modify DTC LBDNs, a service restart is required in order for the new configuration to take effect.

On the appliance, the DNS Traffic Control querying process generates A, AAAA, NAPTR, SRV or CNAME records for an LBDN, called LBDN records. LBDN records are served by DNS Traffic Control servers. An LBDN record must be associated with an authoritative zone. For more information about LBDN records, see Managing LBDN Records below.

To configure an LBDN, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, click the arrow next to the Add icon, and select **LBDN**.
   or
   From the **Data Management** tab -> **DNS** tab -> **Zones** tab -> *authoritative_zone* -> **Records** tab, click the Add icon, and select **Record** -> **DTC LBDN**.
2. In the *DTCLBDN* wizard, complete the following:
    - **Display Name**: Enter a display name for the LBDN.
    - **Patterns**: Click the Add icon to add an LBDN pattern. For more information, see *Configuring LBDN Patterns*.
      To delete an LBDN pattern, select the checkbox next to the pattern and click the Delete icon.

- **Load Balancing Method**: From the drop-down list, select the method you want to use for load balancing. You can select one of the following: **Global Availability**, **Source IP Hash, Ratio:Fixed**, **Round Robin**, and **Topology**. The default is **Round Robin**. For more information about the load balancing methods, see *Load Balancing Methods for DNS Traffic Control*.
- **Topology Ruleset**: This is displayed only when you select the Topology load balancing method. In the drop-down list, only the topology rulesets with the Pool destination type are displayed. Select a topology ruleset for the Topology load balancing method. For more information, see *Defining Topology Rulesets*.
- **Persistence**: Select this checkbox and enter a value greater than zero seconds to enable persistence for the LBDN. You can specify a period between one second to 2 hours. Even if the DNS restart takes longer than the value specified in the **Persistence** field, the DNS server directs the request to the same server. If you specify zero, the appliance does not cache the requests. When you enable persistence for an LBDN, the appliance stores the results for specific LBDN responses in the DNS Traffic Control cache. When a request originates from the respective FQDN or an IP address within the specified period, the DNS server directs the request to the same server.
  Note that when the persistence is enabled, cached results are not guaranteed to persist for the configured duration. The maximum size of the persistence cache is limited globally by the platform. When the limit exceeds the maximum size, the oldest results are deleted. The appliance might discard persistence results if the relevant configuration changes. HA DTC cache replication works on both active and passive nodes and during an HA failover, the DTC cache is replicated from the active node to the passive node. DTC cache replication in HA mode is supported only for IPv4 communications.
- **Priority**: Select a priority value, **1** (High), **2** (Normal), or **3** (Low). The priority value is used when there are LBDNs that have patterns matching the same FQDN and that are assigned to the same zone. In this case, the matching LBDN with the highest priority is used. For example, an LBDN with "*.*foo.com*" and an LBDN with "www.*.com" patterns can be linked to the same zone "*foo.com*" if the LBDN with the "*.*foo.com*" pattern has priority 1 and the LBDN with the "www.*.com" pattern has priority 2 or 3. If there are no matches, the default LBDN is used.
- **Comment**: Enter additional information about the LBDN object.
- **Auto Consolidated Monitors**: Select this option to enable auto managing DNS Traffic Control Consolidated Monitors on DNS Traffic Control Pools linked to the LBDN. This option will lock all the DNS Traffic Control Consolidated Monitor settings on affected DNS Traffic Control Pools, and creates a DNS Traffic Control Consolidated Monitor for each health monitor with the following settings:
  - Availability - ALL
  - Full health communication - Yes
  - Listen To members - all DNS Traffic Control members that serve particular LBDN.
    The **Auto Consolidated Monitor** option also helps to synchronize the health statuses of DNS Traffic Control objects in the LBDN for each DNS Traffic Control Grid member, which means if one Grid member considers that the DNS Traffic Control Server is RED, this server will be RED for each Grid member performing the health check.
    For information on Limitations and Warnings of the **Auto Consolidated Monitors** Option, see *Limitations for DNS Traffic Control LBDN.*
- **Disabled**: Select this to disable the LBDN.

3. Click **Next** and complete the following:
   - **Return these record types for the associated zones**: Select any or all of the following LBDN record types: **A**, **AAAA**, **NAPTR**, **SRV,** and **CNAME**. You must select at least one record type for the LBDN, otherwise the LBDN is disabled. The patterns and the record types can overlap with another LBDN that is linked to the same zone only if their priorities differ.

     If you select the **A** or **AAAA** record type, the LBDN returns the corresponding record and/or a CNAME record when the client queries for any record type and if the server selected by DNS Traffic Control has the required data.

     However, if the client queries for CNAME explicitly, ensure that you select the **CNAME** record type checkbox for the CNAME records to be returned.

     If you select the **CNAME** or **NAPTR** record type, the LBDN returns the CNAME or NAPTR record respectively when the client queries for those records and if the server selected by DNS Traffic Control has the required data. As the CNAME response must be unique, the CNAME record type is unavailable for an LBDN if any pool in that LBDN uses the All Available load balancing method.

Unlike other DNS Traffic Control record types, **SRV** record type has a name. If the QNAME matches the pattern in LBDN and the QTYPE is enabled, a server is selected and all the records of the QTYPE configured for the server are returned. DNS Traffic Control SRV name is not used in name matching during DNS resolution in BIND.
To receive distinct responses, use separate LBDNs as well as separate servers for every service/protocol/domain combination.

- **Associated Zones**: Click the Add icon to associate zones with the LBDN. Select a zone from the *ZoneSelector* dialog box and click **OK**. The appliance displays the following information:
  - **Zones**: The name of the selected zone.
  - **DNS View**: The DNS view associated with the selected zone (if there is more than one DNS view).

  The LBDN is active only when you associate zones with it. You can associate only authoritative forward-mapping zones with the LBDN. The LBDN must contain at least one matching pattern for the zone. For example, an LBDN with patterns "www.*.com" and "www.*.net" may be linked to a zone "*foo.com*". For more information, see Managing LBDN Records below.
- You can also associate LBDNs with DNSSEC signed zones. For more information, see Associating LBDNs with DNSSEC Signed Zones below.

4. Click **Next** and click the Add icon to associate pools with the LBDN. Select a pool from the *DNS Traffic Control Pool Selector* dialog box and click **OK**. The appliance displays the following information:
   - **Name**: The name of the selected pool.
   - **Ratio**: The ratio of the associated server. You can edit this value.
   - **Comment**: Displays information that you specified for the pool.
   - **Members**: Displays the member associated with the pool.
   - **Order**: Displays the order of the pools.

   To dissociate a pool associated with an LBDN, select the checkbox next to the respective pool name and click the Delete icon.
5. Click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.
6. To schedule the change, click **Next** or **Schedule for Later**. In the *Schedule Change* panel, select **Now** to immediately execute this task. Or select **Later** to schedule this task, and then specify a date, time, and time zone.
7. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring LBDN Patterns

An LBDN pattern is a domain name. You can define a pattern with multiple * and ? in any position of the domain name. Note the following about * and ?:

- A sequence of *s has the same effect as a single *.
- A sequence of **?**s will match exactly as many octets as there are **?**s.
- A * terminates on label boundaries and will not match a label separator. For example, *.com matches *foo.com* but not *www.foo.com*.
- A **?** does not match a label separator.
- An empty LBDN pattern will match the root and it is automatically changed to "." when you save the LBDN.
- An LBDN pattern matches an FQDN if the entire FQDN matches.
- LBDN patterns may contain special characters. For example, a\032 *b.com* contains two adjacent spaces.
- LBDN patterns do not support IDN and they will not convert Unicode to punycode. You can enter punycode, but note that the LBDN pattern matching does not support punycode.

> ⚠ Note
> There are many cases where the use of wildcards within LBDN patterns is advisable; however, Infoblox recommends using wildcards with caution in the left-most position because it may lead to unexpected behavior or responses. When in doubt, the most predictable behavior comes from using the target domain name as the pattern when configuring the LBDN.

Managing LBDN Records

In order to manage an LBDN in an authoritative zone, you must enable the authoritative zone and associate it with the LBDN. If an LBDN pattern matches a zone name, the records of type "DTC LBDN Record" are created in that zone as proxies for the LBDN.

To view DTC LBDN records, complete the following:

- Select the **Data Management** tab -> **DNS** tab -> **Zones** tab -> *authoritative_zone* -> **Records** tab.

The record name is the zone-relative portion of the pattern, including wildcards. For example, when you link an LBDN with patterns "www*.*.com", "www.a*z.*.com", "*.com", "bar.*.net" to zone "*foo.com*", the appliance creates three LBDN records with names "" (zone origin), "www", and "www.a*z" in the zone. These records will refer to their respective LBDN. You cannot modify LBDN records. The appliance creates or deletes LBDN records based on the matched LBDN patterns. When you delete an LBDN, the appliance automatically deletes linked zones associated with it and deletes all LBDN records. You can edit the pattern that is associated with the respective LBDN record. For more information, see Modifying DNS Traffic Control LBDNs below.

Note that an LBDN record is a separate object from the LBDN and each of these have separate permissions. For more information, see *License Requirements and Admin Permissions*.

> **Note**
> **SRV** record type uses a name. If the QNAME matches the pattern and the QTYPE is enabled, then a server is selected and ALL records of the QTYPE configured for the server are returned. For distinct responses use separate LBDNs as well as separate servers for every service/protocol/domain combination. DTC SRV name is not used in name matching during DNS resolution in BIND.

Associating LBDNs with DNSSEC Signed Zones

If a zone is DNSSEC signed, you can still associate an LBDN, but some restrictions apply. You can set either Signed or Unsigned mode for the response from DNSSEC signed zones.

The following restrictions apply in the Signed mode:

- You cannot assign an LBDN to a zone or unassign an LBDN from a zone while signing, i.e. key rollover, is in progress for that zone. For information about key rollovers, see *About Key Rollovers.*
- If an LBDN is assigned to a zone for which signing is in progress, then all changes to that LBDN and its dependent configuration (including pools, servers, and topologies) are prohibited until signing completes. The only thing you can do while signing is in progress is to assign an LBDN already assigned to a signed zone to another unsigned zone.
- An LDBN assigned to a signed zone cannot use the All Available load balancing method or have a pattern with a wildcard in the zone. Also, you cannot sign an unsigned zone with such an LBDN assigned.

In the Unsigned mode, unsigned responses in signed zones are returned.

For more information about how to set the Signed or Unsigned mode, see *Configuring Grid DNS Traffic Control Properties*.

> **Note**
> You cannot assign any signed zone during staged Grid upgrade if not all of the NIOS appliances have been moved to a new software version. This restriction is working in both Signed and Unsigned modes.

Modifying DNS Traffic Control LBDNs

To modify an LBDN, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, click the Action icon next to the LBDN name and select **Edit** from the menu.

2. The *DTC LBDN* editor contains the following tabs from which you can modify data. For information about how to modify data, see Configuring DNS Traffic Control LBDNs above.
    - **General**: This tab displays the **Display Name**, **Patterns**, **Load Balancing Method**, **Persistence**, **Priority**, and **Comment** of the LBDN object. Here you can also disable the LBDN.
    - **Associated Zones and Records**: This tab displays the record types that can be returned for the associated zones, the **TTL**, and the **Associated Zones**. You can select any or all of the following record types: **A**, **AAAA**, **SRV**, and **NAPTR**. Note that the default TTL value is 8 hours and is inherited from the associated zones of the Infoblox Grid. You can override this value or associate new zones with the LBDN to inherit a new value.
    - **Pools**: This tab displays the pools that are associated with the LBDN. You can delete an existing pool or add new pools.
    - **Extensible Attributes**: Add and delete extensible attributes that are associated with the LBDN. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.
3. To schedule this task, click the Schedule icon at the top of the wizard. In the *Schedule Change* panel, select **Later** and enter a date, time, and time zone. The Schedule icon is green when there is a pending scheduled task. For information, see *Scheduling Tasks*.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Testing DNS Traffic Control LBDNs

You can select an LBDN and test the DTC response for the respective LBDN. To test an LBDN, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab.
2. In the **Traffic Control** panel, select the LBDN object that you want to test and click **Test LBDN** in the Toolbar.
3. In the *Test DTC LBDN* dialog box, complete the following:
    - **Query Source**: Enter the client IP address.
    - **Query Name**: Enter the FQDN of the record that you are requesting.
    - **Member**: Click **Select** to select the Grid member that will return the response. The dialog box displays the list of members that have a DTC license.
    - **Record Type**: Select a record type, **A**, **AAAA**, **SRV**, or **NAPTR** from the drop-down list.
4. Click **Start**.

    The appliance displays the response for the request in the text output area. To clear the response from the text area, click **Clear**.

Managing DNS Traffic Control Servers

DNS Traffic Control servers are objects that are associated with synthesized A, AAAA, SRV, or CNAME records. DNS Traffic Control servers can be in multiple pools and can be the destination for multiple topology rulesets. You can disable a server while in use, but note that this affects the pools that are associated with the server. You cannot disable a server if it is the last active server for any pool with which it is associated. To disable such a server, first remove it from the associated pools and topology rulesets.

Configuring DNS Traffic Control Servers

You can add a DNS Traffic Control server on the **Traffic Control** tab. Alternatively, you can do this on the **DNS** -> **Zones** tab or **Members/Servers** tab by selecting an existing A, AAAA, or host record in the table, and then clicking **Create DTC Server** in the Toolbar or in the record's action menu.

You can also add a DTC server on the **Data Management** -> **IPAM** tab based on a selected existing A or host record. You can do so on both **IP Map** and **List** subtabs.

If you use multi-tier architecture and want to monitor the availability of separate components of the DNS Traffic Control server, you can add a health monitor for an individual IP address or domain name of the server. You can do it after you have initially configured the server. For information, see Modifying DNS Traffic Control Servers below.

To configure a DNS Traffic Control server, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab.
2. In the Toolbar, click the arrow next to the Add icon and select **Server**.

3. In the *DTC Server Wizard*, under **Select an existing DNS record or enter the Name and Host fields**, perform one the following:
    - Optionally, click **Select** and choose an existing DNS record which will pre-populate the server information:
        i. Select a zone using the filter and click **Apply**.
        ii. Select the record type, **Host**, **A**, or **AAAA**, by which to filter the records list.
        iii. Click the required record name to select it.
    - Specify the DTC server name and host:
        - **Name**: Enter the name of the DTC server.
        - **Host**: Specify the server host by selecting and specifying one of the following:
            - **IP Address**: The DTC response from the server will contain an auto-created A (IPv4) or AAAA (IPv6) record with this IP address.
            - **Domain Name**: The DTC response from the server will contain an auto-created CNAME record that uses this domain name.
            This step only applies if you create a DTC server from the **Traffic Control** tab. If you create a DTC server on the **DNS** -> **Zones**, **DNS** -> **Members/Servers** tab, or **Data Management** -> **IPAM** tab, the record is already selected so this step is not available in the *DTC Server Wizard.*
4. **Auto-create DTC records**: If this is enabled and the Host field contains an IP address, an A (IPv4), or AAAA (IPv6) record will be created. If the Host field contains a domain name, a CNAME record will be created. If you do not enable auto-created DTC records, you must create those records manually. For more information, see Managing DTC Server Records below.
A record type that corresponds to the Host field must exist in order for the DTC Server to return a response.
5. **Comment**: Enter additional information about the server.
6. **Disabled**: Select this to disable the server.
7. Click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.
8. To schedule the change, click **Next** or **Schedule for Later**. In the *Schedule Change* panel, select **Now** to immediately execute this task. Or select **Later** to schedule this task, and then specify a date, time, and time zone.
9. Save the configuration.

Managing DTC Server Records

You can create A, AAAA, CNAME, SRV, and NAPTR records in a DTC server similar to the NAPTR record in a DNS zone.

A NAPTR (Name Authority Pointer) record specifies a rule that uses a substitution expression to rewrite a string into a domain name or URI (Uniform Resource Identifier). A URI is either a URL (Uniform Resource Locator) or URN (Uniform Resource Name) that identifies a resource on the Internet. For information about NAPTR records, see *Managing NAPTR Records*.

You can assign multiple A, AAAA, and NAPTR records simultaneously to a DTC server or only one CNAME record. An enabled CNAME record cannot coexist with an enabled A, AAAA, or NAPTR record. A disabled CNAME record cannot coexist with an enabled CNAME record.

This section describes how to add, modify, and delete records in a DTC server. It includes the following sections:

- Adding DTC Records
- Viewing DTC Records
- Modifying DTC Records
- Deleting DTC Records

Adding DTC Records

To add a DTC record, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab.
2. Click the server name to which you want to add the records. Details of the records added to the server are displayed.
3. Click the arrow next to the **Add** icon and select the type of record you want to add. (A Record, AAAA Record, CNAME Record, SRV Record, NAPTR Record, or Unknown record).
4. Enter the following information in the *Add <Record_Type> Record* wizard:

- For an A record, complete the following:
  - **IP address**: Enter an IPv4 address for the A record on the DTC server.
  - **Comment**: Optionally, enter additional information about the A record.
  - **Disable**: Select this checkbox to disable the record. Clear the checkbox to enable it.
- For an AAAA record, complete the following:
  - **IP address**: Enter an IPv6 address for the AAAA record on the DTC server.
  - **Comment**: Optionally, enter additional information about the AAAA record.
  - **Disable**: Select this checkbox to disable the record. Clear the checkbox to enable it.
- For a CNAME record, complete the following:
  - **Canonical name**: Enter the complete canonical (or official) name of the host.
  - **Comment**: Optionally, enter additional information about the CNAME record.
  - **Disable**: Select this checkbox to disable the record. Clear the checkbox to enable it.
- For a NAPTR record, complete the following:
  - **Service**: Specifies the service and protocol used to reach the domain name that results from applying the regular expression or replacement. You can enter a service or select a service from the list.
  - **Flags**: The flag indicates whether the resulting domain name is the endpoint URI or if it points to another record. Select one of the following:
    - **U**: Indicates that the output maps to a URI.
    - **S**: Indicates that the resulting domain name has at least one SRV record.
    - **A**: Indicates that the resulting domain name has at least one A or AAAA record.
    - **P**: Indicates that this record contains information specific to another application. Leave this blank to indicate that the DNS client must use the resulting domain name to look up other NAPTR records. You can use the NAPTR records as a series of rules that are used to construct a URI or domain name.
  - **Order**: Select an Integer from 10 to 100, or enter a value from 0 to 65535. This value indicates the order in which the NAPTR records must be processed. The record with the lowest value is processed first.
  - **Preference**: Select an Integer from 10 to 100, or enter a value from 0 to 65535. Similar to the **Preference** field in MX records, this value indicates which NAPTR record should be processed first when the records have the same Order value. The record with the lowest value is processed first.
  - **REGEX**: The regular expression that is used to rewrite the original string from the client into a domain name. RFC 2915 specifies the syntax of the regular expression. Note that the appliance validates the regular expression syntax between the first and second delimiter against the Python re module, which is not 100% compatible with POSIX Extended Regular Expression as specified in the RFC. For information about the Python re module, refer to *http://docs.python.org/release/2.5.1/lib/module-re.html .*
  - **Replacement**: This specifies the domain name for the next lookup. The default is a dot (.), which indicates that the regular expression in the **REGEX** field provides the replacement value. Alternatively, you can enter the replacement value in FQDN format.
  - **Comment**: Optionally, enter a descriptive comment for this record.
  - **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.
- For an SRV Record, complete the following:
  - **Display input as**: Select the format in which you want the SRV record to be displayed. When you select RFC 2782 format, the appliance follows the *_service._protocol.name* format as defined in RFC 2782. When you select Free format, enter the entire name in the Domain field.
  - **Service**: Specify the service that the host provides. You can either select a service from the list or type in a service, if it is not on the list. For example, if you are creating a record for a host that provides FTP service, select _ftp. To distinguish the service name labels from the domain name, the service name is prefixed with an underscore. If the name of the service is defined at *http://www.iana.org/assignments/service-names-port-numbers/service-names-port-numbers.xml*, use that name. Otherwise, you can use a locally-defined name.
  - **Protocol**: Specify the protocol that the host uses. You can either select a protocol from the list or type in a protocol, if it is not on the list. For example, if it uses TCP, select _tcp. To distinguish the protocol name labels from the domain name, the protocol name is prefixed with an underscore.
  - **Domain:** Specify the name determined by LBDN.
  - **Preview**: After you have entered all the information, this field displays the FQDN, which is the concatenation of the Service, Protocol, and Domain fields.

- **Priority**: Select or enter an integer from 0 to 65535. The priority determines the order in which a client attempts to contact the target host; the domain name host with the lowest number has the highest priority and is queried first. Target hosts with the same priority are attempted in the order defined in the **Weight** field.
- **Weight**: Select or enter an integer from 0 to 65535. The weight allows you to distribute the load between target hosts. The higher the number, the more that host handles the load (compared to other target hosts). Larger weights give a target host a proportionately higher probability of being selected.
- **Port**: Specify the appropriate port number for the service running on the target host. You can use standard or nonstandard port numbers, depending on the requirements of your network. You can select a port number from the list or enter an integer from 0 to 65535.
- **Target**: Enter the canonical domain name of the host (not an alias). For example, *www2.corpxyz.com*
  In addition, you need to define an A record mapping as the canonical name of the host to its IP address.
- **Comment**: Enter a descriptive comment for the record.
- **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.

- For an Unknown record:
  - **Domain name**: Enter the complete canonical (or official) name of the host.
  - **Comment**: Optionally, enter additional information about the CNAME record.
  - **Disable**: Select this checkbox to disable the record. Clear the checkbox to enable it.

5. To schedule the change, click **Next** or **Schedule for Later**. In the *Schedule Change* panel, select **Now** to immediately execute this task. Or select **Later** to schedule this task, and then specify a date, time, and time zone.
6. Save the configuration and click **Restart** if it appears at the top of the screen.

Viewing DTC Records

To view the records associated with a DTC server, go to the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab -> *DTC server*. The Grid Manager displays the following for each DTC record:

- **Name:** The name of the record.
- **Type**: The type of record.
- **Data**: The data that the record contains. For a NAPTR record, this field displays the following data: Order, Preference, Flags, Services, REGEX, and Replacement.
- **Comment**: Comment that was entered for the record.
- **TTL**: The TTL (time-to-live) value of the record.
- **Disabled**: Indicates if the record is disabled.

You can perform the following:

- Click the Add icon to add a DTC record.
- Select a record and click the Edit icon to edit the configuration. You can also click the Action icon next to the record and select **Edit** from the menu.
- Select a record and click the Delete icon to delete it. You can also click the Action icon next to the record and select **Delete** from the menu.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Click the Export icon to export the list of DTC records to a .csv file.
- Click the Print icon to print the list of DTC records.

Modifying DTC Records

To modify a DTC record, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab -> *DTC server*.
2. Select the DTC record you want to modify, and click the Edit icon.
3. The *DTC Record* editor contains the following tabs from which you can modify information:
   - **General**: You can modify most of the information, except for the read-only fields, such as the DNS view. For a description of the fields, see Adding DTC Records above.
   - **TTL**: You can modify the TTL setting. For information, see *Specifying Time To Live Settings*.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

> ⚠ Note
> When you modify an existing A record, AAAA record, or a Host record connected to a DNS Traffic Control server, new DNS Traffic Control configurations are applied after the DNS Traffic Control health update or after the specified TTL expires for the given record.

Deleting DTC Records

To delete a DTC record, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab -> *DTC server*.
2. Select the DTC record you want to delete, and click the Delete icon.
3. When the confirmation dialog box displays, select **Yes**.

Grid Manager moves the DTC record to the Recycle Bin, from which you can restore or permanently delete the record. For information, see *Using the Recycle Bin*.

Modifying DNS Traffic Control Servers

To modify a DNS Traffic Control server, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, click the Action icon next to the DTC server and select **Edit** from the menu.
2. The *DTC Server* editor contains the following tabs from which you can modify data.
    - **General**: This tab displays the **Name, Host**, **Auto-create DTC records**, and **Comment** that you entered while configuring the server. You can enable or disable the server. For information about how to modify the server data, see *Configuring DNS Traffic Control Servers*. Additionally, specify the Server Name Indication setting:
        - **Use Alternate SNI Hostname**: If the SNI name is different from what is configured in the address field, select this checkbox and enter the required hostname by which an HTTPS health monitor should connect to the server.
        - **Health Monitors**: Define health monitors for the DTC server:
            1. Click the Add icon. A new row appears in the table.
            2. In **Health Monitor**, select the monitor type: icmp, http, https, sip, pdp, or snmp.
            3. In **Domain Name or IP Address**, type either the FQDN or the IP address to monitor.
            4. If required, add more health monitors for the server as described above. You can add up to ten health monitors per server.
               In **Health Monitors from Pools**, you can see other health monitors assigned to the pools that the server belongs to. The availability requirement for the pools must be set to either “All” or “Any” for you to be able to add server-specific health monitors. For information, see *Configuring DNS Traffic Control Pools*.
            5. Save the configuration.
    - **Extensible Attributes**: Add and delete extensible attributes that are associated with the server. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.
      For information on warnings related to **Auto Consolidated Monitor**, see *Warnings for DNS Traffic Control Servers*.
3. To schedule this task, click the Schedule icon at the top of the wizard. In the *Schedule Change* panel, select **Later** and enter a date, time, and time zone. The Schedule icon is green when there is a pending scheduled task. For information, see *Scheduling Tasks*.
4. Save the configuration.

Visualization for DNS Traffic Control Objects

Grid Manager provides a visual tree view that you can use to quickly understand an overall traffic control structure of a selected DTC object. The visualization panel is displayed by default on the **Traffic Control** tab.
To view a visualization of the DNS traffic control structure for an object:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab.

2. Select the checkbox next to the DTC object for which you want to view, for example, LBDN. The LBDN structure tree is displayed in the visualization panel.

The tree shows the selected object and its relationships with other associated DTC objects. The DTC objects are represented as nodes in the hierarchical order of LBDN -> pool -> server levels. Note that when a DTC server is associated with multiple pools, the appliance displays the connection to the selected pool only, not showing the other pools that the server is assigned to. If an LBDN has more than one pool associated, it displays the servers for only one pool at a time. Clicking on another pool of the LBDN displays the servers for that pool.
You can hover your mouse over an object to display a tooltip that contains the following information:

- The name and status of the DTC object. For more information about the possible statuses, see Understanding DTC Object Status below.
- **Load Balancing Method**: This is displayed only for LBDN objects.
- **Preferred Load Balancing Method**: This is displayed only for pool objects.
- **Alternate Load Balancing Method**: This is displayed only for pool objects.
- **Host**: The domain name or IP address of a server object.
- **Last Updated**: The timestamp when the object was last discovered.
- **Health Monitors:** This displays health monitors status for pools and servers.
  The health status displayed for a DTC server includes health monitors assigned through the pool as well as individual health monitors per IP address or domain name of the server, if assigned. For example, monitor_name(monitor_type) for a pool monitor, and IP_address_or_FQDN(monitor_type) for an individual server monitor.
- **Ratio: Dynamic**: In DTC pools and servers visualization, this displays traffic distribution across members and servers with the Ratio: Dynamic load balancing method applied.
- **Number of Pools**: Shows the number of pools for the LBDN.
- **Number of Servers:** Shows the number of servers for the pool.
- **Used by these LBDNs**: Shows all LBDNs that use the pool.
- **Used by these Pools:** Shows all pools that use the server.

To hide or show the visualization panel, click **Hide Visualization** or **Show Visualization** in the Toolbar.

From a DTC object tooltip, you can perform certain actions on the object or add the default visualization in the panel as discussed later in this topic

> **Note**
>
> Grid Manager can display a maximum of 100 nodes for each level associated with the currently visualized node.

Understanding DTC Object Status

The DTC object status can be one of the following:

Icon (Visualization Panel)	Status and Meaning (Visualization Panel)	Status and Meaning (Traffic Control Tab)
	**Running**: The object is fully available and operational.	**Running** with a green background: The object is fully available and operational.
	**Warning**: The object has a warning message. You can check the syslog for any messages.	**Warning** with a yellow background: The object has a warning message. You can check the syslog for any messages.
	**Error**: The object has an error. You can check the syslog for any messages.	**Error** with a red background: The object has an error. You can check the syslog for any messages.

Icon (Visualization Panel)	Status and Meaning (Visualization Panel)	Status and Meaning (Traffic Control Tab)
	**Disabled** (in the legend) and **Requires Manual Enabling** (on mouse hover): The object is disabled due to a configuration setting and it must be enabled manually.	**Requires Manual Enabling** with a white background: The object is disabled due to a configuration setting and it must be enabled manually.
	**Temporarily Disabled** (in the legend) **Will be enabled at <*time_stamp*>** (On mouse hover): The object is disabled for a specified duration due to a configuration setting. It will be automatically enabled at the displayed time. Or **Temporarily Disabled** (On mouse hover): The object is disabled due to a configuration setting and will be enabled when the DNS service restarts.	**Temporarily Disabled** with a dark grey background: The object is disabled due to a configuration setting. This might be due to different reasons, such as the "Disable" flag being set, the DNS service not running on the selected member, a zone not assigned to an LBDN, or the LBDN not associated with a zone for the selected DTC member. When multiple DTC Grid members are configured with different disable options for a DTC object, collectively the status shows as **Temporarily Disabled**. You can view the member level status in the visualization panel.
	**Disabled, Working** (in the legend) and **Will be disabled at <*time_stamp*>** (On mouse hover): The object is working fine, but it will be disabled at the displayed time.	**Running** with a green background: The object is fully available and operational.
	**Disabled, Error** (in the legend) and **Will be disabled at <*time_stamp*>** (On mouse hover): The object has failed. It will be disabled at the displayed time.	**Error** with a red background: The object has an error. You can check the syslog for any messages.
	**Unknown**: The DTC object status has not yet been determined.	**Unknown**: The DTC object status has not yet been determined.
	**Unlicensed**: The object does not have a DNS Traffic Control license.	**Unlicensed**: The object does not have a DNS Traffic Control license.

It may take a few minutes for the status of an object to be updated after a configuration change.
Grid Manager calculates the status differently for the DTC objects list view and the visualization.

Calculating the Status

A DTC pool may use multiple health monitors and it has an availability option for these monitors that is used to determine the status of a DTC server. For example, if the availability requirement is "All", then the server is considered to be 'Running' if all the pool health monitors report the server as 'Running'. Servers may appear in multiple pools that have different health monitors and different availability settings. Thus, a DTC server status can be different for different pools. You can filter the DTC objects visualization by all members or a specific member. A DTC Grid member uses health monitors to determine the status of a DTC server. A Grid member is associated with an LBDN if that Grid member is assigned a name server for a zone that is associated with an LBDN. A DTC server is associated with an LBDN if it is part of a DTC pool which is used by the LBDN. Thus, if a DTC Grid member is associated to a DTC server through an LBDN, the Grid member checks the status of the DTC server using the health monitors associated with the DTC server's pool. When the visualization is filtered by a specific DTC Grid member, the displayed status of the DTC servers is the status that was determined by that specific DTC Grid member. When you select **All Members** in the visualization, the displayed status is an aggregated status across all DTC Grid members.
For the DTC objects list view, the status is calculated as follows:

- Server: Aggregated status from all pool monitoring across all DTC Grid members.
- Pool: Aggregated status for all its servers across all DTC Grid members.
- LBDN: Aggregated status for all its pools across all DTC Grid members.

For the visualization panel, the status is calculated as follows:

- Server: Status from selected pool monitoring for selected DTC Grid member.
- Pool: Aggregated status for all its servers for selected DTC Grid member.
- LBDN: Aggregated status for all its pools for selected DTC Grid member.

> **Note**
>
> If a pool has no health monitors configured, then the servers and pool report a status of 'Running'.

Working with the Visualization Panel

You can do the following in the visualization panel:

- Resize the visualization panel in relation to the DTC objects list view by dragging the vertical separator between the panel and the list view.
- Filter the visualization by Grid members associated to DTC objects through LBDNs: In the **Member** drop-down list, select **All Members** or a specific member. For more information about how the object status is determined for all members and for a specific member, see Calculating the Status above. Note that the appliance displays only members that have the DNS Traffic Control license.
- Filter by the DTC status: **All DTC Status** or **Non-Running** only. You can combine this filter with the members filter.
- Zoom the map in and out by moving the Zoom slider. You can also zoom in and out by using the mouse wheel.
- Click the **Adjust tree size to window size** icon to adjust the tree size after you zoomed it in our out.
- Change the tree orientation by clicking the Change Tree Orientation icon. The default orientation is vertical.
- Click the **Expand Visualization** icon to open the DTC structure in a separate window. Alternatively, you can click the Action icon ☰ next to the required DTC object in the table and select **Expand Visualization**.
- Click **Show Legend/Hide Legend** to show or hide the legend when the visualization is expanded.
- Click the Refresh icon to refresh the tree. You can also select the **Auto Refresh** checkbox to turn on auto-refresh.
- Click anywhere in the tree and hold your mouse to drag the tree to a desired location in the panel or window.
- Hover your mouse over an LDBN to display the tooltip and do the following:
  - Test the LBDN.
  - Add an existing pool to the LBDN.
  - Add a new pool to the LBDN.
  - Disable or enable the LBDN.
  - Edit the LBDN.
  - Delete the LBDN.
  - Schedule the deletion of the LBDN.
  - Switch to the LBDN visualization mode if you are currently in the pool visualization mode.
- Hover your mouse over a pool to display the tooltip and do the following:
  - Add the pool to an LBDN.
  - Add an existing server to the pool.
  - Add a new server to the pool.
  - Disable or enable the pool.
  - Edit the pool.
  - Switch to the pool visualization mode if you are currently in the LBDN or server visualization mode.
- Hover your mouse over a server to display the tooltip and do the following:
  - Add the server to a pool.
  - Disable or enable the server.
  - Edit the server.
  - Switch to the server visualization mode if you are currently in the LBDN visualization mode.

Adding Default Visualization

The default visualization allows you to design a DNS Traffic Control structure in the inverse order—first, add a visualization of the default DTC objects structure and create the default disabled objects, and then define the objects one by one.
To add the default visualization:

1. On the **Traffic Control** tab, click the arrow next to the Add icon and select **Default Visualization**.
   The default basic DTC objects structure is displayed in the visualization panel. It consists of the default server, pool, and LBDN. By default, they are disabled.
   The corresponding server, pool, and LBDN objects are added in the DTC objects list view.
2. Configure the DTC objects in any of the following ways:
   For information about the configurable properties of DTC objects, see *Managing DNS Traffic Control Objects*.
   - Hover your mouse over an object to display the tooltip, click the required button, and make the necessary configurations.
   - In the DTC objects list view, select the required object, click the Edit icon, and make the necessary configurations.
3. If necessary, configure the topology rulesets, topology database, and DTC health monitors used in your DTC structure. For information, see *Defining Topology Rulesets*, *Importing a Topology Database,* and *Using DNS Traffic Control Health Monitors* correspondingly.
4. After you configured the DTC objects, enable each one of them:
   - Hover your mouse over an object.
   - Click **Enable** in the tooltip.

Once all objects are enabled and all necessary service restarts are performed, the whole DTC structure starts working.

Backing Up DTC Configuration Files

Infoblox recommends that you regularly back up DTC configuration files. You can either schedule a backup to run at a designated date and time or you can manually back up the files. You can back up the DTC files to the following:

- A local directory
- A TFTP server
- An FTP server. This option requires that you have a valid username and password on the server prior to backing up files.
- An SSH server that supports SCP. This option requires that you have a valid username and password on the server prior to backing up files.

For information about these options, see *Backing Up and Restoring Configuration Files*.

Automatically Backing Up DTC Files

To automatically back up DTC configuration files:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Backup** -> **DTC Backup** -> **Schedule Backup** from the Toolbar.
2. In the *Schedule DTC Backup* dialog box, select the destination of the backup file from the **Backup to** drop-down list:
   - **TFTP**: Back up system files to a TFTP server.
     - **Keep local copy**: Select this to also save a local copy of the backup file on your appliance. This is disabled by default. The local backup contains only the Grid backup, it does not contain backups for reporting and Network Automation. Note that when you select this, the total backup time will increase.
     - **IP Address of TFTP Server**: Enter the IP address of the TFTP server to which you want to back up the system files.
     - **Directory Path**: Enter the directory path of the file. For example, you can enter **/archive/backups**. The directory path cannot contain spaces. The folder or directory you enter here must already exist on the specified server. Do not include the file name in the directory path.

- **Recurrence**: Select how often you want to back up the files. You can select **Weekly**, **Daily**, or **Hourly** from the drop-down list. When you select **Weekly**, complete the following:
  - **Every:** Choose a day of the week from the drop-down list.
  - **Time**: Enter a time in the hh:mm:ss AM/PM format. You can also click the clock icon and select a time from the drop-down list. The Grid Master creates a backup file on the selected day and time every week.
    When you select **Daily**, enter a time in the hh:mm:ss AM/PM format. You can also select a time from the drop-down list.
    When you select **Hourly**, complete the following:
  - **Minutes after the Hour**: Enter the minute after the hour when the Grid Master creates a backup file. For example, enter 5 if you want the Grid Master to create a backup file five minutes after the hour every hour.
- **Disable Scheduled Backup:** Select this if you want to disable automatic backups from occurring now. You can still save the settings for future use.

- **FTP**: Back up system files to an FTP server.
  - **Keep local copy**: Select this to also save a local copy of the backup file on your appliance. This is disabled by default. The local backup contains only the Grid backup, it does not contain backups for reporting and Network Automation. Note that when you select this, the total backup time will increase.
  - **IP Address of FTP Server**: The IP address of the FTP server.
  - **Directory Path**: Enter the directory path of the file. For example, you can enter **/archive/backups**. The directory path cannot contain spaces. The folder or directory you enter here must already exist on the specified server. Do not include the file name in the directory path.
  - **Username**: Enter the username of your FTP account.
    Note if you have configured AD server for authentication, you must specify "domain name\ \username".
  - **Password**: Enter the password of your FTP account.
  - **Recurrence**: Select how often the scheduled backups should occur. You can select **Weekly**, **Daily**, or **Hourly**.
  - **Every**: Choose a day of the week from the drop-down list.
  - **Disable Scheduled Backup:** Select this if you want to disable automatic backups from occurring now, but want to save the settings for future use.
- **SCP**: Back up system files to an SSH server that supports SCP.
  - **Keep local copy**: Select this to also save a local copy of the backup file on your appliance. This is disabled by default. The local backup contains only the Grid backup, it does not contain backups for reporting and Network Automation. Note that when you select this, the total backup time will increase.
  - **IP Address of SCP Server**: The IP address of the SCP server.
  - **Directory Path**: Enter the directory path of the file. For example, you can enter **/archive/backups**. The directory path cannot contain spaces. The folder or directory you enter here must already exist on the specified server. Do not include the file name in the directory path.
  - **Username**: Enter the username of your SCP account.
    Note if you have configured AD server for authentication, you must specify "domain name\ \username".
  - **Password**: Enter the password of your SCP account.
  - **Recurrence**: Select how often the scheduled backups should occur. You can select **Weekly**, **Daily**, or **Hourly**. For information, see the TFTP section.
  - **Every**: Choose a day of the week from the drop-down list.
  - **Disable Scheduled Backup:**Select this if you want to disable automatic backups from occurring now. You can still save the settings for future use.
    When you select **FTP** or **SCP**, ensure that you have a valid user name and password on the server prior to backing up the files.
- **Grid Master (local)**: Back up to a local directory on the Grid Master. This is the default.
  By default, the Grid Master generates a backup file and saves it locally in its own storage at 3:00 AM daily. Be aware that backing up the Grid and saving it locally on an hourly basis increases the turnover of files stored on the Grid Master. Backing it up hourly to a remote server increases the overall amount of traffic on your network.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Manually Backing Up DTC Files

You can manually back up DTC configuration files in addition to scheduling your backups. To back up manually:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Backup** -> **DTC Backup** -> **Manual Backup** from the Toolbar.
2. In the *Manual DTC Backup* wizard, select the destination of the backup file from the **Backup to** drop-down list:
   - **My Computer**: Back up system files to a local directory on your computer. This is the default.
   - **TFTP**: Back up system files to a TFTP server.
     - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter `/archive/backups/Infoblox_2009_10_20_15_30.`
     - **IP Address of TFTP Server**: Enter the IP address of the TFTP server to which you want to back up the system files.
   - **FTP**: Back up system files to an FTP server.
     - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter **/archive/backups/Infoblox_2009_10_20_15_30**.
     - **IP Address of FTP Server**: The IP address of the FTP server.
     - **Username**: Enter the username of your FTP account.
       Note if you have configured AD server for authentication, you must specify "domain name// username".
     - **Password**: Enter the password of your FTP account.
   - **SCP**: Back up system files to an SSH server that supports SCP.
     - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter **/archive/backups/Infoblox_2009_10_20_15_30**.
     - **IP Address of SCP Server**: The IP address of the SCP server.
     - **Username**: Enter the username of your SCP account.
       Note if you have configured AD server for authentication, you must specify "domain name// username".
     - **Password**: Enter the password of your SCP account.
       When you select **FTP** or **SCP**, ensure that you have a valid username and password on the server prior to backing up the files.
3. Click **Backup**.

Downloading DTC Backup Files

You can save an existing backup file, or create and save a new one to your local management system, a TFTP server, an FTP server, or a SCP server.
To download an existing backup file:

1. From the **Grid** tab, select the **Grid Manager** tab, and the click **Backup** -> **DTC Backup** -> **Manage Local Backup** from the Toolbar. Grid Manager displays the current backup files in the *Manage Local Backups* dialog box.
2. To download a backup file, select the checkbox of a backup file, and then click the Transfer icon. You cannot select multiple files for downloading.
3. Select one of the following from the **Backup to** drop-down list:
   - **My Computer**: Backup to a local directory on your computer. This is the default.
   - **TFTP**: Save the backup file to a TFTP server.
     - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter `/archive/backups/Infoblox_2009_10_20_15_30`.
     - **IP Address of TFTP Server**: Enter the IP address of the TFTP server to which you want to save the backup file.
   - **FTP**: Save the backup file to an FTP server.
     - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter `/archive/backups/Infoblox_2009_10_20_15_30.`
     - **IP Address of FTP Server**: The IP address of the FTP server.
     - **Username**: Enter the username of your FTP server account.
     - **Password**: Enter the password of your FTP server account.
   - **SCP**: Save the backup file to an SSH server that supports SCP.

- **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter **/archive/backups/Infoblox_2009_10_20_15_30**.
- **IP Address of SCP Server**: The IP address of the SCP server.
- **Username**: Enter the username of your SCP server account.
- **Password**: Enter the password of your SCP server account.
  When you select **FTP** or **SCP**, ensure that you have a valid username and password on the server prior to backing up the files.

4. Click **Transfer Copy**.

Restoring DTC Backup Files

You must log in with a superuser account to back up and restore files. NIOS provides three ways to restore a backup file:

- From a local directory or the management system you use to operate the appliance
- From a TFTP server
- From a remote server using FTP. This option requires that you have a valid username and password on the FTP server prior to performing a backup or restore.

> **Note**
>
> When you restore NIC interfaces to a VM, ensure that you provision appropriate NIC interfaces with the database content that must be restored to avoid any errors.

To restore a DTC backup file to the same independent appliance or Grid Master:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Restore** -> **Restore DTC** from the Toolbar.
2. In the *Restore* dialog box, choose one of the following from the **Restore from** drop-down list:
   - **My Computer**: Restore a file from your local computer. This is the default.
     - **Filename**: Click **Select File** to navigate to the configuration file.
   - **TFTP**: Restore a file from a TFTP server.
     - **Filename**: Enter the directory path and the file name you want to restore. For example, you can enter `/archive/backups/Infoblox_2009_10_20_15_30`.
     - **IP Address of TFTP Server**: Enter the IP address of the TFTP server from which you restore the configuration file.
   - **FTP**: Restore a file from an FTP server.
     - **Filename**: Enter the directory path and the file name of the backup file. For example, you can enter `/archive/backups/Infoblox_2009_10_20_15_30.`
     - **IP Address of FTP Server**: The IP address of the FTP server.
     - **Username**: Enter the username of your FTP server account.
     - **Password**: Enter the password of your FTP server account.
   - **Grid Master (Local)**: Restore from a local directory on the Grid Master. In the *Backup Set* table, select the file you want to restore.
3. To restore NIOS configuration data, select the **NIOS data** checkbox.
4. To download a backup file from one appliance to a different appliance, select **Force Restore from Different Grid** to enable the feature, and then select one of the following:
   - **Retain Current Grid Master IP Settings** (this is the default)
   - **Overwrite Grid Master IP Settings**
5. Click **Restore**. In the *Confirm Restore* dialog box, click **Yes**.
   After restoring the file, the appliance restarts. The restore process overwrites all existing data. All pending scheduled tasks are not restored or reverted.
6. Close your current browser window, wait a few minutes, and then reconnect to the NIOS appliance.

Downloading DTC Backup Files from a Different Appliance

When you "force restore" a NIOS appliance, you download a backup file from one appliance to a different appliance. To restore a backup file to the same appliance or Grid Master, use the Restore function as described in the previous section,

see Restoring DTC Backup Files.
To download a backup file from one appliance to a different appliance:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Restore** -> **Restore DTC** from the Toolbar.
2. In the *Restore* wizard, do the following:
    - **Restore from:** Choose a source from which you restore the configuration file, as described in as described in the previous section, see Restoring DTC Backup Files.
3. Select **Force Restore from Different Grid** to enable the feature, and then select one of the following:
    - **Retain Current Grid Master IP Settings** (this is the default)
    - **Overwrite Grid Master IP Settings**
4. Click **Restore**. In the *Confirm Restore* dialog box, click **Yes**.
   After restoring the file, the appliance reboots. The restore process overwrites all existing data. All pending scheduled tasks are not restored or reverted.
5. Close your current browser window, wait a few minutes, and then reconnect to the NIOS appliance.

Using DNS Traffic Control Health Monitors

Health monitors determine the availability of DTC servers. You associate health monitors with pools. Every health monitor checks each server that is associated with the pool. Additionally, if you use multi-tier architecture, you can assign health monitors to individual IP addresses of a DTC server. You can use pre-defined health monitors or create custom monitors. You can configure health monitors of the following types:

- HTTP health monitors
- ICMP health monitors
- PDP health monitors
- SIP health monitors
- SNMP health monitors
- TCP health monitors

For more information, see the following sections:

- *Configuring HTTP Health Monitors*
- *Configuring ICMP Health Monitors*
- *Configuring PDP Health Monitors*
- *Configuring SIP Health Monitors*
- *Configuring SNMP Health Monitors*
- *Configuring TCP Health Monitors*

When you install the DNS Traffic Control license, each Grid member that is associated with an LBDN independently monitors the health of a server. The appliance resolves the server FQDN using the system resolver. The appliance performs a health check on both the IPv4 and IPv6 addresses. If the member does not have the same IP address types as the server or if the DNS name resolution for A or AAAA records fail to return results, the corresponding health check is considered to be a failure. The appliance caches the addresses that are resolved.
Note that monitoring is done by each Grid member that has a DNS Traffic Control license and is associated with a zone that has an LBDN record. This implies that firewall policies should be such that the member can reach every server it is monitoring. Otherwise, DNS Traffic Control cannot direct responses to servers that are not accessible.
By default, all monitor checks are initiated from the virtual interface of the member that is performing the health check. If the monitored server has only an IPv4 or IPv6 address, then the interface must have the corresponding IP address type. You can configure the DTC monitor source to use the VIP, MGMT, LAN2 (WHERE), or ANY (normal routing) NIOS network interface, or one of the loopback additional IP addresses for the Grid member. You can configure the loopback IP address in the Grid member editor or network configuration.
The status of a DTC server for a specific pool depends upon the status of all the health monitors that are checking it. The status of a pool depends upon the status of all the servers in the pool. The status of an LBDN depends upon the status of all the pools assigned to the LBDN.
For the HTTPS and SIP monitor types, you can upload client certificates and associate them with the monitors to provide when connecting to a DTC server. For information, see ManagingHealthMonitorCertificates below.
Vice versa, DTC servers provide certificates to authenticate themselves to the HTTPS and SIP monitors. You enable DTC server certificate validation when configuring HTTPS and SIP health monitors.

Configuring HTTP Health Monitors

An HTTP health monitor sends either an HTTP or HTTPS request to the server. The health monitor then examines the response received from the server. The validation is successful if the server returns a response with the expected result code.
The HTTP/HTTPS monitor can validate the response code and response content. The response content is checked only when the response code is valid. You can define regular expressions to use for the response content check. The supported regular expression syntax is POSIX Extended Regular Expression. For information, see *Supported Expressions for Search Parameters*.
If the DTC server certificate validation is enabled in the HTTPS health monitor, you can use the Server Name Indication (SNI) feature for remote DTC servers. SNI is an extension to the TLS computer networking protocol by which a client indicates which hostname it attempts to connect to at the start of the handshaking process. This allows a server to present multiple certificates on the same IP address and TCP port number. Thus, multiple secure (HTTPS) websites (or any other service over TLS) can be served off the same IP address without all those sites having to use the same certificate.
After you configure an HTTP/S monitor, you can test its performance. See TestingHTTPHealthMonitors below.

> ⚠ **Note**
> The HTTP health monitor does not support user name or password authentication.

To configure an HTTP health monitor, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Health Monitors** in the Toolbar.
2. In the Health Monitors Manager, click the arrow next to the Add icon and select **HTTP Health Monitor**.
3. In the *HTTP Health Monitor Wizard*, complete the following:
   - **Name**: Enter a name for the HTTP monitor.
   - **Interval (seconds)**: Enter the interval value in seconds. The interval value is measured from the end of the previous monitor cycle. The default value is five.
   - **Timeout (seconds)**: Enter the timeout value in seconds. The monitor waits for the number of seconds that you specify after sending a response. If it does not receive a response within the number of seconds that you specify, then the appliance considers this check as failed. The monitor discards any response it receives after the timeout. The default value is 15.
   - **Retry Up Count**: Enter a retry up count integer value. Retry up count is a value that determines how many valid responses or good health checks in a row must be received by the Grid member from the DTC server for setting the DTC server health status to green. When you specify a value, the appliance computes the duration for which health check must be performed based on the following:

     `interval*retry up count`

     For example, If the DTC server has had a red status for a long time because all the HTTP health checks have failed, and when the Grid receives the first good HTTP health check result, the health check counter is set as 1; however, the status of the DTC server is still retained as red. If you specify the **Retry Up Count** as 3 and the health check interval as 5, when three consecutive good health check results are received, the health check counter value becomes 3 and the DTC server health status now changes to green (3 good health check results in a row at an interval of 5 seconds each over a span of 3*5=15 seconds).
   - **Retry Down Count**: Enter a retry down count integer value. It is the opposite of the retry up count. Retry down count is a value that determines how many red status health checks (server is unavailable) in a row must be collected by the Grid member from the DTC server to switch the health status from green to red. For example, for a Grid member whose connection to the DTC server is not stable and has its Retry Down Count set as 5, if the health check results received by the Grid member is in the sequence: green, red, red, red, green, then the health status of the DTC server will be retained as green.

     Note that red health status is set when the health monitor reaches the timeout value that is `[health check interval + timeout]` seconds without a valid response.
   - **Comment**: Enter information about the HTTP monitor.

4. Click **Next** and complete the following:
   Port: For HTTP, the appliance displays port number 80 by default. If you select Use HTTPS, the appliance displays 443 by default.
   Use HTTPS: Select the checkbox to enable HTTPS. Specify any of the following options that become available when you select to use HTTPS:
   - **Client Certificate**: Optionally, you can select a certificate to use while opening the SSL connection for HTTPS. The monitor does not inspect or validate the server certificate, if any. For information about how to upload certificates, see ManagingHealthMonitorCertificates below.
   - **Ciphers**: Specify a list of SSL ciphers in an OpenSSL format. You can specify cipher texts up to 1024 characters. The client certificate and cipher list are only used for HTTPS transport.
     The following example commands list some available ciphers:
     Example 1:

     ```
     $ openssl ciphers 'HIGH:!DES'
     DHE-RSA-AES256-SHA:DHE-DSS-AES256-SHA:DHE-RSA-CAMELLIA256-SHA:
     DHE-DSS-CAMELLIA256-SHA:ADH-AES256-SHA:ADH-CAMELLIA256-SHA:AES256-
     SHA: CAMELLIA256-SHA:PSK-AES256-CBC-SHA:EDH-RSA-DES-CBC3-SHA:
     EDH-DSS-DES-CBC3-SHA:ADH-DES-CBC3-SHA:DES-CBC3-SHA:DES-CBC3-MD5:
     PSK-3DES-EDE-CBC-SHA:KRB5-DES-CBC3-SHA:KRB5-DES-CBC3-MD5:DHE-RSA-
     AES128-SHA: DHE-DSS-AES128-SHA:DHE-RSA-CAMELLIA128-SHA:DHE-DSS-
     CAMELLIA128-SHA:
     ADH-AES128-SHA:ADH-CAMELLIA128-SHA:AES128-SHA:CAMELLIA128-SHA: PSK-
     AES128-CBC-SHA
     ```

     Example 2:

     ```
     $ openssl ciphers 'DEFAULT:!EDH+aRSA'
     DHE-DSS-AES256-SHA:DHE-DSS-CAMELLIA256-SHA:AES256-SHA:CAMELLIA256-
     SHA:
     PSK-AES256-CBC-SHA:EDH-DSS-DES-CBC3-SHA:DES-CBC3-SHA:PSK-3DES-EDE-
     CBC-SHA: KRB5-DES-CBC3-SHA:KRB5-DES-CBC3-MD5:DHE-DSS-AES128-SHA:DHE-

     MD5:EXP-RC4-MD5: EXP-KRB5-RC4-SHA:EXP-KRB5-RC4-MD5
     ```

     Note:
     The DHE cipher list family ("Diffie-Hellman key agreement" plus "RSA authentication") could consume excessive CPU and is excluded from the defaults used by DNS Traffic Control health monitors. Although you can enable these ciphers by explicitly configuring them in the cipher list for HTTPS and SIP monitors, you should be aware that doing so will increase CPU usage. Since health monitoring in general does not require high security, Infoblox recommends that you enable these ciphers only for target servers that do not accept other types of ciphers.

- **Enable Certificate Validation**: It is highly recommended to select this for the DTC server certificate to be validated by NIOS.
    - **Enable SNI (Server Name Indication)**: Specify if you want to use SNI for the health monitor to connect to a specific DTC server by hostname. In addition, you should indicate an alternate SNI hostname in the DTC server editor.

5. Click **Next** and complete the following:
    - **HTTP Request**: Specify the HTTP request to send the query from the client to the server. The appliance displays **GET/** by default. You can specify an HTTP request up to 1024 characters. For more information, see EditingHTTPRequestforHTTPHealthMonitor below.
    - **Response Code Check**: Specify in which case the response code from the server is valid:
        - Select **Any response code is valid**, if any response code from the server is required.
        - Select **A valid response code**, select **equals** or **does not equal**, and then specify a value. The default value is 200.
    - **Response Content Check**: Specify an option for checking the server response content:
        - Select **Do not check the response content** to not perform any content check.
        - Select **Search for a string in the response content** to search for a string in the response content. Then do the following:
            1. In the **Search in** drop-down list, choose where to perform the search for a string: in **Both the header or body**, **Body**, or **Headers** of the HTTP request. The search is limited to the first five kilobytes of the response.
            2. In the **Regular Expression** field, specify a regular expression that will be used to search for a string in the response content.
            3. In the drop-down list **The content is valid if the regular expression is**, select either **found** or **not found**. If you select **found**, the content is valid if it corresponds to the regular expression you specify. If you select **not found**, the content is valid if it does not correspond to the regular expression you specify.
        - Select **Extract content from the response and compare it to a value** to extract a certain part of the content and compare it to a specific string or integer value. Then do the following:
            1. In the **Search in** drop-down list, choose where to perform the search for a string: in **Both the header or body**, **Body**, or **Headers** of the HTTP request. Note that the search is limited to the first five kilobytes.
            2. In the **Regular Expression** field, specify a regular expression for content extraction. The regular expression can contain subexpressions that you may specify in the next step. If you set **1st** as the value for **Check content that is extracted using the <...> subexpression**, the format of the **Regular Expression** must be `expression(sub_expression1)`. The number of subexpressions must be same as or can be more than the value you specify for **Check content that is extracted using the <...> subexpression**. For example, the format must be `expression(sub_expression1)(sub_expression2)` when the **Check content that is extracted using the <...> subexpression** is set to **2nd**, which means that there must be at least two subexpressions.
            3. Select **Check all extracted content** to or select **Check content that is extracted using the <...> subexpression** and choose a number of the subexpression from the drop-down list. You can choose from the first to the eighth subexpression previously defined in the **Regular Expression** field.
            4. In the field **The extracted content is valid if it is a**, select the expected data type of the extracted content, **string** or **integer**, and select a comparison operator. Then specify a value in the text field.
6. Click **Next** to add extensible attributes. For information, see *Using Extensible Attributes*.
7. To schedule the change, click **Next** or **ScheduleforLater**. In the *ScheduleChange* panel, click **Now** to immediately execute this task. Or, click **Later** to schedule this task, and then specify a date, time, and time zone.
8. Save the configuration.

Editing HTTP Request for HTTP Health Monitor

You can specify a multi-line message and include HTTP headers in the request by using the **HTTP Request** field in the HTTP health monitor properties. The header lines of an HTTP request have the simple name: value syntax. The request

headers are used to pass cookies, authentication, and provide information about the client to the server, etc.
The HTTP 1.1 contains a request line and a single host header:

Example 1:

```
GET / HTTP/1.1
Host: www.yoursite.com
Connection: close
```

Example 2:

```
GET /index.html HTTP/1.1
Host: www.example.com
```

Note that the lines are terminated with two chars

`\r\n`. The whole request terminates with an empty line "`\r\n\r\n`" character sequence. NIOS adds `\r\n\r\n` string if it is absent. You can request `GET /` instead of "`GET/index.html`".
The host header differentiates between several HTTP servers that are running on a single IP address on the same port.

In an HTTP 1.1 request, the server keeps the connection alive by default after the response is sent. You can disable the connection by adding a `Connection: close` header line to the request.

An HTTP 1.0 request may consist of a single line followed by the automatically added `\r\n\r\n`:

```
GET /index.html HTTP/1.0
```

Or in the most simple form:

```
GET / HTTP/1.0
```

The server closes the connection after the response has been sent. You can use `Connection: Keep-Alive` header to alter this behavior. The `Content-Length` header is important to determine the end of the response for keep-alive connections.
Apart from HTTP 1.0/1.1, NIOS also supports a request format known as HTTP 0.9:

```
GET /index.html
```

or

```
GET /
```

Normally, the response header consists of a response line, such as `HTTP/1.1 200 OK` or `HTTP/1.0 400 Bad Request`, followed by a couple of header lines, and then by an empty line which signals the end of the response header. With HTTP 0.9, the response immediately starts with the content of the requested file, which means that there is no HTTP return code for an HTTP 0.9 request.

Testing HTTP Health Monitors

After the HTTP health monitor is configured, you can test the configuration for a specific DTC server. Note that if you make changes to the HTTP health monitor settings, you must save the configuration so you can run the test.
To test the HTTP health monitor, do the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Health Monitors** in the Toolbar.
2. In the Health Monitors Manager, click the Action icon

next to the HTTP health monitor name and select **Edit**.
3. Select the **Request/Response** tab.
4. Click **Test HTTP Health Monitor**.
5. In the field **Select a DTC Server or enter the IP address or domain name of an HTTP server**, do one of the following to specify the server to test:
    - Click **Select** to select an existing DTC server.
    - Enter the IP address or host name of an HTTP server. The IP address can be IPv4 or IPv6.
6. In the field **Select a Grid member that is running DTC**, select a DTC server on which the test will be run.
   If there is only one DTC server with the DTC license, it is selected by default. If there are several DTC servers with the license, the Grid Master is selected by default. If there is no Grid Master with the DTC license and there are several member servers with the license, click **Select** and choose a server.
7. Click **Test**.
8. In the result of the test, the following information is returned:
    a. Test status
    b. Status message

Note: If you configure an HTTP or HTTPS monitor for a pool and try to test the monitor for HTTP version 1.1 using the **Test HTTP Health Monitor** option, you must add the host header for the health check to be successful.

Configuring ICMP Health Monitors

An ICMP monitor sends an ICMP or ICMPv6 echo request to the IP address of the target server and expects an ICMP/ ICMPv6 echo response. The ICMP monitor determines the health of a server by monitoring the response to an ICMP ping.

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Health Monitors** in the Toolbar.
2. In the Health Monitors Manager, click the arrow next to the Add icon and select **ICMP Health Monitor**.
3. In the *ICMP Health Monitor Wizard,* complete the following:
    - **Name**: Enter a name for the ICMP health monitor.
    - **Interval (seconds)**: Enter the interval value in seconds. The health monitor runs only for the specified interval and it is measured from the end of the previous monitor cycle. The default value is five.
    - **Timeout (seconds)**: Enter the timeout value in seconds. The monitor waits for the number of seconds that you specify after sending a response. If it does not receive a response within the number of seconds that you specify, then the appliance considers this check as failed. The monitor discards any response it receives after the timeout. The default value is 15.
    - **Retry Up Count**: Enter a retry up count integer value. Retry up count is a value that determines how many valid responses or good health checks in a row must be received by the Grid member from the DTC server for setting the DTC server health status to green. When you specify a value, the appliance computes the duration for which health check must be performed based on the following:

      `interval*retry up count`

      For example, If the DTC server has had a red status for a long time because all the ICMP health checks have failed, and when the Grid receives the first good ICMP health check result, the health check counter is set as 1; however, the status of the DTC server is still retained as red. If you specify the **Retry Up Count** as 3 and the health check interval as 5, when three consecutive good health check results are received, the health check counter value becomes 3 and the DTC server health status now changes to green (3 good health check results in a row at an interval of 5 seconds each over a span of 3*5=15 seconds).
    - **Retry Down Count**: Enter a retry down count integer value. It is the opposite of the retry up count. Retry down count is a value that determines how many red status health checks (server is unavailable) in a row must be collected by the Grid member from the DTC server to switch the health status from green to red. For example, for a Grid member whose connection to the DTC server is not stable and has its Retry Down Count set as 5, if the health check results received by the Grid member is in the sequence: green, red, red, red, green, then the health status of the DTC server will be retained as green.

Note that red health status is set when the health monitor reaches the timeout value that is `[health check interval + timeout]` seconds without a valid response.

- **Comment**: Enter information about the ICMP health monitor.

4. Click **Next** to add extensible attributes. For information, see *Using Extensible Attributes*.

5. To schedule the change, click **Next** or **Schedule for Later**. In the *Schedule Change* panel, select **Now** to immediately execute this task. Or select **Later** to schedule this task, and then specify a date, time, and time zone.

6. Save the configuration.

Configuring PDP Health Monitors

A PDP (Packet Data Protocol) monitor sends a standard `GTP ECHO` request to the server. The GTP (GPRS Tunneling Protocol) echo message is used to ping the server. The connection is successful when the monitor receives an ECHO response from the server. If the server does not respond after a specified number of echo requests, the server is declared down by the monitor. You cannot modify the request or response.

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Health Monitors** in the Toolbar.
2. In the Health Monitors Manager, click the arrow next to the Add icon and select **PDP Health Monitor**.
3. In the *PDP Health Monitor Wizard,* complete the following:
   - **Name**: Enter a name for the PDP health monitor.
   - **Interval (seconds)**: Enter the interval value in seconds. The health monitor runs only for the specified interval and it is measured from the end of the previous monitor cycle. The default value is five.
   - **Timeout (seconds)**: Enter the timeout value in seconds. The monitor waits for the number of seconds that you specify after sending a response. If it does not receive a response within the number of seconds that you specify, then the appliance considers this check as failed. The monitor discards any response it receives after the timeout. The default value is 15.
   - **Retry Up Count**: Enter a retry up count integer value. Retry up count is a value that determines how many valid responses or good health checks in a row must be received by the Grid member from the DTC server for setting the DTC server health status to green. When you specify a value, the appliance computes the duration for which health check must be performed based on the following:

     `interval*retry up count`

     For example, If the DTC server has had a red status for a long time because all the PDP health checks have failed, and when the Grid receives the first good PDP health check result, the health check counter is set as 1; however, the status of the DTC server is still retained as red. If you specify the **Retry Up Count** as 3 and the health check interval as 5, when three consecutive good health check results are received, the health check counter value becomes 3 and the DTC server health status now changes to green (3 good health check results in a row at an interval of 5 seconds each over a span of 3*5=15 seconds).
   - **RetryDownCount**: Enter a retry down count integer value. It is the opposite of the retry up count. Retry down count is a value that determines how many red status health checks (server is unavailable) in a row must be collected by the Grid member from the DTC server to switch the health status from green to red. For example, for a Grid member whose connection to the DTC server is not stable and has its Retry Down Count set as 5, if the health check results received by the Grid member is in the sequence: green, red, red, red, green, then the health status of the DTC server will be retained as green.

     Note that red health status is set when the health monitor reaches the timeout value that is `[health check interval + timeout]` seconds without a valid response.
   - **Port**: Specify a port for PDP connection. The appliance displays 2123 by default. You can specify a value between zero and 65535.
   - **Comment**: Enter information about the PDP health monitor.

4. Click **Next** to add extensible attributes. For information abut using attributes, see *Managing Extensible Attributes.*

To schedule the change, click **Next** or **Schedule for Later**. In the *Schedule Change* panel, select **Now** to immediately execute this task. Or select **Later** to schedule this task, and then specify a date, time, and time zone.

5. Save the configuration.

Configuring SIP Health Monitors

A SIP monitor sends a standard `SIP OPTIONS` request to the server. You cannot modify this request. The monitor accepts only direct responses from the server and does not open alternate connections. The SIP monitor determines the health of the SIP server such as SIP proxies and session border controllers, and SIP gateways by issuing `SIP OPTIONS` to the server and examining the response provided by the server. The service is considered available if the response received from the server matches the expected response.
The SIP monitor does not support SCTP transport. It does not receive SIP connections. Responses are normally received over the same connection as the request was sent. The server does not attempt to open a new connection to send the response when it encounters an error message.

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Health Monitors** in the Toolbar.
2. In the Health Monitors Manager, click the arrow next to the Add icon and select **SIP Health Monitor**.
3. In the *SIP Health Monitor Wizard,* complete the following:
    - **Name**: Enter a name for the SIP health monitor.
    - **Interval (seconds)**: Enter the interval value in seconds. The health monitor runs only for the specified interval and it is measured from the end of the previous monitor cycle. The default value is five.
    - **Timeout (seconds)**: Enter the timeout value in seconds. The monitor waits for the number of seconds that you specify after sending a response. If it does not receive a response within the number of seconds that you specify, then the appliance considers this check as failed. The monitor discards any response it receives after the timeout. The default value is 15.
    - **Retry Up Count**: Enter a retry up count integer value. Retry up count is a value that determines how many valid responses or good health checks in a row must be received by the Grid member from the DTC server for setting the DTC server health status to green. When you specify a value, the appliance computes the duration for which health check must be performed based on the following:
      `interval*retry up count`
      For example, If the DTC server has had a red status for a long time because all the SIP health checks have failed, and when the Grid receives the first good SIP health check result, the health check counter is set as 1; however, the status of the DTC server is still retained as red. If you specify the **Retry Up Count** as 3 and the health check interval as 5, when three consecutive good health check results are received, the health check counter value becomes 3 and the DTC server health status now changes to green (3 good health check results in a row at an interval of 5 seconds each over a span of 3*5=15 seconds).
    - **Retry Down Count**: Enter a retry down count integer value. It is the opposite of the retry up count. Retry down count is a value that determines how many red status health checks (server is unavailable) in a row must be collected by the Grid member from the DTC server to switch the health status from green to red. For example, for a Grid member whose connection to the DTC server is not stable and has its Retry Down Count set as 5, if the health check results received by the Grid member is in the sequence: green, red, red, red, green, then the health status of the DTC server will be retained as green.
      Note that red health status is set when the health monitor reaches the timeout value that is `[health check interval + timeout]` seconds without a valid response.
    - **Comment**: Enter information about the SIP health monitor.
      When the DTC server is up, health checks are sent from the Infoblox member every number of seconds specified in the **Interval** field. When the DTC server is down, health checks are sent every number of seconds specified in the **Interval** field + the **Timeout** field.
4. Click **Next** and complete the following:

- **Expected Return Code:** The response code expected from the server. Select a value from the drop-down list: **any**, **equals**, and **does not equals**. When you select **equals** or **does not equals**, the appliance displays 200 by default. You can specify a value between zero and 999.
- **Port**: Specify a port for SIP connection. The appliance displays 5060 for **TCP** and **UDP** transport by default. When you select **SIPS** and **TLS** transport options, the appliance displays 5061 by default. You can specify a value between zero and 65535.

- **Transport**: Select a transport option from the drop-down list: **SIPS**, **TCP**, **TLS**, and **UDP**. If you select **SIPS** or **TLS**, specify any of the following related options that become available:
  - **Client Certificate**: Click **Certificate** to select a client certificate. Select a certificate from the dialog box. Click **Clear** to delete the certificate that you have uploaded. The monitor does not inspect or validate the server certificate, if any. For information about how to upload certificates, see ManagingHealthMonitor Certificates below.
  - **Ciphers**: Specify a list of SSL ciphers in an OpenSSL format. You can specify text up to 1024 character.
  - **Enable Certificate Validation**: It is highly recommended to select this for the DTC server certificate to be validated by NIOS.
    The following example commands list some available ciphers:

Example 1:

```
$ openssl ciphers 'HIGH:!DES'
DHE-RSA-AES256-SHA:DHE-DSS-AES256-SHA:DHE-RSA-CAMELLIA256-SHA:
DHE-DSS-CAMELLIA256-SHA:ADH-AES256-SHA:ADH-CAMELLIA256-SHA:AES256-SHA:
CAMELLIA256-SHA:PSK-AES256-CBC-SHA:EDH-RSA-DES-CBC3-SHA:
EDH-DSS-DES-CBC3-SHA:ADH-DES-CBC3-SHA:DES-CBC3-SHA:DES-CBC3-MD5:
PSK-3DES-EDE-CBC-SHA:KRB5-DES-CBC3-SHA:KRB5-DES-CBC3-MD5:DHE-RSA-AES128-SHA:
DHE-DSS-AES128-SHA:DHE-RSA-CAMELLIA128-SHA:DHE-DSS-CAMELLIA128-SHA:
ADH-AES128-SHA:ADH-CAMELLIA128-SHA:AES128-SHA:CAMELLIA128-SHA: PSK-AES128-CBC-
SHA
```

Example 2:

```
$ openssl ciphers 'DEFAULT:!EDH+aRSA'
DHE-DSS-AES256-SHA:DHE-DSS-CAMELLIA256-SHA:AES256-SHA:CAMELLIA256-SHA:
PSK-AES256-CBC-SHA:EDH-DSS-DES-CBC3-SHA:DES-CBC3-SHA:PSK-3DES-EDE-CBC-SHA:
KRB5-DES-CBC3-SHA:KRB5-DES-CBC3-MD5:DHE-DSS-AES128-SHA:DHE-DSS-SEED-SHA: DHE-
DSS-CAMELLIA128-SHA:AES128-SHA:SEED-SHA:CAMELLIA128-SHA:
PSK-AES128-CBC-SHA:RC4-SHA:RC4-MD5:PSK-RC4-SHA:KRB5-RC4-SHA:KRB5-RC4-MD5: EDH-
DSS-DES-CBC-SHA:DES-CBC-SHA:KRB5-DES-CBC-SHA:KRB5-DES-CBC-MD5:
EXP-EDH-DSS-DES-CBC-SHA:EXP-DES-CBC-SHA:EXP-RC2-CBC-MD5:EXP-KRB5-RC2-CBC-SHA:
EXP-KRB5-DES-CBC-SHA:EXP-KRB5-RC2-CBC-MD5:EXP-KRB5-DES-CBC-MD5:EXP-RC4-MD5: EXP-
KRB5-RC4-SHA:EXP-KRB5-RC4-MD5
```

Note

The DHE cipher list family ("Diffie-Hellman key agreement" plus "RSA authentication") could consume excessive CPU and is excluded from the defaults used by DNS Traffic Control health monitors. Although you can enable these ciphers by explicitly configuring them in the cipher list for HTTPS and SIP monitors, you should be aware that doing so will increase CPU usage. Since health monitoring in general does not require high security, Infoblox recommends that you enable these ciphers only for target servers that do not accept other types of ciphers.

5. Click **Next** to add extensible attributes. For information, see *Using Extensible Attributes*.

6. To schedule the change, click **Next** or **Schedule for Later**. In the *Schedule Change* panel, select **Now** to immediately execute this task. Or select **Later** to schedule this task, and then specify a date, time, and time zone.

7. Save the configuration.

Configuring SNMP Health Monitors

An SNMP health monitor sends an SNMPv1, SNMPv2c, or SNMPv3 request to the monitored server. The SNMP agent in the managed server provides the data in the form of variables, and each variable is associated with an unique OID (object identifier). An OID is a dotted-decimal number that defines the location of the object in the universal MIB tree. You can manually enter up to 15 OIDs to be monitored by the SNMP monitor. The server is considered available if the response received from the server matches the expected result for all OIDs. If the server does not respond after a specified number of requests, the server is declared down by the monitor.

To configure an SNMP OID health monitor, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Health Monitors** in the Toolbar.
2. In the Health Monitors Manager, click the arrow next to the Add icon and select **SNMP Health Monitor**.
3. In the *SNMP Health Monitor Wizard,* complete the following:
   - **Name**: Enter a name for the SNMP monitor.
   - **Interval (seconds)**: Enter the interval value in seconds. The health monitor runs only for the specified interval and it is measured from the end of the previous monitor cycle. The default value is five.
   - **Timeout (seconds)**: Enter the timeout value in seconds. The monitor waits for the number of seconds that you specify after sending a response. If it does not receive a response within the number of seconds that you specify, then the appliance considers this check failed. The monitor discards any responses it receives after the timeout. The default value is 15.
   - **Retry Up Count**: Enter a retry up count integer value. Retry up count is a value that determines how many valid responses or good health checks in a row must be received by the Grid member from the DTC server for setting the DTC server health status to green. When you specify a value, the appliance computes the duration for which health check must be performed based on the following:

     `interval*retry up count`

     For example, If the DTC server has had a red status for a long time because all the SNMP health checks have failed, and when the Grid receives the first good SNMP health check result, the health check counter is set as 1; however, the status of the DTC server is still retained as red. If you specify the **Retry Up Count** as 3 and the health check interval as 5, when three consecutive good health check results are received, the health check counter value becomes 3 and the DTC server health status now changes to green (3 good health check results in a row at an interval of 5 seconds each over a span of 3*5=15 seconds).
   - **Retry Down Count**: Enter a retry down count integer value. It is the opposite of the retry up count. Retry down count is a value that determines how many red status health checks (server is unavailable) in a row must be collected by the Grid member from the DTC server to switch the health status from green to red. For example, for a Grid member whose connection to the DTC server is not stable and has its Retry Down Count set as 5, if the health check results received by the Grid member is in the sequence: green, red, red, red, green, then the health status of the DTC server will be retained as green.

     Note that red health status is set when the health monitor reaches the timeout value that is `[health check interval + timeout]` seconds without a valid response.
   - **Port**: Specify a port for the SNMP connection. The appliance displays 161 by default. You can specify a value between zero and 65535.
   - **Comment**: Enter information about the SNMP health monitor.
4. Click **Next** and complete the following:
   - **Version**: Select the SNMP version, **v1**, **v2c**, or **v3**. Note that the available options for versions v1 and v2c differ from those for v3 version.
   - (SNMPv1 and SNMPv2c only) **Community**: Enter the text string that the SNMP monitor must send along with the queries to the server for authentication. The community string is similar to a password and the server accepts queries only from the SNMP monitor that provide the correct community string. Note that this community string must match exactly what you enter in the management system. The default value is **public**.
   - (SNMPv3 only) **SNMPv3User**: Click **Select** or **Create** to specify an SNMPv3 user. For information about SNMPv3 users, see *Configuring SNMP*.

If you are modifying an already existing SNMPv3 health monitor in the SNMP Health Monitor editor, two additional optional fields become available:

- **Context**: enter an arbitrary string.
- **EngineID**: enter an arbitrary string that can contain from 10 to 64 hexadecimal digits (5 to 32 octet numbers).

Click the Add icon above the **Health Monitor SNMP OIDs** table to add an SNMP OID entry. Complete the following:

- **OID**: Specify the object identifier. An OID is a unique dotted-decimal number that identifies the location of the object in the MIB tree. For more information about OIDs, see *SNMP MIB Hierarchy*.
- **Type**: Select either **String** or **Integer** from the drop-down list.

  Note: If you use this SNMP monitor with the Ratio: Dynamic load balancing method, note that only integer OID type is supported for this method.

- **Operator**: Select one of these operators from the drop-down list: **Any**, **Equals**, **Larger or equals**, **Range**, and **Smaller or equals**.
- **Value**: If the operator is **Equals**, **Larger or equals**, or **Smaller or equals**, enter a value. If the operator is **Range**, enter the minimum and maximum values in the **Min value** and **Max value** fields respectively.
- **Comment**: Enter information about the SNMP OID entry.
- Click **Add** to add the SNMP OID to the table.

5. Click **Next** to add extensible attributes. For information, see *Using Extensible Attributes*.

6. To schedule the change, click **Next** or **Schedule for Later**. In the *Schedule Change* panel, select **Now** to immediately execute this task. Or select **Later** to schedule this task, and then specify a date, time, and time zone.

7. Save the configuration.

Configuring TCP Health Monitors

A TCP monitor opens a TCP connection to communicate between the appliance and server. The connection is successful only when the handshake is complete. A successfully opened connection will be immediately closed or reset.

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Health Monitors** in the Toolbar.
2. In the Health Monitors Manager, click the arrow next to the Add icon and select **TCP Health Monitor**.
3. In the *TCP Health Monitor Wizard*, complete the following:
   - **Name**: Enter a name for the TCP health monitor.
   - **Interval (seconds)**: Enter the interval value in seconds. The health monitor runs only for the specified interval and it is measured from the end of the previous monitor cycle. The default value is five.
   - **Timeout (seconds)**: Enter the timeout value in seconds. The monitor waits for the number of seconds that you specify after sending a response. If it does not receive a response within the number of seconds that you specify, then the appliance considers this check as failed. The monitor discards any response it receives after the timeout. The default value is 15.
   - **Retry Up Count**: Enter a retry up count integer value. Retry up count is a value that determines how many valid responses or good health checks in a row must be received by the Grid member from the DTC server for setting the DTC server health status to green. When you specify a value, the appliance computes the duration for which health check must be performed based on the following:

     `interval*retry up count`

     For example, If the DTC server has had a red status for a long time because all the TCP health checks have failed, and when the Grid receives the first good TCP health check result, the health check counter is set as 1; however, the status of the DTC server is still retained as red. If you specify the **Retry Up Count** as 3 and the health check interval as 5, when three consecutive good health check results are received, the health check counter value becomes 3 and the DTC server health status now changes to green (3 good health check results in a row at an interval of 5 seconds each over a span of 3*5=15 seconds).
   - **Retry Down Count**: Enter a retry down count integer value. It is the opposite of the retry up count. Retry down count is a value that determines how many red status health checks (server is unavailable) in a row must be collected by the Grid member from the DTC server to switch the health status from green to red. For example, for a Grid member whose connection to the DTC server is not stable and has its Retry Down

Count set as 5, if the health check results received by the Grid member is in the sequence: green, red, red, red, green, then the health status of the DTC server will be retained as green.

Note that red health status is set when the health monitor reaches the timeout value that is `[health check interval + timeout]` seconds without a valid response.

- **Port**: Specify a port for TCP connection. You can specify a value between zero and 65535.
- **Comment**: Enter information about the TCP health monitor.

4. Click **Next** to add extensible attributes. For information, see *Using Extensible Attributes*.
5. To schedule the change, click **Next** or **Schedule for Later**. In the *Schedule Change* panel, select **Now** to immediately execute this task. Or select **Later** to schedule this task, and then specify a date, time, and time zone.
6. Save the configuration.

Managing Health Monitor Certificates

You can upload multiple certificates to the appliance and associate them with HTTP and SIP health monitors. The appliance supports certificates that are in PEM or PKCS#12 format only. A PEM file can contain more than one certificate. Note that the uploaded certificate must include both the client certificate and the private key. You can add, delete or view certificates.
To upload a health monitor certificate:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Health Monitors** in the Toolbar.
2. In the Health Monitors Manager, click the Manage Health Monitor Certificates icon.
3. In the **Health Monitor Certificates** window, click the Add icon.
4. In the **Upload** window, click **Select** and navigate to the certificate you want to upload.
5. Select the file and click **Upload**.

Grid Manager displays the following information in the **Health Monitor Certificates** window:

- **Issuer**: The name of the trusted CA that issued the certificate.
- **Valid From**: The date from which the certificate becomes valid.
- **Valid To**: The date until which the certificate is valid.
- **Subject**: The name of the certificate.

To upload a certificate from a web browser:

1. Export a PEM file from a web browser.
2. Generate a private key using the following command:
   `– openssl req -x509 -nodes -days 365 -newkey rsa:1024 -keyout mycert.pem -out mycert.pem`
3. Copy the private key section out of mycert.pem and add it to the PEM file from the web browser.
4. Or add both the PEM and the private key together as PKCS#12.

You can also do the following in the **Health Monitor Certificates** window:

- Click the checkbox next to the issuer and click the Delete icon to delete it.
- Print the data or export it in .csv format.

Modifying Health Monitors

To modify a health monitor:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Health Monitors** in the Toolbar.
2. In the Health Monitors Manager, click the Action icon next to the health monitor name, and select **Edit** from the menu.
3. The *Health Monitor* editor contains the following tabs from which you can modify data:
   - **General**: This tab displays the health monitor **Name, Comment, Interval, Timeout, Retry Up Count,** and **Retry Down Count** fields. You can edit the values.
   - (HTTP, SIP, and SNMP health monitors) **Protocol**: This tab displays the protocol data that you can modify.

- (HTTP/S health monitors only) **Request/Response**: This tab displays HTTP request and response check options for HTTP/S health monitors.
- **Extensible Attributes**: Add and delete extensible attributes that are associated with the pool. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.

For information about modifying the details of specific monitors, see the corresponding sections above.

4. To schedule this task, click the Schedule icon at the top of the wizard. In the *Schedule Change* panel, select **Later** and enter a date, time, and time zone. The Schedule icon is green when there is a pending scheduled task. For information, see *Scheduling Tasks.*

5. Save the configuration.

Viewing Health Monitors

You can view health monitors that you have created. You can add new health monitors, delete existing monitors, modify health monitors, or associate extensible attributes to them. You can also upload and manage health monitor certificates. To view health monitors:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Health Monitors** in the Toolbar.
2. The Health Monitors Manager displays the following information:
   - **Name**: The name of the health monitor.
   - **Type**: The type of health monitor.
   - **Comment**: Displays information about the health monitor.
   - **Interval**: The interval value in seconds.
   - **Timeout**: The timeout value in seconds.
   - **Retry Up Count:** The retry up count specified for the respective health monitor.
   - **Retry Down Count**: The retry down count specified for the respective health monitor.
   - **Port**: The port number specified for the respective health monitor. Note that this is not valid for an ICMP monitor.
   - **Site**: Value that was entered for the respective health monitor.

You can do the following in the Health Monitors Manager:

- Define new health monitors. For more information, see the following sections:
  - ConfiguringHTTPHealthMonitors
  - ConfiguringICMPHealthMonitors
  - ConfiguringPDPHealthMonitors
  - ConfiguringSIPHealthMonitors
  - ConfiguringSNMPHealthMonitors
  - ConfiguringTCPHealthMonitors
- Edit existing health monitors.
- Manage health monitor certificates.
- Delete existing health monitors. .
- Click the Export icon to export the list of monitors to a .csv file.
- Click the Print icon to print the list of monitors.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the monitor from the possible matches. Create a quick filter to save frequently used filter criteria. For information about using quick filters, see *Finding and Restoring Data*.

Deleting Health Monitors

To delete a health monitor:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab, and then click **Manage Health Monitors** in the Toolbar.
2. In the Health Monitors Manager, click the Action icon next to the health monitor name and select **Delete** from the menu.

3. In the *Delete Confirmation* dialog box, click **Yes** to delete or **No** to cancel.

   Click **Schedule Deletion** and in the Schedule Change panel, enter a date, time, and time zone to schedule deletion at a later date and time. For more information about schedule deletion , see *Scheduling New IPAM/DHCP Objects and Associated Port Configurations.*

Configuring DTC Monitors for Health Check

You can choose DNS Traffic Control health monitors whose DNS Traffic Control health checks are considered when calculating the health status of a member in a pool. You can create a consolidated health monitor in a DNS Traffic Control pool with its own set of members for each monitor. The status of a health check can then be determined according to the consolidated health monitor you created with selected members and availability condition.

To configure DNS Traffic Control monitors whose health check status must be shared from selected members, perform the following steps:

1. From the **Data Management** tab, select the **DNS** tab -> **Traffic Control** tab.
2. Select the pool for which you want to configure monitors and click the **Edit** icon.
3. Click the **Health Monitors** tab -> **Advanced** tab.
4. Click the **Add** icon.
5. From the **Monitor** drop-down list, choose the monitor whose health checks you want to be considered.
6. From the **Availability Requirement** drop-down list, you can either select all members of the pool to pass the health check for the selected monitor or for any of the pool member to pass the health check for the selected monitor. A passed health check is denoted by the green status.
7. From the **Share state from** box, select the members that you want the health check to be calculated. Select the members and move them to the **Selected** box.
8. Select the **Full Health Communication** checkbox to perform health checks on each and every member of the Grid which are part of LBDN and to send the status to all the Grid members which are in non selected list and the status is shared between grid members which are in selected list. This checkbox is disabled by default. By default, NIOS performs health checks only on Grid members from the selected list.
9. Click **Add**.
   The monitor along with its associated members and full health communication details are displayed in the **Consolidated Health Monitor Settings** area.
10. Click **Save & Close**.

> **Note**
>
> - To add DNS Traffic Control pool with consolidated monitors using CSV import, you must first import the DNS Traffic Control pool objects without consolidated monitor data (if the CSV file contains consolidated monitors, you must manually remove the data before importing the DNS Traffic Control pool objects). Once the DNS Traffic Control pool objects are in the system, you can run the CSV override to add consolidated monitors using a CSV file that contains all the data, including the DNS Traffic Control pool objects and consolidated monitors.
> - An error is displayed if there are no members added to consolidated health monitor, as the health status of DNS Traffic Control pool objects is not set properly.

You can now view a snapshot of any member in the pool and the monitors associated with it, along with their health status. To view the snapshot, complete the following:

1. Click the server for which you want to see the consolidated monitors.
2. In the **Server Visualization** area, select the member for which you want to see the associated monitors.

A visualization chart is displayed that represents the pool hierarchy. You can hover over the server icons to view the health status of the monitors associated with the server. For more information about health monitors, see *Using DNS Traffic Control Health Monitors*.

Configuring IP Routing Options

You can configure multiple IP addresses and enable anycast addressing on the loopback interface of the NIOS appliance, allowing the appliance to function in different network deployments.
Configuring non-anycast IP addresses on the loopback interface assists in server migration and network address change. Configuring anycast addresses on the appliance allows you to add redundancy and improve reliability for DNS services. You can use OSPF (Open Shortest Path First), BGP (Border Gateway Protocol), or both, as the routing protocol for anycast advertising.

Configuring IP Addresses on the Loopback Interface

The loopback interface is a virtual network interface on the appliance. You can do the following on the loopback interface:

- Configure IP addresses to consolidate DNS servers for migration purposes. For information, see *Configuring IP Addresses*.
- Add anycast addresses to improve the reliability and performance of DNS services in multiple locations. For information, see *About Anycast Addressing for DNS*.
- Separate DNS traffic by assigning an IP address as the source port for DNS queries. For information, see *Specifying Source Ports*.

When you use the loopback interface for anycast addressing, the upstream and neighboring routers can continue to advertise anycast addresses without being affected by hardware malfunctions.

To configure non-anycast addresses on the loopback interface, complete the following:

1. Add IP addresses to the loopback interface. For information, see *Configuring IP Addresses*.
2. Enable DNS services on the loopback addresses. For information, see *Specifying Port Settings for DNS* and its subtopic, *Specifying Source Ports*.

To configure DNS anycast addresses and their advertising protocols, complete the following:

1. Add anycast addresses to the loopback interface. For information, see *Configuring Anycast Addresses*.
2. Configure anycast addressing protocols. For information about Configuring OSPF on the NIOS *Appliance* and Configuring BGP in the NIOS Appliance, see *IP Routing Options*. This is the primary application for routing protocols in the NIOS appliance.
3. Enable the DNS anycast addresses. For information, see *Specifying Port Settings for DNS* and its subtopic, *Specifying Source Ports*.

To separate DNS queries from DNS transfers and notify messages, complete the following:

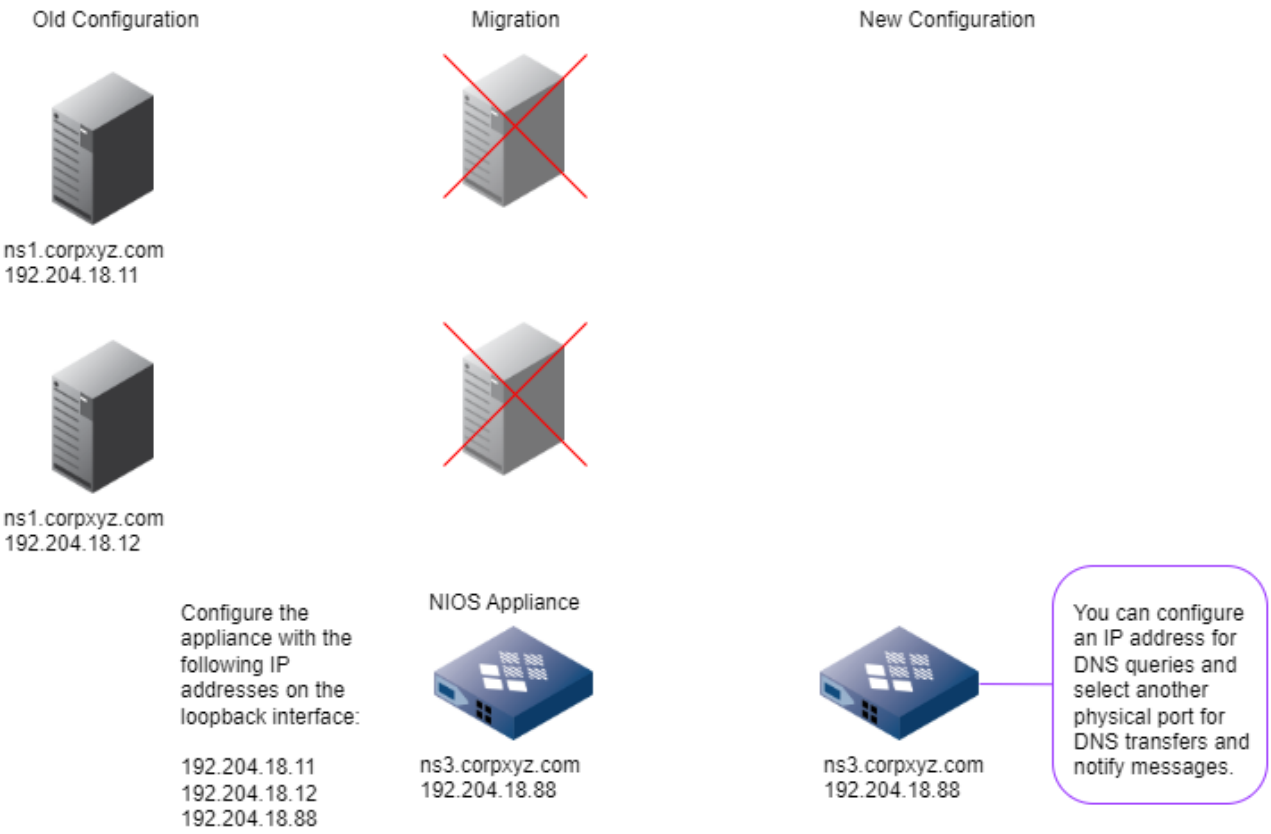
1. Add an IP address of the source port for DNS queries. For information, see *Configuring IP Addresses*.
2. Select the source IP for DNS queries. For information, see *Specifying Source Ports*.

Configuring IP Addresses

You can configure IP addresses on the loopback interface to minimize service downtime during a server migration. As illustrated in the figure DNS Server Migration Using the Loopback Interface below, you have two existing DNS servers (*ns1.corpxyz.com* 192.204.18.11 and *ns2.corpxyz.com* 192.204.18.12) and you want to replace these servers with a new one (*ns3.corpxyz.com* 192.204.18.88). The migration takes a few weeks and you want DNS services to be available on all three addresses during the migration. You can add all three IP addresses to the loopback interface of a

NIOS appliance, and then configure the appliance to provide DNS services on all addresses. After the server migration, you can shut down the old servers and use the new one for services.

DNS Server Migration Using the Loopback Interface



You can also add an IP address that is used solely for DNS queries, to separate the DNS traffic. You first add an IP address you want to use for DNS queries on the loopback interface. You then configure the appliance to listen for DNS queries solely on this address. For information, see *Specifying Source Ports*.

When you configure non-anycast addresses on the loopback interface, ensure that you establish a static route between the appliance and the router so queries to these addresses are routed correctly. For information, see *Advertising Loopback Addresses to the Network*.

> **Note**
>
> You can configure multiple interfaces on the Infoblox-4030-10GE appliance only. To configure LAN1, LAN2 and MGMT interfaces to the same IPv4 or IPv6 subnet, provide the same netmask for IPv4, or a CIDR prefix for IPv6, as the LAN1 interface. Alternatively, you can use a /32 netmask (255.255.255.255) for IPv4, or /128 CIDR prefix for IPv6 with the same subnet as LAN1 interface to configure multiple interfaces. An Infoblox-4030-10GE can replace three DNS cache servers that are active on the same network. When you configure multiple interfaces on the same subnet, the outgoing traffic from NIOS host which is received through LAN2 and MGMT is directed to the LAN1 router for all interfaces on the LAN1 subnet, irrespective of the destination IP. However, if the LAN1 interface fails, the outgoing traffic will not be re-directed to any other interface and access to LAN2 and MGMT also fails.

To configure an IP address on the loopback interface:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox -> Edit icon.
2. In the *Grid Member Properties Editor*, select the **Network** tab -> **Basic** tab.
   You can add an IPv4 or IPv6 address on the loopback. You define each type in their own table.

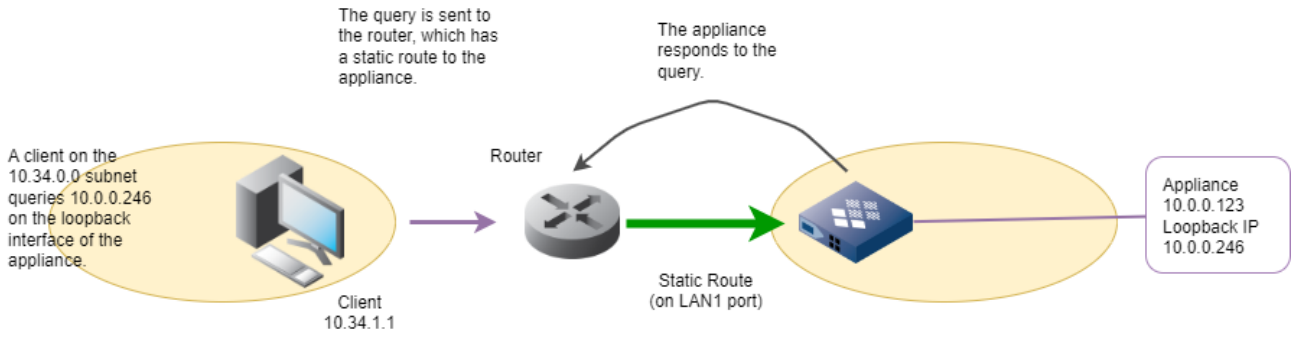
3. Click the Add icon in the Additional Ports and Addresses table and select **Additional Address (loopback) (IPv4)** or **Additional Address (loopback) (IPv6)** from the drop-down list.
   You cannot configure **Additional Address (loopback) (IPv4)** interface for an IPv6 Grid member and **Additional Address (loopback) (IPv6)** interface for an IPv4 Grid member. You can only enter the IP address you want to add to the loopback interface. You cannot configure the subnet mask, prefix length, gateway, or port settings.
   The appliance adds a row to the table. Complete the following:
   - **Interface**: Displays **Additional Address (loopback)**. You cannot modify this.
   - **Address:** Enter the IP address you want to add to the loopback interface. An IPv6 address is a 128-bit number in colon hexadecimal notation. It consists of eight 16-bit groups of hexadecimal digits separated by colons (example: 2001:db8:0000:0123:4567:89ab:0000:cdef or 2001:db8::123:4567:89ab:0:cdef).
   - **Subnet Mask (IPv4) or Prefix Length (IPv6):** You cannot change the netmask of the loopback interface. It is set to 255.255.255.255, or /32. For an IPv6 address, the mask is set to 128 and cannot be modified. You cannot configure the gateway address and port settings.
4. Save the configuration and click **Restart** if it appears at the top of the screen.
   To add multiple IP addresses on the loopback interface, repeat the steps for each IP address.

> ⚠ Note
>
> If you are configuring the loopback interface on a Grid Master, the Grid is temporarily disrupted upon saving the configuration and restarting services on the appliance. The Grid reconnects automatically and the appliance regains the role as Grid Master after a short delay.

Advertising Loopback Addresses to the Network

Advertising IP addresses on the loopback interface relies on the upstream router to populate routes to the loopback interface. As illustrated in the figure Static Route for Loopback IP Addresses below, when a client on a different subnet queries an IP address on the loopback interface, it sends the request to the router. If the IP address on the loopback interface is not advertised to the router, the request cannot reach the appliance. Therefore, when you configure non-anycast addresses on the loopback interface, or if OSPF or BGP is not configured within your network, you must configure the upstream router to reach the NIOS appliance through a static route on the LAN1 interface.
Note that when an appliance is configured for both authoritative and recursive queries, you should connect your internet interface through the LAN1 port to allow for maximum flexibility while using auxiliary LAN2 and MGMT ports. Consult with your network administrator for information about configuring static routes from the router to the additional IP addresses on the loopback interface.

Static Route for Loopback IP Addresses



Note

To enable the loopback address functionality on vNIOS for Azure instances, you must configure the following settings in the Microsoft Azure or the Microsoft Azure Stack Hub portal according to the environment in which you have deployed the vNIOS instance:

- Add an inbound port rule for the vNIOS VM on the *virtual machine* > **Settings** > **Networking** tab to allow inbound packets to the loopback address interface on port 53 (for DNS).
- Add a route to your subnets. To add, create a route table (if the subnet does not have one already) and add the static route to the loopback address in the route table. Ensure to associate the route table with the subnet if you created a new route table."

When you configure DNS anycast addresses on the loopback interface, you can select OSPF, BGP, or both, to advertise the addresses to upstream and neighboring routers, without establishing a static route. For information, see *About Anycast Addressing for DNS*.

About Anycast Addressing for DNS

Four types of communications are utilized within an IP network:

- **Unicast** describes a one-to-one network communication between a single sender and a single recipient. The routing protocol determines the path through the network from the sender to the recipient based on the specific protocol or routing scheme. Unicast also describes the address type assigned to the recipient.
- **Multicast** describes a one-to-many network communication between a single sender and a specific group of recipients. All members within the group are intended recipients and each member receives a copy of the data from the sender. Multicast also describes the address type assigned to a group of recipients, used by the routing protocol to determine the path to the group.
- **Broadcast** is similar to multicast, the exception being that data is sent to every possible destination regardless of the groups or subnetwork. There is no specific group of recipients.
- **Anycast** describes a one-to-nearest communication between a single sender and the nearest recipient within a group. The routing protocol chooses one recipient within a target group based on the routing algorithm for the specific protocol, and sends data to that recipient only.

The NIOS appliance provides the following support for DNS anycast addressing:

- You can configure up to 20 anycast IP addresses on the loopback interface of each Grid member.
- Anycast IP addresses can be in IPv4 or IPv6 format. For all anycast IP addresses, the subnet mask value is always set to /32 for an IPv4 anycast IP or 128 for a 128-bit IPv6 address. These values are separate and distinct from the IP configuration on the NIOS appliance LAN port.
- The appliance advertises routing information of the anycast addresses through OSPF or BGP, or (seldom) both, depending on the deployment. Routers use the configured routing protocols to determine the best path to the nearest server. The appliance advertises the route information to the upstream or neighboring router, a router that forwards data on the network link and determines the forwarding path to destinations. For information, see *IP Routing Options*.
- The appliance advertises and withdraws route information based on reachability information to DNS servers sent by the IP route advertisements.
- When you configure DNS anycast addressing on an appliance and use it as an NTP server, the appliance can answer NTP requests through the anycast IP address. For information about how to configure an appliance as an NTP server, see *Configuring a NIOS Appliance as an NTP Server.*

Anycast addressing for DNS provides the following benefits:

- **Improved Reliability**: Anycast provides improved reliability because DNS queries are sent to an anycast IP address that is defined on multiple DNS servers in the NIOS Grid. If the nearest server somehow goes offline, then the router forwards the request to the next nearest DNS server advertising the target anycast IP address (see *Anycast Addressing for DNS Using OSPF* for an example).
- **Load Distribution**: Anycast distributes the load across multiple DNS servers based on network topology.

- **Improved Performance**: The NIOS appliance uses OSPF or BGP, depending on your configuration, to advertise anycast routing information to the upstream and neighboring routers. The routers determine the best route to the nearest DNS server. Anycast enables the queries to reach the nearest server more quickly, providing faster responses to DNS queries.

> ⚠ Note
>
> For more information about anycast addressing, refer to *RFC 1546 "Host Anycasting Service"*.

Configuring Anycast Addresses

Anycast addressing is supported on loopback interfaces on the NIOS appliance. IP configuration must be defined on the LAN1 interface before configuring DNS anycast addresses. Before creating IPv6 anycast IPs on the loopback interface, IPv6 must be enabled and configured on the LAN1 interface for the NIOS appliance, including the correct IPv6 gateway IP address.

> ⚠ Note
>
> When you add an anycast address, you need to start the service for the advertising to take place. However, when you remove an anycast address, no service restart is required to stop the service. Anycast advertising stops immediately.

To enable and configure anycast addressing:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox -> Edit icon.
2. In the *Grid Member Properties* editor, Click **Toggle Advanced Mode**.
3. When the additional tabs appear, click the **Anycast** tab.
4. Click the Add icon and choose **IPv4 Address** or **IPv6 Address**.
5. In the **Anycast Interfaces** list, enter the values or select the options for the new entry:
   - **Anycast Interface**: Anycast addressing is supported on the **loopback** only. This value is filled in automatically.
   - **Address:** Enter the IP address you want to assign as the anycast address to the loopback interface. Specify an IPv4 Address or an IPv6 Address based on the chosen type of address.
     Subnet Mask: You cannot change the subnet mask of a loopback interface. The netmask is automatically set to 255.255.255.255, or /32; or 128 for IPv6.
   - **OSPF**: Select if you want the appliance to use OSPF to advertise the anycast address, and if necessary configure the OSPF settings. For information, see *Configuring OSPF on the NIOS Appliance*. IPv4 and IPv6 options are configurable for this protocol. This is supported only for IPv4 and dual mode appliances, but not for IPv6 appliances.
   - **BGP**: Select this if you want the appliance to use BGP to advertise the anycast address, and then configure the BGP settings. This is supported only for IPv4 and dual mode appliances, but not for IPv6 appliances.
     You must configure at least one routing method for DNS anycast. You can configure OSPF, BGP, or both (in most cases only one protocol will be used). The appliance cannot save the anycast address if you do not complete at least one routing configuration. Anycast cannot be used without dynamic routing.
   - **Comments:** Enter a text string to help identify this interface and IP address.
6. *If using OSPF for the current appliance*: Under **OSPF Area Configuration**, click the Add icon. A new configuration block appears in the properties editor.
   - Enter the values for the OSPF configuration as described in the section *Configuring OSPF on the NIOS Appliance*.
   - Click the **Add** down arrow icon in the **OSPF Area Configuration** section. The new OSPF configuration is saved into a table.
7. *If using BGP for the current appliance*: In the properties editor, scroll down to the configuration block for **BGP Configuration**. For information, see *Configuring BGP in the NIOS Appliance.*

- In the **ASN** field, enter the Autonomous System ID number in which the NIOS appliance resides.
- If necessary, modify the **BGP Timer Keep Alive** and **Hold Down** values. In most circumstances these values should be left at their defaults. Check your network's defined policies for the desired values if necessary.
- Click the Add icon.
- Enter the **Neighbor Router** IP address. This can be an IPv4 address or an IPv6 address.
- Enter the **Remote ASN** (Autonomous System ID number) for the adjacent router.

8. Save the configuration. The system will warn that you must restart the appliance services in order to use the new configuration.
9. Log back in to the appliance.
10. From the **Data Management** tab, select the **DNS** tab -> **Members/Servers** tab -> *Grid_member* checkbox -> Edit icon.
11. Select **Toggle Advanced Mode** (if necessary), click **General** and the **Advanced** tab.
12. Under **Listen on these additional IP addresses**, click the Add button. The list of one or more previously created IPv4 and IPv6 addresses for the loopback interfaces (created in Step 4) appear in this table. (If the Add button is not active here, this indicates that you have not configured any loopback interfaces with their IP addresses.) Should you need to configure other DNS properties on this page, see the topics in *Configuring the Grid to provide DNS Services*.
    Note that if you remove an IP address from the list of Listen on these additional IP addresses, anycast advertising will stop immediately. No service restart is required to stop anycast from listening on this IP address.
13. Click **Save and Close**.

Configured anycast interfaces are now enabled to carry DNS traffic. For further information, see *Specifying Source Ports*.

Note

You can select different options for the restart sequence for anycast service with DNS, when the DNS restart is invoked. You can manage this sequence with the help of CLI commands.
For more information on the CLI commands, see

- *set restart_anycast_with_dns_restart*
- *show restart_anycast_with_dns_restart*

Best Practices for Configuring Anycast Addresses

Infoblox highly recommends that you do the following before you configure an anycast address:

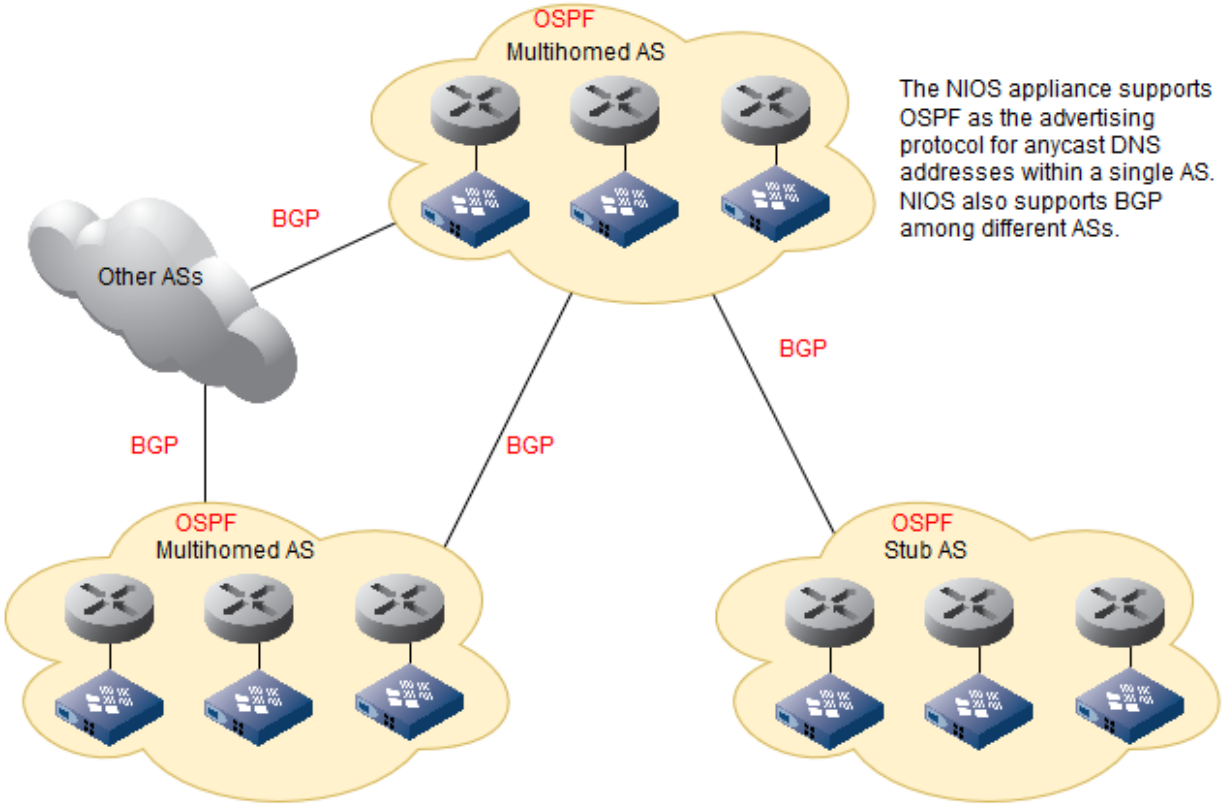
- Enable the anycast feature in the NIOS application.
- Install a valid DNS license, enable DNS and ensure that the DNS service is active.
- When you configure OSPF or OSPFv6, ensure that the OSPF monitor runs every four seconds.
- You must configure an IP address on the loopback interface.

IP Routing Options

IP routing is a set of protocols that determine the path IP packets follow in order to travel across multiple networks from the source to the destination. When information travels through a series of routers and across multiple networks, IP routing protocols enable the routers to build up a forwarding table that correlates the final destination with the next upstream routers.
For routing purposes, the internet is divided into ASs (Autonomous Systems). Data is routed within an AS using an IGP (Interior Gateway Protocol) and routed between different ASs using an EGP (Exterior Gateway Protocol). NIOS appliances support OSPFv2 (for IPv4) and OSPFv3 (for IPv6) for a routing IGP, and BGP4 to advertise DNS anycast addresses in the larger internetwork.
As noted in the section *Configuring Anycast Addresses*, you configure OSPF or BGP4 to advertise anycast addresses, which configured on the loopback interface of NIOS appliances. Use of either protocol depends on the

network topology, based on whether the advertisements will propagate only within a single AS or between more than one AS. The following figure shows a simplified example.

OSPF and BGP Routing Example



Within each AS, OSPF is the protocol used to forward anycast advertisements. Between ASs, BGP is the protocol selected to advertise anycast addresses. Using this technique, DNS servers in diverse locations can operate together to ensure continuous service.

About OSPF

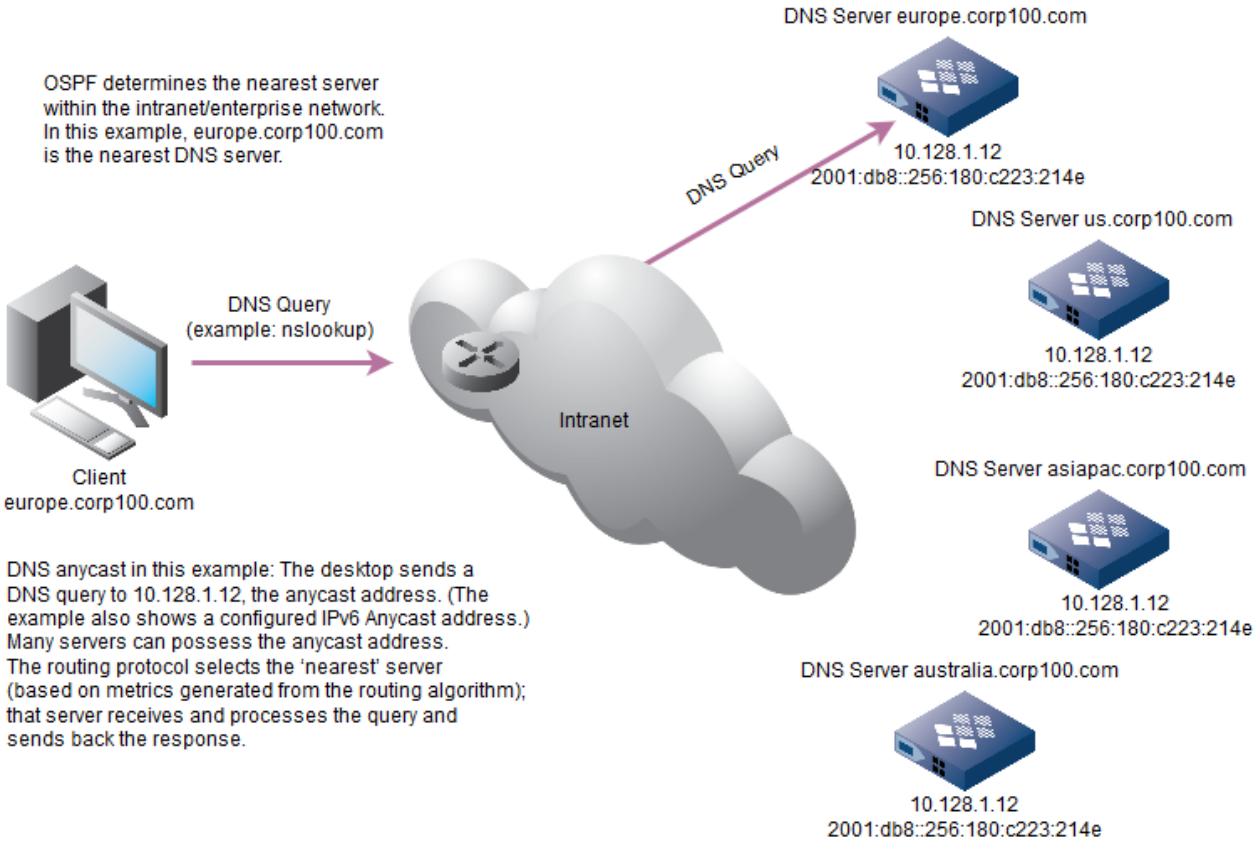
OSPF is a link-state protocol based on the Dijkstra algorithm used to calculate the shortest path to a destination address within an internetwork. This protocol uses a link-state database created using routing information advertised from neighbors and peers, each with costs based on the state of that link to the destination.
OSPF network topologies consist of administrative domains called OSPF areas. An area is a logical collection of OSPF routers, servers and other network devices that have the same area identifier. A router within an area keeps an OSPF database for its OSPF area only, reducing the size of the database that is maintained.

Anycast and OSPF

NIOS appliances can use the OSPF routing protocol to advertise routes for DNS anycast addresses to an upstream router within the autonomous system. The upstream router uses the OSPF advertisement to determine the nearest DNS server from a group of servers within the internetwork. In practice, the NIOS appliance relies upon OSPF to determine the best route for DNS queries to take to the nearest DNS server. The upstream router then forwards the query to the chosen DNS server.
As illustrated in the figure Anycast Addressing for DNS Using OSPF below, to enable anycast for DNS queries, you configure two or more DNS servers within the AS routing domain with the same anycast address on their loopback interfaces. When you select OSPF as the routing protocol, the upstream router determines the nearest server within the group of servers configured with that anycast address. (The "nearest" DNS server may not necessarily be the

geographically closest DNS server; it is the DNS server with the lowest cost associated with its reachability from the current node. This is calculated through the OSPF routing algorithm, a discussion of which is far beyond the scope of this manual.) The nearest DNS server configured with the correct anycast address then responds to the DNS query. In the case where the nearest server becomes unavailable, the next nearest server responds to the query. OSPF anycast provides a dynamically routed failover to ensure that DNS can always resolve client requests within the AS. From the client perspective, anycasting is transparent and the group of DNS servers with the anycast address appears to be a single DNS server.

Anycast Addressing for DNS Using OSPF



After you configure or change DNS anycast settings, you must restart the DNS services for the settings to take effect. When you enter any OSPF command and wait for the interface to return more information, the appliance disconnects your CLI session after you restart services or make other OSPF configuration changes through Grid Manager. Re-enter your credentials to log back in to the CLI. (For information, refer to the *Infoblox CLI Guide*.)

To enable the appliance to support OSPF and advertising anycast addresses on OSPF from the loopback, you must first configure the LAN1 or LAN1 (VLAN) interface as an OSPF advertising interface. For information about VLAN, see *About Virtual LANs*.

You can also configure authentication for OSPF advertisements to ensure that the routing information received from a neighbor is authentic and the reachability information is accurate. This process can be implemented for OSPF over IPv4 networks but is not supported for IPv6/OSPFv3.

> **Note**
>
> For more information about the OSPF routing protocol, refer to *RFC 2328 "OSPFv2" and RFC 5340 "OSPF for IPv6"*.

Configuring OSPF on the NIOS Appliance

> **Note**
>
> Use the CLI command **show ospf** or show ipv6_ospf to display configuration and statistical information about the OSPF protocol running on the appliance. You can also use the **set ospf** or set ipv6_ospf command to write OSPF statistical information to the syslog. In the NIOS appliance, configuration of OSPF is limited to Syslog and the DNS anycast application.

To support DNS anycast and other routing-dependent applications on NIOS appliances, you must first configure the LAN1 or LAN1 (VLAN) interface as an OSPF advertising interface, and then assign an area ID on the interface to associate it with a specific OSPF area. The interface advertises the OSPF routing information to the network so that routers can determine the best server to query. Note that the appliance automatically uses the HA interface as the advertising interface for an HA pair, even though you select the **LAN1** interface. For anycasting, the advertising interface sends out routing advertisements about the anycast address into the network out to upstream routers.

> **Note**
>
> IPv6 is not supported for the **Stub** and **Not-so-stubby** area types.

To configure the LAN1 (HA) or LAN1(VLAN) interface to be an OSPF advertising interface, perform the following tasks:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. Select the **Anycast** tab in the *Grid Member Properties* editor.
   The **Anycast Interfaces** appear in a table. You can add new anycast interfaces when needed.
3. Click the Add icon of the OSPF Area Configuration table and choose **IPv4 Configuration** or **IPv6 Configuration** to define a new OSPF Area. The OSPF Area Configuration will show a similar set of **Add (IPv4/IPv6) OSPF Area** configuration settings based on the protocol type. Enter the following information to configure the LAN1, or LAN1 (VLAN) as the OSPF advertising interface:
   - **Advertising Interface**: Displays the interface that sends out OSPF routing advertisement. OSPF advertisements are supported on the LAN1 and LAN1(VLAN) interfaces. For an HA pair, select **LAN1** and the appliance automatically uses the HA interface as the advertising interface.
   - **Area ID:** Enter the OSPF area identifier of the network containing the upstream routers, in either an IP address format or a decimal format. All network devices configured with the same OSPF area ID belong to the same OSPF area. The area ID configured on the Grid member must match the area ID of the upstream router configuration. Area ID numbers are defined in the same format for IPv6 and IPv4.
   - **Area Type:** Select the type of OSPF area to associate with the advertising interface from the drop-down list. The area type configured on the Grid member must match the area type of the upstream router configuration. The supported area types are described as follows:
     - **Standard**: A standard area has no restrictions on routing advertisements, and connects to the backbone area (Area 0) and accepts both internal and external link-state advertisements.
     - **Stub**: A stub area is an area that does not receive external routes.
     - **Not-so-stubby**: A not-so-stubby area (NSSA) imports autonomous system (AS) external routes and sends them to the backbone, but cannot receive AS external routes from the backbone or other areas.
       OSPF for IPv6 (known as OSPFv3) configuration does not support OSPF authentication options.
   - **AuthenticationType:** Select the authentication method to use to verify OSPF routing advertisements on the interface. The authentication type configured on the Grid member must match the authentication type of the upstream router configuration. The supported authentication types are described as follows:
     - **None**: No authentication for OSPF advertisement.
     - **Simple**: A simple password for OSPF advertisement authentication, in clear text.
     - **MD5**: An MD5 hash algorithm to authenticate OSPF advertisements. This is the most secure option.

- **Authentication Key ID:** Enter the key identifier to use to specify the correct hash algorithm after you select **MD** as your OSPF authentication type. The authentication key ID configured on the Grid member must match the authentication key ID of the upstream router configuration.
- **Authentication Key:** Enter the authentication password to use to verify OSPF advertisements after you select **Simple** or **MD** as your OSPF authentication type. Specify a key string between 1 to 8 characters for Simple authentication, and a string between 1 to 16 characters for MD5 authentication. The authentication key configured on the Grid member must match the authentication key of the upstream router configuration.
- **Cost**: Select one of the following:
  - **Calculate Automatically:** Select this checkbox to auto generate the cost to associate with the advertising OSPF interface to the appliance. If this checkbox is not selected, then you specify the cost value explicitly. Calculate the cost as 100,000,000 (reference bandwidth) divided by the interface bandwidth. For example, a 100Mb interface has a cost of 1, and a 10Mb interface has a cost of 10.
  - **Fixed Metric:** Enter the cost to associate with the advertising OSPF interface to the appliance.
- **Hello Interval:** Specify how often to send OSPF hello advertisements out from the appliance interface, in seconds. Specify any number from 1 through 65,535. The default value is 10 seconds. The hello interval configured on the Grid member must match the hello interval of the upstream router configuration.
- **Dead Interval:** Specify how long to wait before declaring that the NIOS appliance is unavailable and down, in seconds. Specify any number from 1 through 65,535. The default value is 40 seconds. The dead interval configured on the Grid member must match the dead interval of the upstream router configuration.
- **Retransmit Interval:** Specify how long to wait before retransmitting OSPF advertisements from the interface, in seconds. Specify any number from 1 through 65,535. The default value is 5 seconds. The retransmit interval configured on the Grid member must match the retransmit interval of the upstream router configuration.
- **Transmit Delay:** Specify how long to wait before sending an advertisement from the interface, in seconds. Specify any number from 1 through 65,535. The default value is 1 second. The transmit interval configured on the Grid member must match the transmit interval of the upstream router configuration.
- Click **Add** to add the interface to the table.
  The **Cost**, **Hello Interval**, **Dead Interval**, **Retransmit Interval** and **Transmit Delay** settings can be configured for IPv6 deployments. OPSF authentication is not supported for IPv6 on the NIOS platform.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing OSPF

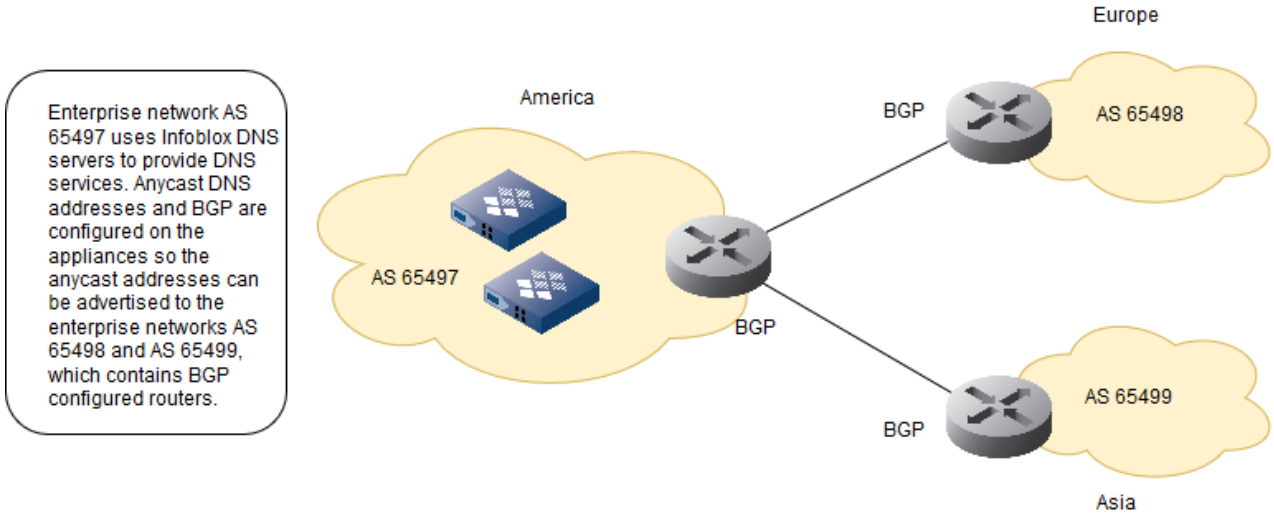
- OSPF advertises the route when the DNS service starts. The start DNS command creates an interface and starts the OSPF daemon.
- OSPF stops advertising the route when the DNS service stops. The stop DNS command stops the OSPF daemon and deletes the interface.
- The NIOS application does not support a route flap. For example, temporary DNS downtime such as restart, does not stop or re-instate the OSPF advertisement.
- The OSPF advertisement stops if DNS service is down for more than 40 seconds.

Anycast and BGP4

> **Note**
>
> Use the CLI command `show bgp` or `show ipv6_bgp` to display configuration and statistical information about the Border Gateway Protocol running on the appliance. You can also use the `set bgp` command to write OSPF statistical information to the syslog. In the NIOS appliance, configuration of BGP is limited to Syslog and the DNS anycast application.

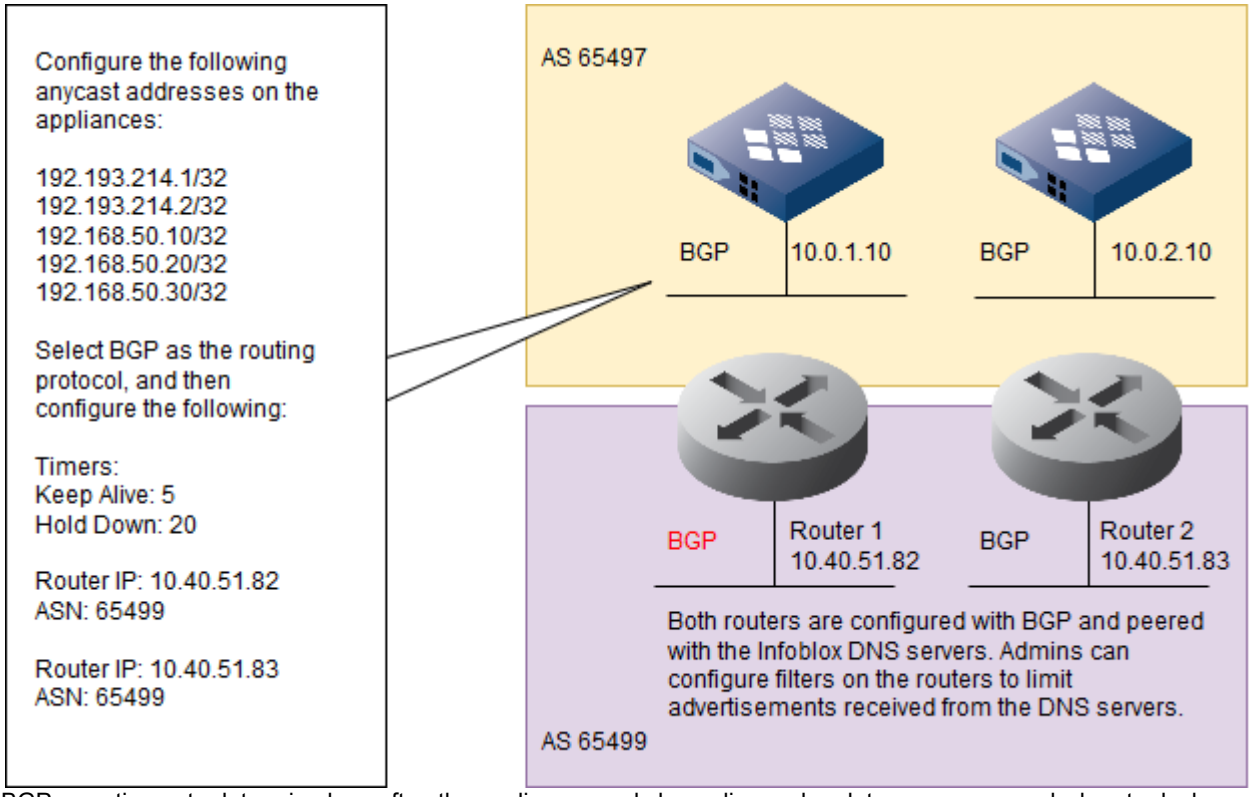
BGP4 (henceforth referred to as BGP) is designed to distribute routing information among ASs and exchange routing and reachability information with other BGP systems using a destination-based forwarding paradigm. Unlike OSPF, which calculates routes within a single AS, BGP is a vector routing protocol that distributes routing information among different ASs. A unique ASN (autonomous system number) is allocated to each AS to identify the individual network in BGP routing. A BGP session between two BGP peers is an eBGP (external BGP) session if the BGP peers are in different ASs. A BGP session between two BGP peers is an iBGP (internal BGP) session if the BGP peers are in the same AS. BGP configuration enables large enterprises using BGP as the internetworking protocol to provide resilient DNS services using the Infoblox solution. While BGP is mostly used by ISPs, it is also used in larger enterprise environments that must interconnect networks that span geographical and administrative boundaries. In these environments, it is required to use BGP to advertise anycast routes. Using BGP allows the appliance to advertise DNS anycast addresses to neighboring routers across multiple ASs that also use BGP as their routing protocols.
As illustrated in the figure Anycast Addressing for DNS using BGP below, to enable anycast for DNS queries among three different networks that span different geographical regions, you can configure two DNS servers with the same DNS anycast addresses in the AS 65497 network. Since other network routers in AS 65498 and AS 65499 also use BGP as the routing protocol, the DNS anycast addresses can be advertised across these networks.

Anycast Addressing for DNS using BGP



To enable DNS anycast addressing across different ASs, you configure BGP as the routing protocol on the NIOS appliance. (As illustrated in the figure Anycast and BGP Configuration on Infoblox Appliances below, the AS 65497 network contains the Infoblox DNS anycast servers, and the AS 65499 network contains Router 1 and 2. The routers use BGP and are peered with the DNS servers. You can configure anycast addressing on the loopback interface of the DNS servers and select BGP as the protocol to advertise the anycast addresses to Router 1 and 2 in AS 65499. For information, see *Configuring Anycast Addresses*. Once you have configured the DNS servers, the appliances automatically add filters on the advertising interfaces to limit the advertisements to the configured anycast IP addresses. Similarly, BGP filters are applied to ensure that the DNS servers only receive default route advertisements from the neighboring routers.

Anycast and BGP Configuration on Infoblox Appliances



BGP uses timers to determine how often the appliance sends keepalive and update messages, and when to declare a neighboring router out of service. You can configure the time intervals for these timers. For information, see Configuring BGP in the NIOS Appliance below.

The BGP protocol service is automatically configured to send SNMP queries about BGP runtime data. The appliance sends SNMP traps to its neighboring routers when it encounters issues with the protocol. BGP is configured to send SNMP traps as defined in *RFC4273 Definitions of Managed Objects for BGP-4*. You must enable and configure the SNMP trap receiver on the Grid member for the member to send SNMP traps. For information, see *SNMP MIB Hierarchy*.

You can use the `set bgp` command to set the verbosity levels of the BGP routing service. The appliance writes BGP statistical information to the syslog. After you configure the settings, you must restart the DNS services for the settings to take effect. For information, refer to the *Infoblox CLI Guide*. Note that when you enter any BGP command and wait for the interface to return more information, the appliance disconnects your CLI session if you restart services or make other BGP configuration changes through Grid Manager. You must re-enter your credentials to log back in to the CLI.

You can configure BGP on any interface to advertise anycast addresses across multiple ASs.

> **Note**
>
> NIOS selects the interface for BGP advertisement based on the routing configuration.

The appliance supports BGP version 4. For more information about BGP, refer to *RFC4271, A Border Gateway Protocol 4 (BGP-4)*.

Configuring BGP in the NIOS Appliance

You can configure the appliance as a BGP advertising interface for anycast addresses. The NIOS appliance advertises the BGP routing information to the network so routers can determine the nearest server to query. The NIOS appliance does not perform dynamic routing itself; it can use dynamic routing protocols to advertise its DNS anycast availability. You must define the ASN of the interface and list any neighboring routers that will receive the BGP announcements. On an HA pair, BGP runs only on the active node. In an HA failover, the BGP service resumes on the new active node.

Note

If you encounter Malformed AS_PATH error, then remove the dont-capability-negotiate option. Infoblox doesn't provide an option to create confederation of autonomous systems if the BGP peer is configured by enabling the dont-capability-negotiate option.

Authenticating BGP Neighbors

You can configure authentication for BGP advertisements to avoid any malicious interference by ASs. This ensures that the routing information exchanged between BGP peers is authentic, and it is accepted only if the authentication is successful. BGP authentication must be configured with the same password on both BGP peers. Otherwise, the connection between them is not established. The Infoblox BGP authentication fully conforms to RFC 2385. For information about BGP authentication, refer to RFC 2385, *Protection of BGP Sessions via the TCP MD5 Signature Option*.

Note
If you upgrade from a previous NIOS version to NIOS 6.11.0 or later, BGP authentication is disabled for existing BGP neighbors.

The BGP service restarts automatically when any of the following authentication changes are made:

- MD5 authentication is enabled or disabled for a BGP neighbor.
- Change the authentication password of a BGP neighbor, for which MD5 authentication is enabled.

To configure BGP for anycast addresses:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the *Grid Member Properties* editor, select the **Anycast** tab.
3. In the BGP Configuration section, complete the following:
    - **Interface Link Detection**: Select this checkbox to enable link detection when the default connection fails. This enables the router to track the next available route. For example, if LAN1 is set as the default gateway when both LAN1 and LAN2 are working, and LAN1 later fails, the router will switch to LAN2. When LAN1 reconnects, the router will then switch back to LAN1.
    - **ASN**: Enter the autonomous system number of the interface. You can enter an ASN number from 1 to 4294967295. You can configure only one ASN on each Grid member.
    - **BGP Timers**: BGP uses timers to control how often the interface sends KEEPALIVE messages and how long it waits before declaring a neighboring router out of service. The keepalive timer determines the time interval at which the interface sends KEEPALIVE messages to a neighboring router to inform the neighbor that the appliance is alive. The hold down timer determines how long the interface waits to hear a KEEPALIVE or UPDATE message before it assumes its neighbor is out of service. If a neighboring router is down, the interface terminates the BGP session and withdraws all the BGP routing information to the neighbor.
        - **Keep Alive**: Enter the time interval in seconds when the interface sends keepalive messages. You can enter a time from 1 to 21845 seconds. The default is four seconds.
        - **Hold Down**: Enter the time in seconds that the interface waits to hear a keepalive message from its neighbor before declaring the neighbor out of service. You can enter a time from 3 to 65535 seconds. The default is 16 seconds.
          Click the Add icon to add a neighboring router to receive BGP advertisements from the NIOS appliance. The appliance adds a new row to the table. Complete the following:
    - **Neighbor Router IP**: Enter the IP address (IPv4 or IPv6) of the neighboring BGP router. The neighboring router can be within the same AS (the most likely case) or from a router in an external AS.
    - **Remote ASN**: Enter the ASN of the neighboring router. You can enter an ASN number from 1 to 4294967295.
    - **MD5 Authentication**: Select this checkbox to enable MD5 authentication for the BGP neighbor. When you enable MD5 authentication, you must enter the authentication password in the **Password** field.

- **Password**: Enter the authentication password that the NIOS appliance uses to connect to the BGP neighbor.You can enter up to 80 printable ASCII characters. The password configured on the Grid member must match the password of the BGP neighbor.
  When you enter the password for a BGP neighbor, it will be preserved even if you disable MD5 authentication for the BGP neighbor later. But if you change the IP address for any existing BGP neighbor, you must re-enter the authentication password for the BGP neighbor, even if the authentication password remains the same.
- **Comment**: Enter useful information about this neighboring router.
  Click the Add icon again to add another neighboring router. You can add up to 10 neighboring routers.

4. Save the configuration and click **Restart** if it appears at the top of the screen.
5. Anycast configuration is complete. To activate anycast, see *Specifying Port Settings for DNS* and its subtopic, *Specifying Source Ports*.

About BFD (Bidirectional Forwarding Detection)

NIOS supports Anycast addressing for DNS using BGP and OSPF routing protocols. Since BGP and OSPF have timer granularity in seconds, the network re-convergence is slow in case of faults in forwarding path. BFD protocol is designed to provide faster failure detection using millisecond timer intervals. It can be enabled with routing protocols to achieve fast network re-convergence.

You can use BFD to detect failures early on and create adjacency with the next router. BFD can be enabled for OSPF or BGP and you can create BFD templates and assign it to OSPF Area or BGP neighbors. You can enable BFD simultaneously for OSPF and BGP, but only one BFD session will be created for a given neighbor. Infoblox recommends that you use the same BFD template for both the OSPF and BGP neighbors whenever such a configuration is required. When BFD is enabled on an anycast daemon, any failure on the DNS service also restarts the anycast daemon. When the anycast restart behavior is 'off', the BFD restarts only when there is a configuration change.

When the BFD protocol gets enabled, it by default also starts an internal DNS monitor to check whether the DNS service is up and running. The BFD DNS monitor works by sending a DNS query for the root zone "." to the configured anycast addresses. If the internal DNS monitor does not receive a DNS response, the DNS service is assumed to be down. The internal DNS monitor then sends the BFD down message and retracts the anycast route.

The BFD protocol feature is supported in NIOS 8.0 and later releases. This section provides a brief overview about enabling BFD for OSPF area and BGP neighbors, creating BFD templates, SNMP, and CLI commands.

Warning

The default advertised setting for BFD holddown is 300 ms (100 ms transit/ receive intervals and detection multiplier 3). This setting is optimized for typical routers and directly connected endpoint configurations. If your network requires an implementation of L2 multi-path or port redundancy, you must adjust the holddown interval value higher than the spanning-tree rebalance latency to avoid unnecessary changes to the L3 network topology or the forwarding path for DNS traffic.

Note

You can enable or disable the **BFD Internal DNS Monitoring** checkbox only if you select the **Enable BFD** checkbox. When you enable the **BFD Internal DNS Monitoring** checkbox, Infoblox recommends that you also select the **Enable DNS Health Check** checkbox in the *Grid Properties Editor* or the *Member Properties Editor*. The **BFD Internal DNS Monitoring** checkbox is enabled by default.

Enabling BFD for OSPF

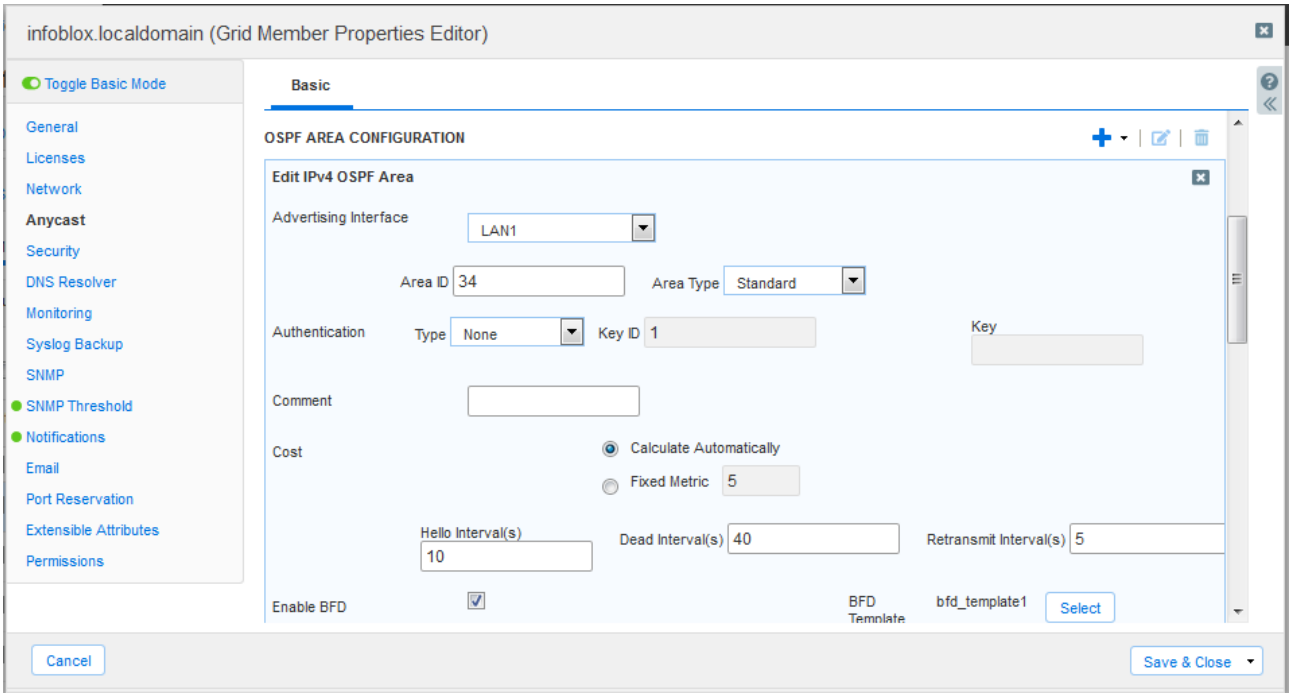
You can enable BFD for both IPv4 and the IPv6 OSPF areas. To support DNS anycast and other routing-dependent applications on NIOS appliances, you must first configure the LAN1, LAN1 (VLAN), or HA (for HA pairs only) interface as an OSPF advertising interface, and then assign an area ID on the interface to associate it with a specific OSPF area.

To enable BFD for the IPv4 or the IPv6 OSPF area:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the *Grid Member Properties* editor, select the **Anycast** tab.
3. In the OSPF Area Configuration table, select the OSPF advertising interface, click the Edit icon, and then complete the following:
    - **Enable BFD**: Select this checkbox to enable BFD for the OSPF advertising interface.
    - **BFD template**: Click **Select BFD Template** and select a BFD template from the *Select BFD Template* dialog box. You can click **Clear** to remove the selected BFD template and select a new one.
    - **BFD Internal DNS Monitoring**: Select this checkbox to enable the internal DNS monitor to send and receive DNS responses and to retract the OSPF route if it does not receive a DNS response.
4. Save the configuration.

When OSPF session with a neighbor router in the OSPF Area reaches FULL state, BFD session is automatically created. By default, BFD runs with no authentication and timer intervals of 100ms transmit, 100ms receive and multiplier 3 (hold down time = 300ms). The actual runtime intervals are negotiated with the peer as per BFD standard RFC 5880. If these intervals are not suitable or authentication needs to be enabled for BFD, you must create a BFD template.

Enabling BFD for OSPF



You can use the `show ipv6_ospf neighbor` CLI command to view runtime BFD information for OSPF.

Enabling BFD for BGP Neighbor

BFD can be enabled for each configured BGP neighbor individually. You can also use the Enable Multi-hop option, which allows BGP to connect to BGP neighbors which are more than one IP hops away.
To enable BFD for the BGP neighboring router:

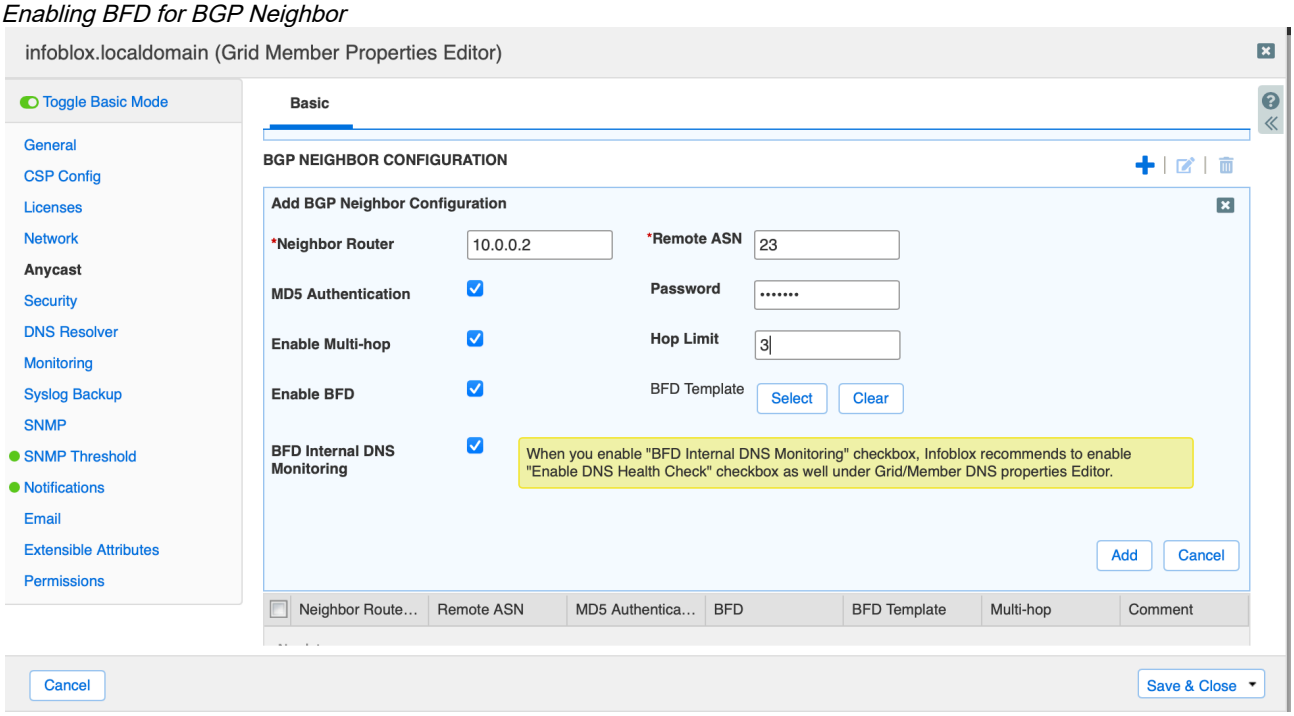
1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the *Grid Member Properties* editor, select the **Anycast** tab.
3. In the BGP Neighbor Configuration table, select the BGP neighboring router, click the Edit icon, and then complete the following:
    - **Enable Multi-hop (optional)**: Select this checkbox to allow BGP to connect with the neighbors which are more than one IP hops away.
    - **Hop Limit**: Enter the maximum hop limit. The default value is 255.

- **Enable BFD**: Select this checkbox to enable BFD for the BGP neighboring router.
- **BFD template**: You can assign a BFD template to the BGP neighboring router to run BFD with non-default settings. Click **Select BFD Template** and select a BFD template from the *Select BFD Template* dialog box. You can click **Clear** to remove the selected BFD template and select a new one.
- **BFD Internal DNS Monitoring**: Select this checkbox to enable the internal DNS monitor to send and receive DNS responses and to retract the BGP route if it does not receive a DNS response.

4. Save the configuration.

The BFD session for a given BGP neighbor is created when the BGP state reaches 'Established'.

Enabling BFD for BGP Neighbor



Viewing Runtime BFD Information for BGP

You can use the `show bgp neighbor` CLI command to view runtime BFD information for BGP. For more information, see *show bgp*.

Creating a BFD Template

BFD advertises the default hold-down interval of 300ms and authentication is disabled, by default. In order to configure faster or slower hold-down intervals, you can create BFD templates and assign it to the OSPF Area or BGP neighbors. You can configure a BFD template at the Grid level and assign it to multiple Grid members. The BFD template can be assigned to the BGP neighbor or OSPF Area of any Grid member in the Grid and it can be assigned to multiple BGP neighbors or OSPF Areas.
To create BFD templates:

1. From the **Grid** tab -> **Grid Manager** tab, expand the Toolbar and click **Manage BFD Templates**.
2. In the *Manage BFD Templates* wizard, click the Add icon, and then complete the following:
   - **Name**: Enter the name of the BFD template.
   - **Authentication Type**: Select the authentication type from the drop-down list. You can select one of the following authentication types: **MD5**, **SHA-1**, **Meticulous MD5**, or **Meticulous SHA-1**. The BFD authentication type fully conforms to RFC 5883.
   - **Authentication Key ID**: Enter the key identifier to use to specify the correct hash algorithm after you select the authentication type. If you do not enter a value here, the appliance by default sets 'one' as the

authentication key ID. The authentication key ID configured on the Grid member must match the authentication key ID of the upstream router configuration.

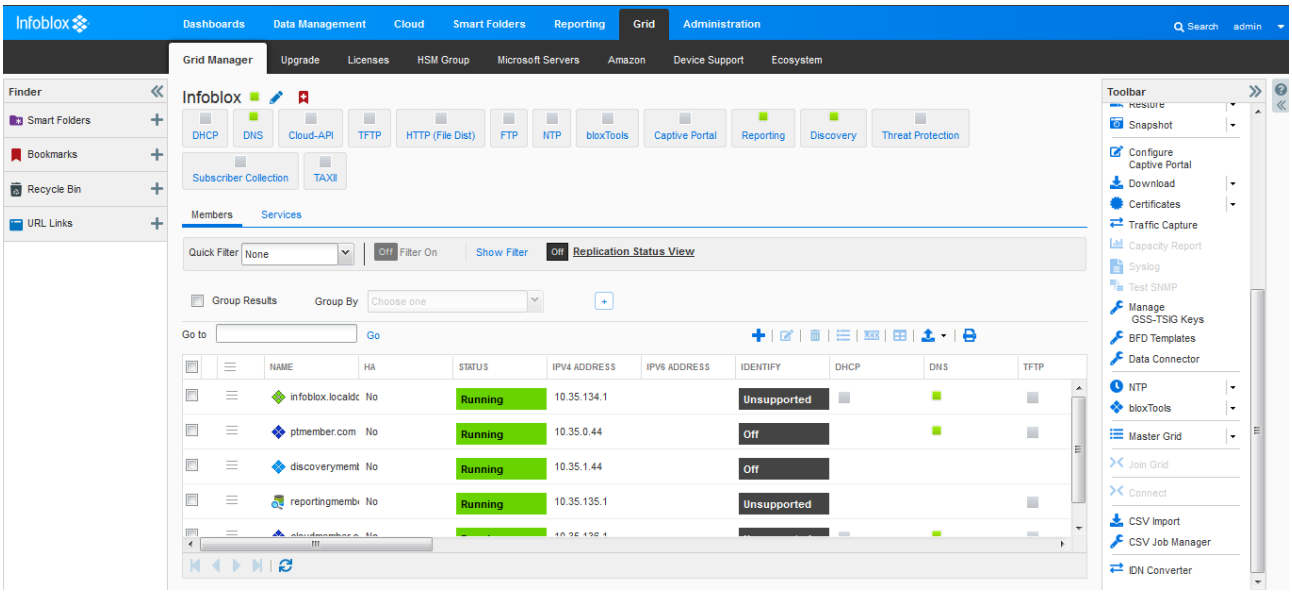
- **Authentication Secret/Password**: Enter the authentication password to use to verify after you select the authentication type. You can enter password with 4-16 printable ASCII characters. The authentication password configured on the Grid member must match the authentication key of the upstream router configuration.
- **Intervals**: Specify the following BFD timer intervals for each router interface.
  - **Min Rx Interval (ms)**: Enter the minimum receive interval. The default is 100ms. The minimum receive interval value must be an integer between 50 and 9999 (both inclusive).
  - **Min Tx Interval (ms)**: Enter the minimum transmit interval. The default is 100ms. The minimum transmit interval value must be an integer between 50 and 9999 (both inclusive).
  - **Multiplier**: Enter the detection multiplier. You can enter a value between 3 and 50. The default is 3.

3. Click **Add**.

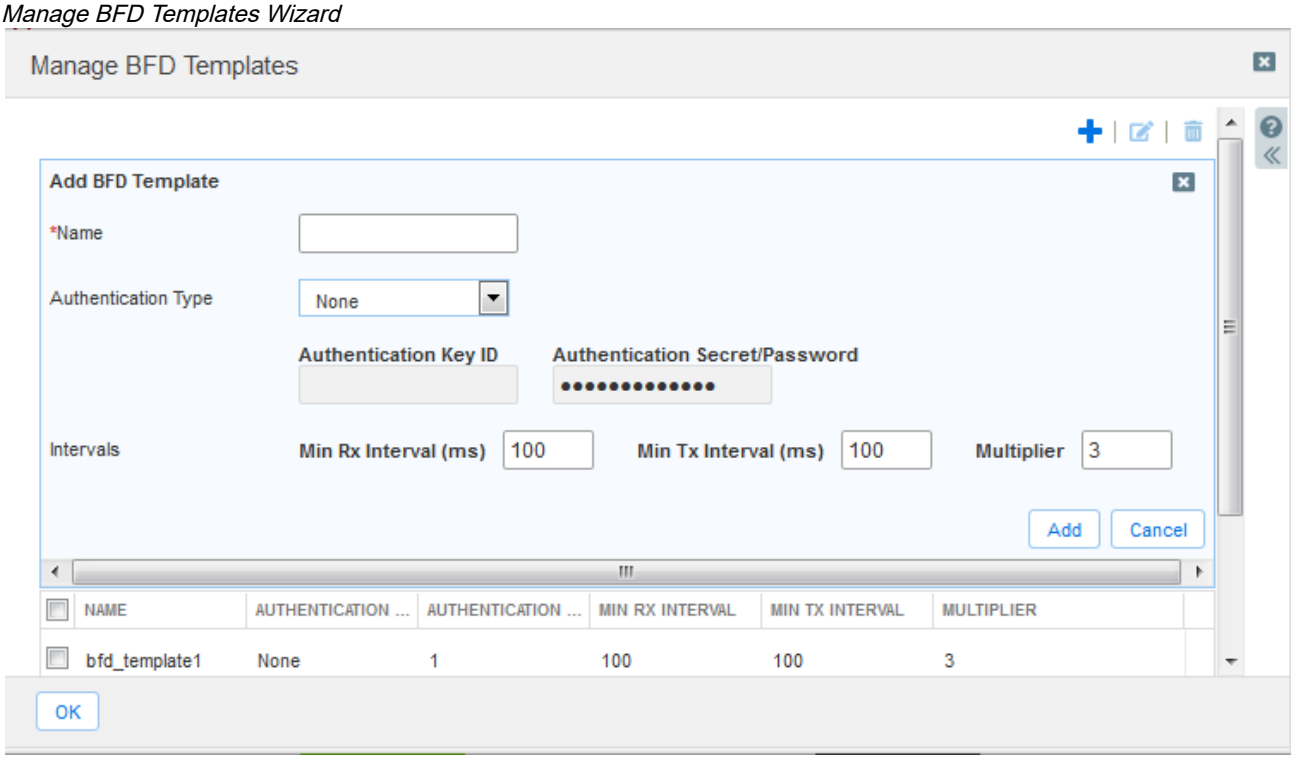
After you have added BFD templates, you can do the following:

- Select a BFD template and click the Edit icon to edit the configuration.
- Select a BFD template and click the Delete icon to delete it.

Manage BFD Templates



Manage BFD Templates Wizard



Enabling and Disabling DNS Health Check Monitor

In order to minimize downtime for DNS and ensure high availability, NIOS implements DNS process monitoring and self-recovery on each Grid member, in order to minimize downtime for DNS and ensure high availability. You can enable the DNS health check monitor to monitor whether the DNS server is responding to client requests. When you enable this feature, the appliance sends a query to the DNS server and waits for the response until the specified timeout duration. If the appliance is unable to receive a response from the DNS server after the specified number of retries, the appliance sends SNMP traps and email notifications about the failure. The appliance performs the DNS health check periodically based on the specified time interval.
If BFD is used for anycast fault detection, the BFD session state advertised from the member can be in the Down state whenever there is a DNS health check failure. This allows quick anycast route tear-down and the network might converge with another DNS server that can serve same anycast IP.

Additionally, you can also configure domain names in the DNS health check monitor, which are probed simultaneously and if any one of the domains fail to resolve for consecutive attempts, the DNS health is considered as Down. If recursion is enabled on the Grid member, the queries to these domains help to assert the ability of the DNS server to reach the external authoritative servers and optionally trigger network re-convergence in case of a failure. When no domains are configured, local PTR queries are used to probe the DNS process.

> **Warning**
>
> *The DNS health check monitor might not work properly if the DNS blackhole feature is enabled or if any named ACL is blocking the query sent to the loopback interface.*

To enable or disable the DNS health check monitor:

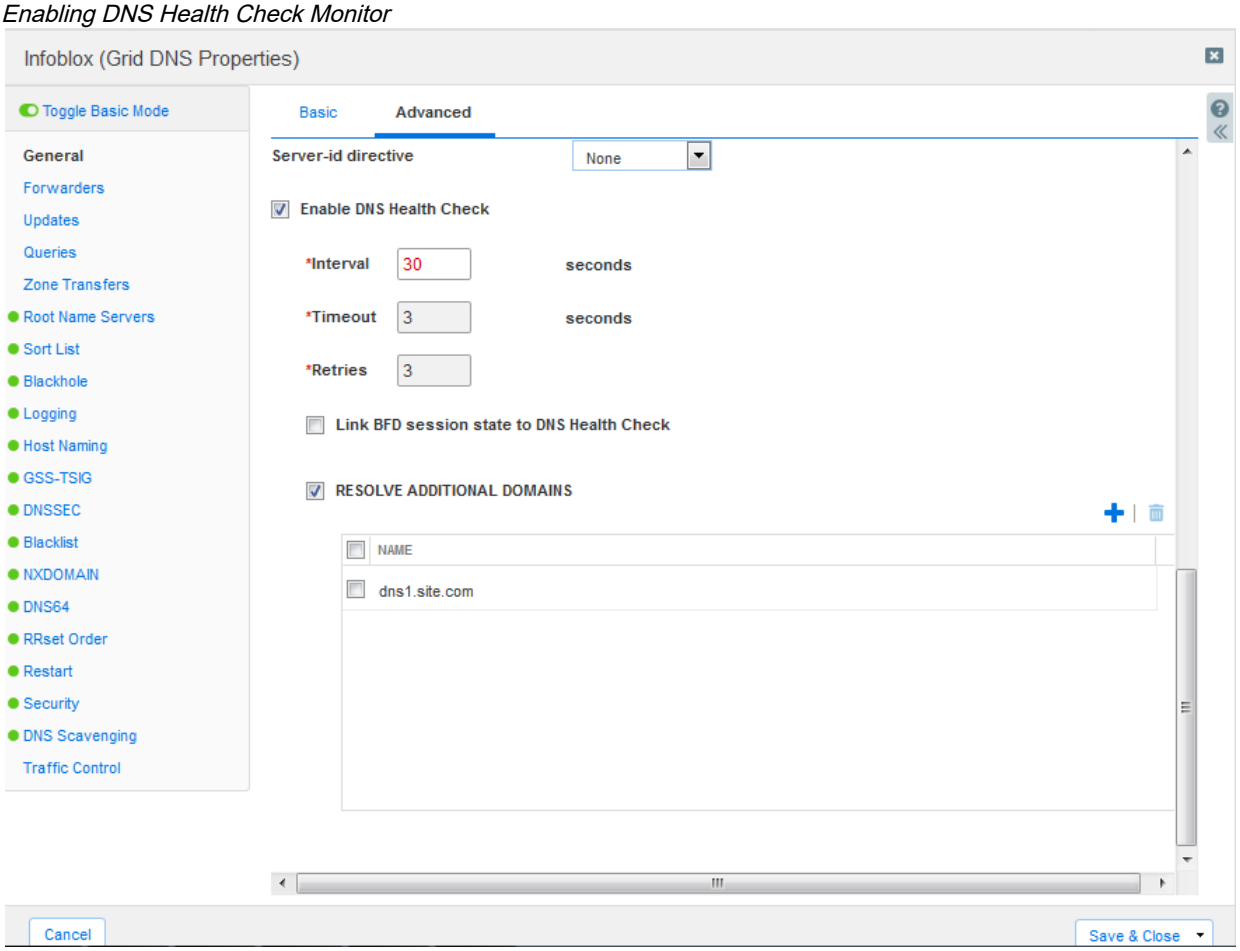
1. **Grid**: From the **Data Management** tab, select the **DNS** tab, and then select **Grid DNS Properties** from the Toolbar. **Member**: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.

In the *Grid DNS Properties* or the *Member DNS Properties* editor, click **Toggle Advanced Mode** if the editor is in the basic mode.

2. Click the **Advanced** subtab of the **General** tab and then complete the following:
    - **Enable DNS Health Check**: This checkbox is deselected by default, meaning the DNS health check monitor is disabled. Select this checkbox to enable the DNS health check monitor and specify the following:
    - **Interval**: Enter the time interval in seconds. The interval value is measured from the end of the previous monitoring cycle. The default is 30 seconds. You can enter a value between 10 and 21600 seconds.
    - **Timeout**: Enter the timeout value in seconds. This is the time the appliance waits for a response to the query. The default is 3 seconds. You can enter a value between 1 and 10 seconds.
    - **Retries**: Enter the number of times the appliance tries to send the query after a failed attempt. The default is 3. You can enter a value between 1 and 10.
    - **Link BFD session state to DNS Health Check**: Select this checkbox to link the BFD session state with the DNS health check monitor.
    - **Resolve Additional Domains**: Click the Add icon and enter the domain name. The DNS health check monitor sends recursive queries to the local DNS server (BIND/Unbound) for the domain names listed in this table. You can add up to 16 domain names.
3. Save the configuration.

> **Note**
>
> You must carefully select the domain names for DNS health check monitor with BFD session in order to avoid unnecessary changes in downstream DNS traffic due to transient health check query failures. Setting a higher timeout or retry count might help in avoiding false alarms.

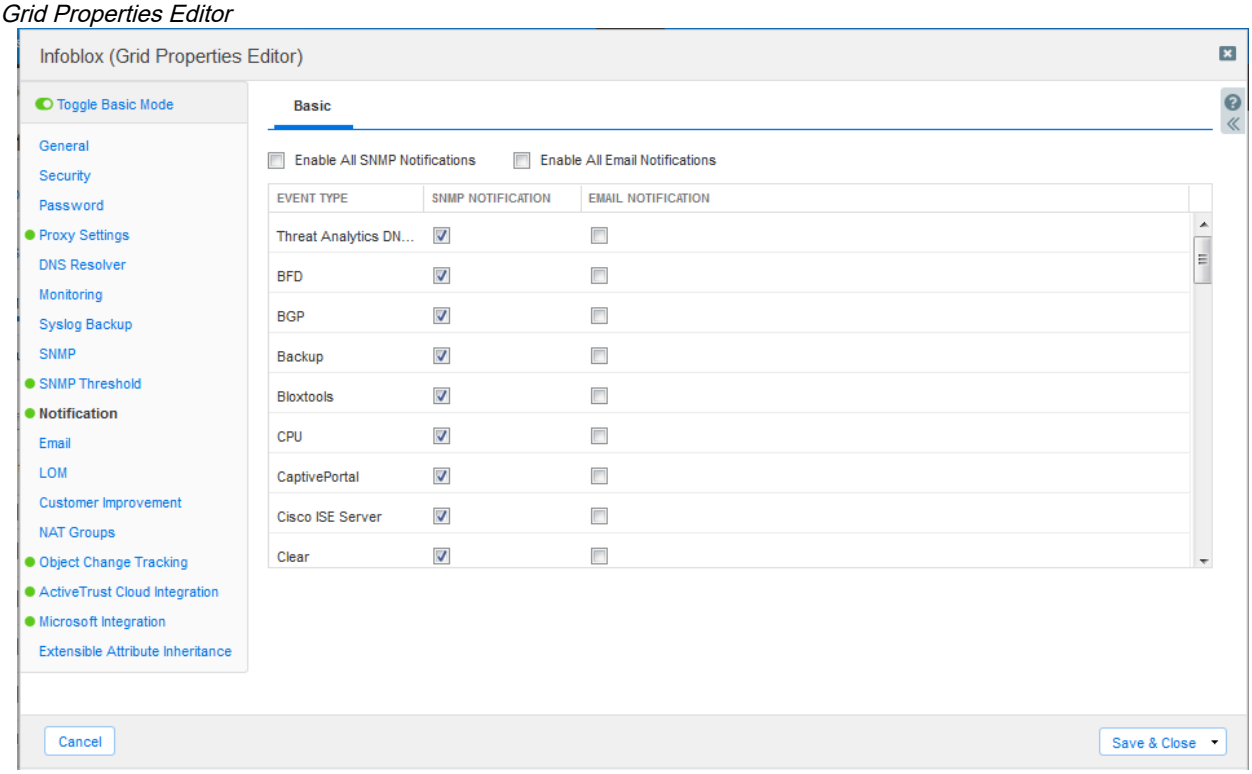
Enabling DNS Health Check Monitor



Monitoring with SNMP

Infoblox MIBs (IB-TRAP-MIB, IB-PLATFORMONE-MIB) are updated to include a notification for BFD process failure (ibBFDSoftwareFailure). By default, SNMP notifications are enabled for the BFD process failure event. You can enable or disable SNMP and email notifications for specific event types, by selecting the corresponding checkboxes in the **Notification** tab of the *Grid Properties* or *Member Properties* editor.

Grid Properties Editor



In addition, the BFD process can generate SNMP traps for session state changes according to the standard BFD MIBs described in *RFC 7330* and *RFC 7331*:

- .1.3.6.1.2.1.222.0.1 (bfdSessUp): This notification (aka trap) is sent when one of the neighbors changes the BFD-session state as 'Up.'
- .1.3.6.1.2.1.222.0.2 (bfdSessDown): This notification (aka trap) is sent when one of the neighbors changes the BFD-session state as 'Down' or 'AdminDown.'
- .1.3.6.1.2.1.222.1.2.1.13 (bfdSessDiag): The diagnostic code which can be one of the following:
    - noDiagnostic (0)
    - controlDetectionTimeExpired (1)
    - echoFunctionFailed (2)
    - neighborSignaledSessionDown (3)
    - forwardingPlaneReset (4)
    - pathDown (5)
    - concatenatedPathDown (6)
    - administrativelyDown (7)
    - reverseConcatenatedPathDown (8)
    - misConnectivityDefect (9)

Note that you must download the following MIBs to enable the trap-receiver to parse the notifications:

- BFD-STD-MIB
- BFD-TC-STD-MIB
- DIFFSERV-MIB
- DIFFSERV-DSCP-TC
- INTEGRATED-SERVICES-MIB
- IANA-BFD-TC-STD-MIB

DHCP

This section describes how to configure the Grid to provide DHCP services. It includes the following topics:

Configuring Infoblox DHCP Services

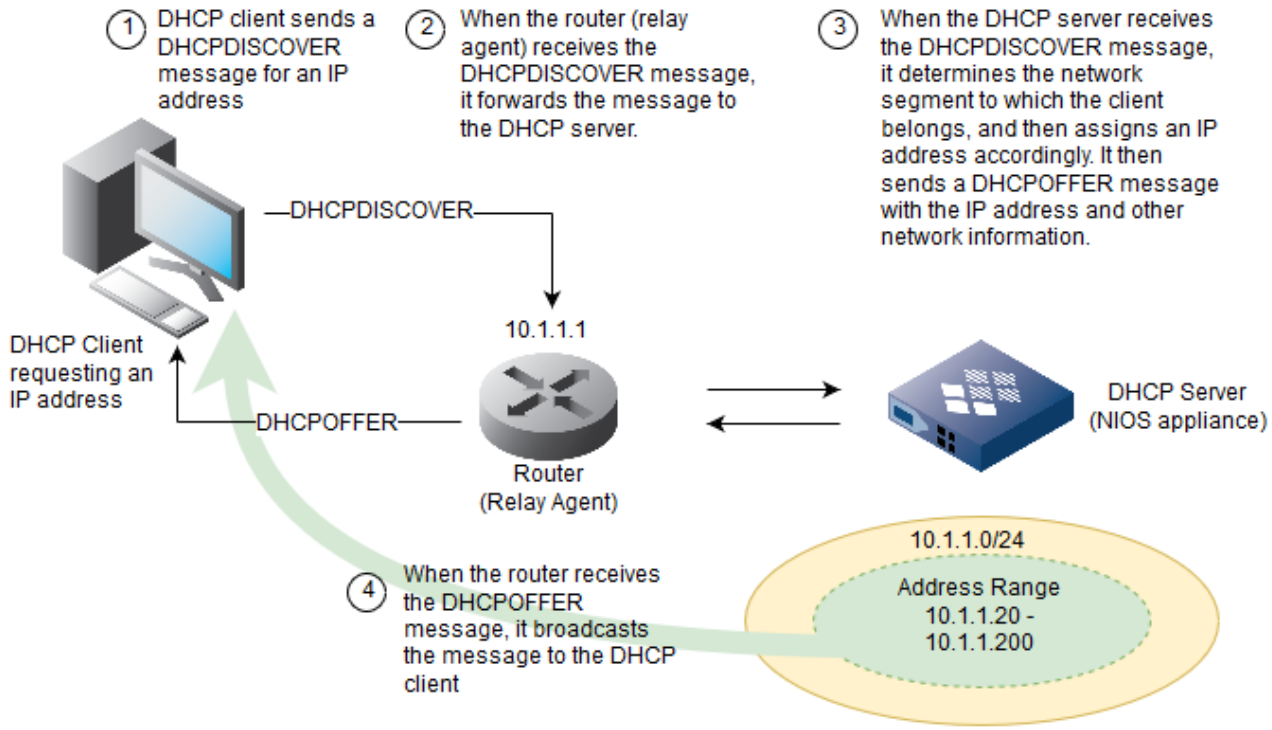
DHCP (Dynamic Host Configuration Protocol) is a network application protocol that automates the assignment of IP addresses and network parameters to DHCP-configured network devices (DHCP clients). When a DHCP client connects to a network, it sends a request to obtain an IP address and configuration information from the DHCP server. The DHCP server manages a pool of IP addresses and configuration information such as default gateway, domain name, and DNS server. Depending on the configuration, the DHCP server either assigns or denies an IP address to a client request. It also sends network configuration parameters to the client.
You can configure a NIOS appliance to provide DHCP service for IPv4 and IPv6. The Infoblox DHCP server complies with a number of DHCP and DHCPv6 RFCs (see Appendix A Product Compliance). Limited-access admin groups can access certain DHCP resources only if their administrative permissions are defined. For information on setting permissions for admin groups, see *Managing Administrators*.

This section provides an overview of the Infoblox DHCP services for IPv4 and IPv6. It contains the following topics:

IPv4 DHCP Protocol Overview

As illustrated in the figure below, when a DHCP client requests an IP address, it sends a DHCPDISCOVER message to the router, which can act as a relay agent. The router forwards the message to the DHCP server. When the DHCP server receives the DHCPDISCOVER message, it determines the network segment to which the client belongs and assigns an IP address. The DHCP server then sends a DHCPOFFER message that includes the IP address and other network configuration information. When the router receives the DHCPOFFER message, it broadcasts the message to the client that sent the DHCPDISCOVER message.

IP Address Allocation Process

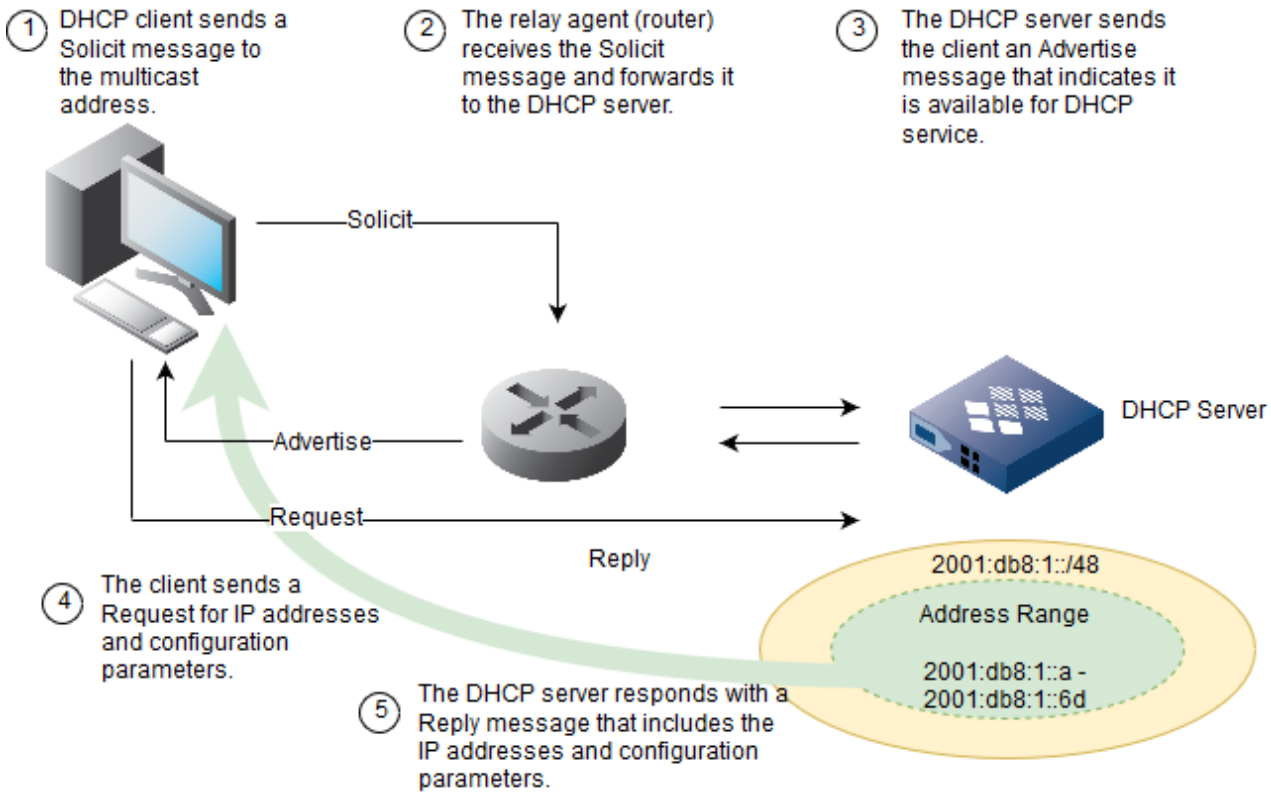


IPv6 DHCP Protocol Overview

You can configure NIOS appliances to support DHCP for IPv6 (DHCPv6), the protocol for providing DHCP services for IPv6 networks. The DHCPv6 client-server model is similar to that of IPv4. DHCP clients and servers use a reserved, link-scoped multicast address to exchange DHCP messages. When a DHCP client needs to send messages to a DHCP server that is not attached to the same link, a DHCP relay agent can be used to relay messages between the client and server. Each IPv6 DHCP server and client has a unique DHCP unique identifier (DUID). DHCP servers use DUIDs to identify clients when providing configuration parameters, and clients use DUIDs to identify the source of the DHCP messages from servers.

As illustrated in the figure Client DHCPv6 Configuration Workflow below, a DHCP client that needs an IPv6 address sends a Solicit message to the well-known multicast address. DHCPv6 servers then send Advertise messages to the client to indicate that they are available. The client sends a Request message to a specific DHCPv6 server to request IP addresses and configuration parameters. The DHCPv6 server responds with a Reply message that contains the IP addresses and configuration parameters. You can view statistics about the IPv6 messages on the Dashboard.

Client DHCPv6 Configuration Workflow



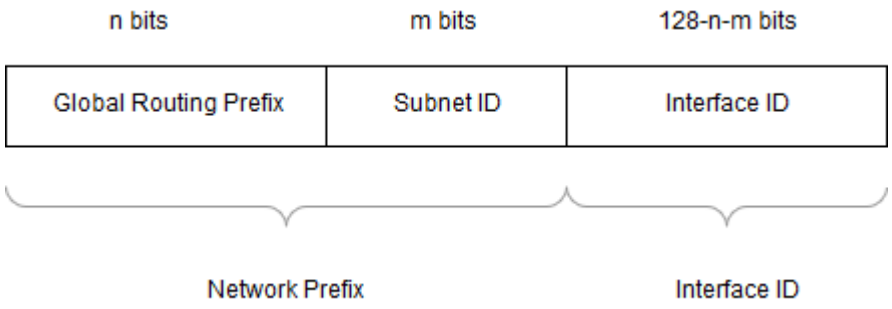
Infoblox DHCP servers also supports stateless configuration in which a DHCP client does not need IP addresses, but needs configuration information only. The DHCP client sends an Information-Request packet to obtain configuration information, and the server sends a Reply message with the requested information. For more information, refer to *RFC 2462, IPv6 Stateless Address Autoconfiguration*.

IPv6 Address Structure

An IPv6 address consists of the following:

- Global Routing Prefix — Global routing prefix is a (typically hierarchically-structured) value assigned to a site. For example, an ISP can delegate a prefix to your site, which you can then divide into subnets.
- Subnet ID — Subnet ID is an identifier of a link within the site.
- Interface ID — Interface Identifier. This portion of the address identifies the interface on the subnet. This is equivalent to the host identifier for IPv4 addresses.

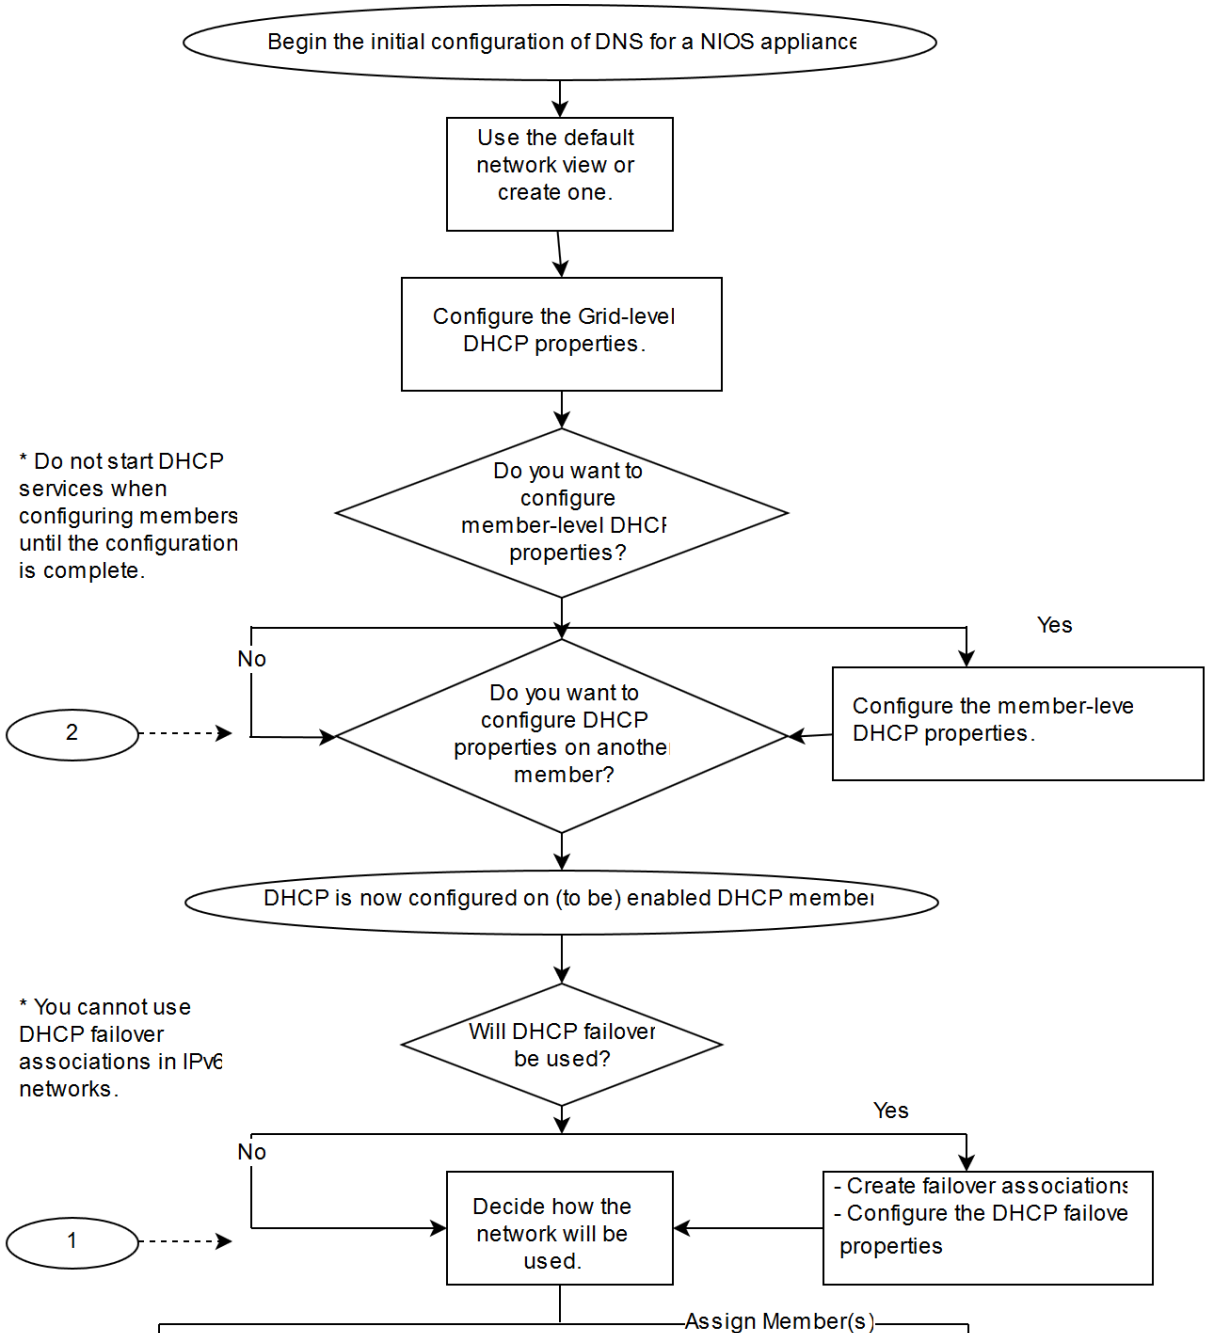
IPv6 Address Structure

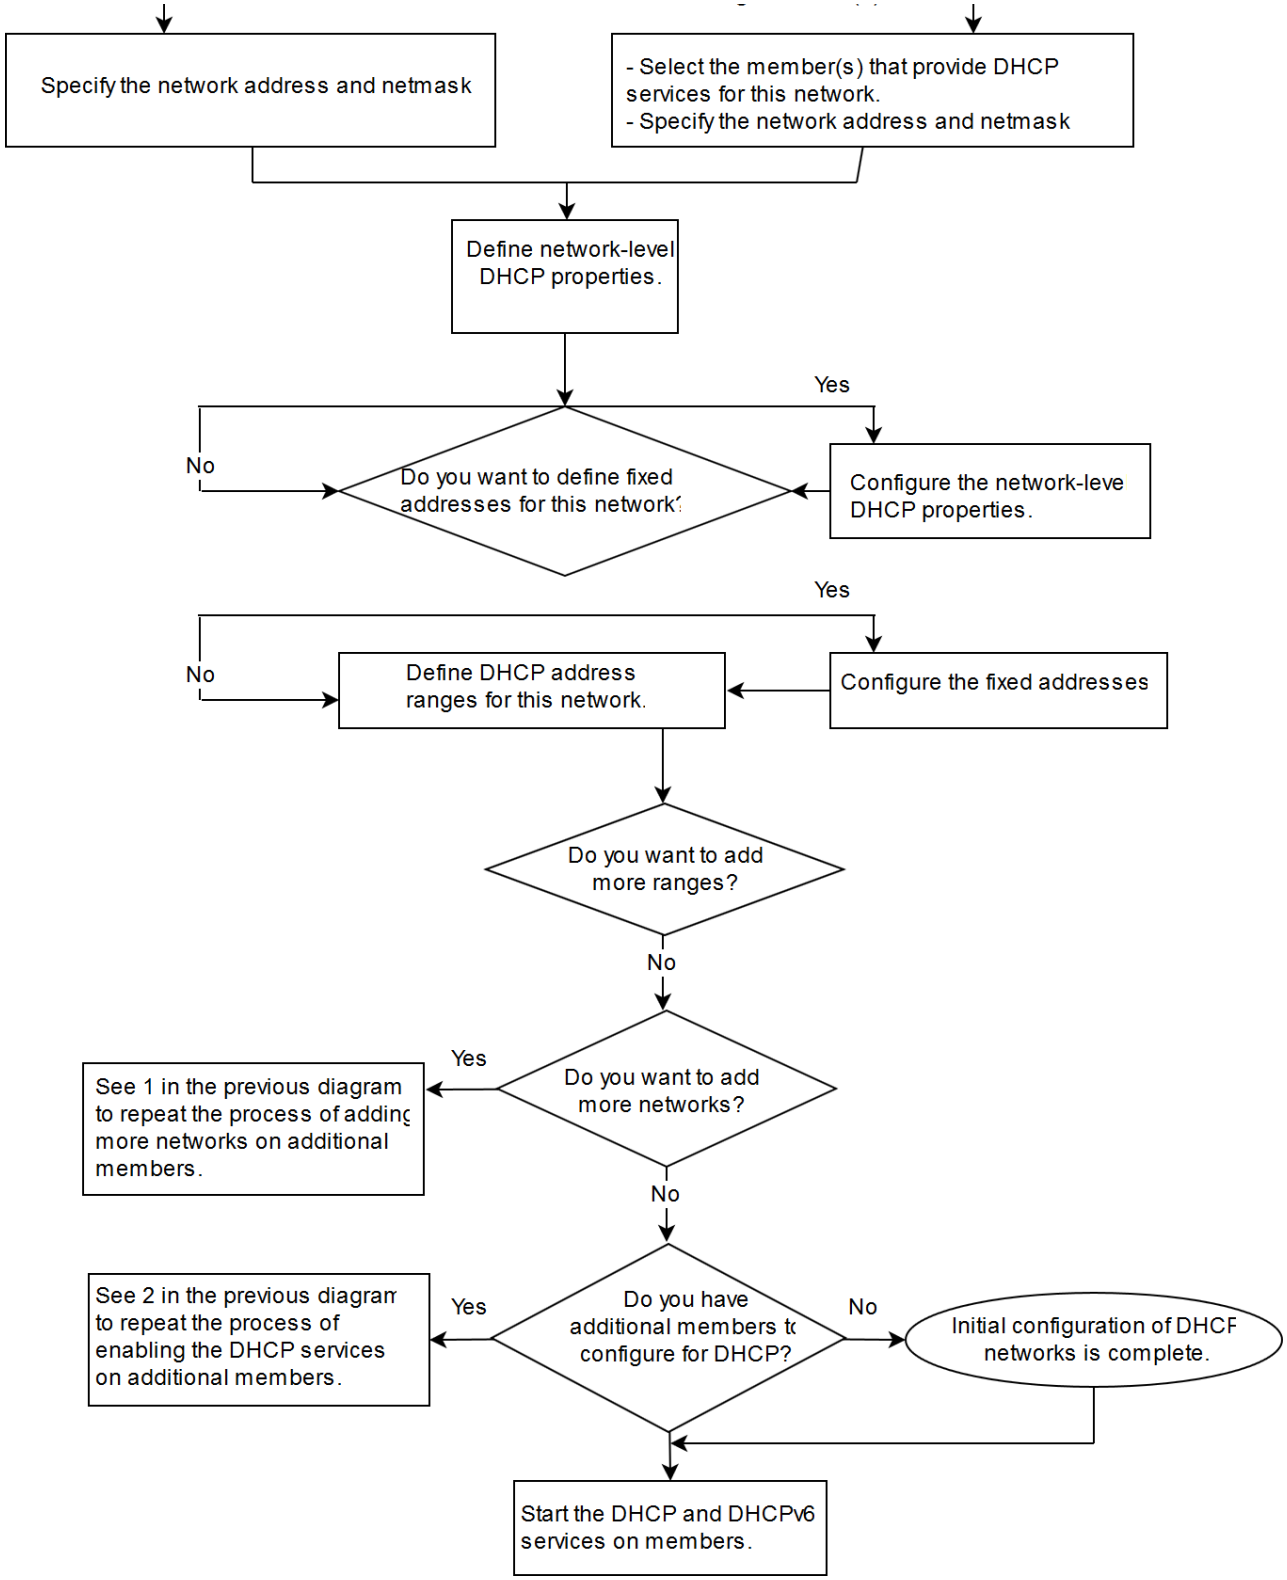


When you enter an IPv6 address in Grid Manager, you can use double colons to compress a contiguous sequence of zeros. You can also omit any leading zeros in a four-hexadecimal group. For example, the complete IPv6 address 2006:0000:0000:0123:4567:89ab:0000:cdef can be shortened to 2006::123:4567:89ab:0:cdef. Note that if there are multiple noncontiguous groups of zeros, the double colon can only be used for one group to avoid ambiguity. The NIOS appliance displays an IPv6 address in its shortened form, regardless of its form when it was entered.

Configuring DHCP Overview

An overview of the complete DHCP configuration process is outlined in the following diagram, illustrating the main steps for preparing a NIOS appliance for use. Note that the process for configuring the DHCP server is the same for IPv4 and IPv6 networks, except that failover associations are not supported in IPv6 networks.





Configuring the Connecting Switch

To ensure that VRRP (Virtual Router Redundancy Protocol) works properly, configure the following settings at the port level for all the connecting switch ports (HA, LAN1, and LAN2):

- Spanning Tree Protocol: Disable.
  For vendor specific information, search for "HA" in the Infoblox Knowledge Base system at *https://support.infoblox.com*.
- Trunking: Disable.
  If VLAN tagging in enabled on an Infobolox HA appliance, you must enable trunking at the port level.
- EtherChannel: Disable.
- IGMP Snooping: Disable.
- DHCP Snooping: Disable or Enable Trust Interface.
  You must disable DHCP Snooping to successfully run DHCP services on the Grid. For more information about DHCP services, see *Configuring Infoblox DHCP Services*.
  Port Channeling: Disable.
- Speed and Duplex settings: Match these settings on both the Infoblox appliance and switch.
- Disable other dynamic and proprietary protocols that might interrupt the forwarding of packets.
  By default, a NIOS appliance automatically negotiates the optimal connection speed and transmission type (full or half duplex) on the physical links between its LAN1 or LAN1 (VLAN), HA, and MGMT ports and the Ethernet ports on the connecting switch. If the two appliances fail to auto-negotiate the optimal settings, see as described in *Modifying Ethernet Port Settings* for steps you can take to resolve the problem.

Managing DHCP Data

You can configure a NIOS appliance to provide DHCP service for IPv4 and IPv6, and manage both IPv4 and IPv6 objects. When you define DHCP objects, you can track specific information about a network device by defining extensible attributes. Extensible attributes are fields that you define to track properties such as network locations or device models. For more information, see *Managing Extensible Attributes*.

About Networks

You can configure DHCP IPv4 and IPv6 properties for the Grid and its members, and then define the IPv4 and IPv6 networks that they serve.
All networks, both IPv4 and IPv6, must belong to a network view. The appliance has one default network view and unless you create additional network views, all networks belong to the default view. Note that because network views are mutually exclusive, you can create networks with overlapping IP address spaces in two different network views. For more information, see *Configuring Network Views*.

> **Note**
>
> The 255.255.255.255 limited broadcast address is reserved. The appliance does not automatically create glue A records for this address. You can however create an NS record without the associated glue records. For more information, see *Changing the Interface IP Address.*

About Shared Networks

A shared network is a network segment to which you assign two or more subnets. When subnets in a shared network contain IP addresses that are available for dynamic allocation, the addresses are put into a common pool for allocation when client requests arise. When you create a shared network, the DHCP server can assign IP addresses to client requests from any subnet (that resides on the same network interface) in the shared network. For example, when you have networks A, B, and C on the same network interface and you assign them to a shared network, the DHCP server can allocate available IP addresses from any DHCP range within networks A, B, and C even when all the client requests originate from network A. When adding subnets to a shared network, ensure that the subnets are assigned to the same

members to avoid DHCP inconsistencies.
Before creating a shared network, you must first create the subnets. For example, you must first create the IPv4 networks `10.32.1.0` and `10.30.0.0` before designating them to a shared network or create the IPv6 networks 2001:db8:1::/48 and 2001:db8:2::/48 before designating them to a shared network.
After you create a network, you can define their DHCP resources such as DHCP ranges, fixed addresses, reservations, host records, and roaming hosts. IPv4 and IPv6 support most of the same DHCP objects, except that IPv6 does not support reservations.

About DHCP Ranges

A DHCP range is a pool of IP addresses from which the appliance allocates IP addresses. You must add a DHCP address range in your network so the appliance can assign IP addresses to DHCP clients within the specified range. IPv6 DHCP ranges can also contain a range of IPv6 prefixes that it delegates to DHCP clients that request them.
You must assign a DHCP range to a Grid member. Note that you can only assign DHCP ranges to members and networks that are in the same network view. If the server is an independent appliance, you must specify this appliance as the member that serves the DHCP range. In addition, you can also assign IPv4 DHCP ranges to failover associations.

About Exclusion Ranges

You can define an exclusion range within a DHCP range. Creating an exclusion range prevents the appliance from assigning the addresses in the exclusion range to clients. IP addresses in an exclusion range are excluded from the pool of IP addresses. You can use exclusions to split a DHCP range into multiple blocks of ranges. You can also use addresses in the exclusion ranges as static IP addresses for network devices such as legacy printers that do not support DHCP. An exclusion in a range can help prevent address conflicts between statically configured devices and dynamically configured devices.

About Fixed Addresses

You can configure fixed addresses for network devices, such as routers and printers, that are not frequently moved from network to network. By creating fixed addresses for network devices, clients can reliably reach them by their domain names. Some network devices, such as web or FTP servers, can benefit from having fixed addresses for this reason. In IPv4 and IPv6 networks, you can also reserve an IP address that is not part of a DHCP range by defining a reservation. For information about creating reservations, see *Configuring IPv4 Reservations*.

About Hosts

Infoblox hosts are data objects that contain DNS, DHCP, and IPAM data of the assigned addresses. You can assign multiple IPv4 and IPv6 addresses to a host. When you create a host, you are specifying the name-to-address and address-to-name mappings for the IP addresses that you assign to the host. For information about Infoblox hosts, see *About Host Records*.

DHCP Configuration Checklists

After you complete the appliance configuration for each member in the Grid, as described in *Managing Appliance Operations*, you can configure DHCP services.
The following checklist includes the major steps for configuring DHCP service for IPv4:

IPv4 DHCP Configuration Checklist

Step	For more information
Configure DHCP properties for the Grid and members.	• *Configuring IPv4 DHCP Properties* • *Understanding DDNS Updates from DHCP* • *Configuring DHCP IPv4 and IPv6 Common Properties* • *Configuring the Lease Logging Member*
Decide if you want to configure a DHCP failover association.	• *Configuring Failover Associations*
Configure networks based on your network requirements and decide if you want to override the Grid or member DHCP configuration for the networks	• *Configuring IPv4 Networks* • *Configuring IPv4 Shared Networks*
Decide if you want to configure fixed addresses and reservations, and whether to override the *Configuring IPv4 Reservations* upper level DHCP properties for the fixed addresses and reservations.	• *Configuring IPv4 Fixed Addresses* • *Configuring IPv4 Reservations*
Define DHCP ranges and decide whether to override the upper level DHCP properties for the ranges.	• *Configuring IPv4 Address Ranges*
Enable DHCP services on the member.	• *Starting DHCP Services on a Member*

The following checklist includes the major steps for configuring DHCP service for IPv6:

IPv6 DHCP Configuration Checklist

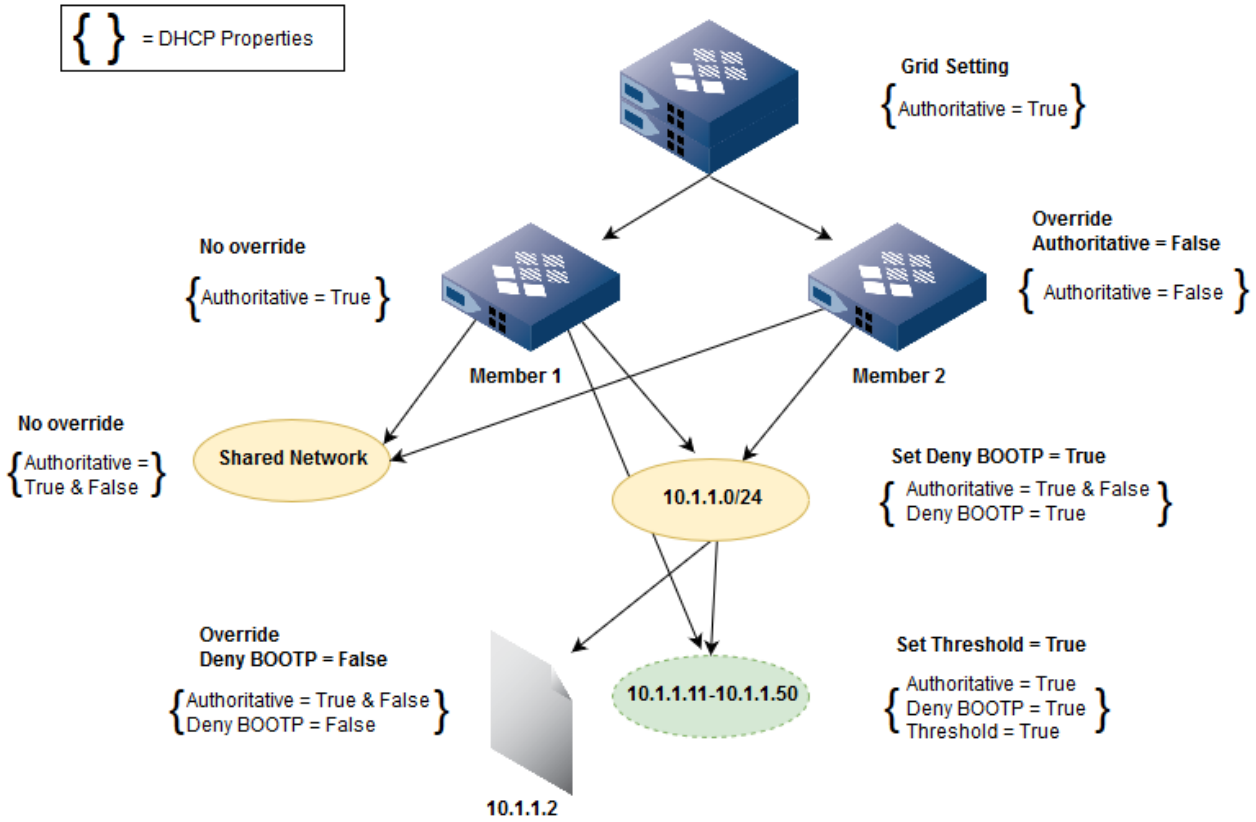
Step	For more information
Configure DHCP properties for the Grid and members.	• *Configuring DHCPv6 Properties* • *Understanding DDNS Updates from DHCP* • *Configuring DHCP IPv4 and IPv6 Common Properties* • *Configuring the Lease Logging Member*
Configure networks based on your network requirements and decide if you want to override the Grid or member DHCP configuration for the networks.	• *Configuring IPv6 Networks* • *Configuring IPv6 Shared Networks*
Decide if you want to configure fixed addresses and reservations, and whether to override the upper level DHCP properties for the fixed addresses and reservations.	• *Configuring IPv6 Fixed Addresses*
Define DHCP ranges and decide whether to override the upper level DHCP properties for the ranges	• *Configuring IPv6 Address Ranges*
Enable DHCP services on the member.	• *Starting DHCP Services on a Member*

DHCP Inheritance

When you configure DHCP properties for the Grid, members, networks, shared networks, DHCP ranges, fixed addresses, reservations, host addresses, and roaming hosts, the appliance applies the configured properties hierarchically. In addition, IPv4 DHCP objects inherit IPv4 specific properties and IPv6 objects inherit IPv6 specific properties. For example, when you set DHCP IPv4 properties for the Grid, all DHCP IPv4 objects inherit the properties from the Grid unless you override them at a specific level, and the same applies for IPv6 properties and objects. Properties set at the member level override Grid-level settings and apply to the objects that the member serves. Properties set at the network level override member-level settings and apply to the objects within the network. Properties set for a DHCP range override those set at higher levels. You can also set specific properties that apply only to fixed addresses, reservations, host addresses, and roaming hosts.

The figure Inheritance Hierarchy in a Grid below illustrates some inheritance scenarios that can occur in a Grid. As shown in the figure, the authoritative server configuration set for the Grid is inherited by the members. Since Member 1 has no overrides and Member 2 overrides the authoritative server configuration, they have different DHCP configurations. Grid Manager applies DHCP properties hierarchically from the Grid down. Therefore, a DHCP object below the member level can inherit DHCP properties with multiple values from multiple sources. In Inheritance Hierarchy in a Grid, network 10.1.1.0/24 inherits multiple values (True and False) from the members for the authoritative server configuration. The shared network, which includes 10.1.1.0/24, inherits DHCP properties from both members. For DHCP range 10.1.1.11 - 10.1.1.50, since Member 1 is the assigned member, it inherits properties from Member 1 and the network. The fixed address 10.1.1.2 overrides the BOOTP settings and inherits the authoritative server configuration from both members and the network.

Inheritance Hierarchy in a Grid



When a DHCP property contains inherited values from different sources, the appliance displays the corresponding information when you create or modify an object. Based on the information provided, you can then decide whether to

override or keep the inherited values. You must have read/write permissions to the DHCP resources to override inherited values. You can only view inherited values and paths if you have read-only permissions.

Overriding DHCP Properties

DHCP properties configured at the Grid level apply to the entire Grid. You can choose to keep the inherited properties or override them when you configure the properties for a member, network, shared network, DHCP range, fixed address, host address, or roaming host. For example, you can override the values of DHCP properties inherited from a member and enter unique values for a network that is configured for DHCP.
To override an inherited value:

1. In a wizard or editor, click **Override** next to a property to enable the configuration. The **Override** button changes to **Inherit**.
2. Enter a new value to override the inherited value.

Viewing Inherited Values

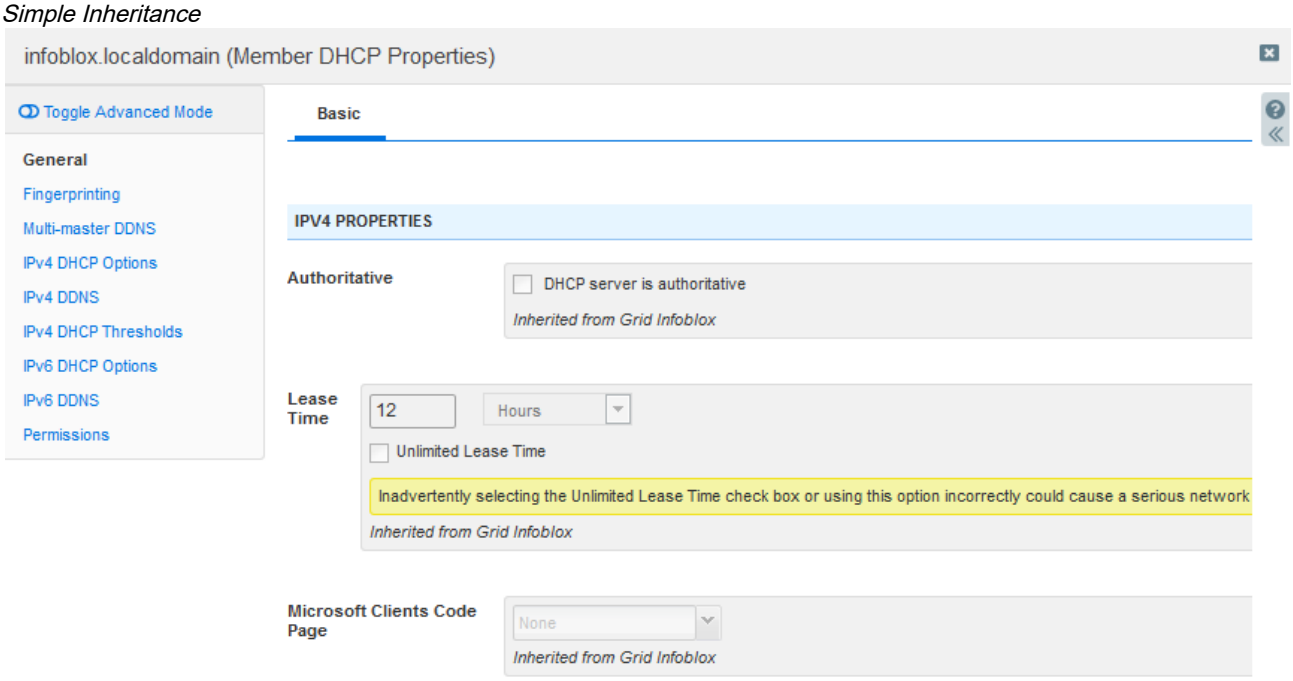
When you configure DHCP properties that contain inherited values, the appliance displays the information based on the inheritance sources. The following table summaries what the appliance can display:

When you see...	it means...	For details, see...
Inherited From *<object>*	the DHCP property has a definite value from an inheritance source.	Simple Inheritance below
Inherited From Upper Level	the appliance cannot determine the inherited value or inheritance source for the DHCP property.	Unknown Inheritance below
Inherited From Multiple	the DHCP property has the same value that it inherits from multiple sources.	Multiple Inheritance below
Settings Inherited from Multiple Ancestors, View Multiple Inheritance Scenarios	the DHCP property has multiple values that it inherits from multiple sources, and you can view the values and their corresponding sources by clicking the **View Multiple Inheritance Scenarios** link.	Multiple Inheritance below

Simple Inheritance

When a DHCP property has an inherited value from a specific source, the appliance displays the value. It also displays **Inherited From *<object>*** (where *<object>* can be the Grid, member, network, shared network, or DHCP range) to indicate the source from which the value is inherited.
For example, when you set DHCP properties at the Grid level and do not override the properties at any level, the members, networks, shared networks, DHCP ranges, fixed addresses, reservations, host addresses, and roaming hosts inherit these properties from the Grid. The appliance displays the property value and **Inherited From Grid Infoblox** for each configured DHCP property, as shown in the figure Simple Inheritance below.

Simple Inheritance



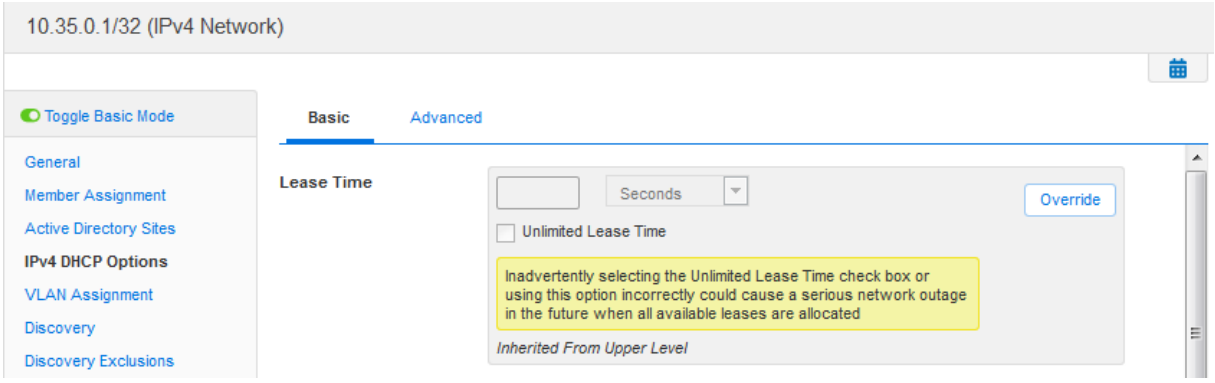
Unknown Inheritance

In some cases, DHCP properties may not have definite inherited values and inheritance sources. The following are examples of unknown inheritance:

- The appliance cannot determine the inheritance sources of the DHCP properties in a template until you use the template to create an object.
- When a network or a DHCP range does not have an assigned member, it does not have a clear definition of an inheritance source because a network or a DHCP range inherits properties from a member.
- When individual networks in a shared network do not have member assignments, the shared network has unknown inheritance because the shared network inherits DHCP properties from a member and its networks.
- All roaming hosts have unknown inheritance because the DHCP properties can be inherited from different DHCP ranges within a network view.

In cases where the source of the inheritance is unknown, the appliance displays **Inherited From Upper Level** as the inheritance source. As shown in the figure Unknown Inheritance, network 10.1.1.0 has unknown lease time value because it does not have any assigned member.

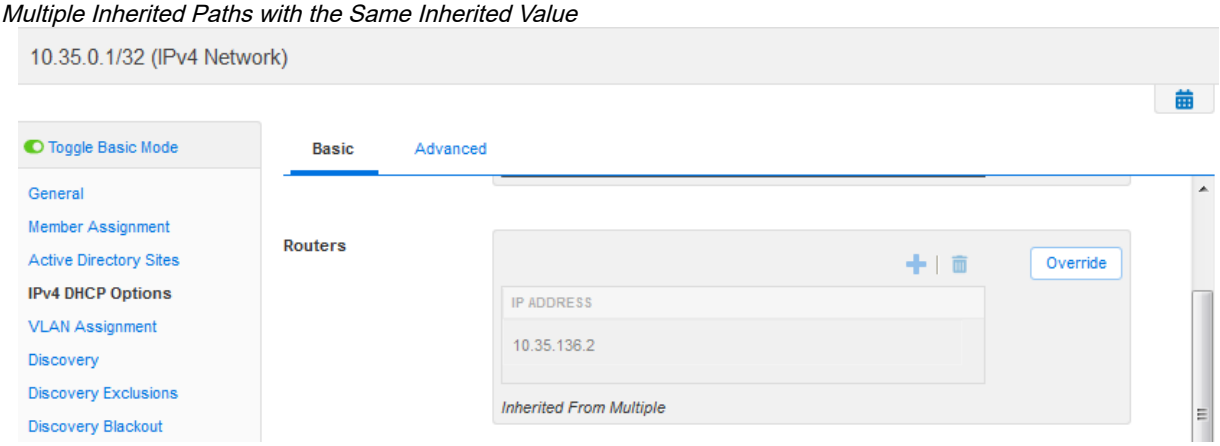
Unknown Inheritance



Multiple Inheritance

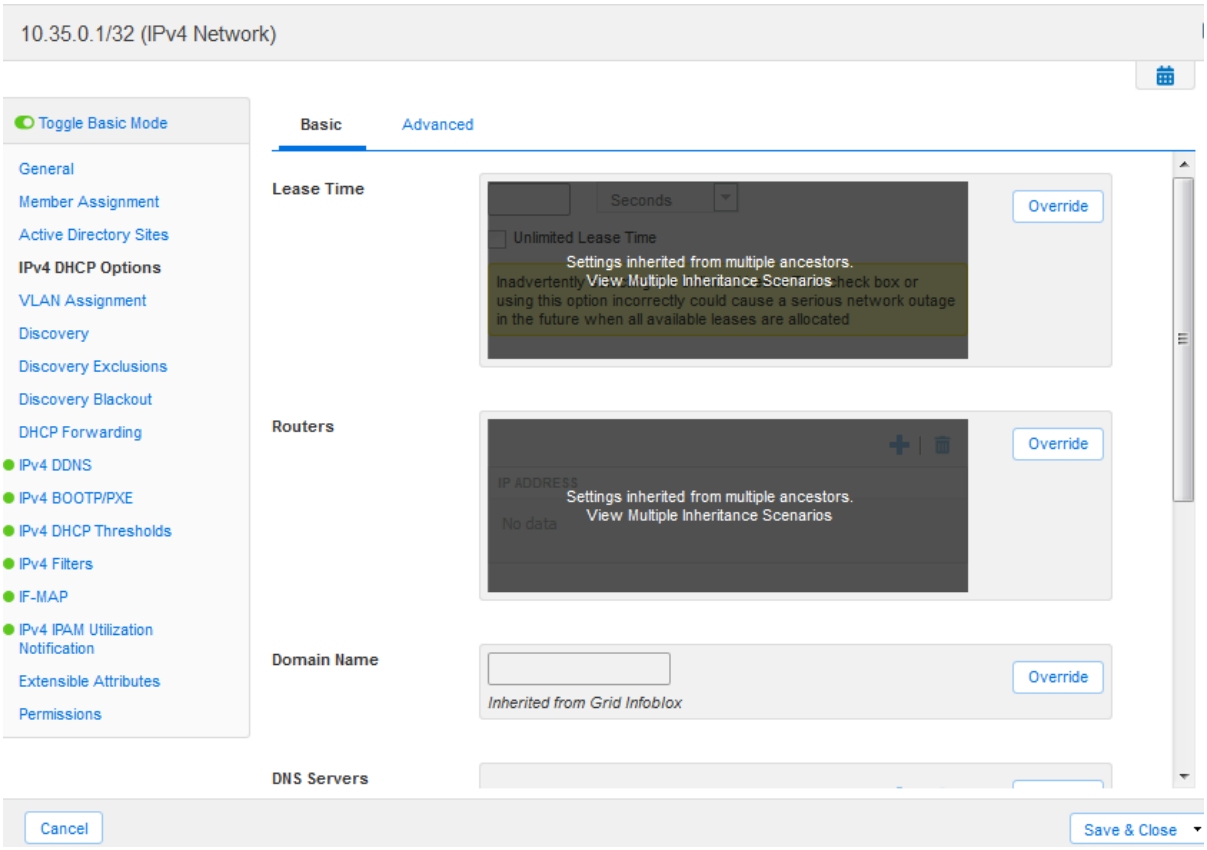
As illustrated in the figure Multiple Inherited Paths with the Same Inherited Value, a network can have multiple inherited values and inheritance sources for DHCP properties when it is served by multiple members. When an object inherits a DHCP property from different sources, the property value can be the same from all sources or it can be different. When the value is the same, the appliance displays the value in the property field. When there are multiple values inherited from multiple paths, the appliance displays the information to indicate so.
In a Grid, when two members serve the same network, the network inherits DHCP properties from both associated members. If both members have the same configured DHCP property, the network inherits the same value from both members. For example, when DHCP network 10.1.1.0 has two associated members and both members have the lease time set for 20 hours, the appliance displays the lease time value and **Inherited From Multiple** to indicate the value is inherited from multiple sources, as shown in the following figure.

Multiple Inherited Paths with the Same Inherited Value



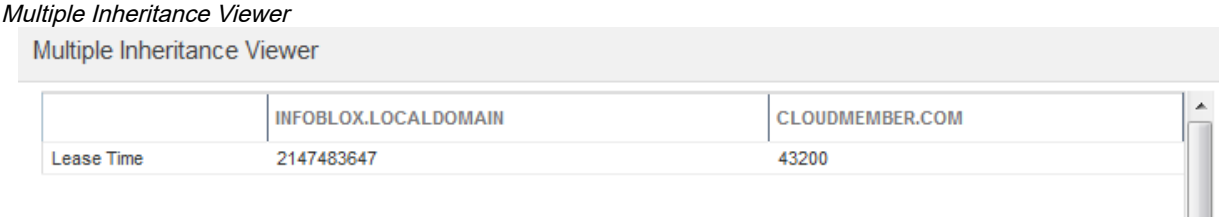
In the same Grid with the two members serving the same network, the network inherits different values for the same properties if you override the Grid configuration on one member but not on the other. For example, you can configure different PXE lease times for the members and configure a member as an authoritative DHCP server for the domain and the other not. In this case, the appliance displays **Settings inherited from multiple ancestors** and provides a **View Multiple Inheritance Scenarios** link so you can view the inherited values and paths, as shown in Multiple Inheritance Sources with Multiple Values.

Multiple Inheritance Sources with Multiple Values



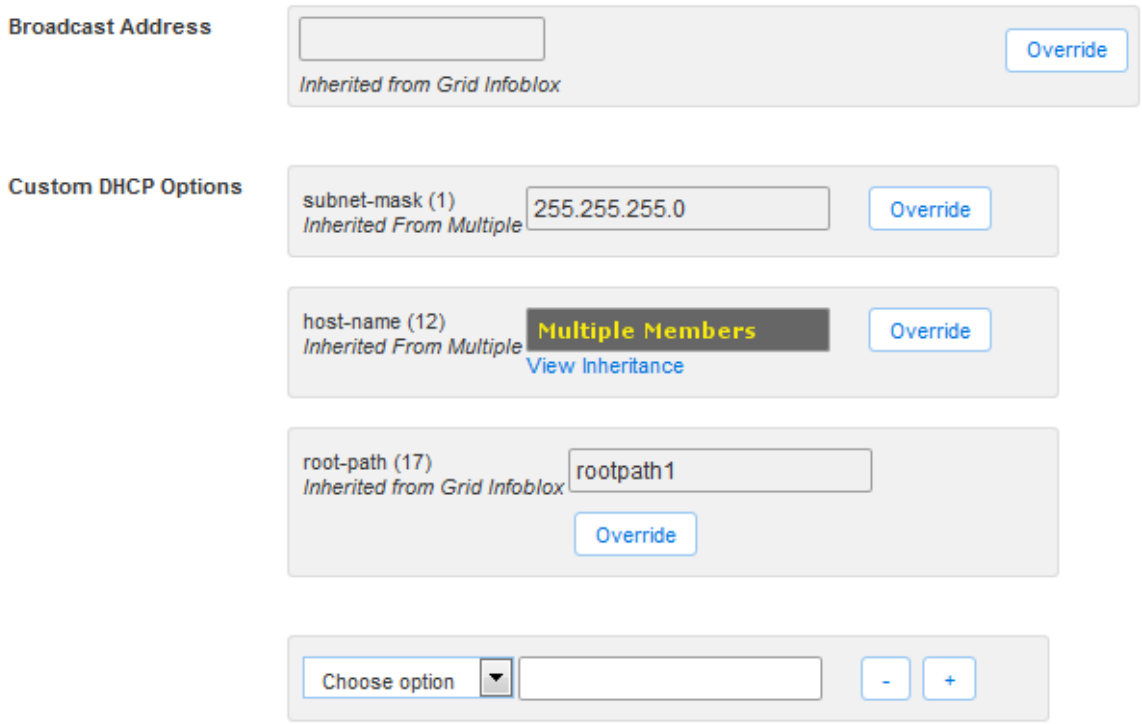
For example, to view the multiple inherited values of the **Authoritative** field, click **View Multiple Inheritance Scenarios**, and the *Multiple Inheritance Viewer* displays the inherited values from the two members. Since member1.foo.net does not have a configured value for this field, the viewer displays **Not Set**, as shown in the figure Multiple Inheritance Viewer below. You can use this information to determine whether you want to keep the inherited values or configure new ones.

Multiple Inheritance Viewer

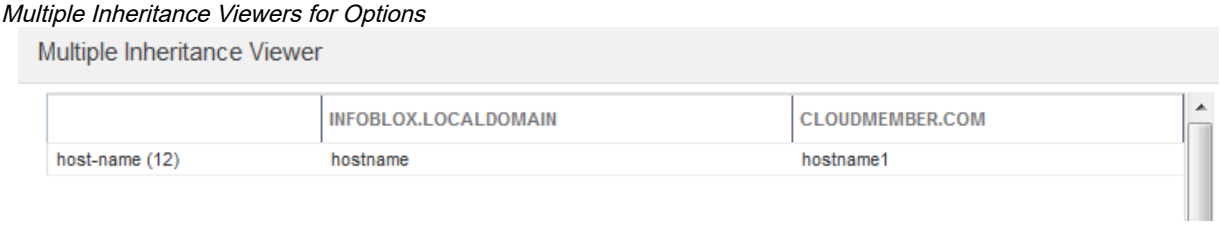


Another scenario of multiple inherited levels is when you have multiple DHCP properties that can inherit the same or multiple values from different sources. For example, when you configure multiple DHCP custom options, each of the options can inherit the same or multiple values from multiple paths. You can override the inherited options and configure new ones at a specific level other than the Grid level. Though these options are grouped under *DHCP Custom Options*, the appliance treats each of them as a separate property. The appliance groups the inherited options at the top, as shown in DHCP Custom Options with Multiple Inheritance Sources. You can override these options but you cannot delete them. For multiple values inherited from multiple sources, you can view the values in the Multiple Inheritance Viewer by clicking **View Inheritance**, as shown in the figure Multiple Inheritance Viewers for Options.

DHCP Custom Options with Multiple Inheritance Sources



Multiple Inheritance Viewers for Options



When you configure email notification for the Grid or Grid member from the **Data Management** tab -> **Grid** tab, the email address you enter there is inherited by the DHCP configuration for the Grid, members, networks, and DHCP ranges unless you override it at a specific level. The appliance uses this email address to send notification for a DHCP range when the DHCP usage crosses either the effective watermark threshold. For information, see *Configuring Thresholds for DHCP Ranges*.

A network container inherits DHCP options from its parent and grandparent network containers. A network container does not inherit DHCP options defined at the Grid or member level.

Note the following about the DHCP option inheritance:

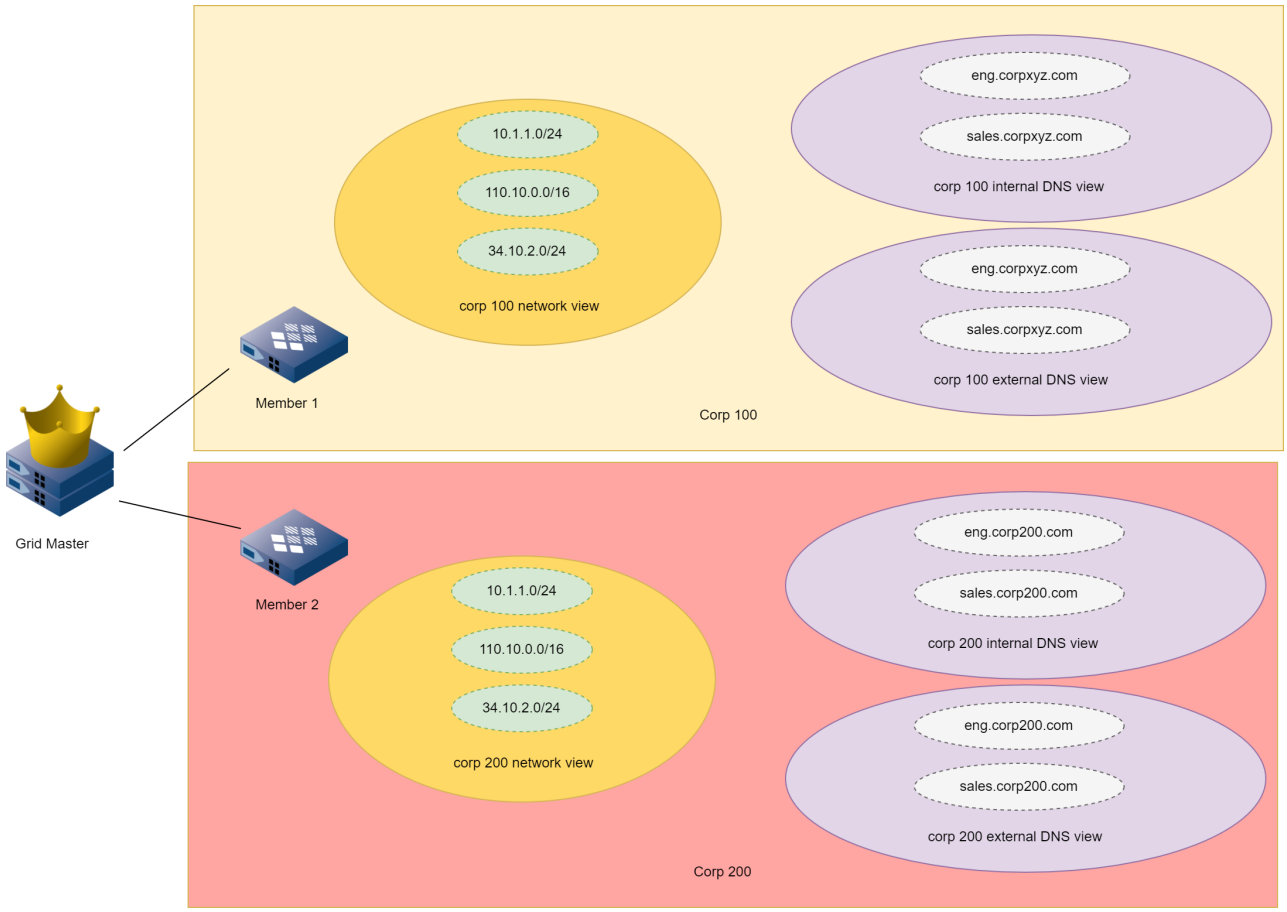
- For networks and shared networks, you can override an inherited DHCP option defined at the Grid or Member level.
- A shared network without a parent network container continues to inherit DHCP options from its parent Grid or member. The parent object is derived from the first network within the shared network.
- A network inherits DHCP option from its parent object. For example, if a network has a parent network container parent and parent shared network parent, if a DHCP option is overridden on the shared network, then this overridden value gets inherited. If the DHCP option is overridden on a network container, then this overridden value gets inherited. Otherwise, the network continues to inherit from its parent Grid or member.

Configuring Network Views

A network view is a single routing domain with its own networks and shared networks. A network view can contain both IPv4 and IPv6 networks. All networks must belong to a network view.

You can manage the networks in one network view independently of the other network views. Changes in one network view are not reflected in other network views. Because network views are mutually exclusive, the networks in each view can have overlapping address spaces with multiple duplicate IP addresses without impacting network integrity.
For example, two corporations, Corp 100 and Corp 200, merge. They each have their own networks and DNS domains. They also have their own private IP address spaces in the 10.0.0.0/24 network. Both corporations have DHCP and DNS servers, and use dynamic DNS updates. The DHCP servers of each corporation serve IP addresses for networks in their respective corporations. The DHCP clients in each corporation update DNS zones within their DNS domains.
They plan to migrate the networks and hosts in Corp 200 to the Corp 100 address space and the corpxyz.com domain. To support both networks in the meantime and to facilitate the migration, you can configure an Infoblox Grid to centrally manage the networks and domains of both corporations. As shown in the figure *Two Network Views Managed by a Grid*, you can configure network views for each corporation and manage their networks independently of the other.
Member 1 serves DNS and DHCP to Corp 100. The networks of Corp 100 are contained in the corp 100 network view, which is associated with both the internal and external DNS views of the corpxyz.com domain. Member 2 serves DNS and DHCP to Corp 200. The networks of Corp 200 are in the corp 200 network view, which is associated with both the internal and external DNS views of the corp200.com domain The two corporations have one overlapping network, 10.1.1.0/24.

Two Network Views Managed by a Grid



A Grid member can serve one network view only, but a network view can be served by multiple Grid members. DHCP failover associations must be defined within a single network view, and both the primary and secondary peer must serve

the same network view.
The NIOS appliance provides one default network view. You can rename the default view and change its settings, but you cannot delete it. There must always be at least one network view in the appliance. If you do not need to manage overlapping IP address spaces in your organization, you can use the system-defined network view for all your networks. You do not need to create additional network views. But if there are overlapping IP address spaces and you need more than one network view, you can create up to 1000 network views.
Each network view must be associated with at least one DNS view. The default network view is always associated with the default DNS view, which also cannot be deleted. When you create a network view, the appliance automatically creates a corresponding DNS view with the same name as the network view, but with "default" prepended to the name. You can then rename that system-defined DNS view, but you cannot delete it.
A network view can be associated with multiple DNS views (as shown in the figure *Two Network Views Managed by a Grid*), but a DNS view cannot be associated with more than one network view. Each network view must be associated with a unique set of DNS views.
You can initiate a network discovery in only one network view at a time. When you run a discovery task, the appliance sends updates to all DNS views associated with the network view. (For information about network discoveries, see *IP Discovery and vDiscovery*.

Adding Network Views

All networks must belong to a network view. You can use the default network view on the appliance and create additional network views, as needed. If you plan to enable DDNS (dynamic DNS) updates on any of the networks, DHCP ranges and fixed addresses in the network view, you must set parameters that specify which DNS view is updated for each network view.

> ⚠ Note
>
> If there are more than 20 network views, the appliance lists the available network views in the *Network View Selector* dialog box. If there are 20 or less than 20 network views, the appliance displays them in the drop-down list.

To create a network view:

1. From the **Administration** tab, select the **Network Views** tab, and then click the Add icon.
2. In the *Network View* wizard, do the following:
   - **Name**: Enter the name of the network view.
   - **Comment**: Enter useful information about the network view.
     The **Cloud** section displays if the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*.

     Delegate authority from the Grid Master
   - **Delegate To**: This field indicates whether the authority for the network view you want to create has already been delegated to a Cloud Platform Appliance. Click **Select** to choose the Cloud Platform Appliance to which you want to delegate authority. The *Member Selector* displays only Cloud Platform Appliances in the Grid. Click the member, and Grid Manager displays the member name next to this field. This cloud member now assumes authority for this network view, and the Grid Master does not have authority anymore. You can also click **Clear** to remove authority delegation from the selected Cloud Platform Appliance and return authority back to the Grid Master.
     Note that you need to install CP license before you configure a Grid with CP member. If you attempt to add a network view without installing CP license, the **Delegate To** field shows the following warning message:
     There are no objects to select on the wizard.
     NIOS does not display any warning message that prompts you to install the CP license.

     Restricting synchronization of network views
   - **Disable sync to MGM**: Select this checkbox to disable synchronization. This will restrict the synchronization of all objects that are associated with the network view. This checkbox is available only on the managed Grid when it remains joined with the Multi-Grid Master.

3. Click **Next** to enter values for required extensible attributes or add optional extensible attributes for the network view. For information, see *About Extensible Attributes*.
4. Click **Next**, and then save the configuration or select:

Configure DDNS Properties: Configure the DNS zones that are associated with the network view to receive DDNS updates. When you select this option, the *Configure DDNS Properties* dialog box appears. The appliance saves the network view entry before it opens the *Configure DDNS Properties* dialog box. For information, see *Configuring DDNS Updates*.

Modifying Network Views

1. From the **Administration** tab, select the **Network Views** tab -> *network_view* checkbox, and then click the Edit icon.
2. The *Network View* editor provides the following tabs from which you can edit data:
    - **General**: You can modify **Name** and **Comments** in this tab. When the Cloud Network Automation license is installed on the Grid Master, Grid Manager displays the following in the **Cloud** section:
      You see the following when Cloud Network Automation is deployed (For information, see *Deploying Cloud Network Automation*):
        - **Cloud Usage**: This field indicates whether this object is associated with any specific cloud extensible attributes or within a scope of delegation. It can be one of the following:
            - **Cloud from adapter**: Indicates that this object has been created by a cloud adapter and it may or may not be within a scope of delegation at the moment.
            - **Cloud from delegation**: Indicates that this object is within the scope of delegation or the object itself defines a scope of authority delegation, and it is not created by a cloud adapter.
            - **Used by cloud**: Indicates that this network or network container is associated with the extensible attribute **Is External** or **Is Shared** and the value is set to True, which implies the network is a private or shared network managed by the CMP, and it is not **Cloud from adapter** or **Cloud from delegation**.
            - **Non-cloud**: The object is a regular NIOS object and is not within the scope of any authority delegation nor is it associated with any of these extensible attributes: **Cloud API Owned**, **Is External**, or **Is Shared**. NIOS admin users can modify this object based on their permissions.
        - **Owned By**: A cloud object can be owned by the Grid Master or the cloud adapter. When the object is created by the Cloud Platform member, this shows **Grid**. If the object is created by the cloud adapter, this shows **Adapter**.
        - **Delegated To**: This tells you whether a cloud object has been delegated to a Cloud Platform Appliance or not. If the cloud object has a parent object and the parent has been delegated, this field shows the parent delegation and you cannot modify the field.
          Restricting synchronization of network views
        - **Disable sync to MGM**: Select this checkbox to disable synchronization. This will restrict the synchronization of all objects that are associated with the selected network view. This checkbox is available only on the managed Grid when it remains joined with the Multi-Grid Master.
    - **Members**: This tab displays the members that provide DHCP services for the networks in this network view.
      You cannot modify information in this tab. It displays the following:
        - **Name**: The name of the DHCP member.
        - **IP Address**: The IP address of the DHCP member.
        - **Failover Association**: The name of the failover association to which the DHCP member belongs. If there are multiple failover associations, only the first one is displayed.
        - **Comment**: The information that you entered for the DHCP member.
          You can sort the information in the table by column. You can also print and export the information.
    - **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific network view. You can also modify the values of extensible attributes. For information, see *About Extensible Attributes*.
    - **Permissions**: This tab displays only if you belong to a superuser admin group. For information, see *Administrative Permissions for DHCP Resources*.

Deleting Network Views

You can delete any network view, except for the default network view. You can delete a network view that has only one DNS view associated with it. You cannot delete a network view that has more than one DNS view associated with it. When you delete a network view, the appliance deletes all the networks and records within the network view.

To delete a network view:

1. From the **Administration** tab, select the **Network Views** tab -> *network_view* checkbox, and then click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes**.

The appliance removes the network view and its associated DNS views. You can restore the network view from the Recycle Bin, if enabled. If you restore a network view, the appliance restores the associated DNS views as well. For information about the Recycle Bin, see *Using the Recycle Bin*.

> ⚠ Note
>
> You cannot delete a network view that has a VLAN object assigned to it. For more information, see *Assigning VLANs to a Network*.

Configuring DHCP Properties

When you configure a NIOS appliance to function as a DHCP server, you can set DHCP properties that control how the appliance operates and enable DHCP service for IPv4 and IPv6.
You can also specify configuration information the appliance includes in its IPv4 and IPv6 DHCP messages. When a DHCP server assigns an IP address to a client, it can include information the client needs to connect to the network and communicate with other hosts and devices on the network. You can set these properties at the Grid level and override them for a member, network, shared network, DHCP range, fixed address, IPv4 reservation, host address, or roaming host.
When you configure a DHCP object that has inherited DHCP properties, you can either keep the inherited properties or override them. The appliance displays the inherited values and the levels from which the DHCP properties are inherited. For information, see *DHCP Inheritance*.

This section explains how to configure DHCP IPv4 and IPv6 properties. It contains the following topics:

- *Configuring General IPv4 DHCP Properties*
- *Configuring Ping Settings*
- *Configuring DHCP Lease Management*
- *Ignoring DHCP Client Identifiers*
- *Configuring IPv4 BOOTP and PXE Properties*
- *About IPv4 DHCP Options*
- *Configuring Thresholds for DHCP Ranges*
- *Configuring DHCPv6 Properties*
- *About DHCPv6 Options*
- *Configuring DHCP IPv4 and IPv6 Common Properties*
- *Configuring DHCP Logging*
- *Configuring IF-MAP*
- *Starting DHCP Services on a Member*
- *Viewing DHCP Member Status*

Configuring General IPv4 DHCP Properties

When you configure general IPv4 DHCP properties at the Grid level, the configuration applies to the entire Grid. Though you can set DHCP properties at the Grid level, you can enable DHCP services at the member level only. Infoblox recommends that you configure the DHCP properties before you enable DHCP on the appliance. Depending on the properties, you can override some of them for the members, networks, DHCP ranges, fixed addresses, reservations, host addresses, and roaming hosts. To override an inherited DHCP property, click **Override** next to the property to enable the configuration.

Specifying Authoritative

Only authoritative DHCP servers can send clients DHCPNAK messages when they request invalid IP addresses. For example, a client moves to a new subnet and broadcasts a DHCPREQUEST message for its old IP address. An authoritative DHCP server responds with a DHCPNAK, causing the client to move to the INIT state and to send a DHCPDISCOVER message for a new IP address. Authoritative servers also respond to DHCPINFORM messages from clients that receive their IP addresses from the DHCP server and require additional options after the initial leases have been granted.

Defining Lease Times

When you configure DHCP general properties, you can specify the length of time the DHCP server leases an IP address to a client. The default on the appliance is 12 hours, and you can change this default according to your network requirements. There are a number of factors to consider when setting the lease time for IP addresses, such as the types of resources and clients on the network, and impact to traffic and performance. With NIOS appliances, you can set lease times at different levels, based on these factors. You can also select the **Unlimited Lease Time** checkbox to grant unlimited lease time to IP addresses.

> Warning
>
> *Inadvertently selecting the Unlimited Lease Time checkbox could cause a network outage when the address range runs out of IP addresses.*

You can set a default lease time at the Grid level and then override this setting for specific members, network containers, networks, IP address ranges or fixed addresses when appropriate.

Configuring General IPv4 Properties

To configure general IPv4 DHCP properties:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
   Network: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon.
   Network Container: From the **Data Management** tab, select the **IPAM** tab -> *network_container* checkbox, and then click the Edit icon.
   DHCP Range: From the **Data Management** tab, select the **DHCP** tab–> **Networks** tab -> **Networks** -> *network->addr_range* checkbox, and then click the Edit icon.
   Fixed Address: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network->fixed_address* checkbox, and then click the Edit icon.
   Reservation: From the **Data Management** tab, select the **DHCP** tab > **Networks** tab -> **Networks** -> *network->reservation* checkbox, and then click the Edit icon.

2. In the *DHCP Properties* editor of a Grid or member, select the **General Basic** tab. For all other objects, click **Toggle Advanced Mode** if the editor is in basic mode. When the additional tabs appear, select the **IPv4 DHCP Options Advanced** tab.
3. Complete the following:
    - **Authoritative:** Select **DHCP server is authoritative** to set the DHCP server as authoritative for the domain. This can be set for the Grid, member, network container, network and range.
    - **Lease Time**: Enter the lease time and select the time unit from the drop-down list. The default is 12 hours.
        - **Unlimited Lease Time**: Select this option to set an infinite lease time for all IP addresses.
          To set all other properties for a Grid or member, toggle to the advanced mode and select the **General Advanced** tab to complete the following:
    - **Ignore Optionlist**: Select **Ignore optionlist requested by client and return all defined options** if you want the appliance to ignore the requested list of options in the DHCPREQUEST messages it receives from DHCP clients, and to include all the configured options in the DHCPACK and DHCPOFFER messages it sends back to the clients.
    - **LEASEQUERY**: Select **Allow LEASEQUERY** to enable the DHCP server to respond to DHCPLEASEQUERY messages.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Warning
Inadvertently selecting the Unlimited Lease Time checkbox could cause a network outage when the address range runs out of IP addresses.

Configuring Fixed Addresses without Restarting the DHCP Service

When you configure or modify a fixed address, a DHCP service restart is required by default for the new configuration to take effect. You can override this default behavior by enabling the appliance to take immediate action when you configure or modify a fixed address outside a DHCP range without restarting DHCP service. This feature applies to host records for which DHCP is enabled, as it creates both the host address and the fixed address. You can enable this feature at the Grid or member level. Note that when you enable this feature, you cannot use the CLI command `set dhcp_expert_mode`.

Note

- Enabling this feature might have a significant performance impact on your appliance, depending on the number of fixed addresses you have configured.
- This feature works only for fixed addresses outside of a DHCP range. If you make a change to a fixed address inside a DHCP range, you must manually restart the DHCP service.

For Cloud Network Automation deployment, this feature is automatically enabled on the Cloud Platform Appliance that has a valid Cloud Platform license installed. For information about Cloud Network Automation, see *Deploying Cloud Network Automation*.
To enable immediate fixed address configuration:

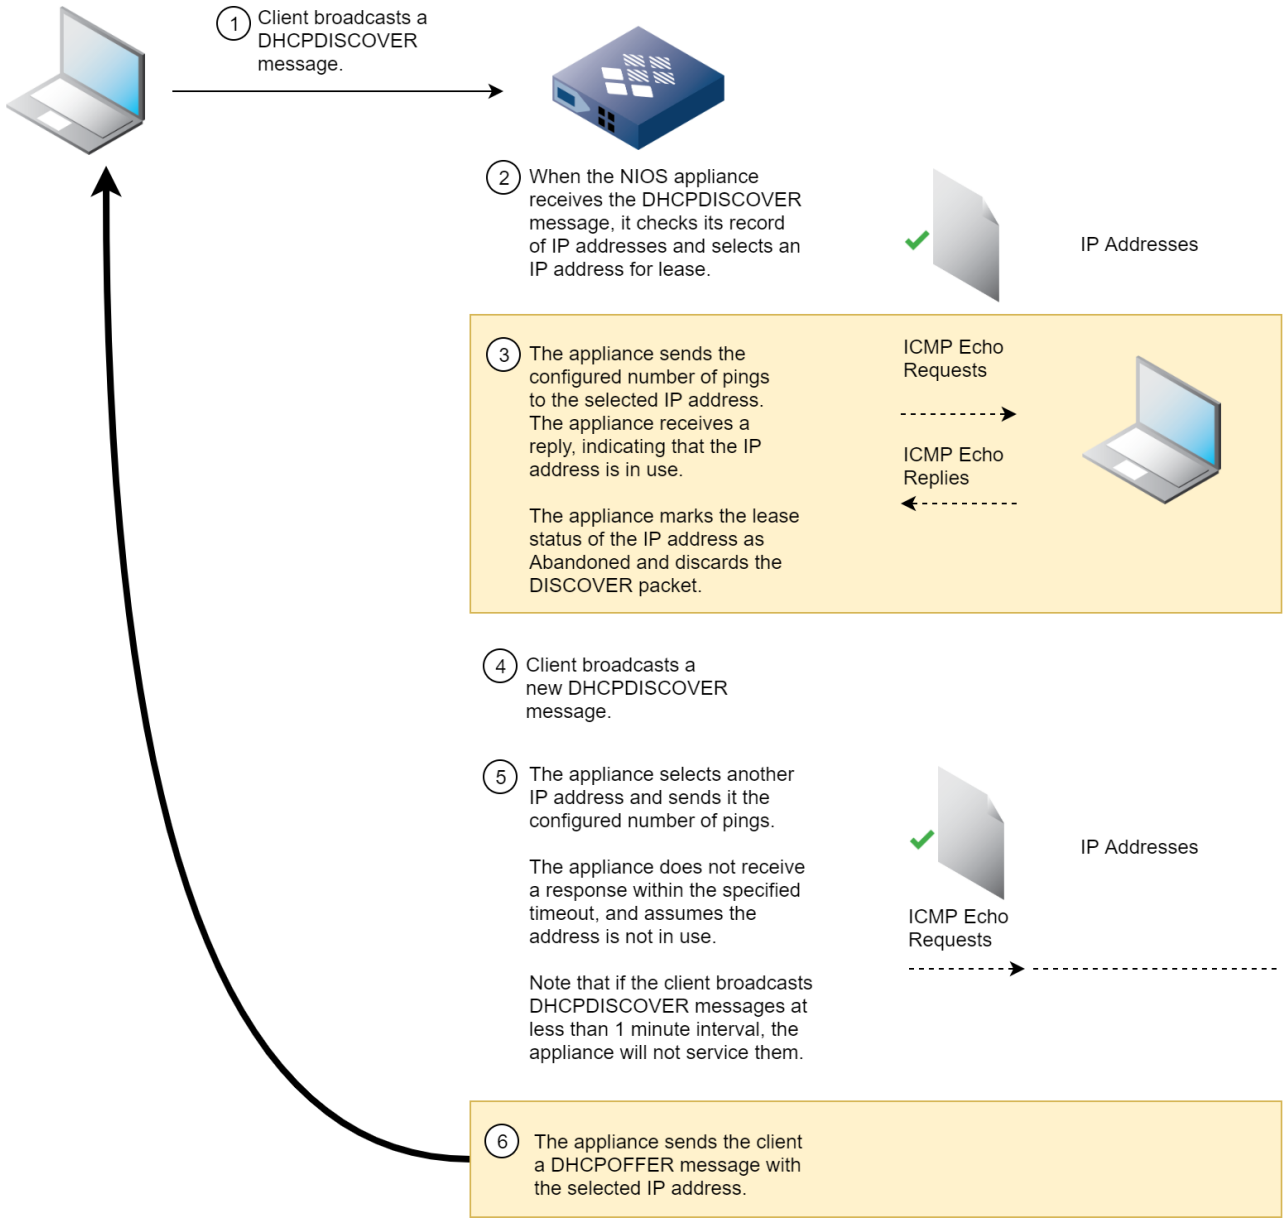
1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *DHCP Properties* editor, click **Toggle Advanced Mode** if the editor is in basic mode. When the additional tabs appear, click the **General** tab -> **Advanced** tab and complete the following:
    - **Immediate FA Configuration**: Select this checkbox to enable the new configuration immediately without restarting DHCP service when you modify or delete a fixed address.
3. Save the configuration and restart DHCP service.

Configuring Ping Settings

When a DHCP client first tries to connect to a network, it broadcasts its request for an IP address. When the appliance receives such a request, it checks its record of assigned IP addresses and leases. Because there are a limited number of IP addresses available, the appliance reassigns IP addresses whose leases might have expired. Therefore, once the appliance selects a candidate IP address for lease, it sends an ICMP echo request (or ping) to the IP address to verify that it is not in use.

If the appliance receives a response, this indicates that the IP address is still in use. Note that the lease status for this IP address is **Abandoned**. Only after the DHCP client broadcasts a new request for an IP address that the appliance selects another candidate IP address and sends it a ping. This flow continues until the appliance finds an IP address that does not respond to the ping as depicted in the figure Ping Overview below. The appliance then sends a DHCPOFFER message with the unused IP address to the DHCP client.

Figure 26.1 Ping Overview



By default, the appliance pings the candidate IP address once and waits one second for the response. You can change these default settings to better suit your environment. Though you can increase the ping or timeout value to accommodate delays caused by problems in the network, increasing any of these values increases the delay a client experiences when acquiring a lease. You can also disable the appliance from sending pings by changing the number of pings to 0.
You can define ping settings for an entire Grid, and when necessary, define different ping settings for a member. Settings at the member level override settings at the Grid level.
To configure ping settings:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
2. In the *DHCP Properties* editor, click **Toggle Advanced Mode** if the editor is in basic mode. When the additional tabs appear, click the **General** tab -> **Advanced** tab and complete the following:
   - **Number of Ping Requests**: Enter the number of pings the appliance sends to an IP address to verify that it is not in use. The range is 0 to 10, inclusive. Enter 0 to disable DHCP pings.
   - **Ping Timeout**: Select the ping timeout value from the drop-down list.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring DHCP Lease Management

When setting up DHCP properties, you can configure how the appliance handles lease management. For example, when a DHCP client moves from one network to another, the DHCP lease granted by the DHCP server in the previous network remains associated with the network device until the lease expires. When this happens to multiple clients, the address range could run out of IP addresses; thus, preventing other clients from retrieving an IP address. To avoid this, you can configure the DHCP server to release a lease when a client moves out of the network. Note that this is valid only if the client has included the client ID while requesting a lease. For example, a DHCP IPv4 client has included the client ID while requesting a lease from network A. This client then moves from network A to B. The DHCP server immediately releases the lease for reuse by another client on network A, based on the client ID. If the client does not include the client ID in the request, the lease on network A remains active until the lease expires.
You can also enable one-lease-per-client to ensure that each DHCP IPv4 client receives only one lease at any given time. When you enable one-lease-per-client and a DHCP client sends a DHCPREQUEST for a particular lease, the appliance releases other leases that the client holds, on the interface that the client is currently using.
Enabling one-lease-per-client is useful when you want to control the number of leases on your subnets and ensure that each DHCP client receives only one lease at a time. Typically, you enable one-lease-per-client for a DHCP client that moves around a lot within different subnets and uses long leases.
Note that this feature supports only DHCP IPv4 clients. When you configure lease management at the Grid level, all members inherit the setting. You can override the Grid setting for each member.

> **Note**
>
> One-lease-per-client enables a single lease per client on a per member basis, not on a Grid wide basis. Lease information is not replicated among members. Note that you must restart the DHCP service for the changes to take effect.

To configure DHCP lease management:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
   Standalone DHCP: From the **Data Management** tab, select the **DHCP** tab, expand the Toolbar and click **System DHCP Properties**.
2. In the *DHCP Properties* editor, click **Toggle Advanced Mode** if the editor is in basic mode. Click the **General** tab -> **Advanced** tab and select the respective radio button under **Multiple Lease Management**:

- **Release leases for clients with Client IDs:** Select this option to release only those leases that have a client ID when the clients move from one network to another before the leases expire. This is selected by default.The DHCP server does not release leases that do not have a client ID.
- **Retain leases for clients with Client IDs:** Select this option to retain all the leases the client holds. The DHCP server retains all the leases either with or without a client ID. The amount of time taken by the DHCP server to find a lease for a client might increase if you use this option when the pools are almost full. Choosing this option might also increase the amount of active leases in the pools when the client moves from one network to another.
- **Allow only one lease per client**: Select this option to enable one-lease-per-client per Grid member. This is valid for leases both with and without client IDs.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Ignoring DHCP Client Identifiers

You can set the DHCP server to ignore the UID (unique client identifier) and MAC address (hardware address) of a DHCP client when it places a request to the DHCP server for a new lease. When you configure the appliance to ignore the MAC address of a DHCP client, you can specify the list of MAC addresses. You can enter up to 10 MAC addresses to be ignored. The appliance ignores all the MAC addresses if you do not specify any MAC addresses. If the **Ignore Hardware Address** option is enabled and a DHCP client makes a request without a client UID for a new lease, then the appliance drops this request. This option is disabled by default. When you enable "Ignore DHCP Client ID" and a DHCP client sends a DHCPREQUEST for a lease, the DHCP server identifies the DHCP client using the physical MAC address of the appliance while the UID is ignored. The DHCP server then allocates an IP address based on the MAC address of the DHCP client.
For example, when a DHCP client places a request for a new lease, the DHCP server identifies the DHCP client with the MAC address and allocates the same IP address that was previously allocated for that MAC address.
You can define this feature at the Grid level, which is inherited at the member, shared network, IPv4 network and range level. This feature is disabled by default.

> ⚠ **Note**
>
> This feature is applicable only to dynamic leases and does not have any effect on the static lease generated for fixed addresses or roaming hosts.

To ignore the client identifier of DHCP clients:

1. **Grid:** From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the **Toolbar**.
   Member: From the **Data Management** tab, select the **DHCP** tab -> and click the **Members** tab -> *member* checkbox -> *Edit* icon.
   Standalone DHCP: From the **Data Management** tab, select the **DHCP** tab, and then click **System DHCP Properties.**
   Shared Network Editor: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Shared Networks** section -> *shared_network* checkbox, and then click the *Edit* icon.
   IPv4 Network Editor: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section ->*network* checkbox, and then click the *Edit* icon.
   IPv4 Range Editor: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> click on the network address. Select the *IP address range* checkbox, and then click the *Edit* icon.
2. In the *DHCP Properties* editor, select the **General** tab -> **Advanced** tab (or click **Toggle Advanced Mode**) and then complete the following:
   - **Accept Client Identifier and MAC Address:** Select this checkbox to instruct the DHCP server to recognize MAC address and client UID of a DHCP client when it requests for a new lease.
   - **Ignore Client Identifier**: By default, this checkbox is not selected at the Grid level. Select this checkbox to ignore the client identifier of a DHCP client while placing a request to the DHCP server for a new lease. The DHCP server will only identify the MAC address and ignores the client identifier. DHCP clients requesting leases with different client UIDs receive the same IP address based on the MAC address. The

initial default state is inherited from the Grid level. Click **Override** to modify the inherited setting. To inherit the Grid settings, click **Inherit** at the member, IPv4 network and range, or shared network level.

- **Ignore MAC Address:** By default, this checkbox is not selected at the Grid level. Select this checkbox to ignore MAC address of a DHCP client while placing a request to the DHCP server for a new lease. To override the value that has been inherited from the Grid, click **Override**. Click the Add icon, the appliance adds a row to the table. Click the row and enter the MAC address to be ignored. You can also select a checkbox and click the Delete icon to delete the MAC address. To inherit the Grid settings, click **Inherit** at the member, IPv4 network and range, or shared network level.

3. Save the configuration and click **Restart** at the top of the screen.

Limitations of the Ignore Client ID Feature on DHCP Failover Associations

- You cannot assign a DHCP range that has the ignore DHCP client ID feature enabled to a DHCP failover association if:
  - one of the members is an external DHCP server in the failover association.
  - one of the members is running a NIOS version earlier than 6.12.
- The DHCP failover association does not work if a DHCP range having multiple inherited values has the ignore DHCP client ID feature enabled on one server and disabled on the other.
- The range assigned to a DHCP failover association and the member (failover peer) must have the same DHCP range setting. The DHCP failover association does not work if a range associated with it does not have the same ignore DHCP client ID setting as the member.

Configuring IPv4 BOOTP and PXE Properties

You can configure the DHCP server to support IPv4 clients that use BOOTP (bootstrap protocol) or that include the TFTP server name option and boot file name option in their DHCPREQUEST messages. You can specify the name or IP address of the boot server and the name of the file the host needs to boot.
In addition, you can configure the DHCP server to support hosts that use PXE (Preboot Execution Environment) to boot remotely from a server. When such a host starts up, it first requests an IP address so it can connect to a server on the network and download the file it needs to boot. After it downloads the file, the host reboots and sends another IP address request. To better manage your IP resources, set a different lease time for PXE boot requests. You can configure the DHCP server to allocate an IP address with a shorter lease time to hosts that send PXE boot requests, so IP addresses are not leased longer than necessary.

> **Note**
>
> When you assign a failover association to serve DHCP ranges and networks, NIOS denies dynamic BOOTP clients by default, regardless of whether you select or deselect the **Deny BOOTP Requests** option from Grid Manager. However, if the DHCP ranges or networks are assigned to a single DHCP server (not a failover association), NIOS does not automatically deny dynamic BOOTP clients. In this case, you must manually select the **Deny BOOTP Requests** option through Grid Manager to ensure that NIOS denies BOOTP requests to avoid problems such as receiving two IP addresses for the same network device.

You can configure BOOTP and PXE properties at the Grid level and override them for members, IPv4 network containers, IPv4 networks, DHCP ranges, fixed addresses, and reservations, host addresses, and roaming hosts. You cannot configure BOOTP and PXE properties for IPv6 DHCP objects.
To configure or override BOOTP and PXE properties:

1. **Grid Level**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member Level: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
   Network Level: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon.
   Network Container: From the **Data Management** tab, select the **IPAM** tab -> *network_container* checkbox, and then click the Edit icon.
   DHCP Range Level: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** ->

network-> addr_range checkbox, and then click the Edit icon.
Fixed Address Level: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network ->fixed_address* checkbox, and then click the Edit icon.
Reservation: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network –> reservation* checkbox, and then click the Edit icon.

2. In the *DHCPProperties* editor, select the **BOOTP/PXE** tab and complete the following:
    - **PXE Lease Time**: Click **Override** and select **Enable PXE Lease Time** if you want the DHCP server to use a different lease time for PXE clients. You can specify the duration of time it takes a host to connect to a boot server, such as a TFTP server, and download the file it needs to boot. For example, set a longer lease time if the client downloads an OS (operating system) or configuration file, or set a shorter lease time if the client downloads only configuration changes. Enter the lease time for the preboot execution environment for hosts to boot remotely from a server.
    - **Deny BOOTP Requests**: Select this checkbox to disable the BOOTP settings and deny BOOTP boot requests. If you assign DHCP ranges or networks to a single DHCP server (not a failover association), NIOS does not automatically deny dynamic BOOTP clients. In this case, you must select this option to ensure that NIOS denies BOOTP requests to avoid problems such as receiving two IP addresses for the same network device.
    - Complete the following in the **BOOTP Settings** section:
        - **Boot File:** Enter the name of the boot file the client must download.
        - **Next Server:** Enter the IP address or hostname of the boot file server where the boot file is stored. Complete this field if the hosts in your network send requests for the IP address of the boot server. If the TFTP server is the NIOS appliance that is also serving DHCP, enter the IP address of the appliance.
        - **Boot Server:** Enter the name of the server on which the boot file is stored. Clients can request for either the boot server name or IP address. Complete this field if the hosts in your network send requests for the boot server name. If the TFTP server is the appliance that is also serving DHCP, enter the name of the appliance

> **Note**
>
> Enter values in both the **Next Server** and **Boot Server** fields if some hosts on your network require the boot server name and others require the boot server IP address.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Note that a few characters need manual escaping when you configure a DHCP boot file name, in order to keep the dhcpd.conf file consistent. If you do not use appropriate escape characters, then it might lead to a non working boot file name. The following characters require manual escaping:

- `'\t'` - Tabulation character
- `'\r'` - Carriage return
- `'\n'` - New line
- `'\b'` - Bell
- `'\xYY` '- YY hex-number (a-f, 0-9)

For example, if you set the 'Boot File' to:

```
'\x86\topdir\subdir\file.img'
```

You might need to enter \x and \t as the manual escape characters:

```
'\\x86\\topdir\subdir\file.img'
```

You can also specify all \ as the manual escape character:

```
'\\x86\\topdir\\subdir\\file.img'
```

The above commands result in the underlying dhcpd.conf file:

`'\x5cx86\x5ctopdir\\subdir\\file.img'`

or

`'\x5cx86\x5ctopdir\x5csubdir\x5cfile.img'`

About IPv4 DHCP Options

DHCP options provide specific configuration and service information to DHCP clients. These options appear as variable-length fields at the end of the DHCP messages that DHCP servers and clients exchange. For example, DHCP option 3 is used to list the available routers in the network of the client and option 6 is used to list the available DNS servers.

An option space is a collection of options. ISC (Internet Systems Consortium) DHCP has five predefined option spaces: dhcp, agent, server, nwip, and fqdn. The NIOS appliance supports only the predefined DHCP option space, which contains the industry standard options as well as additional options you can configure as needed:

- Predefined options: These are option codes 1 to 125. They are allocated by the IANA and defined by IETF standards. The DHCP server knows these standard options, and they are predefined on the server. You cannot redefine these options or delete them from the DHCP option space.
- Custom options: These are option codes 126 to 254. They are not defined by IETF standards and are available for private use. You can use these option codes to provide configuration or service information that none of the predefined options provide.

You can also create option spaces to define new groups of options. For example, you can create additional option spaces to define vendor specific options, which are encapsulated in option 43. When a DHCP client requests vendor specific options, it makes a request using the vendor identifier set in option 60 and a list of requested vendor specific options (option 43). The DHCP server then responds with the list of replies for the various options encapsulated into option 43.
Note that custom options defined in the DHCP option space are included in the options section of the DHCP messages that DHCP servers and clients exchange. Custom options defined in a user-defined option space are always encapsulated in option 43 in DHCP messages.
You can apply options globally at the Grid level, or more specifically at the member, network, network container, range, host and roaming host levels.
A network inherits DHCP options from its parent object. You can override the inherited DHCP options configured at the Grid or Member level for the networks and shared networks. If a network has a parent network container and parent shared network and if you override the DHCP options on the shared network, then the network inherits the shared network values. If you override the DHCP options at the network container level, then the network inherits the network container values. Otherwise, the network continues to inherit DHCP options from its parent Grid or member. A shared network without a parent network container continues to inherit DHCP options from its parent Grid or member. The parent object is derived from the first network within the shared network. A network container inherits DHCP options from its parent and grandparent network containers. A network container does not inherit DHCP options defined at the Grid or member level.
To override an inherited value, click **Override** next to it and complete the appropriate fields. When you click **Override**, the appliance displays the value inherited from its parent object (if any). If you do not set any value at the higher level, the appliance displays the default DHCP options. The following table lists the default DHCP Options:

Default DHCP Options

	Name	Default Value
IPV4 Common DHCP Options	Enable PXE Lease Time	Disabled
	Lease Time	43200
	Routers	Empty List

	Name	Default Value
	Domain Name	Empty
	DNS Servers	Empty List
	Broadcast Address	127.0.0.1
	Custom DHCP Options	""
	Lease Scavenging	Disabled
	Authoritative (Advanced)	Disabled
	Lease Deletion (Advanced)	Disabled
	Ignore Optionlist (Advanced)	Disabled
IPv4 DDNS	Enable DDNS Updates	Disabled
	DDNS Domain Name	""
	DDNS Update TTL	0
	DDNS Update Method	Interim
	Generate Hostname	Disabled
	Fixed Address Updates	Disabled
	Option 81 Support	Disabled
	Lease Renewal Update	Disabled
IPv4 Threshold Options	Enable DHCP Thresholds	Disabled
	High - Trigger	95
	High - Reset	85
	Low - Trigger	0
	Low - Reset	10
	Enable SNMP Warnings	Disabled

	Name	Default Value
	Enable Email Warnings	Disabled
	Email Addresses	Empty List
IPv4 BOOTP/PXE	Enable PXE Lease Time	Disabled
	Lease Time (Value)	0
	Deny-BOOTP-Requests	Disabled
	Boot File	""
	Next Server	""
	Boot Server	""
IPv6 DHCP Options	Valid Lifetime	43200
	Preferred Lifetime	27000
	Domain Name	""
	DNS Servers	
	Custom DHCP Options	
	Lease Deletion	Enabled
	Lease Scavenging	Disabled
IPv6 DDNS Options	Enable DDNS Updates	
	DDNS Domain Name	""
	DDNS Update TTL	0
	DDNS Update Method	Interim
	Generate Hostname	Disabled
	FQDN Support • DHCP server always updates DNS • DHCP server updates DNS if requested by client	Disabled

	Name	Default Value
	Lease Renewal Update	Disabled

You can also create an option filter the appliance uses to filter address requests by the DHCP options of requesting hosts. The filter instructs the appliance to either grant or deny an address request if the requesting host matches the filter. For information, see *Defining Option Filters*.

The DHCP option configuration conforms to the following RFCs:

- *RFC 2132*, *DHCP Options and BOOTP Vendor Extension*
- *RFC3046*, *DHCP Relay Agent Information Option*. The supported options include option 60 (Client Identifier), 21 (Policy Filter), 22 (Maximum Datagram Reassembly Size), 23 (Default IP Time-to-Live), and 82 (Support for Routed Bridge Encapsulation).
- *RFC3925*, *Vendor-Identifying Vendor Options for Dynamic Host Configuration Protocol version 4* (DHCPv4)
- *RFC2939*, *Procedures and IANA Guidelines for Definition of New DHCP Options and Message Types*

DHCP Option Data Types

Each DHCP option is identified by a name and an option code number, and specifies a data type. The data type for some options is predefined. For example, in the DHCP option space, the data type for option 1: subnet-mask is an IP address. You cannot change the data type for this option. The data type for some options is user-defined and can be in one of the formats shown in the below table.

DHCP Option Data Types

Data type	Specifies
String	An ASCII text string (the same as the text data type) or a list of hexadecimal characters separated by colons Formatting to distinguish an ASCII text string from a hexadecimal string is important. For details, see the following section
Boolean	A flag with a value of either true or false (or on or off)
IP address	A single IP address
Array of IP addresses	A series of IP addresses, separated by commas You can optionally include a space after each comma
Text	An ASCII text string
8-, 16-, or 32-bit unsigned integer	A numeric range of the following possible values 8-bit unsigned integer: from 0 to 255 16-bit unsigned integer: from 0 to 65,535 32-bit unsigned integer: from 0 to 4,294,967,295
8-, 16-, or 32-bit signed integer	A numeric range of the following possible values 8-bit signed integer: from -128 to 127 16-bit signed integer: from -32,768 to 32,767 32-bit signed integer: from -2,147,483,648 to 2,147,483,647

Data type	Specifies
Domain-list	A list of domain names, separated by spaces

When defining a hexadecimal string for a DHCP option (such as option 43, vendor encapsulated options), use only hexadecimal characters (0-9, a-f, or A-F) without spaces and separated by colons. The accepted form for a hexadecimal string, as presented in a regular expression, is [0-9a-fA-F]{1,2}(:[0-9a-fA-F]{1,2})*

Two examples of correctly written hexadecimal strings:

- aa:de:89:1b:34
- 1C:8:22:A3 (Note that the DHCP module treats a single hexadecimal character, such as "8" as "08".)

A few examples of incorrectly written hexadecimal strings:

- :bb:45:d2:1f – Problem: The string erroneously begins with a colon.
- bb:45:d2:1f: – Problem: The string erroneously ends with a colon.
- bb:4 5:d2:1f – Problem: The string erroneously includes a space between two characters ("4" and "5").
- bb:45:d2:1g – Problem: The string erroneously includes a nonhexadecimal character ("g").

The DHCP module treats incorrectly written hexadecimal strings as simple text strings, not hexadecimal strings. If the string appears in quotes, it is a text string.

Configuring IPv4 DHCP Options

To use DHCP options, you can do the following:

- Define basic DHCP options, as described in the next section Defining IPv4 DHCP Options.
- Configure one or more option spaces, as described in the next section Defining IPv4 Option Spaces.
- Define custom options in the predefined DHCP option space or add options to an option space that you configured. For more information, see Configuring Custom DHCP Options below.
- Specify values for the options and apply them to the Grid, or to a member, network, range, fixed address, reservation, host, or roaming host. For more information, see Applying DHCP Options below.

Defining IPv4 DHCP Options

You can define basic DHCP options that the DHCP server uses to provide configuration information to DHCP clients. The server includes these options in its DHCP messages.
To define DHCP options:

1. **Network**: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* check box, and then click the Edit icon.

   Network Container: From the **Data Management** tab, select the **IPAM** tab -> *network_container* check box, and then click the Edit icon.
   DHCP Range: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network*-> *DHCP_range* check box, and then click the Edit icon.
   Fixed Address: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network*-> *fixed_address* check box, and then click the Edit icon.
   Reservation: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *reservation* check box, and then click the Edit icon.
   Host Address: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *host_record* check box, and then click the Edit icon. Select the host IP address, and then click the Edit icon.
   Roaming Host: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Roaming Hosts** -> *roaming_host* check box, and then click the Edit icon.

2. In the *DHCP Properties* editor, select the **IPv4 DHCP Options** tab and complete the following:
   - **Routers**: Click the Add icon. Grid Manager adds a row to the table. In the table, enter the IP address of the router that is connected to the same network as the DHCP client. When configuring this for a template,

enter the offset value of the IP address of the router. The DHCP server includes this information in its DHCPOFFER and DHCPACK messages.
- **DomainName**: Enter the name of the domain for which the Grid serves DHCP data. The DHCP server includes this domain name in Option 15 when it responds with a DHCPOFFER packet to a DHCPDISCOVER packet from a client. If DDNS is enabled on the DHCP server, it combines the host name from the client and this domain name to create the FQDN (fully-qualified domain name) that it uses to update DNS. For information about DDNS, see *Configuring DDNS Updates*.
  When overriding the domain name already set by a parent object, enter the new value for the selected option or use "" to clear the value.
- **DNS Servers**: Click the Add icon. Grid Manager adds a row to the table. In the table, enter the IP address of the DNS server to which the DHCP client sends name resolution requests. The DHCP server includes this information in the DHCPOFFER and DHCPACK messages.
- **Broadcast Address**: Enter the broadcast IP address of the network to which the DHCP server is attached. When configuring this for a template, enter the offset value of the broadcast IP address of the network.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Defining IPv4 Option Spaces

DHCP members support the DHCP option space by default. You can create additional option spaces to provide additional configuration or service information. Note that custom options defined in a user-defined option space are always encapsulated in option 43 in DHCP messages
To add a custom option space:

1. From the **Data Management** tab, select the **DHCP** tab -> **Option Spaces** tab.
2. Click the Add icon -> **IPv4 Option Space**.
3. In the *Option Space* wizard, do the following:
   - **Name**: Enter the name of the option space.
   - **Comment**: Enter useful information about the option space.
   - **Options**: Click the Add icon to add options. For additional information, see the next section, Configuring Custom DHCP Options.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

After you create an option space and add options to it, you can apply the options as described in Applying DHCP Options below.

Configuring Custom DHCP Options

You can define custom options in the DHCP option space or in an option space that you configured, as follows:

1. From the **Data Management** tab, select the **DHCP** tab -> **Option Spaces** tab.
2. Select either the **DHCP** option space or an IPv4 option space that you configured, and then click the Edit icon.
3. In the *Option Space* editor, click the Add icon to add a custom option. In the new row, complete the following:
   - **Name**: Enter the name of the custom DHCP option.
   - **Code**: Select an option code from the drop-down list. Select a number between 126 and 254 if you are adding custom options to the **DHCP** option space. If you are adding custom options to an IPv4 option space you configured, you can enter a number between 1 and 254.
   - **Type**: Select the option type (such as ip-address, text, boolean, and string as described in the DHCP Option Data Types table above).
     For example, to create an option that defines the IP addresses of Solaris root servers, enter the name SrootIP4, select option code 126, and then select the type as ip-address.
     Click the Add icon to add more options.
4. Save the configuration.

Applying DHCP Options

Some options may apply to all networks and some may apply to specific ranges and even hosts. When you apply an option, you select the object to which the option is applied, such as the Grid member, or network, and then specify a

value for the option.
Use the following guidelines when specifying option values:

- Enter **false** or **true** for a Boolean Flag type value.
- Enter an ASCII text string, or enter a series of octets specified in hex, separated by colons.
- Separate multiple values by commas. For example, to enter multiple IP addresses for netbios-name-servers, enter a comma between each IP address.

Here are some examples of option names and correctly formatted values:

Option name	Value	Comment
option 61 dhcp-client-identifier	MyPC	Double quotes are no longer needed for string type values
dhcp-client-identifier	43:4c:49:45:54:2d:46:4f:4f	Series of octets specified in hex, separated by colons for a Data-string type value
netbios-name-servers	10.1.1.5,10.1.1.10	Multiple IP addresses separated by commas
option-80	ABC123	Custom option number 80 set to the string ABC123.

To apply DHCP options:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* check box, and then click the Edit icon.
   Network: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* check box, and then click the Edit icon.
   Network Container: From the **Data Management** tab, select the **IPAM** tab -> *network_container* check box, and then click the Edit icon.
   DHCP Range: From the **DataManagement** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *addr_range* check box, and then click the Edit icon.
   Fixed Address: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *fixed_address* check box, and then click the Edit icon.
   Reservation: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *reservation* check box, and then click the Edit icon.
   Host Address: From the **Data Management** tab, select the **DHCP** tab tab -> **Networks** tab -> **Networks** -> *network* -> *host_record* check box, and then click the Edit icon. Select the host IP address, and then click the Edit icon.
   Roaming Host: From the **Data Management** tab, select the **DHCP** tab tab -> **Networks** tab -> **Roaming Hosts** -> *roaming_host* check box, and then click the Edit icon.
2. In the *DHCP Properties* editor, select the **IPv4 DHCP Options** and complete the following:
   - The **Custom DHCP Options** section displays two fields. The first field displays **Choose option**. Click the arrow and select an option from the list. In the second field, enter a value for the selected option. Note that certain options have predefined data types and their values must be entered in a specific format. For information about the data types, see as described in the DHCP Option Data Types table above.
   - Click **+** to add another option, or click **-** to delete a previously specified option. When overriding an option already set by a parent object, enter the new value for the selected option or use "" to clear the value. Note that if you created an option space as described in Defining IPv4 Option Spaces above, this section displays a list of option spaces in the first drop-down menu, so you can select the option space of the option you want to define.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuration Example: Defining a Custom Option

In this example, you configure two custom options in the DHCP option space, and apply them to a DHCP range in the network 192.168.2.0/24.
Add the custom options to the DHCP options space:

1. From the **Data Management** tab, select the **DHCP** tab -> **Option Spaces** tab.
2. Select the **DHCP** check box, and click the Edit icon.
3. In the *DHCP (Option Space)* editor, click the Add icon. In the new row, complete the following:
    - **Name**: Enter **tftp-server**.
    - **Code**: Enter **150**.
    - **Type**: Select **array of ip-address**.
4. Click the Add icon to add another option.In the new row, complete the following:
    - **Name**: Enter **pxe-configfile**.
    - **Code**: Enter **209**.
    - **Type**: Select **text**.
5. Click **Save & Close.**

Enter values for the newly defined custom options and apply them to a DHCP range:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** subtab, and click the 192.168.2.0/24 network.
2. Click the 192.168.2.10 - 100 check box, and then click the Edit icon.
3. In the *DHCP Properties* editor, select the **DHCP** tab and complete the following in the **Custom DHCP Options** section:
    - From the drop-down list of options, select **tftp-server (150) array of address**. In the second field, enter **192.168.1.2**.
      Click **+** to add another option.
    - From the drop-down list of options, select **pxe-configfile (209) text**. In the second field, enter **pxe.config**, which is the file name of the boot image.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

The member then includes options 150 and 209 in its DHCP messages to clients that are allocated IP addresses from the DHCP range 192.168.2.10 - 100.

Defining Option 60 Match Rules

The appliance uses option 60 (vendor-class-identifier) to forward client requests to the DHCP server for services that the clients require. You can define option 60 match rules and filter on these rules. You can set these rules for the Grid and override for a member.
To define option 60 for the Grid or member:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* check box, and then click the Edit icon.
2. In the *DHCP Properties* editor, click **Toggle Advanced Mode** if the editor is in basic mode. When the additional tabs appear, click the **DHCP Options** tab -> **Advanced** tab and complete the following:
   To override the Grid configuration for a member, click **Override** next to the property. Grid Manager hides the Grid configuration. You can then add new values for the member.
    a. **Option60 (Vendor Class Identifier) Match Rules**: Click the Add icon if you want to add a match rule to a vendor class option. The appliance adds a row to the table. Complete the following:
        - **Option Space**: Select an option space from the drop-down list. This field appears only when you have custom option spaces. The appliance uses the default **DHCP** option space if you do not have custom option spaces.
        - **Match Value**: Enter the value you want the appliance to use when matching vendor class options.
        - **Is Substring**: Select this check box if the match value is a substring of the option data.
        - **Substring Offset**: Enter the number of characters at which the match value substring starts in the option data. Enter 0 to start at the beginning of the option data, enter 1 for the second position,

and so on. For example, when you enter 2 here and have a match value of RAS, the appliance matches the value RAS starting at the third character of the option data.
- **Substring length**: Enter the length of the match value. For example, if the match value is SUNW, the length is 4.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

About the DHCP Relay Agent Option (Option 82)

A typical relationship between a DHCP client, relay agent, and the NIOS appliance on a network is as follows:

1. A DHCP client broadcasts a DHCPDISCOVER message on its network segment.
2. A DHCP relay agent on that segment receives the message and forwards it as a unicast message to one or more DHCP servers (such as NIOS appliances).
3. If the NIOS appliance accepts the address request, it responds to the relay agent with a DHCPOFFER message. If the appliance denies the request, it does not send any response in case other DHCP servers that might be involved respond instead.
4. The relay agent forwards the response to the client, usually as a broadcast message.

The situation is different for individual hosts connecting to the Internet through an ISP, usually over a circuit-switched data network.

1. A host connects to its ISP's circuit access concentration point, authenticates itself, and requests an IP address.
2. The circuit access unit relays the address request to a DHCP server, which responds with a DHCPOFFER message.

To avoid broadcasting the DHCPOFFER over the network segment on which the host made the request, the relay agent sends the response directly to the host over the established circuit.

Option 82 assists the agent in forwarding address assignments across the proper circuit. When a relay agent receives a DHCPDISCOVER message, it can add one or two agent IDs in the DHCP option 82 suboption fields to the message. The relay agent IDs are:

- **Circuit ID:** This identifies the circuit between the remote host and the relay agent. For example, the identifier can be the ingress interface number of the circuit access unit (perhaps concatenated with the unit ID number and slot number). The circuit ID can also be an ATM virtual circuit ID or cable data virtual circuit ID.
- **Remote ID:** This identifies the remote host. The ID can be the caller ID telephone number for a dial-up connection, a user name for logging in to the ISP, a modem ID, and so on. Because the remote ID is defined on the relay agent, which is presumed to have a trusted relationship with the DHCP server, and not on the untrusted DHCP client, the remote ID is also presumably a trusted identifier.

> ⚠ **Note**
>
> For information about the relay agent option, refer to *RFC3046, DHCP Relay Agent Information Option*.

In addition to the relay agent IDs, NIOS also supports the Option 82 Link Selection and Server ID Override sub-options, which allow DHCPv4 to operate in a network architecture where direct communication between the DHCP server and DHCP client is undesirable or infeasible. You can configure these sub-options to direct DHCP traffic to go through the relay agent and have more control over your DHCP communications.

The Link Selection sub-option provides a mechanism to separate the subnet/link in which the DHCP client resides from the GIADDR (Gateway IP address). The GIADDR field in a DHCP message is populated by the relay agent and is typically used to inform the DHCP server about the subnet in which the DHCP client resides and to inform the DHCP server of the IP address to use to communicate with the relay agent. In situations where the GIADDR might not be the appropriate subnet from which IP addresses should be allocated, you can use the Link Selection sub-option to explicitly set the subnet from which IP addresses are allocated to the client.

The Server ID Override sub-option allows the relay agent to tell the DHCP server what IP address, instead of the server's address, must be used in the response. Generally, the response from the server contains the IP address of the DHCP server itself in the Server-ID option. You can use the Server ID Override sub-option to specify a new value for the server ID that is inserted in the reply packet by the DHCP server. Configuring the Server ID Override sub-option allows the relay agent to have the clients send all unicast messages to the relay agent instead of the DHCP server.

> **Note**
>
> If you want the Link Selection and Server ID Override sub-options to be included in the DHCP relayed messages, you must configure them on the DHCP relay agent. You cannot configure them on NIOS. For more information about these sub-options, refer to *https://tools.ietf.org/html/rfc3527* and *https://tools.ietf.org/html/rfc5107*.

On the NIOS appliance, you can do the following with option 82:

- Screen address requests through a relay agent filter you set up using option 82. For more information, see *About Relay Agent Filters*.
- Use the relay agent information (circuit ID or remote ID) as a host identifier when configuring a fixed address, though you cannot do so in a host record. For information about how to configure a circuit ID or remote ID as an identifier, see as described in *Adding IPv4 Fixed Addresses*.
- Define how Grid Manager displays the relay agent ID, circuit ID, and remote ID (when applicable) in the detailed lease information panel. For information about how to configure the logging format for option 82, see Defining Logging Format for DHCP Option 82 below.

Defining Logging Format for DHCP Option 82

When you define the circuit ID or remote ID of the relay agent as a host identifier, you can choose the logging format Grid Manager uses to display the IDs in the detailed lease information panel. For information about viewing lease information, see *Viewing Detailed Lease Information*.
To define logging format for the agent ID, circuit ID and remote ID, complete the following:

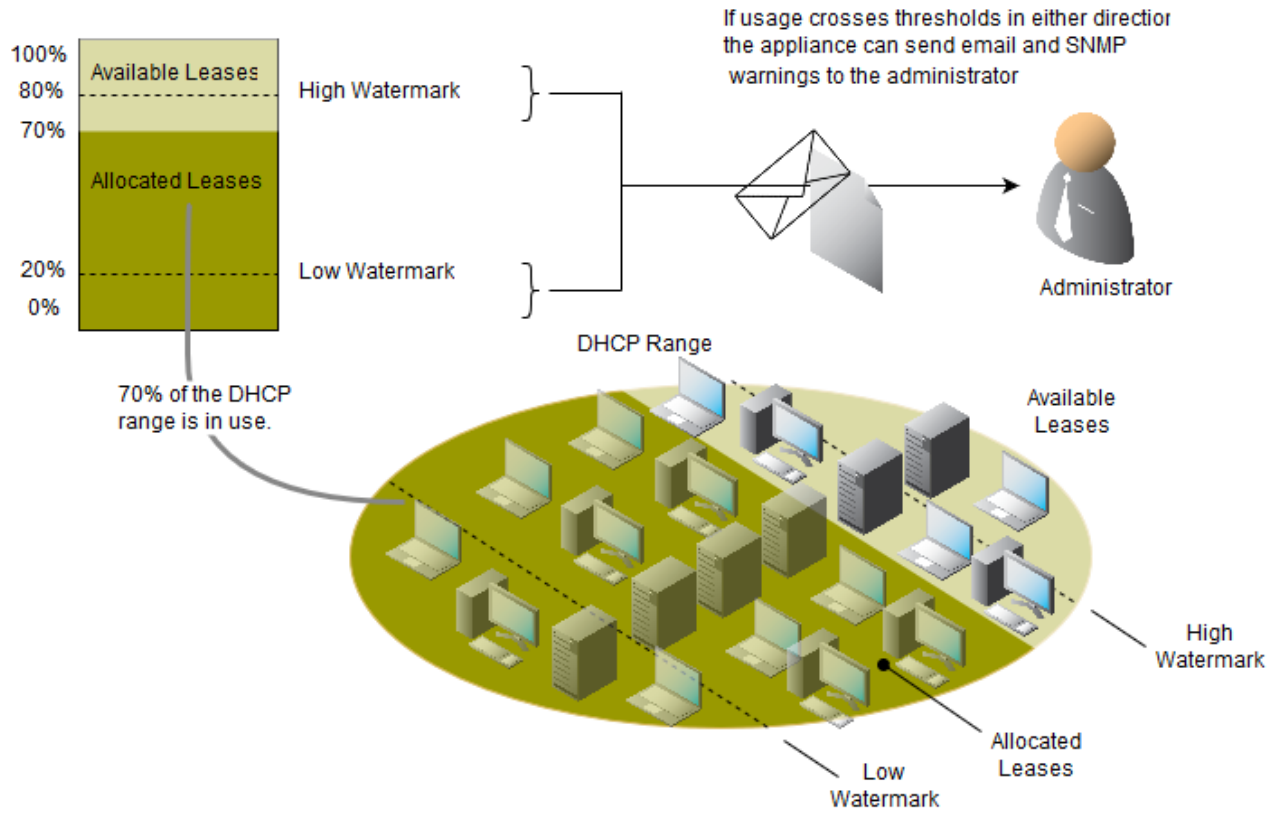
1. **Grid:** From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the **Toolbar**.
   Independent Appliance: From the **Data Management** tab, select the **DHCP** tab, and then click **System DHCP Properties.**
2. In the *Grid DHCP Properties* or *System DHCP Properties* editor, select the **General** tab -> **Advanced** tab.
3. Select one of the following for **Logging format for Option 82**:
   - **Hexadecimal**: When you select this, Grid Manager displays the agent ID, circuit ID, and remote ID in hexadecimal format in the detailed lease information. This is the default format.
   - **Plaintext**: When you select this, Grid Manager displays the agent ID, circuit ID, and remote ID in plain text in the detailed lease information.

> **Note**
>
> You cannot override this Grid setting at the member level. Also, changing the logging format requires a DHCP service restart.

Configuring Thresholds for DHCP Ranges

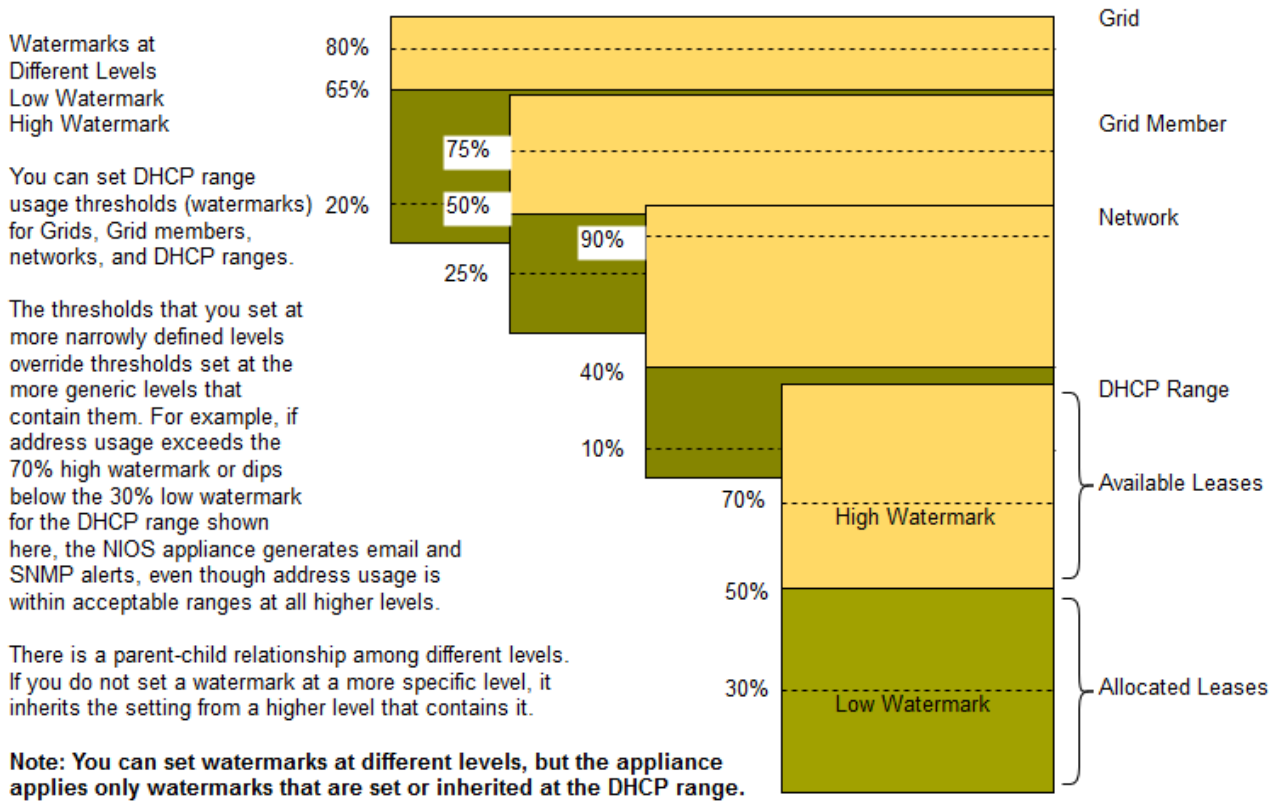
Grid Manager can provide a view of the current overall DHCP range usage for the DHCP ranges defined on each Grid member. The view is in the form of a percent: address leases in use/total addresses for each network. Such information can indicate if there is a sufficient number of available addresses at each of these levels. It can also provide information about the distribution of address resources, indicating if there are too many unused addresses in one location while all the addresses in another are in use.
In addition to viewing the percent of addresses in use, you can also apply high and low thresholds for each DHCP range. These watermarks represent thresholds above or below which DHCP range usage is unexpected and might warrant your attention. For example, usage falling below a low threshold might indicate network issues preventing the renewal of leases. When usage for a DHCP range crosses a threshold, the appliance makes a syslog entry and — if configured to do so — sends the administrator alerts as SNMP traps and email notifications. The figure Overall DHCP Address Usage for a DHCP Range below illustrates the relationship of allocated and available addresses to high and low watermarks in a DHCP range.

Overall DHCP Address Usage for a DHCP Range



You can define watermarks at the Grid, member, network, and DHCP range levels, but the appliance applies them solely to DHCP ranges. Because the appliance applies settings hierarchically in a parent-child structure, by defining watermarks once at a higher level, DHCP ranges can then inherit these settings without your needing to redefine them for each range. For example, if you set high and low watermarks for a Grid, then each Grid member, each network, and each DHCP range inherits these settings. However, if you override these settings at the member level, then the network and DHCP ranges for that member inherit its settings. If you override the Grid member settings at the network level, then that network and any DHCP ranges within that network inherit the network-level settings. Finally, you can set high and low watermarks for an individual DHCP range, which override anything set at a higher level.
The below figure shows different high and low watermark settings at different levels. Although you can set thresholds at four levels (Grid, Grid member, network, and DHCP range), the NIOS appliance applies them to DHCP ranges.

High and Low Watermarks



Address usage in a DHCP range can trigger an event and an email notification when it crosses a watermark. You must enable DHCP threshold and email warnings to receive events and notifications. The following are actions that do and do not trigger an address usage event and notification:
Address usage triggers an event and the appliance sends a notification when the percentage of the allocated addresses in the DHCP range:

- Exceeds the high watermark
- Drops below or equals to the high watermark after exceeding it
- Drops below the low watermark
- Exceeds the low watermark after dropping below it

Address usage does not trigger an event when the percentage of the allocated addresses in the DHCP range:

- Never exceeds the low watermark
- Initially exceeds the low watermark
- Reaches a watermark but does not cross it

> **Note**
>
> You can effectively disable address usage events for a DHCP range by setting its high watermark at 100% and the low watermark at 0% (default setting for the low watermark). Because address usage cannot cross these watermarks, no events can occur.

You can configure the threshold settings at the Grid level and override them at the member, network, and DHCP range levels. To override an inherited DHCP property, click **Override** next to the property to enable the configuration. For information, see *Overriding DHCP Properties*.

To configure thresholds:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member*

checkbox, and then click the Edit icon.
Network: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon.
Network Container: From the **Data Management** tab, select the **IPAM** tab -> *network_container* checkbox, and then click the Edit icon.
DHCP Range: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *addr_range* checkbox, and then click the Edit icon.

2. In the editor, select the **IPv4 DHCP Thresholds** tab and complete the following:
    - **DHCP Thresholds:** Specify the following:
        - **Enable DHCP Thresholds:** Select **Enable DHCP Thresholds** to enable the DHCP threshold feature.
            - **High:** Enter a number between 0 and 100. Enter Trigger and Reset values. If the percentage of allocated addresses in a DHCP range exceeds the Trigger value, the appliance makes a syslog entry and—if configured to do so—sends an SNMP trap and an email notification to a designated destination. When the percentage first reaches the Reset value after it hit the Trigger value, the appliance sends an SNMP trap and an email notification to a designated destination. The default Trigger value is 95, and the default Reset value is 85.
            - **Low:** Enter a number between 0 and 100. If the percentage of allocated addresses in a DHCP range drops below the Trigger value, the appliance makes a syslog entry and—if configured to do so— sends an SNMP trap and an email notification to a designated destination. When the percentage first reaches the Reset value after it hit the Trigger value, the appliance sends an SNMP trap. The default Trigger value is 0 and the default Reset value is 10.
        - **Enable SNMP Warnings:** Select this for the appliance to send an SNMP trap to the trap receiver that you define for the Grid when the address usage in a DHCP range crosses a high or low mark threshold.
        - **Enable Email Warnings:** Select this for the appliance to send an email notification to an administrator if the address usage in a DHCP range crosses a high or low mark threshold.
    - **Email Addresses:** Click **Override** to override the Grid administrator email address configured in the **Data Management** tab -> **Grid** tab. This address is not hierarchically inherited from the Grid DHCP configuration. Click the Add icon, and then enter an email address to which you want the appliance to send email notifications when the DHCP range for the network crosses a threshold. You can create a list of email addresses.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring DHCPv6 Properties

The following sections describe how to configure properties and options that apply to DHCPv6 objects only. You can configure and define the following DHCP properties:

- General properties, as described in the next section, see Defining General IPv6 Properties.
- DHCP options, as described in *About DHCPv6 Options*.

Defining General IPv6 Properties

You can configure general DHCPv6 properties at the Grid level and override them at the member and lower levels.

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
Network: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon.
Network Container: From the **Data Management** tab, select the **IPAM** tab -> *network_container* checkbox, and then click the Edit icon.
Fixed Address: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network*-> *Fixed address* checkbox, and then click the Edit icon.

2. In the *DHCP Properties* editor, select the **IPv6 DHCP Options** tab, and complete the following:
    - **Valid Lifetime:** Specify the length of time addresses that are assigned to DHCP clients remain in the valid state. When this time expires, an address becomes invalid and can be assigned to another interface.
    - **Preferred Lifetime:** Specify the length of time that a valid address is preferred. A preferred address can be used with no restrictions. When this time expires, the address becomes deprecated.
    - **Domain Name**: Enter the name of the domain for which the Grid serves DHCP data.
    - **DNS Servers**: Click the Add icon. Grid Manager adds a row to the table. In the table, enter the IPv6 addresses of DNS recursive name servers to which the DHCP client can send name resolution requests. The DHCP server includes this information in the DNS Recursive Name Server option in Advertise, Rebind, Information-Request, and Reply messages.
    - **Custom IPv6 DHCP Options**: In the first field, select one of the following from the drop-down list:
        - **DHCPv6**: Select this to apply DHCPv6 options.
        - **DHCP**: Select this to apply DHCP options (dhcp-renewal-time or dhcp-rebinding-time).
    - Click the **Choose option** drop down and then select an option from the list.
    - In the third field, enter a value for the selected option. Note that certain options have predefined data types and their values must be entered in a specific format.
      Click + to add another option, or click - to delete a previously specified option. When overriding an option, enter the new value for the selected option.
3. Save the configuration.

About DHCPv6 Options

DHCPv6 options provide configuration and service information to IPv6 clients. Just like IPv4 options, IPv6 options appear as variable length fields at the end of the DHCPv6 messages.
Just as in IPv4, the NIOS appliance supports the following options in the DHCPv6 options space:

- **Predefined options**: These are the option codes defined in RFC 3315. You cannot redefine these options or delete them from the DHCP option space. Option codes 1-48 are reserved and cannot be used to define custom options.
- **Custom options**: These are option codes 49 to 254. They are not defined by IETF standards and are available for private use. You can use these option codes to provide configuration or service information that none of the predefined options provide.

You can also create option spaces to define new groups of options. For example, you can create additional option spaces to define vendor specific options, which are encapsulated in DHCPv6 option 17. When an IPv6 client requests vendor specific options, it makes a request using the vendor specific options (option 17). The DHCP server then responds with the list of replies for the various options encapsulated into option 17.
Note that custom options defined in the DHCP option space are included in the options section of the DHCP messages that DHCP servers and clients exchange.
You can apply options globally at the Grid level, or more specifically at the member, network, range, host and roaming host levels.

Configuring DHCPv6 Options

To use DHCPv6 options, you can do the following:

- Configure one or more option spaces, as described in the next section Defining IPv6 Option Spaces.
- Define custom options in the predefined DHCPv6 option space or add options to an option space that you configured. For more information, see Configuring Custom DHCP Options below.
- Specify values for the options and apply them to the Grid, or to a member, network, fixed address, host, or roaming host. For more information, see Applying DHCPv6 Options below.

Defining IPv6 Option Spaces

DHCP members support the DHCPv6 option space by default. You can create additional option spaces to provide additional configuration or service information.
To add a custom option space:

1. From the **Data Management** tab, select the **DHCP** tab -> **Option Spaces** tab.

2. Click the Add icon -> **IPv6 Option Space**.
3. In the *IPv6 Option Space* wizard, do the following:
    - **Name**: Enter the name of the option space.
    - **Enterprise Number:** Enter the vendor's Enterprise Number that is registered with IANA.
    - **Comment**: Enter useful information about the option space.
    - **Options**: Click the Add icon to add options. For additional information, see the next section, Configuring Custom DHCP Option
4. Save the configuration and click **Restart** if it appears at the top of the screen.

After you create an option space and add options to it, you can apply the options as described in *Applying DHCP Options*.

Configuring Custom IPv6 DHCP Options

You can define custom options in the DHCP option space or in an option space that you configured, as follows:

1. From the **Data Management** tab, select the **DHCP** tab -> **Option Spaces** tab.
2. Select either the **DHCPv6** option space or an IPv6 option space that you configured, and then click the Edit icon.
3. In the *Option Space* editor, click the Add icon to add a custom option. In the new row, complete the following:
    - **Name**: Enter the name of the custom DHCP option.
    - **Code**: Enter a number from 1 to 65535 to add a custom option in the DHCP option space or in an IPv6 option space that you have configured.
    - **Type**: Select the option type (such as ipv6-address, text, boolean, and string as described in *DHCP Option Data Types* table).

      Click the Add icon to add more options.
4. Save the configuration.

Applying DHCPv6 Options

You can apply some options at the Grid or member level, and some options to specific networks, shared networks, fixed addresses and roaming hosts. When you apply an option, you select the object to which the option is applied, such as the Grid, member, or network, and then specify a value for the option.
Use the following guidelines when specifying option values:

- Enter **false** or **true** for a Boolean Flag type value.
- Enter an ASCII text string, or enter a series of octets specified in hex, separated by colons.
- Separate multiple values by commas. For example, to enter multiple IP addresses for netbios-name-servers, enter a comma between each IP address.

DHCPv6 options support the same data types as DHCP IPv4 options. For more information about the data types, see *DHCP Option Data Types*. To apply DHCP options:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then select **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
   Network: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon.
   Network Container: From the **Data Management** tab, select the **IPAM** tab -> *network_container* checkbox, and then click the Edit icon.
   Fixed Address: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *fixed_address* checkbox, and then click the Edit icon.
   Host Address: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *host_record* checkbox, and then click the Edit icon. Select the host IP address, and then click the Edit icon.
   Roaming Host: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Roaming Hosts** -> *roaming_host* checkbox, and then click the Edit icon.
2. In the *DHCP Properties* editor, select the **IPv6 DHCP Options** and complete the following:
    - **Custom IPv6 DHCP Options**: In the first field, select one of the following from the drop-down list:

- **DHCPv6**: Select this to apply DHCPv6 options.
- **DHCP**: Select this to apply DHCP options (dhcp-renewal-time or dhcp-rebinding-time).

In the second field, click the **Choose option** arrow and select an option from the list. In the third field, enter a value for the selected option. Note that certain options have predefined data types and their values must be entered in a specific format. For information about the data types, see *DHCP Option Data Types*.
Click **+** to add another option, or click **-** to delete a previously specified option. When overriding an option, enter the new value for the selected option.
Note that if you created an option space, this section displays a list of option spaces in the first drop-down menu, so you can select the option space of the option you want to define.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Limitations of Custom DHCP Options

Note the following limitations when you enable DHCPv6 rapid commit:

- If you enable DHCPv6 rapid commit at a higher hierarchy level, all child objects at the lower hierarchy levels inherit this option. You cannot override this option for any child objects.
- You cannot add a network with rapid commit enabled to a shared network or define rapid commit in a network that belongs to a shared network.
- If the client does not include the DHCPv6 Rapid Commit option in the SOLICIT messages, the server will respond with an ADVERTISE using the default four-message exchange instead of REPLY using the two-message exchange even though rapid commit is enabled for the DHCP range in which the address is allocated.

Configuring DHCP IPv4 and IPv6 Common Properties

This section describes DHCP properties that apply to both IPv4 and IPv6. It includes the following sections:

Configuring UTF-8 Encoding for Hostnames

When you configure the appliance as a DHCP server, the appliance supports UTF-8 encoding of hostnames that are encoded with Microsoft Windows code pages. You can configure the DHCP services on the appliance to convert these client hostnames to UTF-8 characters. The appliance stores the UTF-8 encoded hostnames in the database. If you also configure the DHCP services on the appliance to perform DDNS updates, the appliance sends the UTF-8 encoded host names in the DDNS updates. You can configure the UTF-8 encoding of host names at the Grid DHCP service and member DHCP service levels. For information on UTF-8 encoding, see *Printing from Grid Manager.*
The appliance displays the host names in their original characters in the following:

- DHCP lease history
- DHCP lease details
- IP address management
- Syslog
- Audit log

To configure UTF-8 encoding for hostnames:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then select **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
2. In the *DHCP Properties* editor, select the **General Basic** tab and complete the following:

- **IPv4 Properties**
  - **Microsoft Clients Code Page**: From the drop-down list, select the code page with which the host names are encoded when the appliance converts the Microsoft code page encoded host names to UTF-8 characters.
- **IPv6 Properties**
  - **Microsoft Clients Code Page**: From the drop-down list, select the code page with which the host names are encoded when the appliance converts the Microsoft code page encoded host names to UTF-8 characters.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Associating Networks with Zones

You can associate IPv4 and IPv6 networks with DNS zones to limit the zones that admins can use when they create DNS records for IP addresses in the networks. When a network is associated with one or more zones and an admin creates a DNS record for one of its IP addresses, Grid Manager allows the admin to create the DNS record in the associated zones only. For example, if you associate the 10.1.0.0/16 network with the corpxyz.com zone, admins are allowed to create DNS records in the corpxyz.com zone only for IP addresses in the 10.1.0.0/16 network; or if you associate the 2001:db8:1::/48 network with the corp200.com zone, admins are allowed to create DNS records in the corp200.com zone only for IP addresses in the 2001:db8:1::/48 network.
This feature applies to A, AAAA and host records only. It does not apply to records in a shared record group. If you are creating a host record with multiple IP addresses in different networks, the networks must be associated with the zone of the host record.
If a network is not associated with a zone, admins can create DNS records for its IP addresses only in zones with no network associations as well.
You can associate a network with any authoritative zone whose primary server is a Grid member or a Microsoft server, or is unassigned. You cannot associate networks with zones that have external primary servers.
You can associate a network with multiple zones, and associate a zone with more than one network. You can associate IPv4 and IPv6 network containers and networks with zones. When you associate a network container with zones, its networks inherit the zone associations. You can override the zone associations at the network level.
If you split a network, the resulting subnets inherit the zone associations. If you join networks, the resulting network retains the zone associations of the network that you selected when you performed the join operation. You can override the inherited zone associations of individual networks. Subzones do not inherit the network associations of their parent zones.
When you import data into a zone that is associated with a list of networks, the imported A, AAAA and host records must have IP addresses in the associated networks. Grid Manager does not allow you to import A, AAAA and host records with IP addresses in unassociated networks.
When you associate a network with a zone, the DNS records created before the association are not affected. But if you edit an A, AAAA or host record after the association, Grid Manager does not allow you to save the record if its IP address is not in an associated network.
To associate an IPv4 or IPv6 network with a zone:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon.
2. In the *DHCP Network* editor, click **Toggle Advanced Mode** if the editor is in basic mode.
3. When the additional tabs appear, click the **Advanced** subtab of the **General** tab.
4. Click the Add icon and select the zone you want to associate with the network.
   - Optionally, select a default zone. When you create or edit an A, AAAA or host record from a network in the **IPAM** tab, Grid Manager automatically selects the default zone that is assigned to the network.
5. Save the configuration or click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks.*

Viewing the Networks Associated with a Zone

You can view the IPv4 or IPv6 networks associated with a zone from the zone editor. The tab to display network associations in zone editors is visible only if the primary server is a Grid member, a Microsoft server, or unassigned.
To view the network associations of a zone:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and then click the Edit icon.
2. In the *Authoritative Zone* editor, click **Toggle Advanced Mode** if the editor is in basic mode.

3. When the additional tabs appear, click the **Advanced** subtab of the **General** tab.

The Network Associations table lists the networks and their corresponding comments. You cannot change the network associations in this editor. Navigate to the *DHCP Network* editor of the network, to change the zone associations.

Keeping Leases in Deleted IPv4 and IPv6 Networks and Ranges

You can configure the DHCP server to store leases in a deleted DHCP range for up to one week after the leases expire. When you add a new DHCP range that includes the IP addresses of these leases or assign the DHCP range to another member within the Grid, the appliance automatically restores the active leases. You can configure this feature for the Grid, and override the configuration for members, networks, and DHCP ranges.
To keep active leases in a deleted DHCP range:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
   Network: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon.
   Network Container: From the **Data Management** tab, select the **IPAM** tab -> *network_container* checkbox, and then click the Edit icon.
   Range: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *range* checkbox, and then click the Edit icon.
2. In the *DHCP Properties* editor of the Grid or member, click **Toggle Advanced Mode** if the editor is in basic mode, and then click the **General** tab -> **Advanced** tab. In the Network editor or Range editor, click **Toggle Advanced Mode** if the editor is in basic mode, and then click **IPv4DHCPOptions** -> **Advanced** or **IPv6 DHCP Options** -> **Advanced**. Complete the following:
   - **IPv4 Properties**
     - **Lease Deletion**: When you select **Keep leases from deleted range until one week after expiration** and delete a DHCP range with active leases, the appliance stores these leases for up to one week after they expire.
   - **IPv6 Properties**
     - **Lease Deletion**: When you select **Keep leases from deleted range until one week after expiration** and delete a DHCP range with active leases, the appliance stores these leases for up to one week after they expire.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring Fixed Address Leases For Display

You can configure the DHCP server to capture the hostname and lease time of a fixed address when you assign an IPv4 or IPv6 fixed address to a client. The appliance displays the hostname, and the start and end time of each fixed address lease in the *Current Leases* panel in Grid Manager.
You can set this at the Grid level only for IPv4 and IPv6 leases.

1. From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
2. In the *Grid DHCP Properties* editor, click **Toggle Advanced Mode** if the editor is in basic mode. When the additional tabs appear, click the **General** tab -> **Advanced** tab and complete the following:
    - **IPv4 Properties**
        - **Fixed Address Lease**: Select **Capture hostname and lease time when assigning Fixed Addresses**. The appliance displays the host name, and the start and end time of each fixed address lease in the *Current Leases* panel. If there are multiple records (A, host, and lease) for the IP address, it also displays the information for the records. This option is available in the Grid Properties editor only.)
    - **IPv6 Properties**
        - **Fixed Address Lease**: Select **Capture hostname and lease time when assigning Fixed Addresses**. The appliance displays the host name, and the start and end time of each fixed address lease in the *Current Leases* panel. If there are multiple records (AAAA, host, and lease) for the IP address, it also displays the information for the records. This option is available in the Grid Properties editor only.)
3. Save the configuration.

Scavenging Leases

The accumulation of free and backup DHCPv4 leases; and free, expired, and released DHCPv6 leases results in unnecessary growth of database objects. The DHCP lease scavenging feature enables member DHCP servers to automatically delete free and backup IPv4 leases; and free, expired, and released IPv6 leases that remain in the database beyond the specified period of time, thus reducing the number of database objects.
When you enable this feature for DHCPv4 leases, the appliance permanently deletes the free and backup IPv4 leases, and you can no longer view or retrieve the lease information. This option can be enabled globally at the Grid level, and more specifically for a member, shared network, network, network container, DHCP range, network template, DHCP range template.
When you enable this feature for DHCPv6 leases, the appliance permanently deletes the free, expired, and released IPv6 leases, and you can no longer view or retrieve the lease information. This option can be enabled at the Grid level, and overridden at the member level.
The period of time that you specify is the duration after the expiration date of a lease, not its release date. For example, you specify a time period of 5 days when you enable this feature. If the lease time of an IP address is 10 days, but the lease is released after five days, the appliance still deletes the lease from the database after 15 days because the IP address has been leased.

Note that If you plan to enable this feature after upgrading from a previous NIOS version, Infoblox recommends that you enable it during off-peak hours, as it may impact DHCP services.

To enable scavenging of IPv4 and IPv6 leases:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
   Network: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon. This is applicable for IPv4 lease scavenging only.
   Network Container: From the **Data Management** tab, select the **IPAM** tab -> *network_container* checkbox, and then click the Edit icon. This is applicable for IPv4 lease scavenging only.
   DHCP Range: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *addr_range* checkbox, and then click the Edit icon. This is applicable for IPv4 lease scavenging only.
2. In the editor, click **Toggle Advanced Mode** if the editor is in basic mode, and then click the **General** tab -> **Advanced** tab.

   In the Network editor for IPv4 lease scavenging, click **Toggle Advanced Mode** if the editor is in basic mode, and then click **IPv4 DHCP Options** -> **Advanced**.
   Complete the following:
    - **IPv4 Properties**
        - **Lease Scavenging**: This is disabled by default. Select the **Scavenge free and backup leases after** checkbox and specify the number of days or weeks that free and backup IPv4 leases remain in

the database before they are automatically deleted. This can be set for the Grid, member, network, and network container.

- **IPv6 Properties**
  - **Lease Scavenging**: This is disabled by default. Select the **Scavenge free, expired and released leases after** checkbox and specify the number of hours, days, or weeks that free, expired, and released IPv6 leases remain in the database before they are automatically deleted. The minimum is 6 hours and the maximum is 180 days. The default is one week. This can be set at the Grid and member level.

3. Save the configuration.

DHCPv6 Lease Affinity

DHCPv6 ranges are usually large and the DHCPv6 server randomly selects a new lease each time a client requests for a lease. The client can use the lease until it expires. After its expiration, the lease stays in the database with an expired state. These expired leases eventually lead to the increase in the number of database objects, because the probability of expired IPv6 leases getting reused is low.
Infoblox provides a DHCPv6 lease affinity feature that allows you to reuse expired IPv6 leases for DHCP clients. When you enable this feature, the DHCPv6 server automatically renews the expired leases. A DHCP client can retrieve the same lease from the DHCPv6 server after it expires and retains the same IP address. This feature helps reduce the amount of IPv6 leases in the database as the DHCP server issues the same lease multiple times for the same client. The appliance ignores expired leases that are older than the specified period. Such leases are scavenged. Note that the grace period you define for lease scavenging is applicable for DHCPv6 lease affinity also. The minimum time period is six hours, maximum is 180 days and the default is set to seven days. For more information about scavenging leases, see the *Scavenging Leases* section.

The DHCPv6 server offers the same lease for a DHCP client, identified by DUID, after the lease expires and before the end of the grace period. The appliance removes the expired leases that are older than the grace period from the database.

DHCPv6 lease affinity and DHCPv6 lease scavenging are complementary features. For example, consider a scenario in which a visiting user gets an IPv6 lease that is retained for days, weeks, or months depending on the needs and then the user leaves. If the user returns and the lease is still within the grace period, the user gets the same IPv6 lease. This is lease affinity. When the user leaves, the IPv6 lease becomes inactive. This lease is scavenged after the grace period. Note the following about DHCPv6 lease affinity:

- It does not consider expired leases that are older than the grace period.
- It ignores expired leases that do not match known ranges.
- If no existing lease is found, then the DHCPv6 server finds a suitable expired lease that is not older than the grace period, which matches the client DUID and range configuration.
- The impact of the feature on the performance depends on the amount of expired DHCPv6 leases.
- When you activate the feature at the Grid level, it affects all underlying layers of inheritance.
- You cannot enable DHCPv6 lease affinity at the Grid and member levels during a scheduled full upgrade.
- DHCPv6 lease affinity remembers only permanent addresses and does not remember temporary addresses and prefix delegations.
- If the DHCPv6 range is out of available addresses when you enable DHCPv6 lease affinity, then the DHCP server tries to reuse the best abandoned lease, which indicates the lease that was abandoned longest time ago. If there are no such leases in the pool, the DHCP server reuses the best expired lease, which indicates the lease that expired longest time ago. This means that the expired lease becomes active and it is associated with the new client while the DHCP server removes any previous associations of the corresponding lease. Note that this happens only when the DHCPv6 range does not have any available addresses and there are no suitable abandoned leases.

To enable DHCPv6 lease affinity:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.

2. In the editor, click **Toggle Advanced Mode** if the editor is in basic mode, and then click the **General** tab -> **Advanced** tab.
   Complete the following:
   - **IPv6 Properties**
     - **Lease Scavenging**
       - **Remember client association for expired members:** This is disabled by default. Select the checkbox to remember and reuse expired IPv6 leases that are associated with DHCP clients. You can select this checkbox only when you select the **Scavenge free, expired and released leases after** checkbox. This can be set at the Grid and member levels.

         Note that the appliance stores the leases, which are either deleted or removed, in the recycle bin. These leases then become free and are automatically dissociated from their clients. For example, if you delete a range accidentally and restore it again, the IPv6 leases associated with the respective range are no longer associated with the same set of clients.
3. Save the configuration.

Configuring DHCP Logging

If you have a syslog server operating on your network, you can specify in which facility you want the server to display the DHCP logging messages. You can also select the Grid member on which you want to store the DHCP lease history log, as described in the next section Configuring the Lease Logging Member. You can configure DHCP and lease logging only on the Grid and member levels.
To specify DHCP logging for the Grid or member:

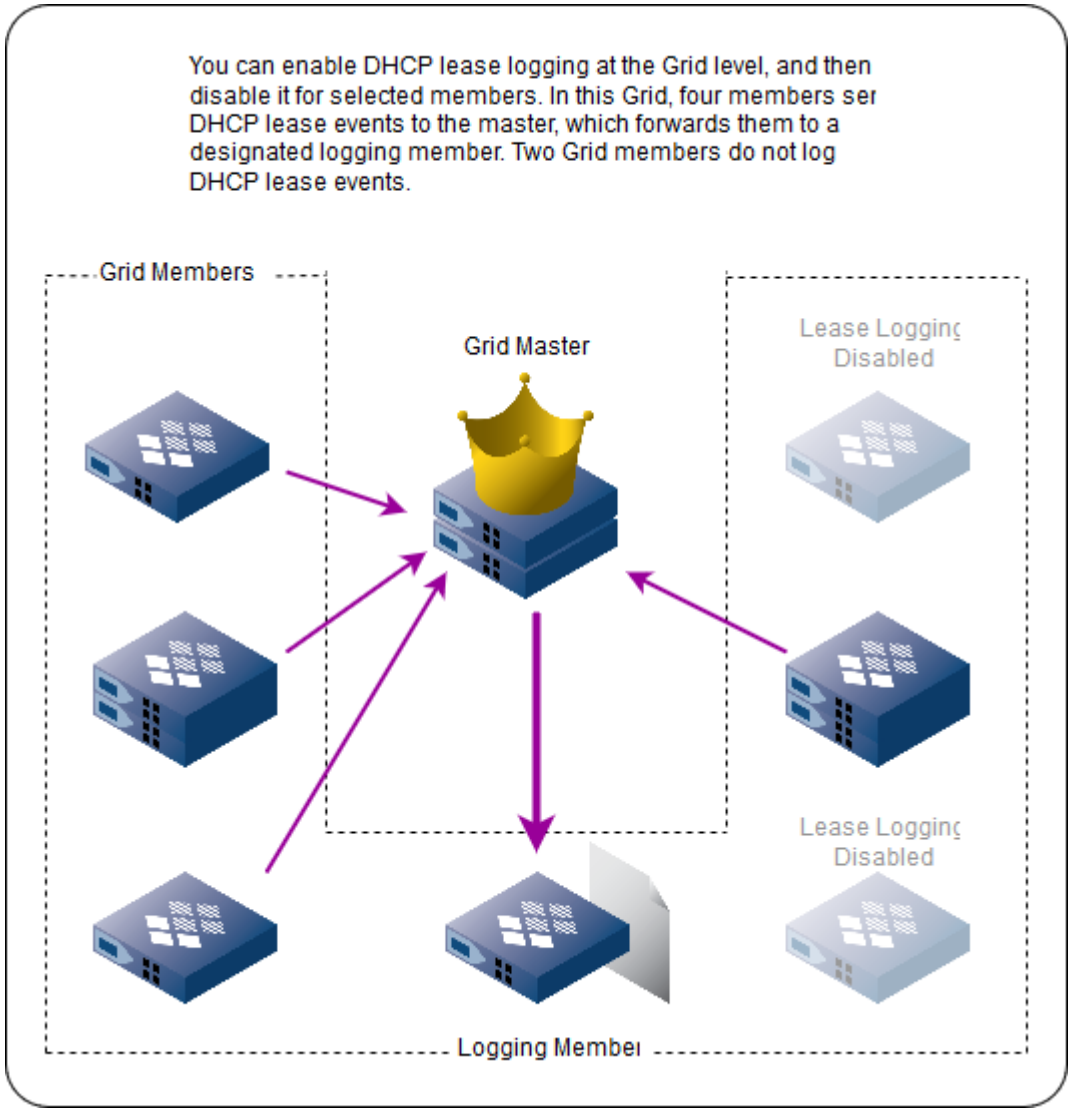
1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
2. In the *DHCP Properties* editor, select the **Logging Basic** tab and complete the following:
   - **Syslog Facility:** From the drop-down list, select the facility that is used to tag syslog messages from the DHCP server. This facility can be used to filter messages on a central syslog server.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring the Lease Logging Member

Logging DHCP lease events makes significant CPU demands, especially when there is heavy DHCP activity. Therefore, Infoblox strongly recommends that you designate a Grid member other than the master as a logging member whenever possible. Another way to manage the increased load that logging introduces is to log selectively per Grid member. For example, you might want to log DHCP leases for members serving critical parts of your network and not keep historical logs for members serving other parts.

DHCP Lease History Logging with Member Overrides



To specify lease logging for a member:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
2. In the **Logging** tab, complete the following:
   - **Lease Logging:** Select **Enable Lease History** (for Grid) or **Log Lease Events from DHCP Server** (for member) to enable DHCP lease logging. To disable DHCP lease logging, clear the checkbox. You can set member overrides if you want to enable or disable lease logging per member.
   - **Send leases to:** For Grid only. Click **Select**. In the *Select Member* dialog box, select the Grid member on which you want to store the DHCP lease history log. Infoblox recommends that you dedicate a member other than the Grid Master as a logging member. If possible, use this member solely for storing the DHCP lease history log. If you do not select a member, no logging can occur. You can click **Clear** to remove the selected Grid member and select a new one.
3. Save the configuration and click **Restart** if it appears at the top of the screen.
4. For information about viewing current leases, see *Viewing Current Leases.*

Configuring IF-MAP

You can configure Infoblox DHCP servers to publish DHCP data to an IF-MAP server. The IF-MAP server takes real-time information from different sources and stores it in a shared database from which clients can retrieve information about network devices, their status and activities. For details about the IF-MAP protocol, refer to *http://www.trustedcomputinggroup.org*. For information about the Infoblox IF-MAP server, refer to the *Infoblox Administrator Guide for Infoblox Orchestration Server*.

Each Infoblox DHCP server in a Grid can function as an IF-MAP client, with the ability to publish lease information to an IF-MAP server. For information about how to configure an IF-MAP client, see Configuring Members as IF-MAP Clients below. You can configure the client to publish ip-mac and ip-duid (for DHCPv6 leases) metadata at the Grid and member levels. You can also configure the client to publish metadata for specific leases by overriding the Grid or member publishing settings at the network (IPv4 and IPv6) or range (IPv4 only) level. The DHCP server sends updates to the IF-MAP server using the XML format and SOAP/HTTPS bindings specified in IF-MAP v1.1r5 and v2.0r26. The DHCP server supports the IF-MAP 2.0 protocol by default. You can also enable the support for IF-MAP 1.1, as described in Configuring a Grid to Support IF-MAP below.

When the DHCP server grants an IPv4 lease and sends the DHCPACK packet to the DHCP client, it updates the link in the IF-MAP server between the leased IP address and client MAC address with ip-mac metadata with the following attributes: start-time, end-time, and dhcp-server. The dhcp-server attribute contains the DHCP server hostname. The ip-mac metadata is attached to a link with:

- An ip-address identifier with the type attribute set to IPv4, a value attribute that contains the leased IP address, and the administrative-domain attribute set to the network view to which the IP address belongs.
- A mac-address identifier with a value attribute that contains the client MAC address. It does not have the administrative-domain attribute.

When the DHCP server grants an IPv6 lease and sends the Reply message to the DHCP client, it updates the link in the IF-MAP server between the leased IP address and client DHCP Unique Identifier (DUID) with ip-duid metadata that contains the following attributes: start-time, end-time, and dhcp-server. The dhcp-server attribute contains the DHCP server hostname. The ip-duid metadata is attached to a link with:

- An ip-address identifier with the type attribute set to IPv6, a value attribute that contains the leased IP address, and the administrative-domain attribute set to the network view to which the IP address belongs.
- A duid identifier with a value attribute that contains the client DUID. It does not have the administrative-domain attribute.

The Infoblox DHCP server also publishes data when an IPv4 or IPv6 lease changes. When a lease is released or when an active lease expires, the DHCP server sends a "publish delete" request to the IF-MAP server.

You can define how the IF-MAP server handles the existing ip-mac and ip-duid information before the DHCP client sends the next update. For example, you can specify the IF-MAP server to always delete existing ip-mac and ip-duid information before the next update. For information, see Deleting Existing Data Before Publishing below.

Following are the tasks to enable DHCP servers in a Grid to function as IF-MAP clients:

1. Enable IF-MAP in the Grid and specify the URL and port of the IF-MAP server, as described in the next section Configuring a Grid to Support IF-MAP.
2. Optionally, enable the validation of the IF-MAP server certificate and import the CA certificate, as described in Validating the IF-MAP Server Certificate below.
3. Enable IF-MAP on each Grid member and specify an authentication method the member uses to connect to the IF-MAP server, as described in Configuring Members as IF-MAP Clients below.
4. Optionally, override publishing settings at the member, network, or range level, as described in OverridingIF-MAP PublishingSettings below.

You can also delete DHCP data published by a specific member, or define how the IF-MAP server deletes existing DHCP data before a client publishes an update. For information, see DeletingDatafromtheIF-MAPServer below.

Configuring a Grid to Support IF-MAP

1. From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
2. In the *Grid DHCP Properties* editor, click **Toggle Advanced Mode**.
3. Click the **IF-MAP** tab, and then complete the following:

- **Enable IF-MAP**: Select this checkbox to enable the IF-MAP service for the Grid. Note that you must enable the IF-MAP service in order to enable or disable publishing at the Grid, member, network, or range level.
- **IF-MAP Server URL**: Enter the URL of the IF-MAP server to which the Grid members publish DHCP data. The URL must begin with **https://**. For example, **https://***<server_ip_addr>***/ifmap**.
- **IF-MAP Server Port**: The default HTTP port is 80 and the default HTTPS port is 443. Optionally, you can specify a different port on the IF-MAP server.
- **Enable IF-MAP publishing**: Select this checkbox to enable IF-MAP publishing for the Grid. When you select this, IF-MAP publishing is enabled for all members, networks (IPv4 and IPv6), and DHCP ranges (IPv4 only). You can override the Grid property at a specific level to control the ip-mac and ip-duid metadata you want the client to publish for specific leases. For information, see Overriding IF-MAP Publishing Settings below.
- **IF-MAP Protocol Version**: Select the IF-MAP protocol version you want the IF-MAP client to use to connect to the IF-MAP server. The default is IF-MAP 2.0.

4. Save the configuration and click **Restart** if it appears at the top of the screen.
5. You can also configure how the IF-MAP server deletes existing metadata before the IF-MAP client publishes another update. For information, see Deleting Data from the IF-MAP Server below.

Validating the IF-MAP Server Certificate

You can configure the IF-MAP client to validate the IF-MAP server certificate before the client establishes a connection or performs IF-MAP transactions. To validate an IF-MAP server certificate, you must first import the certificate of the CA that signs the IF-MAP server certificate.
To configure the IF-MAP client to validate the IF-MAP server certificate:

1. From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
2. In the *Grid DHCP Properties* editor, click **Toggle Advanced Mode**.
3. Click the **IF-MAP** tab and complete the following:
    - **Enable IF-MAP**: Select this checkbox to enable the IF-MAP service for the Grid.
    - **Enable IF-MAP server certificate validation**: Select this checkbox to enable the validation of the IF-MAP server certificate, and then click **Import** to import the CA certificate. In the *Upload* dialog box, click **Select** to navigate to the certificate, and then click **Upload**. You can also copy and paste the CA certificate here.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring Members as IF-MAP Clients

To configure a member to be an IF-MAP client, you must first enable IF-MAP on the member and then configure a client authentication method. The IF-MAP client can authenticate itself to the IF-MAP server through user name and password credentials or digital certificate. Note that each member must have unique credentials or certificates. You cannot use the same credentials or certificates on multiple members. The appliance supports only one CA-signed certificate on each member. If you want to use a roll-over certificate, you must replace the existing certificate and restart services on the member.
To enable an appliance to function as an IF-MAP client:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *Member DHCP Properties* dialog box, click **Toggle Advanced Mode**.
3. Click the **IF-MAP** tab and complete the following:
    - **Enable IF-MAP**: Select this checkbox to enable the IF-MAP service on the member. Note that you must enable the IF-MAP service in order to enable or disable publishing at the network and range levels.
    - **Authentication**: Select one of the following authentication methods:
        - **Certificate**: Select this to use the IF-MAP client certificate for client authentication. You must already have a certificate configured for the member before you can select and save this configuration. For information about creating a client certificate, see Creating IF-MAP Client Certificates below.
        - **Basic**: Select this to use username and password credentials for IF-MAP client authentication. Complete the following:

- **Username**: Enter the username the member uses to connect to the IF-MAP server. This username must have been configured as a valid username on the IF-MAP server. Each member must have its own username.
- **Password**: Enter the password the member uses to connect to the IF-MAP server.
- **ConfirmPassword**: Enter the password again.
  Note when you upgrade to a new NIOS release, the basic authentication credentials are retained if IF-MAP was enabled and basic authentication was used before the upgrade.

- **Enable IF-MAP publishing**: Click **Override** to override the Grid setting. Select this checkbox to enable IF-MAP publishing for all the networks that are served by this member. Ensure that you enable IF-MAP at either the Grid or member level in order to enable IF-MAP publishing for all networks.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Creating IF-MAP Client Certificates

Before you can select "Certificate" as the client authentication method, you must first create a certificate for the specified member.
You can do one of the following to generate an IF-MAP client certificate:

- Generate a self-signed certificate and save it. For information, see Generating Self-Signed Certificates below.
- Request a CA (Certificate Authority) signed certificate. When you receive the certificate from the CA, upload it to the member that you configure as an IF-MAP client.

Generating Self-Signed Certificates

You can replace the default certificate with a self-signed certificate that you generate. When you generate a self-signed certificate, you can specify the correct hostname and change the public/private key size, enter valid dates and specify additional information specific to the member. If you have multiple members, you can generate a certificate for each appliance with the appropriate hostname.
To generate a self-signed certificate:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox, and then click **IF-MAP Client Certificate** -> **Generate Self-signed Certificate** from the Toolbar.
2. In the *Generate Self-Signed Certificate* dialog box, complete the following:
   - **Secure Hash Algorithm and Key Size:** You can select SHA-1 and a RSA key size of 1024 or 2048. SHA-256 (SHA-2) can be selected together with a RSA key size of 2048 or 4096. The default value is SHA-256 2048.
   - **Days Valid:** Specify the validity period of the certificate.
   - **Common Name:** Specify the domain name of the member. You can enter the FQDN (fully qualified domain name) of the appliance.
   - **Organization:** Enter the name of your company.
   - **Organizational Unit:** Enter the name of your department.
   - **Locality:** Enter a location, such as the city or town of your company.
   - **State or Province:** Enter the state or province.
   - **Country Code:** Enter the two-letter code that identifies the country, such as US.
   - **Admin E-mail Address:** Enter the email address of the appliance administrator.
   - **Comment:** Enter information about the certificate.
3. Click **OK**.
4. If the appliance already has an existing client certificate, the new certificate replaces the existing one. In the *Replace IFMAP Certificate Confirmation* dialog box, click **Yes**.

Generating Certificate Signing Requests

You can generate a CSR (certificate signing request) that you use to obtain a signed certificate from your own trusted CA. Once you receive the signed certificate, you can import it to the member, as described in Uploading Certificates below.
To generate a CSR:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox, and then click **IF-MAP Client Certificate** -> **Create Signing Request** from the Toolbar.
2. In the *Create Certificate Signing Request* dialog box, enter the following:
    - **Secure Hash Algorithm and Key Size:** You can select SHA-1 and a RSA key size of 1024 or 2048. SHA-256 (SHA-2) can be selected together with a RSA key size of 2048 or 4096. The default value is SHA-256 2048.
    - **Common Name**: Specify the domain name of the member. You can enter the FQDN of the appliance.
    - **Organization**: Enter the name of your company.
    - **Organizational Unit**: Enter the name of your department.
    - **Locality**: Enter a location, such as the city or town of your company.
    - **State or Province**: Enter the state or province.
    - **Country Code**: Enter the two-letter code that identifies the country, such as US.
    - **Admin E-mail Address**: Enter the email address of the appliance administrator.
    - **Comment**: Enter information about the certificate.
3. Click **OK**.

Uploading Certificates

When you receive the certificate from the CA, the appliance finds the matching CSR and takes the private key associated with the CSR and associates it with the newly imported certificate. The appliance then automatically deletes the CSR.
To import a certificate:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox, and then click **IF-MAP Client Certificate** -> **Upload Certificate** from the Toolbar.
2. Navigate to where the certificate is located and click **Open**.
3. If the appliance already has an existing IF-MAP client certificate, the new certificate replaces the existing one. In the *Replace IF-MAP Certificate Confirmation* dialog box, click **Yes**.

Downloading Certificates

You can download the current certificate or a self-signed certificate. To download a certificate:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox, and then click **IF-MAP Client Certificate** -> **Download Certificate** from the Toolbar.
2. Navigate to where you want to save the certificate, enter the file name, and then click **Save**.

Overriding IF-MAP Publishing Settings

When you enable IF-MAP publishing at the Grid level, all members, networks (IPv4 and IPv6), and DHCP ranges (IPv4 only) in the Grid inherit the same setting. To control which ip-mac and ip-duid metadata is published for specific leases that belong to a specific network or address range, you can override the Grid settings at a specific member, network, or range level. Note that you must first enable the IF-MAP service at the Grid and member levels in order to enable or disable IF-MAP publishing at other levels. For example, if you want the DHCP server to publish IF-MAP data for specific leases in a specific network that is served by a specific member, you must first enable the IF-MAP service at the Grid and member levels, as described in Configuring a Grid to Support IF-MAP above. Then, you can enable IF-MAP publishing at the range level, as described in this section.
Though you can configure and save the settings of IF-MAP publishing any time at any level, the publishing does not actually happen unless the IF-MAP service is enabled at the Grid or member level. If a network or DHCP range is served by a specific member and you want to enable IF-MAP publishing for the network or range, you must first enable the IF-MAP service for the specified member.
To override IF-MAP publishing settings:

1. **Member**: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
   Network: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> *network* checkbox, and then click the Edit icon.
   DHCP Range: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> *networ*k -> *addr_range* checkbox, and then click the Edit icon.
2. In the editor, click **Toggle Advanced Mode**, and then click the **IF-MAP** tab.

3. Click **Override** and complete the following:
    - **Enable IF-MAP Publishing**: Select this checkbox to instruct the DHCP server to publish metadata to the IF-MAP server when the IF-MAP service is enabled for the Grid or member. Clear this checkbox so the DHCP server does not publish metadata to the server.

Deleting Data from the IF-MAP Server

The appliance allows you to delete IF-MAP data from the IF-MAP server. You can delete all IF-MAP data published by a specific member. You can also define how the IF-MAP server handles the deletion of existing metadata before the IF-MAP client publishes another update.

Deleting All Data

You can delete all IF-MAP data published by a specified member. To delete data published by all members in a Grid, you must delete data for each member individually.
To delete IF-MAP data published by a member from the IF-MAP database:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab, and then click **Clear** -> **IF-MAP Data** from the Toolbar.
2. In the *Purge IF-MAP Data* dialog box, click **Select Member** to select a member. If there are multiple members, Grid Manager displays the *Member Selector* dialog box from which you can select one. Click the member name in the dialog box, and then click **Purge** to delete all the DHCP data published by the Grid member. You can also click **Clear** to clear the displayed member and select a new one.

Deleting Existing Data Before Publishing

You can define how the IF-MAP server deletes existing metadata before an IF-MAP client publishes new data. You can configure the IF-MAP client to instruct the server to always delete existing data, never delete it, or delete the data before a specified time period.
To define how the IF-MAP server deletes DHCP data before the next publish:

1. From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
2. In the *Grid DHCP Properties* editor, click **Toggle Advanced Mode**.
3. Click the **IF-MAP** tab and complete the following:
    - **Enable IF-MAP**: Select this checkbox to enable the IF-MAP service.
    - **Delete existing metadata**: You can define how the IF-MAP server deletes the existing metadata before the IF-MAP client publishes new data. Select one of the following:
        - **Always delete**: Select this to always delete existing metadata before the IF-MAP client publishes updates. This is the default.
        - **Do not delete**: Select this to never delete the existing metadata before the IF-MAP client publishes updates.
        - **Earlier than**: Select this to delete metadata that was published before a given time before the IF-MAP client publishes updates. When you select this option, enter a time value, and then select a time unit from the drop-down list.
4. Save the configuration and click **Restart** if it appears if it appears at the top of the screen.

Starting DHCP Services on a Member

The DHCP service is disabled by default. After you complete the DHCP configuration, you can start DHCP service on a member. To enable the member to provide DHCPv6 service as well, you must start the DHCP service and then enable the DHCPv6 service on the member. In addition, you must specify the DHCP Unique Identifier (DUID) of the member. IPv6 clients use DUIDs to identify the source of the DHCP messages from servers.
To start DHCP service on a member:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> -> **Members** -> *member* checkbox.
2. Expand the Toolbar and click **Start**.
3. In the *Start Member DHCP Service* dialog box, click **Yes**.
4. Grid Manager starts DHCP on the selected member.

You can stop DHCP service on a member by selecting the member checkbox and click **Stop** from the Toolbar. This will stop DHCP service enabled on the LAN port.
To stop DHCP service enabled on the LAN2 port:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox.
2. Click the Edit icon.
3. In the *Member DHCP Properties* editor, select the **General Basic** tab.
4. Clear the checkbox for LAN2 under DHCP interfaces.
5. Save the configuration.

To enable DHCPv6 service on the member:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox.
2. In the *Member DHCP Properties* editor, select the **General Basic** tab.
3. In the **IPv6 Properties** section, do the following:
    - **Server DUID:** Enter the DUID of the member.
    - **Enable DHCPv6 Service**: Select this checkbox.
4. Save the configuration.

Viewing DHCP Member Status

You can view DHCP member status after you configure DHCP properties and start or stop DHCP services on a member.
To view member status:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** section.
2. Grid Manager displays the following information:
    - **Name**: The name of the Grid member.
    - **Status**: The status of the DHCP services on the member. This can be one of the following:
        - **Not Running**: DHCP services have not been started on the member.
        - **Running**: The DHCP services are running properly on the member.
        - **Warning**: The member is connecting or synchronizing with its Grid Master.
        - **Error**: The member is offline, is not licensed (that is, it does not have a DNSone license with the Grid upgrade that permits Grid membership), is upgrading or downgrading, or is shutting down. Note that you can mouse over on the informational icon next to the status to view detailed information.
    - **Comment**: The information you entered for the member.
    - **IPv4 DHCP Utilization**: The percentage of the total IPv4 DHCP utilization of the member. This is the percentage of the total number of DHCP hosts, fixed addresses, reservations, and leases assigned to the member versus the total number of IP addresses (excluding IP addresses in the exclusion range) and all DHCP objects assigned to the member. Note that only enabled objects are included in the calculation. It does not include abandoned addresses or leases. The appliance updates the utilization data every 15 minutes. The appliance displays the utilization data in one of the following colors:
        - **Red**: The DHCP resources are 100% utilized.
        - **Yellow**: The utilization percentage is over the effective high watermark threshold.
        - **Blue**: The utilization percentage is below the effective low watermark threshold.
        - **Black**: The utilization percentage is at any number other than 100%, or within the effective thresholds.
    - **Site**: The site to which the member belongs. This is one of the predefined extensible attributes.

You can select the following additional columns for display:

- **Address**: The IP address of the member.
- **Static Addresses**: The number of static IP addresses.
- **Dynamic Addresses**: The number of dynamically assigned IP addresses.
- **IF-MAP Connection**: The status of the IF-MAP service connection on the member. This can be one of the following.
    - **Stopped**: The DHCP or IF-MAP service on the member is stopped, or the IF-MAP service is not enabled.
    - **Running**: The IF-MAP client is connected to the IF-MAP server and the IF-MAP service is running properly.
    - **Failed**: The IF-MAP client cannot publish data to the IF-MAP server due to some errors.

- **Warning**: Some non-fatal errors occurred. The IF-MAP client attempts to reconnect to the server.

> ⚠ Note
>
> You can mouse over on the informational icon next to the status to view detailed information, including the status description and the timestamp when the status initially changed.

- **IF-MAP Last Update**: The timestamp the status of the IF-MAP service was last updated. For example, if the IF-MAP connection status is **Running** and this field shows 2011-11-20 12:30:42 EST, it means that an IF-MAP operation, such as a publish, was last completed on November 20, 2011 at 12:30:42 Eastern Standard Time.

To view status information about the IF-MAP connection on an independent appliance, from the **Data Management** tab -> **DHCP** tab, click **System DHCP Properties** from the toolbar. The appliance displays the following:

- **IF-MAP Connection**: The status of the IF-MAP service on the independent appliance. A color icon associated with the connection status appears before the status.
- **IF-MAP Connection Information**: Detailed information about the status. On a Grid member, this information appears when you mouse over on the informational icon.
- **IF-MAP Last Update**: The timestamp when the status of the IF-MAP service last changed.

> ⚠ Note
>
> For more information about these fields, see descriptions about Grid member status in this section.

You can view detailed information about a specific member by clicking the member link. Grid Manager displays the following information about the selected member:

- **Network**: The network assigned to the member.
- **Comment**: The information about the network.
- **IPv4 DHCP Utilization**: The percentage of the DHCP usage of the network. This is the percentage of the total number of fixed addresses, reservations, hosts, and active leases on the network over the total IP addresses in the range, excluding the number of addresses on the network. Note that only enabled objects are included in the calculation. It does not include abandoned addresses or leases.
- **Site**: The site to which the DHCP object belongs. This is one of the predefined extensible attributes. In the member panel, you can select the following additional fields for display:
- **Disabled**: Indicates whether the member is disabled or not.
- **IPAM Utilization:** When you define a network, this is the percentage based on the IP addresses in use divided by the total addresses in the network. For example, in a /24 network, if there are 25 static IP addresses defined and a DHCP range that includes 100 addresses, the total number of IP addresses in use is 125. Of the possible 256 addresses in the network, the IPAM utilization is about 50% for this network.

  When you define a network container that contains subnets, this is the percentage of the total address space defined within the container regardless of whether any of the IP addresses in the subnets are in use. For example, when you define a /16 network and then 64 /24 networks underneath it, the /16 network container is considered 25% utilized even when none of the IP addresses in the /24 networks is in use.
  You can use this information to verify if there is a sufficient number of available addresses in a network. The IPAM utilization is calculated approximately every 15 minutes.

- Extensible attributes that associate with the network.

You can also sort the data in ascending or descending order by column. For information, see *Customizing Tables*.

Viewing DHCP Configuration Files

You can view the IPv4 and IPv6 DHCP configuration of a selected member. The format of the configuration file depends on the browser you use.
To view the DHCP configuration of a selected member:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox.
2. Expand the Toolbar, select **View DHCP Configuration**, and then select either **IPv4** or **IPv6**. Grid Manager displays the IPv4 or IPv6 DHCP configuration of the selected member in a new browser. You can print and save the file using the corresponding functions in your browser.

Managing IPv4 DHCP Data

To configure DHCP service for an IPv4 network and the resources in the network, perform the following tasks:

1. Create a network and assign it to Grid members or Microsoft DHCP servers, or an interface on an external discovered device. For information about Adding IPv4 Networks and Modifying IPv4 Networks, see *Configuring IPv4 Networks*.
2. Configure DHCP properties for the network. You can override properties set at the Grid or member level and enter unique values for the network. For information, see *Configuring General IPv4 DHCP Properties* and *Configuring DHCP IPv4 and IPv6 Common Properties.*
3. Optionally, assign zones to a network. For information, see *Associating Networks with Zones*.
4. Add a DHCP range to the network and assign it to a member, a failover association, or a Microsoft DHCP server. For information about Adding IPv4 Address Ranges and Modifying IPv4 Address Ranges, see *Configuring IPv4 Address Ranges*.
5. Optionally, add exclusions to the DHCP range for addresses that are not used for dynamic allocation. For information, see *Configuring IPv4 Fixed Addresses.*
6. Optionally, configure DHCP properties for the address range. You can override properties set at an upper level and enter unique values for the address range. For information, see *Modifying IPv4 Address Ranges*.
7. Optionally, define filters for precise address assignments and apply them to the DHCP range. For information, see *About IPv4 DHCP Filters*.
8. Optionally, add fixed addresses and reservations to the network and configure DHCP properties for them. For information, see *Configuring IPv4 Fixed Addresses* and *Configuring IPv4 Reservations*.

This section explains how to configure and manage IPv4 DHCP data. It contains the following topics:

Configuring the Next Available Network or IP Address

When you create certain objects through Grid Manager, the appliance can obtain the next available IPv4 or IPv6 network from a specific network container. It can also obtain the next available IP address from a specific network or address range. This feature automates the allocation of networks and IP addresses so you can manage your network space more efficiently. You can also use this feature to organize network devices. For example, you can create a reserved range called "Printer Range" to reserve static IP addresses for printers in your network. When you allocate IP addresses for printers, you can have the appliance search for the next available IP address within "Printer Range," and then allocate the next available address to a new printer.

When you create a new network, the appliance can look up the next available network address within a specific network container. The next available network address is the first unused network address in the network container to which you have administrative permissions. For information about creating IPv4 and IPv6 networks using the next available feature, see *Adding IPv4 Networks* and *Adding IPv6 Networks*.

You can also obtain the next available IP address when you define a fixed address, reservation, or host record. The next available IP address is the first unused IP address in a specified network, DHCP range, or reserved range to which you have administrative permissions. For information about creating fixed addresses, reservations, and host records using

the next available feature, see *Configuring IPv4 Fixed Addresses*, *Configuring IPv4 Reservations*, and *Adding Host Records*.

Obtaining the Next Available

The appliance searches for the next available network or IP address based on the context you define when you create an object. For example, when you create a network within a specific network container, the appliance searches for the next available network within the specified container. Similarly, when you drill down to an address range and create an object from there, the appliance looks up the next available IP address within that address range. If you are not within a specific network or address range when you create an object, Grid Manager displays a selector from which you can select the network or address range for the next available network or IP address.
For information about how the appliance select the next available network and IP address, see Guidelines for the Next Available Network and IP Address below.

Guidelines for the Next Available Network and IP Address

The appliance follows certain rules when searching for the next available network and IP address in the specified wizard, network container, and address range.
In a wizard where you can obtain the next available network or IP address, the following applies:

- In a wizard, if you add a network or IP address and then delete it, the appliance excludes it from the next available. When you try to obtain the next available network or IP address in the same wizard, the appliance does not return the deleted network or IP address until you exit the wizard.

In a network, the appliance searches for the next IP address that meets all of the following criteria:

- It does not match any DNS resource record, such as an A or PTR record, that is associated with an IP address.
- It is not assigned to a DHCP fixed address or host address record.
- It is not part of any DNS bulk host record.
- It does not match any unmanaged IP address.
- It is not the network (the first) or broadcast (the last) address in the specified network.
- It is not within any DHCP range in this network.
- It is not within any reserved range in this network.
- It is not within an exclusion range.
- It is not part of a scheduled task that involves a fixed address. For information about how to schedule a task, see *Scheduling Tasks*.

In a DHCP range, the appliance searches for the next IP address that meets all of the following criteria:

- It is not assigned to a fixed address or host record.
- It does not match any unmanaged IP address.
- It is not part of an exclusion range within the DHCP range.
- It is not part of a scheduled task that involves a fixed address.
- It does not match any active DHCP lease.

In a reserved range, the appliance searches for the next IP address that meets all of the following criteria:

- It is not assigned to a fixed address or host record.
- It does not match any unmanaged IP address.
- It is not part of a scheduled task that involves a fixed address.

> **Note**
>
> The appliance does not search for deleted leases in the Recycle Bin.

When multiple users simultaneously request for the next available network or IP address, the appliance returns the same unused network or IP address to all users. The user who first saves the task gets the next available network or IP address. In some cases, other users get an error message telling them that the network or IP address is not available when they save their tasks. They can then request another unused network or IP address or enter a new one.

Configuring IPv4 Networks

When you create an IPv4 network, you can do so from scratch or from a network template that contains predefined properties. When you use a template to create a network, the properties of the template apply to the new network. For information about network templates, see *About IPv4 DHCP Templates*. You can also create an IPv4 network from the Tasks Dashboard, as described in *Tasks Dashboard*.

After you create IPv4 networks, you can combine them into shared networks or create ranges and fixed addresses.

Adding IPv4 Networks

When you configure an IPv4 network, you must assign either Grid members or Microsoft servers to the network. A network cannot be served by a mix of Microsoft and Infoblox DHCP servers. Multiple servers can serve a network, but Grid members and Microsoft servers cannot serve the same network.

A Grid member can serve only one network view. Similarly, a Microsoft server can serve only one network view. Therefore when you assign Grid members to networks, you must assign the members to networks in the same network view. For information, see *Managing IPv4 DHCP Data*.

If you have enabled support for RIR (Regional Internet Registry) updates and are adding an RIR IPv4 network container or network to NIOS, Grid Manager displays an RIR section in the *Add IPv4 Network* wizard. You must enter RIR related information in this section in order for NIOS to associate the newly added network with an RIR organization. For more information about RIR address allocation and updates, see *RIR Registration Updates*.

To add an IPv4 network, complete the following:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab.
2. In the **Networks** section, expand the **Toolbar** and click the **Add** drop-down list and select **Network** -> **IPv4** network or, click the Add icon drop-down list and select **IPv4 Network.**
3. In the *Add Network* wizard, select one of the following and click **Next**:
    - **Add Network**: Click this to add a network from scratch.
    - **Add Network using Template**: To use a template, click this, and then click **Select Template** and select a network template. For information, see *About IPv4 DHCP Options*. The appliance populates the template properties in the wizard when you click **Next**. You can then edit the pre-populated properties, except for **Netmask**.
4. Complete the following and then click **Next**:
    - **Regional Internet Registry**: This section appears only when support for RIR updates is enabled. For information about RIR, see *RIR Registration Updates*. Complete the following to create an RIR IPv4 network container or network:
        - **Internet Registry**: Select the RIR from the drop-down list. The default is **RIPE**. When you select **None**, the network is not associated with an RIR organization.
        - **Organization ID**: Click **Select Organization** and select an organization from the *RIR Organization Selector* dialog box.
        - **Registration Status**: The default is **Not Registered**. When adding an RIR allocated network, you can change this to **Registered** and select the **Do not update registrations** checkbox below. Note that when you select **API** as the communication method, the registration status will be updated automatically after the registration update is completed. However, when you select **Email** as the communication method, the registration status will not be automatically updated. If you are creating a new network and the registration update is completed successfully, the status will be changed to **Registered**. If the update fails, the status will be changed to **Not Registered**. The updated status and timestamp are displayed in the **Status of last update** field in the *IPv4 Network Container* or *IPv4 Network* editor.
        - **Registration Action**: Select the registration action from the drop-down list. When you select **Create**, the appliance creates the IPv4 network and assigns it to the selected organization. When you select **None**, the appliance does not send registration updates to RIPE. When you are adding an existing RIR allocated network to NIOS, select **None**. When you are adding networks to an RIR allocated network (a parent network), select **Create**. Ensure that the parent network associated with an RIR organization already exists.

        - **Do not update registrations**: Select this checkbox if you do not want the appliance to submit RIR updates to RIPE. By default, the appliance sends updates to the RIR database based on the configured communication method.
- **Network View**: This appears only when you have multiple network views. From the drop-down list, select the network view in which you want to create the network.
- **Netmask**: Enter the netmask or use the netmask slider to select the appropriate number of subnet mask bits for the network. The appliance supports /1 to /32 netmasks. Note that when you use a template that contains a fixed netmask, you cannot adjust the netmask for this network.
  Microsoft servers can serve networks with /1 to /31 netmasks. Infoblox DHCP servers can serve networks with /8 to /32 netmasks.
  Since Infoblox DHCP servers do not support /1 to /7 networks, you can assign these networks to Microsoft DHCP servers only. You can create DHCP ranges and fixed addresses within these subnets.
- **Networks**: Do one of the following to add new networks:
    - Click the Add icon to enter a new network. Grid Manager adds a row to the table. Enter the network address in the **Network** field. Click the Add icon again to add another network.
      Or
    - Click the Next Available icon to have the appliance search for the next available network. Complete the following in the Next Available Networks section:
    - **Create new network(s) under**: Enter the network container in which you want to create the new network. When you enter a network that does not exist, the appliance adds it as a network container. When you enter a network that is part of a parent network, the parent network is converted into a network container if it does not have a member assignment or does not contain overlapping address ranges, fixed addresses, reservations, shared networks, and host records. When you enter a network that has a lower CIDR than an existing network, the appliance creates the network as a parent network and displays a message indicating that the newly created network overlaps an existing network. You can also click **Select Network** to select a specific network in the *Network Selector* dialog box. For information about how the appliance searches for the next available network, see *Obtaining the Next Available*.
    - **Number of new networks**: Enter the number of networks you want to add to the selected network container. Note that if there is not enough network space in the selected network to create the number of networks specified here, Grid Manager displays an error message. The maximum number is 20 at a time. Note that when you have existing networks in the table and you select one, the number you enter here includes the selected network.
    - Click **Add Next** to add the networks. Grid Manager lists the networks in the table. You can click **Cancel** to reset the values.
      Note that you must click Add Next to add the network container you enter in the Next Available Networks section. If you enter a network in the Next Available Networks section and then use the Add icon to add another network, the appliance does not save the network you enter in the Next Available Networks section until you click Add Next.
- **Comment**: Enter useful information about the network, such as the name of the organization it serves.
- The **Sync to MGM** drop-down list is available only on the managed Grid when it remains joined with the Multi-Grid Master. Select one of the following from the **Sync to MGM** drop-down list:
    - **Yes**: Select this to enable synchronization of networks between the managed Grid and Multi-Grid Master.
    - **No**: Select this to disable synchronization of networks between the managed Grid and Multi-Grid Master.
      Note that if you have selected No at the parent network (disabled synchronization) and if you try to select Yes when adding a child network, the appliance returns an error. This means that you cannot override the settings at the child level if you have already restricted synchronization at the parent network.
    - **Use Inherited Setting**: Select this is to inherit synchronization settings from the parent object.
- **Automatically Create Reverse-Mapping Zone**: This function is enabled if the netmask of the network equals /8, /16, or /24. Select this to have the appliance automatically create reverse-mapping zones for the network. A reverse-mapping zone is an area of network space for which one or more name servers have the responsibility for responding to address-to-name queries. These zones are created in the DNS view assigned to receive dynamic DNS updates at the network view level.
- **Disable for DHCP**: Select this if you do not want the DHCP server to provide DHCP services for this network at this time. This feature is useful when you are in the process of setting up the DHCP server. Clear this after you have configured the server and are ready to have it serve DHCP for this network. Note

that disabling an IPv4 network may take a longer time to complete depending on the size of the data.

The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*.

To delegate authority for this network, complete the following:

Delegate authority from the Grid Master

- **Delegate To**: This field indicates whether the authority for the network you want to create has already been delegated to a Cloud Platform Appliance. Click **Select** to choose the Cloud Platform Appliance to which you want to delegate authority. The *Member Selector* displays only Cloud Platform Appliances in the Grid. Click the member, and Grid Manager displays the member name next to this field. This cloud member now assumes authority for this network, and the Grid Master does not have authority anymore. You can also click **Clear** to remove authority delegation from the selected Cloud Platform Appliance and return authority back to the Grid Master.

5. Click **Next** and add a Grid member or Microsoft server as a DHCP server for the network. A network can be served by either Grid members or Microsoft servers, but not both at the same time.
    - Click the Add icon and select one of the following options:
        - **Add Infoblox Member**: Select this option to add a Grid member as a DHCP server for the network. Select the Grid member from the *Member Selector* dialog box. Keep in mind, DHCP properties for the network are inherited from this member. The network can be served by multiple members, but a member can serve networks in one network view only.
          Or
        - **Add Microsoft Server**: Select this option to add a Microsoft server as a DHCP server for the network. Select the Microsoft server from the *Microsoft Server Selector* dialog box.
6. Click **Next** to associate Active Directory Sites with the network. For more information, see *Associating Active Directory Sites with Networks*.
7. Click **Next** to override DHCP properties as described in *Configuring DHCP Properties*. This only applies if you are adding a network that is served by an Infoblox Grid member.
   Or
8. (*Applies only with Network Insight*) Click **Next** to initiate or disable discovery of the new network(s). *This step is not required for creating a new network*. Discovery settings differ based on whether you are defining one network or multiple networks.
    - **Configuring one network**: Discovery settings include the following: **Enable Discovery** and **Enable Immediate Discovery**, selecting a Probe member to perform the discovery; and **Polling Options**, which define how the network will be discovered by the Probe member, including the ability to enable or disable the use of **SNMP Credentials** and **CLI Credentials**, along with **Switch Port Data Collection** settings. By default, all Polling Options discovery settings are inherited from the parent network (or Grid, if no parent exists) unless you click **Override**. Polling Options govern the protocols used to query and collect information about the network devices being discovered. For more information, see the section *Configuring Discovery Properties* for a complete description of discovery polling options.
      Or
    - **Configuring more than one network**: If the networks are child networks, they automatically inherit the settings of the parent network, including discovery settings and the discovery member. Discovery is disabled for any parent networks. These settings will not appear in the wizard page. For discovery of multiple networks, you can only enable or disable **Immediate Discovery**.
9. Assign VLAN objects to the network. For more information, see *VLAN Management*.
10. As part of creating a network in IPAM or DHCP, you can provision the network on an actual device (switch, router, or switch-router), that is discovered and managed through the Grid Manager.
    - Begin by checking the **Enable Network Provisioning** checkbox, and clicking the **Select Device** button. Choose your device from the Device Selector dialog. Click **Clear** to remove the setting. For more information, see the section *Using the Device Selector*.
    - If you performed DHCP configuration in the previous step of the Add Network Wizard, the **Router IP** value will automatically be populated with the DHCP Router IP address value. Otherwise, you enter the standard router IP address.
    - For example, if Grid Manager discovers and manages a router 172.16.22.1, the IP value 172.16.22.1 should be entered in the **Router IP** field.

- IF required for the newly provisioned network to ensure that attached devices receive DHCP auto-configuration, enable the **DHCP Forwarding** checkbox. For this setting, if a DHCP Failover was previously configured, the IP addresses defined for DHCP failover are automatically used for the DHCP forwarding configuration.
- You will also need to choose an interface on the selected device on which to provision the network by selecting it from the **Interface** drop-down menu. Grid Manager ensures that only those interfaces that can support provisioning, and are available for provisioning (that do not have an **Operation Status** of Up), appear in the drop-down menu.
- Otherwise, when creating networks and provisioning them on managed devices, you can create a VLAN on which to provision the network by clicking the **Create VLAN** option and entering the **VLAN Name** and **VLAN ID**. Ensure that the **VLAN ID** value you enter is appropriate for the application. Do not create a new VLAN and provision a network for a VLAN value that is already actively carrying traffic for another routing domain.
  If a selected device does not support VLANs, the **Create VLAN** option will not appear.

11. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Managing Extensible Attributes*.
    If you are adding an RIR network, the RIR network attribute table appears. For information about these attributes and how to enter them, see *RIR Network Attributes.* You can preview the information before the appliance submits updates to the RIPE database. To preview registration updates, click **Preview RIR Submissions**. For more information, see *Previewing Registration Updates*.
    You cannot leave an optional RIR attribute value empty. If you do not have a value for an RIR attribute, you must delete it from the table. You can enter up to 256 characters for all RIR attributes.
    You need to assign a **Subscriber Member Site** to add subscriber service related extensible attributes in order to populate Subscriber Cache.
12. As the final step in the Add IPv4 Network wizard, you define when Grid Manager provisions the new network by scheduling it. You also schedule when the associated port control task executes (if a port configuration has been specified).
    - To create the new network and its associated port configuration immediately, select **Now**. Grid Manager synchronizes the port control task to take place at the same time as the creation of the new network.
    - You can choose to have Grid Manager execute the port control task at a later time by selecting **Later**.
    - Choose a **Selected time** by entering or selecting a Start Date (click the calendar icon to choose a calendar date) and a Start Time, and choose a Time Zone.
13. Choose one of the following from the **Save & ...** drop-down menu:
    - Click **Save & Close** to add the new network and close the wizard (this is the default).
    - Click **Save & Edit** to add the new network and launch the editor.
    - Click **Save & New** to add the new network and launch the wizard again to add another network.

> ⚠ Note
>
> At any step during the wizard, you can click **Schedule for Later** to schedule the task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks.*

After you create a network, you can perform the following:

- Use the split network feature to create subnets for the network. For information, see *Splitting IPv4 Networks into Subnets*.
- Use the join networks feature to create a parent network that encompasses multiple subnets into a larger network. For information, see *Joining IPv4 Networks*. You can also create a shared network for subnets that are on the same network segment.

Networks served by Microsoft servers do not support the split and join functions.

Viewing Networks

You can view IPv4 networks from the **IPAM** tab -> Net Map and List panels. The Net Map panel provides a graphical view of your networks and the List panel displays the networks in table format. For more information about *Pv4 Network Map* and IPAM Home see, *Managing IPv4 Networks.*

You can also view a list of IPv4 and IPv6 networks in the **DHCP** tab -> **Networks** tab -> **Networks** panel. This panel displays all IPv4 and IPv6 networks.

In any of these panels, you can use filters or the **Go to** function to navigate to a specific network. You can also create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*. You can add, delete, or edit a network. You can also monitor the DHCP utilization of a selected network.

When viewing networks, you can choose to view them in one of the following views:

- Click **Toggle Hierarchical View** to view networks hierarchically in a parent-child structure (networks in a network container). You can view detailed information about the networks by clicking the network link and drilling down to the lowest hierarchical level, and then opening a network. To go back to a previous hierarchical view, click the link of the corresponding level in the breadcrumb. The hierarchical view is the default view.
- Click **Toggle Flat View** to display a flat list of all networks and network containers. The parent and child networks are listed separately in the flat view.

Depending on where you view your networks, Grid Manager displays some of the following information by default. You can also select specific information for display.

- **Network**: The network address.
  The network is displayed in one of the following colors:
  - **Yellow**: The network is unmanaged.
  - **Blue**: The selected network.
  - **Gray**: The network is currently not available as a NIOS network object.
- **Comment**: The information you entered about the network.
- **IPAM Utilization**: This information is available for IPv4 networks only. It displays the percentage based on the IP addresses in use divided by the total addresses in the network. For example, in a /24 network, if there are 25 static IP addresses defined and a DHCP range that includes 100 addresses, the total number of IP addresses in use is 125. Of the possible 256 addresses in the network, the IPAM utilization is about 50% for this network. The appliance updates the IPAM utilization data immediately for a network container, but for a network, it is updated every 15 minutes.
  The IPAM utilization data is displayed in one of the following colors:
  - **Red**: The IPAM utilization percentage is above the configured Trigger value.
  - **Blue**: The IPAM utilization percentage is below the configured Trigger value.
- **Site**: The site to which the network belongs. This is one of the predefined extensible attributes.
- **Protocol**: Displays whether the network is an IPv4 or IPv6 network.
- **Disabled**: Indicates if the network is disabled. You can double-click a row and select the checkbox in this column to disable the network. Grid Manager displays a warning message when you select the checkbox. Click **Yes** to confirm or **No** to cancel. Note that disabling an IPv4 network may take a longer time to complete depending on the size of the data.
- **Leaf Network**: Indicates whether the network is a leaf network or not. A leaf network is a network that does not contain other networks.
- **IPv4 DHCP Utilization**: This information is available for IPv4 networks only. It displays the percentage of the total DHCP usage of theIPv4 network. This is the percentage of the total number of DHCP hosts, fixed addresses, reservations, and active leases in the network divided by the total number of IP addresses (excluding IP addresses in the exclusion range) and all DHCP objects in the network. Note that only enabled addresses are included in the calculation. It does not include abandoned addresses or leases. The appliance updates the utilization data approximately every 15 minutes. The utilization data is displayed in one of the following colors:
  - **Red**: The DHCP resources are 100% utilized.
  - **Yellow**: The DHCP utilization percentage is over the effective high-water mark threshold.
  - **Blue**: The DHCP utilization percentage is below the effective low-water mark threshold.
  - **Black**: The DHCP utilization percentage is at any number other than 100%, or it is not above and below any threshold.

You see the following when RIR is enabled (for more information, see *RIR Registration Updates*):

- **RIR Organization**: This appears only if support for RIR updates is enabled. This displays the name of the RIR organization to which the network is assigned.
- **RIR Organization ID**: This appears only if support for RIR updates is enabled. This displays the ID of the RIR organization to which the network is assigned.

- **RIR Registration Status**: This appears only if support for RIR update is enabled. This field displays the RIR registration status. This can be **Registered** or **Not Registered**. **Registered** indicates that the network has a corresponding entry in the RIPE database.
- **Last Registration Updated**: Displays the timestamp when the last registration was updated. The displayed timestamp reflects the timestamp used on the Grid Master.
- **Status of Last Registration Update**: Displays the registration status and communication method of the last registration update. The status can be Pending, Sent, Succeeded, or Failed. Each time you send a registration update to create, modify, or delete a network container or network, the updated status will be displayed here. If you have selected not to send registration updates, the previous status is retained.

You see the following only with Network Insight (For information, see *Infoblox Network Insight*):

- **Discovery Enabled**: Indicates whether discovery is allowed on the network container or the network.
- **Managed**: Indicates whether the network is set to Managed status under NIOS.
- **First Discovered**: The date and timestamp of the first occasion that NIOS discovered the network.
- **Last Discovered**: The date and timestamp of the last occasion that NIOS performed discovery on the network.

You see the following when the Cloud Network Automation license is installed on the Grid Master (For information, see *Deploying Cloud Network Automation*):

- **Cloud Usage**: This field indicates whether this object is associated with any specific cloud extensible attributes or within the scope of delegation. It can be one of the following:
  - **Cloud from adapter**: Indicates that this object has been created by a cloud adapter and it may or may not be within a scope of delegation at the moment.
  - **Cloud from delegation**: Indicates that this object is within the scope of delegation or the object itself defines a scope of authority delegation, and it is not created by a cloud adapter.
  - **Used by cloud**: Indicates that this network or network container is associated with the extensible attribute **Is External** or **Is Shared** and the value is set to True, which implies the network is a private or shared network managed by the CMP, and it is not **Cloud from adapter** or **Cloud from delegation**.
  - **Non-cloud**: The object is a regular NIOS object and is not within the scope of any authority delegation nor is it associated with any of these extensible attributes: **Cloud API Owned**, **Is External**, or **Is Shared**. NIOS admin users can modify this object based on their permissions.
- **Owned By**: A cloud object can be owned by the Grid Master or the cloud adapter. When the object is created by the Cloud Platform member, this shows **Grid**. If the object is created by the cloud adapter, this shows **Adapter**.
- **Delegated To**: This tells you whether a cloud object has been delegated to a Cloud Platform Appliance or not. If the cloud object has a parent object and the parent has been delegated, this field shows the parent delegation and you cannot modify the field.
- Extensible attributes (**Building**, **Country**, **Region**, **State**, and **VLAN**): You can select the extensible attributes such as Building, Country, Region, State, and VLAN for display. When you enable other features such as RIR, Network Insight, and Cloud Network Automation, you can select additional attributes for display.

You can sort the list of networks in ascending or descending order by certain columns. For information about customizing tables in Grid Manager, see *Customizing Tables*.

You can also modify some of the data in the table. Double-click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*. You can edit values of inheritable extensible attributes by double-clicking on the respective row. If an extensible attribute has an inherited value, then the cell is highlighted in blue when you perform an inline editing. The *Descendant Actions* dialog box is displayed when you click **Save**. For information, see *Managing Inheritable Extensible Attributes at the Parent and Descendant Level*. If you delete the value of an inheritable extensible attribute at the parent level, you can choose to preserve the descendant value or remove it. For information, see *Deleting Inheritable Extensible Attributes Associated with Parent Objects*.

Viewing Network Details

You can view detailed information about a specific network by clicking the network link. Grid Manager displays the objects in the network, including DHCP ranges, hosts, fixed addresses and roaming hosts. It displays the following information about the network:

- **IP Address**: The IP address of a DHCP object, such as a DHCP range, fixed address, reservation, host configured for DHCP, or roaming host with an allocated IP address. For a DHCP range, this field displays the start

and end addresses of the range. For a host that has multiple IP addresses, each IP address is displayed separately. Note that the appliance highlights all disabled DHCP objects in gray.
The IP address is displayed in one of the following colors:
    - **Yellow**: The IP address is unmanaged.
    - **Blue**: The IP address is excluded.
    - **Pink**: Indicates IP address conflicts.
    - **Gray**: The IP address is currently not available as a NIOS object.
- **Type**: The DHCP object type, such as **DHCP Range** or **Fixed Address**.
- **Name**: The object name. For example, if the IP address belongs to a host record, this field displays the host name.
- **Comment**: The information you entered for the object.
- **IPv4 DHCP Utilization**: The percentage of the total DHCP usage of a DHCP range. This is the percentage of the total number of fixed addresses, reservations, hosts, and active leases in the DHCP range divided by the total IP addresses in the range, excluding the number of addresses in the exclusion ranges. Note that only enabled objects are included in the calculation. It does not include abandoned addresses or leases.
- **Site**: The site to which the DHCP object belongs. This is one of the predefined extensible attributes. You can select the following additional columns for display:
- **Static Addresses**: Indicates whether the IP address is a static address.
- **Dynamic Addresses**: Indicates whether the IP address is a dynamically assigned address.
- **Disabled**: Indicates whether the object is disabled. You can double-click a row and select the checkbox in this column to disable the network. Grid Manager displays a warning message when you select the checkbox. Click **Yes** to confirm or **No** to cancel. Note that disabling an IPv4 network may take a longer time to complete depending on the size of the data.
- **Priority**: Displays the priority of a DHCP range when NAC filters are applied.
- Available extensible attributes.

You can also perform the following in this panel:

- Modify some of the data in the table. Double-click a row, and either modify the data in the field or select an item from a drop-down list. Click **Save** to save the changes. Note that some fields are read-only. You can edit values of inheritable extensible attributes by double-clicking on the respective row. If an extensible attribute has an inherited value, then the cell is highlighted in blue when you perform inline editing. The *Descendant Actions* dialog box is displayed when you click **Save**. For information, see *Managing Inheritable Extensible Attributes at the Parent and Descendant Level*. If you delete the value of an inheritable extensible attribute at the parent level, you can choose to preserve the descendant value or remove it. For information, see *Deleting Inheritable Extensible Attributes Associated with Parent Objects*.
- Sort the displayed data in ascending or descending order by column.
- Click **Go to IPAM View** to view information about the object in the **IPAM** tab.
- Add new objects, such as DHCP ranges, to the network.
- Delete or schedule the deletion of a selected object or multiple objects.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters.*
- Print or export the data.

Modifying IPv4 Networks

You can modify existing network settings and override the Grid or member DHCP properties, with the exception of the network address and netmask.

To modify an IPv4 network, perform the following:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network* checkbox, and then click the Edit icon.
   Or
   From the **Data Management** tab, select the **IPAM** tab -> *network* checkbox, and then click the Edit icon.
2. The *IPv4 Network* editor contains the following basic tabs from which you can modify data:
    - **Genera Basic**: You can modify the following fields:
        - **Comment**: The information you entered for the network.

- **Disabled**: This field is displayed only if the selected network is a network without a child network under it. You can disable and enable existing networks instead of removing them from the database, if the selected network does not have a child subnet. This feature is especially helpful when you have to move or repair the server for a particular network. Note that disabling an IPv4 network may take a longer time to complete depending on the size of the data.
  Restricting synchronization of a network
- **Disable sync to MGM**: Select this checkbox to disable synchronization of a network from the managed Grid to the Multi-Grid Master. This checkbox is available only on the managed Grid when it remains joined with the Multi-Grid Master.
  When the Cloud Network Automation license is installed on the Grid Master, Grid Manager displays the following information in the **Cloud** section: **Cloud Usage**, **Owned By**, and **Delegated To**. You cannot modify these fields. For more information, see Viewing Networks below.
- **Member Assignment**: Add or delete a Grid member that provides DHCP services for this network. For information, see Adding IPv4Networks above.
- **IPv4 DHCP Options**: Keep the inherited DHCP properties or override them and enter unique settings for the network. For information, see *Defining IPv4 DHCP Options*.
- **Discovery**: Checking the **Enable Discovery** checkbox informs NIOS to begin discovering the network after you click **Save and Close**. You manage discovery polling settings local to each network from this page. For a complete overview of features on this page, see *Discovering Devices and Networks* and its subsections.
- **Discovery Exclusions**: IP Addresses and IP ranges can be locally excluded from discovery by clicking the Add icon and selecting **Add IP Address** or **Add IP Range**. These IP addresses or IP ranges are selected from within the chosen network. For related information, see *Excluding IP Addresses from Discovery* and its subsections.
- **Discovery Blackout**: Define extended time periods and regularly scheduled times when discovery and/or Port Configuration tasks will not take place on a network. Editing a network under DHCP, blackout settings apply only to the specified network. You also specify the scheduled time when the blackout period begins, and the duration of the blackout period. By default, the network inherits its discovery blackout settings from the Grid level. For related information, see *Defining Blackout Periods* and its subsections.
  Note that discovery blackout settings also can be defined for DHCP ranges.
- **RIR Registration**: Modify RIR network information. This tab appears only when support for RIR updates is enabled. For information, see *Modifying RIR Network Data*.
- **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific network. You can also modify the values of the extensible attributes. For information, see *About Extensible Attributes.* You can edit values of inheritable extensible attributes by -clicking on the respective column. If an extensible attribute has an inherited value, then the cell is highlighted in blue when you perform inline editing. The *Descendant Actions* dialog box is displayed when you click **Save**. For information, see *Managing Inheritable Extensible Attributes at the Parent and Descendant Level*. If you delete the value of an inheritable extensible attribute at the parent level, you can choose to preserve the descendant value or remove it. For information, see *Deleting Inheritable Extensible Attributes Associated with Parent Objects*.
- **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions Managing Permissions*.

3. Optionally, click **Toggle Advanced Mode** to display the following tabs from which you can modify advanced data.
   - **General Advanced***:* You can associate zones with a network. For information, see *Associating Networks with Zones.*
   - **IPv4 DDNS**: Keep the inherited DDNS settings or override them and enter unique settings for the network. Note that you must click **Override** and select **Enable DDNS updates** for the DDNS settings you configure in this tab to take effect. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
   - **IPv4 BOOTP/PXE**: Keep the inherited BOOTP properties or override them and enter unique settings for the network. For information, see *Configuring IPv4 BOOTP and PXE Properties*.
   - **Filters**: You can keep the inherited IPv4 logic filters or override them and add a new IPv4 logic filter. For information, see *Applying Filters to DHCP Objects.*
   - **IPv4 DHCP Thresholds**: Keep the inherited thresholds settings or override them and enter unique settings for the network. For information, see *Configuring Thresholds for DHCP Ranges*.

4. Save the configuration or click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Deleting IPv4 Networks

When you delete a network, all of its data, including all DHCP records, subnets, and records in its subnets, is deleted from the database. Due to the potentially large loss of data that can occur when you delete a network, the appliance stores the deleted network in the Recycle Bin. You can restore a deleted network from the Recycle Bin, if enabled. You can also disable a network instead of deleting it.

To delete a network, perform the following:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network* checkbox, and then select **Delete** or **Schedule Delete** from the Delete drop-down menu.
2. To delete the network now, in the *Delete Confirmation* dialog box, click **Yes**. Grid Manager displays a warning message. Click **Yes** to continue or **No** to cancel the process. To schedule the deletion, see *Scheduling Deletions*. You can also choose to export all network data to a CSV file before deleting. To do this, click the **Export & Delete** button. For more information about this option, see *Exporting and Deleting Networks*.

The appliance puts the deleted network in the Recycle Bin, if enabled. Click **Restore** in the Recycle Bin to recover the deleted data. Click **Yes** in the *Restore Item* dialog box to restore or **No** to cancel the process.

> ⚠ Note
>
> - Any port reservation associated with the deleted network will also be deleted without user intervention.
> - Deleting and restoring an IPv4 network may take a longer time to complete depending on the size of the data.
> - You cannot delete a network that has a VLAN object assigned to it. For more information, see *Assigning VLANs to a Network*.

Exporting and Deleting Networks

Before deleting a network or scheduling a network for deletion, you can choose to export all network data to a CSV file. To do this, click the **DHCP** tab > **Networks** tab > **Networks** section > *network* checkbox, select **Delete** or **Schedule Delete** > **Export & Delete** button.

The deleted network CSV file is downloaded and saved to your system as a .zip file called DeletedNetworks.zip. All parent networks, sub-parent networks (if they exist), and DHCP objects are exported to the CSV file.

If you schedule a deletion, the **Export & Delete** option is available only for the **Delete Now** option. You cannot export network data if you schedule the deletion for a later date or time.

The **Export & Delete** option supports up to 1.5 million network objects in a single delete operation.

Configuring IPv4 Shared Networks

You can combine individual contiguous networks into a shared network to allow the DHCP server to assign IP addresses from any subnet (that resides on the same network interface) in the shared network.

Before creating a shared network, you must first create the subnets. For example, you must first create the networks `10.32.1.0` and `10.30.0.0` before designating them to a shared network. For more information, see *About Shared Networks.*

Adding IPv4 Shared Networks

To add a shared network, complete the following:

1. Select the **Data Management** tab.
2. If you have more than one network view in the system, select the network view in which you want to add the network.
3. Select the **DHCP** tab -> **Networks** tab.
4. In the **Shared Networks** section, select **IPv4 Shared Network** from the Add icon drop-down menu, or expand the **Toolbar**, click the **Add** drop-down list and select **Shared Network** -> **IPv4.**
5. In the *Add IPv4 Shared Network* wizard, complete the following and click **Next**:
    - **Name**: Enter the name of the shared network.
    - **Comment**: Enter information about the shared network.
    - **Disabled**: Select this if you want to enable the shared network at a later time. You can disable and enable existing networks instead of removing them from the database. This feature is especially helpful when you have to move or repair the server for a particular network.
6. Perform the following to add networks:
    a. Click the Add icon.
    b. In the *Select Network* dialog box, select the networks that you want to include in the shared network. Ensure that the networks are served by the same Grid members to avoid DHCP inconsistencies.
7. Click **Next** to configure or override DHCP options as described in *Defining IPv4 DHCP Options.*
8. Click **Next** to enter values for required extensible attributes or add optional extensible attributes for the shared network. For information, see *Using Extensible Attributes.*
9. Save the configuration or click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks.*

Viewing Shared Networks

To view IPv4 and IPv6 shared networks, complete the following:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Shared Networks**.
2. Grid Manager displays the following information:
    - **Name**: The name of the shared network.
    - **Protocol**: Displays whether the network is an IPv4 or IPv6 network.
    - **Comment**: The information you entered about the shared network.
    - **IPv4 DHCP Utilization**: The percentage of the DHCP utilization of the networks that belong to the shared network. This is the percentage of the total number of available IP addresses from all the networks that belong to the shared network versus the total number of all IP addresses in all of the networks in the shared network.
    - **Site**: The site to which the shared network belongs. This is one of the predefined extensible attributes.

You can select **Disabled** or available extensible attributes for display. You also can view detailed information about a network in a shared network by clicking the network link.

In this panel, you can use filters or the **Go to** function to navigate to a specific network. You can also create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.

You can sort the list of networks in ascending or descending order by columns. For information about customizing tables in Grid Manager, see *Customizing Tables*.

You can also modify some of the data in the table. Double-click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables.*

Modifying IPv4 Shared Networks

You can modify existing network settings and override the Grid or member DHCP properties. To modify, complete the following:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Shared Networks** section -> *shared_network* checkbox, and then click the Edit icon.
2. The *Shared Network* editor contains the following tabs from which you can modify data:
   - **General**: Modify the fields **Name**, **Comments**, and **Disabled** as described in the section Adding IPv4 Shared Networks above.
   - **Networks**: Displays the networks that are currently assigned to the shared network. You can add or delete a network. To add a network, click the Add icon. In the *Select Network* dialog box, select the network you want to add. To delete an existing network, select the *network* checkbox, and then click the Delete icon.
   - **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific network. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes.*
   - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions Managing Permissions*.
3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify advanced data:
   - **IPv4 DHCP Options**: Keep the inherited DHCP properties or override them and enter unique settings for the shared network. For information, see *Defining IPv4 DHCP Options*.
   - **IPv4 DDNS**: Keep the inherited DDNS settings or override them and enter unique settings for the shared network. Note that you must click **Override** and select **Enable DDN Supdates** for the DDNS settings you configure in this tab to take effect. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
   - **IPv4 BOOTP/PXE**: Keep the inherited BOOTP properties or override them and enter unique settings for the shared network. For information, see *Configuring IPv4 BOOTP and PXE Properties*.
   - **Filters**: You can keep the inherited IPv4 logic filters or override them and add a new IPv4 logic filter. For information, see *Applying Filters to DHCP Objects*.
     Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.
4. Save the configuration and click **Restart** if it appears at the top of the screen.
   Or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Deleting IPv4 Shared Networks

Though you can delete the networks in a shared network, a shared network must have at least one network in it. To delete a shared network, complete the following:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Shared Networks** section -> *shared_network* checkbox, and then select **Delete** or **Schedule Delete** from the drop-down menu.
2. To delete the shared network now, in the *Delete Confirmation* dialog box, click **Yes**. To schedule the deletion, see *Scheduling Deletions*.

The appliance puts the deleted shared network in the Recycle Bin, if enabled.

Configuring IPv4 Address Ranges

In a network, you define address ranges from which the DHCP server or failover association assigns IP addresses to client requests. When a DHCP client requests an IP address, the appliance allocates an address within a defined DHCP range. The DHCP client can use the assigned IP address until the lease expires.
When you do not assign a DHCP server or failover association to an address range, the range becomes a reserved range. A reserved range contains IP addresses that are reserved for static hosts, not for dynamic assignments. You can allocate the next available IP from a reserved range.
You can also apply filters to DHCP ranges to control how the DHCP server allocates IP addresses. For information about DHCP filters, see *Configuring DHCP Filters*.

Adding IPv4 Address Ranges

To add an IPv4 address range:

1. Navigate to the IPv4 network to which you want to add an address range, and then select **Range** from the Add drop down menu.
   or
   From any panel in the DHCP tab, expand the Toolbar and click **Add** -> **Range** -> **IPv4**.
2. In the *Add IPv4 Range* wizard, select one of the following and click **Next**:
   - **Add Range**: Select this to add an address range from scratch.
     or
   - **Add Range Using Template**: Click **Select Template** and select the template that you want to use. Note that when you use a template to create an address range, the configurations of the template apply to the new range. The appliance automatically populates the range properties in the wizard. You can then edit the pre-populated properties.
3. Complete the following:
   - **Network**: Click **Select Network**. Grid Manager displays the network address here if you have only one network configured. When there are multiple networks, Grid Manager displays the *Select Network* dialog box from which you can select one.
   - **Start:** Enter the first available IP address in the range.
   - **End:** Enter the last available IP address in the range.
   - **Name:** Optionally, enter a name for the range.
   - **Comment:** Enter additional information about the address range.
   - **Disabled for DHCP:** Select this if you want to save the configuration for the address range but do not want to activate the address range yet. You can clear this checkbox when you are ready to allocate addresses from this range.
     The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*. To delegate authority for this range, complete the following:
     Delegate authority from the Grid Master
   - **Delegate To**: This field indicates whether the authority for the range you want to create has already been delegated to a Cloud Platform Appliance. Click **Select** to choose the Cloud Platform Appliance to which you want to delegate authority. The *Member Selector* displays only Cloud Platform Appliances in the Grid. Click the member, and Grid Manager displays the member name next to this field. This cloud member now assumes authority for this range, and the Grid Master does not have authority any more. You can also click **Clear** to remove authority delegation from the selected Cloud Platform Appliance and return authority back to the Grid Master.
4. Click **Next** and select one of the following:
   - **None (Reserved Range)**: Select this if you want to reserve this address range for static hosts. Addresses in this range cannot be allocated as dynamic addresses. You can allocate the next available IP from this range to a static host. This is selected by default.
   - **Grid Member:** Select this if you want a Grid member to serve DHCP for this address range. Select a Grid member from the drop-down list. The drop-down list displays only the Grid members that are associated with the network to which the DHCP range belongs.
   - **Failover Association:** Select this if you want a failover association to serve DHCP for this address range. Click **Select Association**. In the *DHCP Failover Association Selector* dialog box, choose a failover association, and then click the Select icon. The appliance lists failover associations that serve DHCP in the network view of the DHCP range. For information, see *Configuring DHCP Failover*.
5. Click **Next** to configure or override DHCP options as described in *Defining IPv4 DHCP Options.*

   Steps 6-7 apply only in deployments using Network Insight discovery features. Otherwise, skip to Step 8.
6. Click **Next** to initiate or disable discovery of the new DHCP range.
7. Discovery settings include the following: **Enable Discovery** and **Immediate Discovery**, selecting a Probe member to perform the discovery; and **Polling Options**, which define how the network will be discovered by the Probe member. By default, all Polling Options discovery settings are inherited from the parent network unless you click **Override**. Polling Options govern the protocols used to query and collect information about the network devices being discovered. For more information, see the section *Configuring Discovery Properties* for a complete description of discovery Polling Options.
8. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes.*
9. Save the configuration and click **Restart** if it appears at the top of the screen
   or

Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

For information on viewing address ranges in a network, see *Viewing IPv4 DHCP Objects*.

Modifying IPv4 Address Ranges

You can modify settings for the DHCP range. You can also define an exclusion range to prevent the appliance from assigning the addresses in the exclusion range to clients. IP addresses in an exclusion range are excluded from the pool of IP addresses. For more information, see *About Exclusion Ranges*.
To modify an IPv4 address range:

1. From the **DataManagement** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network* -> *addr_range* checkbox, and then click the Edit icon.
2. The *DHCPRange* editor contains the following basic tabs from which you can modify data:
   - **General**: Modify the fields, except the network address, as described in Adding IPv4 Address Ranges above.
     When the Cloud Network Automation license is installed on the Grid Master, Grid Manager displays the following information in the **Cloud** section: **Cloud Usage**, **Owned By**, and **Delegated To**. You cannot modify these fields. For more information, see Adding IPv4 Address Ranges above.
   - **Member Assignment**: Modify the Grid member or failover association that provides DHCP services for the DHCP range as described in Adding IPv4 Address Ranges above.

     When you change the member assignment of DHCP ranges from **Failover Association** to **Grid Member** and then back to **Failover Association**, the leases in the primary and secondary servers fall out of sync. To resynchronize the peers, the failover association of the secondary server is put in the Recover-Wait state for the entire duration of Maximum Client Lead Time while a forced recovery takes place. During this period, only the IP addresses allocated to the primary server are available for lease.
   - **IPv4 DHCP Options**: Keep the inherited DHCP options or override them and enter unique settings for the DHCP range. For information, see *Defining IPv4 DHCP Options.*
   - **Extensible Attributes**: You can add and delete extensible attributes that are associated with a specific DHCP range. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*. You can edit values of inheritable extensible attributes by double clicking on the respective column. If an extensible attribute has an inherited value, then the cell is highlighted in blue when you perform an inline editing. The *Descendant Actions* dialog box is displayed when you click **Save**. For information, see *Managing Inheritable Extensible Attributes at the Parent and Descendant Level*. If you delete the value of an inheritable extensible attribute at the parent level, you can choose to preserve the descendant value or remove it. For information, see *Deleting Inheritable Extensible Attributes Associated with Parent Objects*.
   - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions Managing Permissions*.
3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify advanced data.
   - **IPv4 DDNS**: Keep the inherited DDNS settings or override them and enter unique settings for the DHCP range. Note that you must click **Override** and select **Enable DDN Supdates** for the DDNS settings you configure in this tab to take effect. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
   - **IPv4 BOOTP/PXE**: Keep the inherited BOOTP properties or override them and enter unique settings for the DHCP range. For information, see *Configuring IPv4 BOOTP and PXE Properties*.
   - **Exclusion Ranges**: Configure a range of IP addresses that the appliance does not use to assign to clients. You can use these exclusion addresses as static IP addresses. Enter the start and end addresses of the exclusion range, and optionally, enter information about this exclusion range.
   - **IPv4 DHCP Thresholds**: Keep the inherited thresholds settings or override them and enter unique settings for the DHCP range. For information, see *Configuring Thresholds for DHCP Ranges*.
   - **Filters**: You can keep the inherited IPv4 logic filters or override them and add a new IPv4 logic filter. For information, see *Applying Filters to DHCP Objects.*
     Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

   or

   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Controlling Lease Assignments

You can set parameters to control how the DHCP server responds to lease requests within a specific DHCP range. When you set a DHCP range to deny all leases requests, the appliance does not assign IP addresses within this range to DHCP clients. This is useful when you want DHCP clients with IP addresses within this range to obtain new IP addresses when they renew their leases. When a client with an IP address within this range broadcasts a DHCPREQUEST message for its old IP address, the authoritative DHCP server responds with a DHCPNAK. This causes the client to move to the INIT state and to send a DHCPDISCOVER message for a new IP address.
You can also configure the DHCP server to assign or deny IP addresses within a DHCP range to known and unknown DHCP clients. Known clients include roaming hosts and clients with fixed addresses or DHCP host entries. Unknown clients include clients that are not roaming hosts and clients that do not have fixed addresses or DHCP host entries.
To control how the appliance assigns leases to client requests:

1. **DHCP Range**: From the **Data Management** tab, select the **DHCP** tab -> Networks tab -> Networks -> network -> *addr_range* checkbox, and then click the Edit icon.
2. In the *IPv4 Range* editor, click **Toggle Advanced Mode** if the editor is in basic mode. When the additional tabs appear, click the **IPv4 DHCP Options** tab -> **Advanced** tab and complete the following:

   The **IPv4 DHCP Options** tab is enabled when you select a **Grid Member** or **IPv4 DHCP Failover Association** in the **Member Assignment** tab.
   - **Allow/Deny Clients**
     - **Known Clients**: Select this checkbox, and then select **Allow** or **Deny** from the drop-down list to assign or deny IP addresses within this range to known DHCP clients. Known DHCP clients include roaming hosts and clients with fixed addresses or DHCP host entries. Note that the appliance cannot deny an IP address to a fixed address within this range. You must disable the fixed address if you do not want it to obtain an IP address here.
     - **Unknown Clients**: Select this checkbox, and then select **Allow** or **Deny** from the drop-down list to assign or deny IP addresses within this range to unknown DHCP clients. Unknown DHCP clients include clients that are not roaming hosts and clients that do not have fixed addresses or DHCP host entries.
     - **Deny Leases**: Select **Deny all lease requests for this range** to deny all lease requests from DHCP clients.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Deleting IPv4 Address Ranges

To delete a DHCP range:

- From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network* -> *addr_range* checkbox, and then click the Delete icon.

Configuring IPv4 Fixed Addresses

A fixed address represents a persistent link between an IP address and one of the following:

- MAC address
- Client identifier
- Circuit ID or remote ID in the DHCP relay agent option (option 82)

You can create fixed addresses as described in Adding IPv4 Fixed Addresses below or from the Tasks Dashboard. For information about the Tasks Dashboard, see *The Tasks Dashboard*. You can also create a fixed address when you create a host record or when you convert an active, dynamically leased address to a fixed address. For more information, see *Adding Host Records* and *Converting DHCP Leases*.

When you create a fixed address, you must define a host identifier that the DHCP server uses to match the DHCP client. Every time the DHCP client with the matching identifier requests an IP address, the DHCP server assigns it the same address.
When a DHCP client sends a DHCPDISCOVER, it can include the MAC address or a unique client identifier as option 61 in the DHCP section of the packet. Using a client identifier is especially useful for virtualized server processes that might be moved to different hardware platforms. For information about option 61, refer to *RFC2132, DHCP Options and BOOTP Vendor Extensions*. You can select either the MAC address or client identifier as the host identifier in a fixed address. The DHCP server matches the option 61 value in the client request using either the MAC address or client identifier, depending on your configuration. When a DHCP client renews an IP address using a matching MAC address or client identifier, the DHCP server tracks the allocation of IP addresses and reserves the same IP address for the client.
When you enter a MAC address, you can use one of the following formats:

- aa:bb:cc:dd:ee:ff — Six groups of two hexadecimal digits separated by colons (:)
- aa-bb-cc-dd-ee-ff — Six groups of two hexadecimal digits separated by hyphens (-)
- aabb.ccdd.eeff — Three groups of four hexadecimal digits separated by periods (.)
- aabbcc-ddeeff — Two groups of six hexadecimal digits separated by a hyphen (-)
- aabbccddeeff — One group of 12 hexadecimal digits without any separator

After you save the entry, the appliance displays the MAC address in the AA:BB:CC:DD:EE:FF format.
When a DHCP client requests an IP address through a DHCP relay agent, the agent adds either the circuit ID or remote ID or both, to the DHCP relay agent information option (option 82). For information, see *About the DHCP Relay Agent Option (Option 82)*. When you select the DHCP relay agent option (circuit ID or remote ID) as the host identifier in a fixed address, the DHCP server matches the DHCP client request using either the circuit ID or the remote ID, depending on your configuration. When a DHCP client renews an IP address using a matching relay agent ID, the DHCP server tracks the allocation of IP addresses and reserves the same IP address for the client. Note that leases are not renewed at the standard renewal time (T1) when option 82 information is not available as a unicast renewal. Instead, leases are renewed at the rebinding time (T2) when renewals are sent as broadcasts to the relay agents and contain option 82 information. For information about how to configure the lease time, see *Configuring General IPv4 DHCP Properties*.

Adding IPv4 Fixed Addresses

For Cloud Network Automation, you can create IPv4 fixed addresses within the delegation authority of a Cloud Platform Appliance. The newly created fixed address is forwarded to the Cloud Platform Appliance. For information, see *About Authority Delegation*.
To add an IPv4 fixed address:

1. Navigate to the network to which you want to add a fixed address, and then select **Fixed Address** from the Add drop-down menu.
   or
   From any panel in the **DHCP** tab, expand the Toolbar and click **Add** -> **Fixed Address** -> **IPv4**.
2. In the *Add IPv4 Fixed Address* wizard, select one of the following and click **Next**:
   - **Add Fixed Address**
     or
   - **Add Fixed Address using Template**
     Click **Select Template** and select the template that you want to use. Note that when you use a template to create a fixed address, the configurations of the template apply to the new address. The appliance automatically populates the fixed address properties in the wizard. You can then edit the pre-populated properties.
     i. Complete the following:
        1. **Network**: Click **Select Network**. When there are multiple networks, Grid Manager displays the *Select Network* dialog box from which you can select one.
        2. **IP Address:** Enter the IPv4 address for the fixed address, or click **Next Available IP** to obtain the next available IP address. For information about obtaining the next available IP address, see *About the Next Available Network or IP Address*. Note that for Cloud Network Automation, Next Available IP is not available if the fixed address you want to create is within a delegated range.
        3. If the network of the IP address is served by a Grid member, Grid Manager displays the **Assign IP Address by** section. Select one of the following to match your criteria:

- **MAC Address**: Select this to assign a fixed address to a host with the MAC address that you specify here. Enter the MAC address in the field. For MAC address format, see *Configuring IPv4 Fixed Addresses*.
- **DHCP Client Identifier:** Select this to assign a fixed address to a host with the DHCP client identifier that you specify here. In the field, enter the client identifier of the host to which you want the DHCP server to assign this IP address. The client identifier must be unique within the network.
    - **Match null (\0) at beginning of DHCP client identifier**: This is enabled when you select **DHCP client identifier**. Select this when a DHCP client sends a \000 prefixed to the DHCP client identifier. \0 is the null character. Some DHCP clients (for example, Microsoft) send the client identifier in a \000foo format (with the null character prefix instead of just foo). The client identifier for the requesting host and the client identifier stored in the appliance must match.
- **DHCP Relay Agent:** Select this to assign a fixed address to a host with the circuit ID or remote ID you specify here. From the drop-down list, select **Circuit ID** or **Remote ID**, and then enter the ID in the field. For information about circuit IDs and remote IDs, see *About the DHCP Relay Agent Option (Option 82)*. You can enter the ID in hexadecimal format, such as ex:aa, ab, 1f:cd, or ef:23:56, or in string format, such as abcd or aa:gg. The appliance matches the value you enter here with the value sent by the DHCP client in counted octet sequence format. For information about how to use hexadecimal values, see *DHCP Option Data Types*. The ID is case sensitive and can contain up to 230 characters. Regardless of the entry you enter here, you can define the logging format for the circuit ID and remote ID when Grid Manager displays them in the detailed lease information page. For information about how to configure the logging format, see *Defining Logging Format for DHCP Option 82*.

  Note that you cannot use the same circuit ID or remote ID for different fixed addresses if the addresses are in the same network or the same shared network.

4. **Name**: Enter a name for the Fixed Address. This field is required if the network is served by a Microsoft server. For information, see *Adding Fixed Addresses/Microsoft Reservations*.
5. **Comment:** Optionally, enter additional information about the fixed address.
6. **Disabled:** Select this if you do not want the DHCP server to allocate this IP address at this time.

The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*. This section displays the following information:

- **Cloud Usage**: This field indicates whether this object is associated with any specific cloud extensible attributes or within a scope of delegation. It can be one of the following:
    - **Cloud from adapter**: Indicates that this object has been created by a cloud adapter and it may or may not be within a scope of delegation at the moment.
    - **Cloud from delegation**: Indicates that this object is within the scope of delegation or the object itself defines a scope of authority delegation, and it is not created by a cloud adapter.
    - **Used by cloud**: Indicates that this network or network container is associated with the extensible attribute **Is External** or **Is Shared** and the value is set to True, which implies the network is a private or shared network managed by the CMP, and it is not **Cloud from adapter** or **Cloud from delegation**.
    - **Non-cloud**: The object is a regular NIOS object and is not within the scope of any authority delegation nor is it associated with any of these extensible attributes: **Cloud API Owned, Is External** or **Is Shared**. NIOS admin users can modify this object based on their permissions.

- **Owned By**: A cloud object can be owned by the Grid Master or the cloud adapter. When the object is created by the Grid Master, this shows **Grid**. If the object is created by the cloud adapter, this shows **Adapter**.

  Delegate authority from the Grid Master
  - **Delegate To**: This field indicates whether the authority for the object you want to create has already been delegated. If so, it displays the name of the delegation.

3. (Optional) Click **Next** to configure or override DHCP options as described in *About IPv4 DHCP Options*.
4. (*Applies only to Network Insight*) *This step is not required for creating a new Fixed Address*. In the following Wizard step, you can optionally define the following identification values and settings for the new object's port reservation:
   - Choose the **Device Type**: **Router**, **Switch-Router**, **Switch**, **MSFT** (Microsoft) **Server**, **NetMRI**, **NIOS**, **VNIOS**, or **ESX** (VMware) **Server**.
     The values on this page are not required for defining the actual port reservation in a later wizard step. Certain device types could be descriptively relevant based on the type of object you are creating. As an example, the **MSFT Server** designator helps identify the new object as a Microsoft Hyper-V Host. The **ESX Server** designator can be used to identify the new object as a VMware ESX Host. These values are not required and will not affect the functionality of the object.
   - Choose the **Device Vendor**: **Cisco**, **Juniper**, **Aruba**, **Dell**, **Infoblox**, or **HP**.
   - You can also enter a **Location** and a **Description**. These values are advisory and not required for configuration.
   - After you define this group of settings, you can also define a device port reservation, which is done in a later step. This is not required for the Fixed Address object creation.
5. Click **Next** to initiate or disable discovery of the new Fixed Address. (*Applies only to Network Insight*) *This step is not required for creating a new Fixed Address*.
   - Choose either **Exclude from Network Discovery** or **Enable Immediate Discovery**. If you choose to Exclude, discovery will not execute on the fixed IP address. If you choose **Enable Immediate Discovery**, discovery will execute on the object after you save your settings. You may also choose to leave both options disabled.
   - By default, the new fixed address object inherits its SNMP credentials from those defined at the grid level. Should you wish to override them for a local set of credentials, check the **Override Credentials** checkbox and select the **SNMPv1/SNMPv2** or **SNMPv3** option and enter the locally used credentials.
   - You may also test the entered SNMP credentials by clicking **Test SNMP Credential**.

     For descriptions of SNMP credentials for discovery, see the section Configuring SNMP1/ v2 Credentials for Polling and Configuring SNMPv3 Properties. These Grid-based values are inherited, by default, by each new object you create.
   - For the new object, you can check the **Override CLI Credentials** checkbox to override the inherited set of CLI credentials taken from the Grid level. This set of credentials may be used for the device that is directly associated with the new object in its port reservation.
   - You can also click **Test CLI Credentials** to enter and test a set of CLI login credentials against a device based on its IP address.
     Port control operations require CLI credentials for the involved devices. (If you are not using port control for the new object, usage of CLI credentials is optional.) Because some IPAM and DHCP objects will use port control features as part of object creation, CLI credentials are automatically leveraged as part of discovery. Ensure you have the correct sets of CLI credentials for devices in your network. For more information, see the section *Configuring CLI Discovery Properties*.
   - SSH is the default for CLI operations. Check the **Allow Telnet** checkbox if you know the device involved in the object assignment may support Telnet but may not support SSH, or if you want Telnet as an option.

     Note that all port configuration operations require CLI credentials to be entered into Grid Manager. Because some IPAM and DHCP objects will use port control features as part of object creation, CLI credentials are automatically leveraged as part of discovery. Ensure you have the correct sets of CLI credentials for devices in your network.
6. Click **Next** to define port connectivity for the device port that will be associated with the new object. *This step is not required for creating a new Fixed Address*. This feature set is also termed *portcontrol* in the NIOS/Grid

Manager system. The device whose interface the new Fixed Address will be associated should already be discovered by Network Insight.
    - After choosing the device, choose the **Interface** with which the port reservation will be bound. The drop-down list shows only interfaces that are most recently found to be available by Grid Manager during the last discovery cycle.
    - The Wizard page also shows a list of any VLANs that are currently configured in the chosen device (**The following VLANs are configured**). This Wizard page allows only the assignment of an existing VLAN in the chosen device to the new port reservation.
    - Check the **Configure Port** checkbox to define port control settings for the port reservation.
    - Choose the **Data VLAN** and/or the **Voice VLAN** settings you may need for the port assignment. Depending on the selected device, you may or may not be able to apply VLAN settings.
    - Set the **Admin Status** to **Up** if you need to activate the port after assignment in the current task. All port control operations require CLI credentials to be configured. Because some IPAM and DHCP objects will use port control features as part of object creation, CLI credentials are automatically leveraged as part of discovery and definition of port configurations such as Admin Up/Down status. Ensure you have the correct sets of CLI credentials for devices in your network.
    - Enter a **Description** for the port assignment. Infoblox recommends doing so to help other technicians to recognize the port assignment task.
7. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*. When you create a new fixed address whose authority is delegated to a Cloud Platform Appliance, the required cloud extensible attributes and their values are automatically populated. You need to assign a **Subscriber Member Site** to add subscriber service related extensible attribute in order to populate Subscriber Cache.
8. As the final step in the Add Fixed Address wizard, you define when Grid Manager creates the new object by scheduling it. You also schedule when the associated port control task executes (if a port configuration is specified).
    - To create the new object and its associated port configuration immediately, select Now. Grid Manager synchronizes the port reservation task to take place at the same time as the activation of the new object.
    - You can choose to have Grid Manager execute the port reservation task at the same time as the Fixed Address object creation. To do so, select **At same time as Fixed Address**.
    - You can choose to have Grid Manager execute the port reservation task at a later time by selecting **Later**. Choose a **Selected time** by entering or selecting a **Start Date** (click the calendar icon to choose a calendar date) and a Start Time, and choose a **Time Zone**.
9. Choose one of the following from the **Save&...** drop-down button menu:
    - Click **Save & Close** to add the new object and close the wizard (this is the default).
    - Click **Save & Edit** to add the new object and launch the editor.
    - Click **Save & New** to add the new object and launch the wizard again to add another Fixed Address object.

Note

At any step during the wizard, you can click **Schedule for Later** to schedule the task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks.* You cannot schedule this task when you are creating an object that is within a delegated scope.
For information on viewing fixed addresses and other DHCP objects, see *Viewing IPv4 DHCP Objects*.

Modifying IPv4 Fixed Addresses

To modify the settings of a fixed address:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network* -> *fixed_address* checkbox, and then click the Edit icon.
2. The *Fixed Address* editor contains the following tabs from which you can modify settings:
    - **General**: You can modify the fields, except the network address, as described in Adding IPv4 Fixed Addresses above.

- **Device Information**: Define general identity/type information for the type of device to which your new object connects. For more information, see step 5 in the previous section, *Adding IPv4 Reservations*.
- **Discovery**: Checking the **Enable Discovery** checkbox informs NIOS to begin discovering the fixed address after you click **Save and Close**. You manage discovery polling settings local to the fixed address from this page. For a complete overview of features on this page, see *Discovering Devices and Networks* and its subsections.
- **IPv4 DHCP Options**: You can keep the inherited DHCP options or override them and enter unique settings for the fixed address. For information, see *Defining IPv4 DHCP Options*.
- **IPv4 Discovered Data**: Displays the discovered data of the fixed address. For information, see *Viewing Discovered Data*.
- **Port Reservation**: Review and edit any device port reservations that may be defined for the current object, or create a new port reservation and schedule it. For a closer look, see the section *Port Control Features in Network Insight*, and steps 4-8 in the section Adding IPv4 Fixed Addresses above.
- **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific network. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*. You can edit values of inheritable extensible attributes by double clicking on the respective column. If an extensible attribute has an inherited value, then the cell is highlighted in blue when you perform an inline editing.
- **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions*.

3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify advanced data.
   - **IPv4 DDNS**: You can keep the inherited DDNS settings or override them and enter unique settings for the fixed address. Note that you must click **Override** and select **Enable DDN Supdates** for the DDNS settings you configure in this tab to take effect. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients.*
   - **IPv4 BOOTP/PXE**: You can keep the inherited BOOTP properties or override them and enter unique settings for the fixed address. For information, see *Configuring IPv4 BOOTP and PXE Properties*.
   - **Filters**: You can keep the inherited IPv4 logic filters or override them and add a new IPv4 logic filter. For information, see *Applying Filters to DHCP Objects*.
     Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

> ⚠ Note
>
> At any step during the wizard, you can click **Schedule for Later** to schedule the task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*. You cannot schedule this task when you are creating an object that is within a delegated scope.

Deleting Fixed Addresses

To delete a fixed address within the DHCP range:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network* -> *fixed_address* checkbox or checkboxes. You cannot delete multiple fixed addresses at the same time if the authority for one of the fixed addresses is delegated to a Cloud Platform Appliance.
2. Select **Delete** from the **Delete** drop-down list.
3. In the *Delete Confirmation* dialog box, do the following:
   - **Delete associated leases with the fixed address (selected fixed IP address)**: When you clear this checkbox and click **Yes**, the appliance changes the status of the associated leases from **Static** to **Active**. When you select this checkbox and click **Yes**, the appliance deletes all the leases associated with the fixed address.

> **Note**
>
> NIOS removes all the static leases associated with a fixed address when you delete a fixed address out of the DHCP range, regardless of the selection of the **Delete associated leases with the fixed address (selected fixed IP address)** checkbox in the *Delete Confirmation* dialog box.

To schedule the fixed address deletion:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network* -> *fixed_address* checkbox.
2. Select **Schedule Delete** from the **Delete** drop-down list.
3. In the *Schedule Deletion* dialog box, complete the following:
    - **Delete Now**: Select this to delete the object upon clicking **Delete Now**.
    - **Delete Later**: Select this to schedule the deletion at a later date and time. Complete the following:
        - **Date**: Enter the date in YYYY-MM-DD (year-month-day) format. The appliance displays today's date. You can also click the calendar icon to select a date from the calendar widget.
        - **Time**: Enter the time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
        - **Time Zone**: Select a time zone for the scheduled date and time from the drop-down list. This field displays the time zone of the browser that the admin uses to log in to Grid Manager.
    - **Delete associated leases with the fixed address**: Select this checkbox to delete all the leases associated with the fixed address.
4. Click **Schedule Deletion**.

The appliance performs the deletion at the scheduled date and time, and puts all deleted objects in the Recycle Bin, if enabled. You can restore the objects if necessary.

Configuring IPv4 Reservations

You can create a reservation as a static IP address for future use. A reservation is a pre-provisioned fixed address that is associated with a MAC address of 00:00:00:00:00:00. Since 00:00:00:00:00:00 is not a real MAC address, no client can receive this IP address from the address pool. You can reserve this static IP address and assign it to a client in the future. To create a reservation, you can do one of the following:

- Add a reservation.
- Convert a fixed address or a dynamic address with an active lease to a reservation. For information, see *Converting Objects Associated with IP Addresses*.
- Define a fixed address with an IP address. For information, see *Adding IPv4 Fixed Addresses.*

Adding IPv4 Reservations

> **Note**
>
> At any step during the wizard, you can click **Schedule for Later** to schedule the task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

To create a reservation:

1. Navigate to the network to which you want to add a reservation, and then select **IPv4 Reservation** from the Add drop down menu.
   or
   From any panel in the DHCP tab, expand the Toolbar and click **Add** -> **IPv4 Reservation**.
2. In the *Add Reservation* wizard, select one of the following and click **Next**:

- **Add Reservation**
  or
- **Add Reservation using Template**
  Click **Select Template** and select the template that you want to use. Note that when you use a template to create a reservation, the configurations of the template apply to the new address. The appliance automatically populates the reservation properties in the wizard. You can then edit the pre-populated properties.

3. Complete the following:
   - **Network**: The displayed network address can either be the last selected network or the network from which you are adding the DHCP range. If no network address is displayed or if you want to specify a different network, click **Select Network**. When there are multiple networks, Grid Manager displays the *Select Network* dialog box from which you can select one.
   - **IP Address:** Enter the IP address that you want to reserve for manual assignment, or click **Next Available IP** to obtain the next available IP address. For information about obtaining the next available IP address, see *Adding IPv4 Fixed Addresses*. Note that for Cloud Network Automation, Next Available IP is not available if the reservation you want to create is within a delegated range.
   - **Name:** Optionally, enter a name for the reservation.
   - **Comment:** Optionally, enter additional information about the reservation.
   - **Disabled:** Select this if you do not want the DHCP server to use this reservation at this time.
     The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*. This section displays the following information:
     - **Cloud Usage**: This field indicates whether this object is associated with any specific cloud extensible attributes or within a scope of delegation. It can be one of the following:
       - **Cloud from adapter**: Indicates that this object has been created by a cloud adapter and it may or may not be within a scope of delegation at the moment.
       - **Cloud from delegation**: Indicates that this object is within the scope of delegation or the object itself defines a scope of authority delegation, and it is not created by a cloud adapter.
       - **Used by cloud**: Indicates that this network or network container is associated with the extensible attribute **Is External** or **Is Shared** and the value is set to True, which implies the network is a private or shared network managed by the CMP, and it is not **Cloud from adapter** or **Cloud from delegation**.
       - **Non-cloud**: The object is a regular NIOS object and is not within the scope of any authority delegation nor is it associated with any of these extensible attributes: **Cloud API Owned, Is External** or **Is Shared**. NIOS admin users can modify this object based on their permissions.
       - **Owned By**: A cloud object can be owned by the Grid Master or the cloud adapter. When the object is created by the Grid Master, this shows **Grid**. If the object is created by the cloud adapter, this shows **Adapter**.

         Delegate authority from the Grid Master
         - **Delegate To**: This field indicates whether the authority for the object you want to create has already been delegated. If so, it displays the name of the delegation.
4. Click **Next** to configure or override DHCP options as described in *Defining IPv4 DHCP Options*.
5. (*Applies only to Network Insight*) *This step is not required for creating a new IPv4 Reservation*. In the following Wizard step, you can optionally define the following identification values and settings for the new object's port reservation:
   - Choose the **Device Type**: **Router**, **Switch-Router**, **Switch**, **MSFT** (Microsoft) **Server**, **NetMRI**, **NIOS**, **VNIOS**, or **ESX** (VMware) **Server**.
     The values on this page are not required for defining the actual port reservation in a later wizard step. Certain device types could be descriptively relevant based on the type of object you are creating. As an example, the **MSFT Server** designator helps identify the new object as a Microsoft Hyper-V Host. The **ESX Server** designator can be used to identify the new object as a VMware ESX Host. These values are not required and will not affect the functionality of the object.
   - Choose the **Device Vendor**: **Cisco**, **Juniper**, **Aruba**, **Dell**, **Infoblox**, or **HP**.
   - You can also enter a **Location** and a **Description**. These values are advisory and not required for configuration.

After you define this group of settings, you will still need to define a device port reservation, which is done in a later step.

6. (*Applies only to Network Insight*) Click **Next** to initiate or disable discovery of the new IPv4 reservation.
    - Choose either **Exclude from Network Discovery** or **Enable Immediate Discovery**. If you choose to Exclude, discovery will not execute on the object. If you choose **Enable Immediate Discovery**, discovery will execute on the object after you save your settings. You may also choose to leave both options disabled.
    - By default, the new object inherits its SNMP credentials from those defined at the grid level. Should you wish to override them for a local set of credentials, check the **Override Credentials** checkbox and select the **SNMPv1/SNMPv2** or **SNMPv3** option and enter the locally used credentials. For more information, see the sections *Configuring SNMP1/v2 Credentials for Polling* and *Configuring SNMPv3 Properties* for a complete description of SNMP credentials for discovery.
    - For the new object, you can check the **Override CLI Credentials** checkbox to override the inherited set of CLI credentials taken from the Grid level. This set of credentials may be used for the device that is directly associated with the new object (in this case, an IPv4 Reservation) in its port reservation.
    - You can also click **Test CLI Credentials** to select and test a set of CLI login credentials against a device based on its IP address.
    - Port control tasks require CLI credentials for the involved devices. (If you are not using port control for the new object, usage of CLI credentials is not required.) Because some IPAM and DHCP objects will use port control features as part of object creation, CLI credentials are automatically leveraged as part of discovery. Ensure you have the correct sets of CLI credentials for devices in your network. For more information, see the section *Configuring CLI Discovery Properties*.
    - SSH is the default for CLI operations. Check the **Allow Telnet** checkbox if you know the device involved in the object assignment may support Telnet but may not support SSH, or if you want Telnet as an option.
7. (*Applies only with Network Insight*) Click **Next** to define optional device port association for the IPv4 reservation. *This step is optional and not required for creating the new IPv4 Reservation*. This feature set is also termed *port control* in the NIOS/Grid Manager system. The device to which the new object will be associated should already be discovered and managed from the Infoblox Grid.
    - Begin by checking the **Reserve Port** checkbox. Note that reserving a switch port does not guarantee its availability.
      Optionally, you can skip connecting port configuration by clicking **Next**.
      Click the **Clear** button to remove the selected device from the configuration.
    - Click the **Select Device** button to choose the device for which the port reservation will be associated. You should know the identity of the device to whose interface the new object will be associated before taking this step. For more information, see the section *Using the Device Selector.*
    - After choosing the device, choose the **Interface** with which the reservation will be bound. The drop-down list shows only interfaces that are most recently found to be available by Grid Manager during the last discovery cycle.
    - The Wizard page also shows a list of any VLANs that are currently configured in the chosen device (**The following VLANs are configured**). This Wizard page allows only the assignment of an existing VLAN in the chosen device to the new port reservation.
    - Check the **Configure Port** checkbox to define specific port configuration settings for the port reservation.
    - Choose the **DataVLAN** and/or the **VoiceVLAN** settings you may need for the port assignment. Depending on the selected device, you may or may not be able to apply VLAN settings.
    - Set the **AdminStatus** to **Up** if you need to activate the port after assignment in the current task.
      All port control operations require CLI credentials to be entered into Grid Manager. Because some IPAM and DHCP objects will use port control features as part of object creation, CLI credentials are automatically leveraged as part of discovery and definition of port configurations such as Admin Up/Down status. Ensure you have the correct sets of CLI credentials for devices in your network.
    - Enter a **Description** for the port reservation. Infoblox recommends doing so to help other technicians to recognize the port assignment task.
8. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
   You need to assign a **Subscriber Member Site** to add subscriber service related extensible attribute in order to populate Subscriber Cache.
9. As the final step in the Add IPv4 Reservation wizard, you define when Grid Manager creates the new object by scheduling it. You also schedule when the associated port control task executes (if a port configuration is specified).

- To create the new IPv4 Reservation and its associated port reservation immediately, select Now. Grid Manager synchronizes the port control task to take place at the same time as the activation of the new object.
- You can choose to have Grid Manager execute the port control task at the same time as the object creation. To do so, select **At same time as IPv4 Reservation**.
- You can choose to have Grid Manager execute the port control task at a later time by selecting **Later**. Choose a **Selected time** by entering or selecting a **Start Date** (click the calendar icon to choose a calendar date) and a **Start Time**, and choose a **Time Zone**.

10. Choose one of the following from the **Save&...** drop-down button menu:
    - Click **Save & Close** to add the new object and close the wizard (this is the default).
    - Click **Save & Edit** to add the new object and launch the editor.
    - Click **Save & New** to add the new object and launch the wizard again to add another IPv4 Reservation object.
11. Click **Restart** if it appears at the top of the screen.

> ⚠ Note
>
> At any step during the wizard, you can click **Schedule for Later** to schedule the task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks.* You cannot schedule this task when you are creating an object that is within a delegated scope.

Modifying IPv4 Reservations

To modify an IPv4 reservation:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network* -> *reservation* checkbox, and then click the Edit icon.
2. The *Reservation Address* editor contains the following tabs from which you can modify data:
    - **General**: Modify the fields, except the network address, as described in Adding IPv4 Reservations above.
    - **Device Information**: Define general identity/type information for the type of device to which your new object connects. For more information, see Step 5 in the previous section.
    - **IPv4 DHCP Options:** Keep the inherited DHCP options or override them and enter unique settings for the reservation. For information, see *Defining IPv4 DHCP Options.*
    - **IPv4 Discovered Data**: Displays the discovered data of the reservation. For information, see *Viewing Discovered Data*.
    - **Port Reservation**: Review and edit any device port reservations that may be defined for the current object, or create a new port reservation and schedule it. For a closer look, see the section *Port Control Features in Network Insight,* and steps 4-8 in the section Adding IPv4 Reservations above.
    - **Extensible Attributes**: Add and delete extensible attributes that are associated with a reservation. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*. You can edit values of inheritable extensible attributes by double clicking on the respective column. If an extensible attribute has an inherited value, then the cell is highlighted in blue when you perform an inline editing. The *Descendant Actions* dialog box is displayed when you click **Save**. For information, see *Managing Inheritable Extensible Attributes at the Parent and Descendant Level*. If you delete the value of an inheritable extensible attribute at the parent level, you can choose to preserve the descendant value or remove it. For information, see *Deleting Inheritable Extensible Attributes Associated with Parent Objects*.
    - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions*.
3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify advanced data.
    - **IPv4 DDNS**: Keep the inherited DDNS settings or override them and enter unique settings for the reservation. Note that you must click **Override** and select **Enable DDN Supdates** for the DDNS settings

you configure in this tab to take effect. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients.*

- **IPv4 BOOTP/PXE**: You can keep the inherited BOOTP properties or override them and enter unique settings for the reservation. For information, see *Configuring IPv4 BOOTP and PXE Properties*.
- **Filters**: You can keep the inherited IPv4 logic filters or override them and add a new IPv4 logic filter. For information, see *Applying Filters to DHCP Objects.*

Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

> **Note**
>
> At any step during the wizard, you can click **Schedule for Later** to schedule the task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*. You cannot schedule this task when you are creating an object that is within a delegated scope.

Viewing IPv4 DHCP Objects

To view the address ranges, fixed addresses and reservations in a network:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *addr_range*.
2. Grid Manager displays the following information:
   - **IP Address**: The IP address of the object in the DHCP range. For exclusion ranges, this displays the start and end IP addresses. For host records with multiple IP addresses, each IP address is displayed separately. The appliance highlights disabled DHCP objects in gray. A DHCP object can be a fixed address, reservation, host configured for DHCP, or roaming host with an allocated IP address.
   - **Type**: The object type, such as **Fixed Address**.
   - **Name**: The object name. For example, if the IP address belongs to a host record, this field displays the hostname.
   - **Fingerprint**: The name of the DHCP fingerprint or vendor ID of the network device that was identified through DHCP fingerprint detection. This field displays **No Match** for devices that do not have any DHCP fingerprint information. For information about DHCP fingerprints, see *DHCP Fingerprint Detection*.
   - **Comment**: The information you entered for the object.
   - **Site**: The site to which the object belongs. This is one of the predefined extensible attributes. You can edit values of inheritable extensible attributes by double clicking on the respective column. If an extensible attribute has an inherited value, then the cell is highlighted in blue when you perform an inline editing.

You can select **Disabled** or available extensible attributes for display.
You can also do the following:

- Sort the data in ascending or descending order by column.
- Create a bookmark for the range.
- Delete or schedule the deletion of a selected object or multiple objects in the range.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Select an object and view detailed information.
- Print or export the data.

About Roaming Hosts

A roaming host is a host with a dynamically assigned IP address and a specific set of properties and DHCP options. When you create a roaming host for a network device, the device can receive any dynamically assigned address from the network to which it belongs. You can create roaming hosts for devices, such as laptop computers and mobile phones, that require different IP addresses each time they are moved from one network to another and require a unique set of DHCP options.

You can configure IPv4 addresses, IPv6 addresses, or IPv4 and IPv6 addresses for roaming hosts that require both types of addresses. When you configure IPv4 addresses for a roaming host, you must specify the host MAC address or a DHCP client identifier that the appliance uses to match the host, and specify DHCP options for the host. The appliance assigns an IP address from the DHCP range associated with the network from which the address request originates. You can configure an IPv6 prefix or address for a DHCP client. When you do, you must specify the DUID of the host so the appliance can use the DUID to match the host.
A roaming host also receives DHCP options from the Grid, member, network, or shared network with which it associates. When you configure a roaming host, you must configure it in a specific network view. If you have multiple network views, you must specify the network view to which the requesting hosts belong so the appliance can assign addresses to the hosts from the networks within the same network view.
After you enable support for roaming hosts at the Grid level, you can add a roaming host that supports IPv4, IPv6, or both protocols. You can also convert an IPv4 roaming host to an IPv6 roaming host and vice versa, or convert an IPv4 or IPv6 roaming host to one that supports both IPv4 and IPv6.

Configuring Roaming Hosts

To configure a roaming host, perform the following tasks:

1. Enable support for roaming hosts at the Grid level. For information, see, Enabling Support for Roaming Hosts below.
2. Add a roaming host.
    - To add an IPv4 roaming host, see Adding IPv4 Roaming Hosts below
    - To add an IPv6 roaming host, see Adding IPv6 Roaming Hosts below
    - To add a dual stack roaming host, see Adding IPv4/IPv6 Roaming Hosts below
    - Optionally, configure DHCP properties for the roaming host. You can override properties set for the upper levels and enter unique values for the roaming hosts. For information, see *Defining IPv4 DHCP Options*.

You can do the following after you configure roaming hosts:

- View the configured roaming hosts.For information, see Viewing Roaming Hosts below.
- Modify existing roaming hosts. For information, see Setting Properties for Roaming Hosts below.
- Delete roaming hosts that are not currently in use. For information, see Deleting Roaming Hosts below.

Enabling Support for Roaming Hosts

You must first enable support for roaming hosts before adding them. After you enable this feature, you can disable it only after you delete all the existing roaming hosts.
To enable support for roaming hosts:

1. From the **Data Management** tab, select the **DHCP** tab.
2. Expand the Toolbar and click **Grid DHCP Properties**.
3. In the *General Advanced* tab, select **Enable support for roaming host**.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Adding IPv4 Roaming Hosts

To add an IPv4 roaming host:

1. From the **Data Management** tab, select the **DHCP** tab.
2. Select a network view from the drop-down list.
3. Expand the Toolbar and click **Add** -> **Roaming Host** -> **IPv4**.
4. In the *Add Roaming Host* wizard, select one of the following and click **Next**:
    - **Add Roaming Host**
      or
    - **Add Roaming Host using Template**
      Click **Select Template** to create a roaming host using a fixed address/reservation template. In the *DHCP Template Selector* dialog box, select the template that you want to use. Note that when you use a template to create a roaming host, the configurations of the template apply to the new host. The appliance automatically populates the host properties in the wizard. You can then edit the pre-populated properties.

5. Complete the following:
    - **Name**: Enter the name of the roaming host. The name must be unique for each roaming host in a given network view.
    - **Assign IPv4 Address by**: Select one of the following criteria on which the appliance matches when assigning an IP address to the host.
        - **MAC Address**: Select this to assign a dynamic IP address to a host, provided that the MAC address of the requesting host matches the MAC address that you specify here.
        - **DHCP Client Identifier**: Select this to assign a dynamic IP address to a host with the same DHCP client identifier that you specify here. When you select this, the **Match null (\0) at beginning of DHCP client identifier** checkbox is displayed. Select this when a DHCP client sends a \000 prefixed to the DHCP client identifier. \0 is the null character. Some DHCP clients (for example, Microsoft) send the client identifier in a \000foo format (with the null character prefix instead of just foo). The client identifier for the requesting host and the client identifier stored in the appliance must match.
    - **Comment**: Enter useful information about the roaming host.
    - **Disabled**: Select this if you do not want the DHCP server to use this roaming host definition. When you disable a roaming host, the host gets an IP address without the defined DHCP options.
6. Click **Next** to configure the IDHCP options for the roaming host, as described in *Defining IPv4 DHCP Options*.
7. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
8. Save the configuration and click **Restart** if it appears at the top of the screen.
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *ScheduleChange* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Adding IPv6 Roaming Hosts

To add an IPv6 roaming host:

1. From the **Data Management** tab, select the **DHCP** tab.
2. Select a network view from the drop-down list.
3. Expand the Toolbar and click **Add** -> **Roaming Host** -> **IPv6**.
4. In the *Add Roaming Host* wizard, select one of the following and click **Next**:
    - **Add IPv6 Roaming Host**
      or
    - **Add Roaming Host Using IPv6 Template**

      Click **SelectIPv6Template** to create a roaming host using an IPv6 fixed address template. In the *DHCPTemplateSelector* dialog box, select the template that you want to use. Note that when you use a template to create a roaming host, the configurations of the template apply to the new host. The appliance automatically populates the host properties in the wizard. You can then edit the pre-populated properties.
5. Complete the following:
    - **Name**: Enter the name of the roaming host. The name must be unique for each roaming host in a given network view.
    - **DUID**: Enter the DHCP unique identifier of the host.
    - **Comment**: Optionally, enter additional information about the roaming host.
    - **Disabled**: Select this if you do not want the DHCP server to use this roaming host definition. When you disable a roaming host, the host gets an IP address without the defined DHCP options.
6. Click **Next** to configure the DHCP options for the roaming host, as described in *Defining General IPv6 Properties.*
7. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes.*
8. Save the configuration and click **Restart** if it appears at the top of the screen.
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Adding IPv4/IPv6 Roaming Hosts

To add an IPv4/IPv6 roaming host:

1. From the **Data Management** tab, select the **DHCP** tab.
2. Select a network view from the drop-down list.
3. Expand the Toolbar and click **Add** -> **Roaming Host** -> **Both**.
4. In the *Add Roaming Host* wizard, select one of the following and click **Next**:
    - **Add Roaming Host**
      or
    - **Add Roaming Host using Both IPv4 and IPv6 Templates**
      When you use both templates to create a roaming host, the appliance applies the IPv4 template and then the IPv6 template. Therefore, the comments and extensible attributes from the IPv6 template override those from the IPv4 template.
5. Complete the following:
    - **Name**: Enter the name of the roaming host. The name must be unique for each roaming host in a given network view.
    - **Assign IP Address by**: Select one of the following criteria on which the appliance matches when assigning an IP address to the host.
        - **MAC Address**: Select this to assign a dynamic IP address to a host, provided that the MAC address of the requesting host matches the MAC address that you specify here.
        - **DHCP Client Identifier**: Select this to assign a dynamic IP address to a host with the same DHCP client identifier that you specify here. When you select this, the **Match null (\0) at beginning of DHCP client identifier** checkbox is displayed. Select this when a DHCP client sends a \000 prefixed to the DHCP client identifier. \0 is the null character. Some DHCP clients (for example, Microsoft) send the client identifier in a \000foo format (with the null character prefix instead of just foo). The client identifier for the requesting host and the client identifier stored in the appliance must match.
    - **DUID**: Specify the DHCP unique identifier of the host.
    - **Comment**: If both IPv4 and IPv6 templates were used to create the host, this field displays the comment from the IPv6 template. You can change or add information.
    - **Disabled**: Select this if you do not want the DHCP server to use this roaming host definition. When you disable a roaming host, the host gets an IP address without the defined DHCP options.
6. Click **Next** to configure the IPv4 DHCP options for the roaming host, as described in *Defining IPv4 DHCP Options*.
7. Click **Next** to configure IPv6 properties described in *Defining General IPv6 Properties*.
8. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. If both IPv4 and IPv6 templates were used to create the host, this panel displays the attributes from the IPv6 template. You can change or add information. For information, see *Using Extensible Attributes*.
9. Save the configuration and click **Restart** if it appears at the top of the screen.

   or

   Click the Schedule icon at the top of the wizard to schedule this task. In the *ScheduleChange* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Viewing Roaming Hosts

To view a list of roaming hosts in a specific network view:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Roaming Hosts**.
2. From the Network View drop-down list, select the network view to which the roaming hosts belong.
3. The Grid Manager displays the following for each roaming host:
    - **Name**: The name of the roaming host.
    - **Address**: The IP address of the roaming host.
    - **Comment**: The information that you entered for the roaming host.
    - **Site**: The site to which the template belongs. This is one of the predefined extensible attributes.

You can select **Disabled** and available extensible attributes for display.

You can also do the following:

- Sort the displayed data in ascending or descending order by column.
- Use filters and the **Goto** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Goto** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.

Setting Properties for Roaming Hosts

You can modify an existing roaming host to add, modify or delete IPv4 or IPv6 addresses, and to set IPv4 and IPv6 DHCP properties.

1. From the **DataManagement** tab, select the **DHCP** tab -> **Networks** tab -> **RoamingHosts** section -> *roaming_host* checkbox, and then click the Edit icon.
2. The *RoamingHost* editor contains the following tabs from which you can modify data:
    - **General**: Edit the fields as described in Adding IPv4 Roaming Hosts above, except for the **Templates** field.
    - **IPv4 DHCP Options**: Keep the inherited DHCP options or override them and enter unique settings for the roaming host. For information, see *Defining IPv4 DHCP Options*.
    - **IPv6 DHCP Options:** Keep the inherited IPv6 DHCP properties or override them. For more information, see *Defining General IPv6 Properties*.
    - **Extensible Attributes**: Add and delete extensible attributes that are associated with a roaming host. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.
    - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions*.
3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify advanced data.
    - **IPv4DDNS**: Click **Override** and select **Enable DDNS updates** for the DDNS settings you configure in this tab to take effect. You can specify the following:
        - **DDNS Domain Name**: Specify the domain name that the appliance uses to update DNS.
        - **DDNS Hostname**: Select the Replace the host name dynamically provided by the client/member with the roaming host name checkbox to use the name of the roaming host record as the name of the client for DDNS updates.

          For information about DDNS, see *Configuring DDNS Updates*.

    - **IPv4 BOOTP/PXE**: Keep the inherited PXE and BOOTP properties or override them and enter unique settings for the roaming host. For information, see *Configuring DHCP for IPv4*.
    - **IPv6 DDNS**: Click **Override** and select **Enable DDNS Updates** for the DDNS settings you configure in this tab to take effect. You can specify the following:
        - **DDNS Domain Name**: Specify the domain name that the appliance uses to update DNS.
        - **DDNS Hostname**: Select the Replace the host name dynamically provided by the client/member with the roaming host name checkbox to use the name of the roaming host record as the name of the client for DDNS updates.

          For information about DDNS, see *Configuring DDNS Updates*.

          Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

   You can also click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Deleting Roaming Hosts

To delete a roaming host:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Roaming Hosts** -> *roaming_host* checkbox, and then select **Delete** or **Schedule Delete** from the drop-down menu.
2. To delete the roaming host now, in the *Delete Confirmation* dialog box, click **Yes**. To schedule the deletion, see *Scheduling Deletions*. The Grid Manager puts the deleted roaming host in the Recycle Bin, if enabled.

Managing DHCP Templates

A template contains a set of predefined properties that you use to create IPv4 and IPv6 DHCP objects. It is metadata that you can modify and reuse. Using a template enables you to create objects in a quick and consistent way. You can define the object properties once in a template, and then create multiple objects that inherit their properties from the template. For example, you can create a network template that has a fixed netmask of /24 and extensible attribute "State" set to California. You can then use the template to create networks in California that contain /24 netmasks.
You can also modify and delete a template. Note that modifying or deleting a template does not affect existing objects created based on the template. You must be a superuser or have read/write permissions to add, modify, or delete a template. A superuser can set other admin group privileges on templates. For information, see *Administrative Permissions for IPv4 or IPv6 DHCP Templates*. You can also define extensible attributes for these templates when you create them. For information, see *Using Extensible Attributes*.

This section explains how to configure and manage IPv4 and IPv6 DHCP templates. It contains the following topics:

- *About IPv4 DHCP Templates*
- *About IPv6 DHCP Templates*
- *About IPv6 Range Templates*
- *About IPv6 Fixed Address Templates*
- *About IPv6 Network Templates*
- *Viewing and Deleting Templates*

About IPv4 DHCP Templates

You can use templates to create DHCP IPv4 ranges, fixed addresses, reservations, roaming hosts, and networks. You can create the following IPv4 templates:

- A DHCP range template, containing DHCP range settings, such as the total number of IP addresses allocated to a range. You can add a DHCP range template to a network template. For information, see About IPv4 Range Templates below.
- A fixed address/reservation template, containing information for creating fixed addresses, reservations, or roaming hosts. You can add a fixed address/reservation template to a network template. For information, see About IPv4 Network Templates below.
- A network template, containing basic network properties for creating networks. It is also a container that holds your DHCP range templates and fixed address/reservation templates. When you create a network using a network template, the network inherits the properties of the range and fixed address/reservation templates. You can create a network in any network view using a network template. For information, see About IPv4 Network Templates below.

Because you can potentially add DHCP range and fixed address/reservation templates to a network template, create the DHCP range and fixed address/reservation templates before you create a network template. For information, see Configuration Example: Creating an IPv4 Network Using a Template below.

About IPv4 Range Templates

When you create an IPv4 range template, the start and end address fields are based on the specified offset from the network start address and the number of IP addresses in the range. After you create a DHCP range template, you can

configure additional properties such as exclusion ranges and DHCP filters, as described in Modifying IPv4 Range Templates below. Then when you use the template to create a DHCP range, the range inherits the properties of the template. You can also include a DHCP range template in a network template to automatically create a DHCP range when you use that network template.
If you have deployed the Cloud Network Automation license on the Grid Master, you can configure range templates for cloud delegation. When you select a default Cloud Platform Appliance for a template, all ranges you create using this template will delegate authority to the same Cloud member. Note that when a Cloud member is removed from the Grid, the delegation will also be removed from the template. For information about Cloud Network Automation, see *Deploying Cloud Network Automation*.

Adding IPv4 Range Templates

To create an IPv4 DHCP range template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab, and then expand the Toolbar and click **Add** -> **Templates** -> **Range** -> **IPv4**.
2. In the *Add IPv4 Range Template* wizard, do the following:
    - **Name:** Enter a name that helps identify the DHCP range template. For example, enter **Region 1 IT** if you want to use this template to create DHCP ranges for the IT department in Region 1.
    - **Offset:** An offset in a DHCP range template determines the starting IP address of the range. The appliance adds the offset value you enter here to the start IP address of the network in which you create a DHCP range using this template. That IP address becomes the start IP address of the DHCP range. For example, you specify an offset value of 25 for a 25.0.0.0/8 network using the DHCP range template, the appliance creates a DHCP range with the start IP address of 25.0.0.25 in the network.
    - **Number of Addresses:** Enter the total number of IP addresses to be included in the DHCP range.
    - **Comment:** Enter useful information about the template.

      The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*. To configure this template for cloud delegation, complete the following:

      Use for cloud delegation: Select this checkbox to enable cloud delegation for this template.

      Delegate authority from the Grid Master
    - **Delegate To**: In a non-cloud API request, this parameter defines the default member to which authority is delegated. In a cloud API request, the appliance ignores this parameter, which allows you to use this template to create an object on different Cloud Platform Appliances. Click **Select** to choose the default Cloud Platform Appliance to which you want to delegate authority. The *Member Selector* displays only Cloud Platform Appliances in the Grid. Click the member, and Grid Manager displays the member name next to this field.
3. Click **Next** and select one of the following to provide DHCP services for the range:
    - **None (Reserved Range)**: Select this if you want to reserve this address range for static hosts. Addresses in this range cannot be allocated as dynamic addresses. You can allocate the next available IP from this range to a static host. This is selected by default.
    - **Grid Member:** Click Select and choose a Grid member from the drop-down list.
    - **Failover Association:** Click Select and choose a failover association. Only failover associations that provide DHCP services in the network view of the DHCP range appear in the drop-down list.
    - **Microsoft DHCP Server:** Click Select and choose a Microsoft server from the drop-down list. The drop-down list displays only the servers that are associated with the network to which the DHCP range belongs.
4. Click **Next** to configure or override DHCP options as described in *Defining IPv4 DHCP Options*.
5. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes.*
6. Save the configuration and click **Restart** if it appears at the top of the screen.

Modifying IPv4 Range Templates

After you use the wizard to create an IPv4 DHCP range template, you can set additional properties for the template. Following are some guidelines:

- In the **DHCP Options** tab of a DHCP range template, the broadcast address is an address offset number rather than a broadcast IP address; network router addresses are offset numbers as well.
  An offset in a DHCP range template indicates the starting IP address of the DHCP range object created from the template. For example, you can create a network template called *test_network_template* and a DHCP range template *test_range_template* linked to this network template. If the *test_range_template* has an offset value 10, when you create a 10.0.0.0/8 network using the *test_network_template*, the appliance creates a DHCP range with the starting IP address 10.0.0.10. If you create a 20.0.0.0/8 network using the *test_network_template*, the appliance creates a DHCP range with the starting IP address 20.0.0.10

For the exclusion range in the template, the start and end addresses are determined by the number of offsets in the DHCP range template's start address and the number of IP addresses in the exclusion range. For more information about exclusion ranges, see *About DHCP Ranges*.

To modify and set properties for a DHCP range template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab -> *template* checkbox, and then click the Edit icon.
2. The *DHCP Range Template* editor contains the following tabs from which you can modify data:
   - **General**: Modify general information described in the previous section Adding IPv4 Range Templates.
   - **Member Assignment**: Change the Grid member, failover association, or Microsoft server that provides DHCP services for this template. You can also add or delete a member or failover association. For information, see *Adding IPv4 Address Ranges*.

     When you change the member assignment of DHCP ranges from **Failover Association** to **Grid Member** and then back to **Failover Association**, the leases in the primary and secondary servers fall out of sync. To resynchronize the peers, the failover association of the secondary server is put in the Recover-Wait state for the entire duration of Maximum Client Lead Time while a forced recovery takes place. During this period, only the IP addresses allocated to the primary server are available for lease.
   - **IPv4 DHCP Options:** Keep the inherited DHCP options or override them and enter unique settings for the template. For information, see *Defining IPv4 DHCP Options*.
   - **Extensible Attributes**: Add and delete extensible attributes that are associated with this template. You can also modify the values of the extensible attributes. For information, see *Using Extensible Attributes*.
   - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *About Administrative Permissions*.
3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify data:
   - **IPv4DDNS**: Keep the inherited DDNS settings or override them and enter unique settings for the template. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
   - **IPv4 BOOTP/PXE**: Keep the inherited BOOTP properties or override them and enter unique settings for the template. For information, see *Configuring IPv4 BOOTP and PXE Properties*.
   - **Exclusion Ranges**: Configure a range of IP addresses that the appliance does not use for dynamic address assignments. Complete the following:
     - **Offset:** An offset for an exclusion range determines the start IP address of the exclusion range. The appliance adds the offset value you enter here to the start IP address of the DHCP range created using this template. That IP address becomes the start IP address of the exclusion range.
     - **Number of Addresses:** Enter the number of IP addresses to be included in the exclusion range.
     - **Comment:** Enter useful information about the exclusion range.
   - **IPv4 DHCP Thresholds**: Keep the inherited thresholds settings or override them and enter unique settings for the template. For information, see *Configuring Thresholds for DHCP Ranges*.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

⚠ Note

Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.

About IPv4 Fixed Address/Reservation Templates

You can use an IPv4 fixed address/reservation template to create fixed addresses, reservations and roaming hosts. When you create an IPv4 fixed address/reservation template, you can specify an offset and number of addresses. This is used when you include the template in a network template. When you include a fixed address/reservation template in a network template, the DHCP server automatically creates reservations based on the offset and number of addresses you specified in the fixed/address reservation template. It does not create fixed addresses.
After you create a fixed address/reservation template using the wizard, you can configure additional properties as described in Modifying IPv4 Fixed Address/Reservation Templates below. Then when you use the template to create a fixed address, it inherits the properties of the template.
If you have deployed the Cloud Network Automation license on the Grid Master, you can configure fixed address templates for cloud delegation. When you configure a template for cloud delegation, all fixed addresses you create using this template will inherit authority delegations from their parent objects. For information about Cloud Network Automation, see *Deploying Cloud Network Automation*.

Adding IPv4 Fixed Address/Reservation Templates

To create an IPv4 fixed address/reservation template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** section.
2. Click the Add drop-down list and select **IPv4 Fixed Address/Reservation Template**.
3. In the *Add IPv4 Fixed Address/Reservation Template* wizard, enter the following:
   - **Name:** Enter a name that helps identify the fixed address/reservation template. For example, you can enter **HP Printer** when you create a template that contains settings for assigning fixed addresses or reservations to HP printers.
   - **Comment:** Optionally, enter additional information about the template.
   - **Use for cloud delegation**: When you select this checkbox, all fixed addresses you create using this template inherit authority delegation from their parent objects.

     In the **Optional Settings For Range of Objects** section, do the following:
   - **Offset:** An offset in a fixed address/reservation template determines the start IP address of the object created from the template. The appliance adds the offset value you enter here to the start IP address of the network in which you create objects using this template. That IP address becomes the start IP address of the object.
   - **Number of Addresses:** Enter the number of IP addresses to be used as fixed addresses, reservations, or roaming hosts.
     Note that the appliance uses the offset and number of addresses only when this template is used in a network template.
4. Click **Next** to configure or override DHCP options as described in *Defining IPv4 DHCP Options*.
5. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
6. Save the configuration and click **Restart** if it appears at the top of the screen.

Modifying IPv4 Fixed Address/Reservation Templates

To modify a fixed address/reservation template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab -> *template* checkbox, and then click the Edit icon.
2. The *Fixed Address/Reservation Template* editor contains the following tabs from which you can modify data:
   - **General**: Modify general information for the template as described in Adding IPv4 Fixed Address/ Reservation Templates above.
   - **IPv4 DHCP Options**: Keep the inherited DHCP options or override them and enter unique settings for the template. For information, see *Defining IPv4 DHCP Options*.

- **Extensible Attributes**: Add and delete extensible attributes that are associated with the template. You can also modify the values of the extensible attributes. For information, see *Using Extensible Attributes*.
- **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *About Administrative Permissions*.

3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify data:
   - **IPv4 DDNS**: Keep the inherited DDNS settings or override them and enter unique settings for the template. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
   - **IPv4 Filters**: You can keep the inherited IPv4 logic filters or override them and add a new IPv4 logic filter for the template. For information, see *Applying Filters to DHCP Objects*.
   - **IPv4 BOOTP/PXE**: Keep the inherited BOOTP properties or override them and enter unique settings for the template. For information, see *Configuring IPv4 BOOTP and PXE Properties*.
     Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

About IPv4 Network Templates

You can create IPv4 network templates to facilitate network configuration. You can use network templates to create networks in any network view. When you create a network template, you do not specify a network address. You enter the network address when you create an actual network from the template. You can specify a netmask or allow the user to define the netmask when they create the actual network.
A network template is useful for setting up a network with fixed addresses and DHCP ranges already defined. You can add DHCP range or fixed address/reservation templates to a network template. Once the fixed address and DHCP range information is set up, the network template contains a range template list and a fixed address/reservation template list. When you enable support for RIR updates, you can create IPv4 network templates specific for RIR associated networks. For information about RIR updates, see *RIR Registration Updates*.
If you have deployed the Cloud Network Automation on the Grid Master, you can configure network templates for cloud delegation. When you select a default Cloud Platform Appliance for a template, all networks you create using this template will delegate authority to the same Cloud member. If you want to associate any range or fixed address templates with a network template, ensure that you enable "**User for cloud delegation**" for the network, range, and fixed address templates. Note that when a Cloud member is removed from the Grid, the delegation will also be removed from the template. For information about Cloud Network Automation, see *Deploying Cloud Network Automation*.

Adding IPv4 Network Templates

To create a network template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** section.
2. Click the drop-down menu of the Add icon and select **IPv4 Network Template**.
3. In the *Add IPv4 Network Template* wizard, do the following:
   - **Regional Internet Registry**: This section appears only when support for RIR updates is enabled. For information about RIR, see *RIR Registration Updates*. Complete the following to create a network template for an RIR IPv4 network container or network:
     - **Internet Registry**: Select the RIR from the drop-down list. The default is **RIPE**. When you select **None**, the network is not associated with an RIR organization.
     - **Organization ID**: Click **Select Organization** and select an organization from the *RIROrganizationSelector* dialog box.
     - **Registration Status**: The default is **Not Registered**. When using this template to add an RIR allocated network, you can change this to **Registered** and select the **Do not update registrations** checkbox below. Note that when you select **API** as the communication method, the registration status will be updated automatically after the registration update is completed. However, when you select **Email** as the communication method, the registration status will not be automatically updated. If you are creating a new network and the registration update is completed successfully, the status will be changed to **Registered**. If the update fails, the status will be changed to **Not Registered**.
     - **Registration Action**: Select the registration action from the drop-down list. When you select **Create**, the appliance creates the IPv4 network and assigns it to the selected organization. When you select **None**, the appliance does not send registration updates to RIPE. When you use this template to add an existing RIR allocated network to NIOS, select **None**. When you use this

template to add networks to an RIR allocated network (a parent network), select **Create**. Ensure that the parent network associated with an RIR organization already exists.
        - **Do not update registrations**: Select this checkbox if you do not want the appliance to submit RIR updates to RIPE. By default, the appliance sends updates to the RIR database based on the configured communication method.
    - **Name:** Enter a name that helps identify the network template. For example, you can enter **Class C** if you want to configure the template for creating Class C networks.
    - **Netmask**: Select one of the following options:
        - **Fixed**: Select this and adjust the netmask slider to a fixed netmask for this network template. When you select this option, users cannot specify another netmask when they use this template to create a network. For example, if you select /24 as the fixed netmask, all networks created using this template have a /24 netmask.
        - **Allow User to Specify Netmask**: Select this to allow users to specify the subnet mask when creating networks using this template.
    - **Comment:** Optionally, enter additional information about the template.
    - **Automatically Create Reverse-Mapping Zone:** This function is enabled if the fixed netmask of the template equals /8, /16, and /24, or if you select the **Allow User to Specify Netmask** option. Select this if you want the appliance to automatically create the corresponding reverse-mapping zone for the networks created using this template. A reverse-mapping zone is an area of network space for which one or more name servers have the responsibility for responding to address-to-name queries. These zones are created in the DNS view assigned to receive dynamic DNS updates at the network level.

      The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*. To configure this template for cloud delegation, complete the following:
      Use for cloud delegation: Select this checkbox to enable cloud delegation for this template.

      When you select this for the network template, all range and fixed address templates that you want to associate with this network template must also be enabled for "**Use for cloud delegation**."

      Delegate authority from the Grid Master

      Delegate To: In a non-cloud API request, this parameter defines the default member to which authority is delegated. In a cloud API request, the appliance ignores this parameter, which allows you to use this template to create an object on different Cloud Platform Appliances. Click **Select** to choose the default Cloud Platform Appliance to which you want to delegate authority. The *Member Selector* displays only Cloud Platform Appliances in the Grid. Click the member, and Grid Manager displays the member name next to this field.
4. Click **Next** and do the following to assign either Grid members or Microsoft DHCP servers to this network template. Ensure that you include members or Microsoft servers that are associated with other templates that you plan to add to this network template. You can assign one or multiple members to this template. However, you cannot assign a combination of NIOS Grid members and vNIOS Grid members to the template. You can also assign multiple Microsoft servers to a template, but you cannot assign a mix of Microsoft servers and Grid members to a template.
    - click the Add icon and select one of the following options:
        - **Add Infoblox Member**: Select this option to add a Grid member as a DHCP server for the networks created using this template. Select the Grid member from the *Member Selector* dialog box. Keep in mind, DHCP properties for the network are inherited from this member. Networks created using this template can be served by multiple members, but a member can serve networks in one network view only.
          or
        - **Add Microsoft Server**: Select this option to add a Microsoft server as a DHCP server for the networks created using this template. Select the Microsoft server from the *Microsoft Server Selector* dialog box.
5. Click **Next** to associate Active Directory Sites with the network. For more information, see *Associating Active Directory Sites with Networks*.
6. Click **Next** and do the following to include IPv4 address range and fixed address/reservation templates in the network template. Note that when you select a fixed address/reservation template, only reservations, not fixed

addresses, are created for networks created using this template. You cannot add a fixed address/reservation template that does not contain an offset value or a total number of IP addresses for a range.
    a. Click the Add icon.
    b. In the *DHCP Template Selector* dialog box, choose the template that you want to include in this network template. You can choose a DHCP range or fixed address/reservation template. Use SHIFT+click and CTRL+click to select multiple templates.
    c. Click the Select icon.
    You can delete a template from the table by selecting it and clicking the Delete icon.
7. Click **Next** to configure or override DHCP options as described in *Defining IPv4 DHCP Options*.
8. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
   If you are adding an RIR network, the RIR network attribute table appears. For information about these attributes and how to enter them, see *RIR Network Attributes*.
9. Save the configuration and click **Restart** if it appears at the top of the screen.

Modifying IPv4 Network Templates

To modify a network template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab -> *template* checkbox, and then click the Edit icon.
2. The *IPv4 Network Template* editor contains the following tabs from which you can modify data:
   - **General**: Modify general information described in Adding IPv4 Network Templates above.
   - **Member Assignment**: Change the Microsoft servers or Grid members that provide DHCP services for this template. For information, see *Adding IPv4 Networks*.
   - **Templates**: Add or delete DHCP range and fixed address/reservation templates. For information, see About IPv4 Range Templates and About IPv4 Fixed Address/Reservation Templates above.
   - **IPv4 DHCP Options**: Keep the inherited DHCP options or override them and enter unique settings for the template. For information, see *Defining IPv4 DHCP Options*.
   - **RIR Registration**: Modify RIR network information. This tab appears only when support for RIR updates is enabled. For information, see *Modifying RIR Network Data*.
   - **Extensible Attributes**: Add and delete extensible attributes that are associated with the template. You can also modify the values of the extensible attributes. For information, see *Using Extensible Attributes*.
   - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions*.
3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify data:
   - **IPv4DDNS**: Keep the inherited DDNS settings or override them and enter unique settings for the template. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
   - **IPv4 BOOTP/PXE**: Keep the inherited BOOTP properties or override them and enter unique settings for the template. For information, see *Configuring IPv4 BOOTP and PXE Properties*.
   - **Filters**: You can keep the inherited IPv4 logic filters or override them and add a new IPv4 logic filter for the template. For information, see *Applying Filters to DHCP Objects*.
   - **IPv4 DHCP Thresholds**: Keep the inherited thresholds settings or override them and enter unique settings for the template. For information, see *Configuring Thresholds for DHCP Ranges*.
     Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuration Example: Creating an IPv4 Network Using a Template

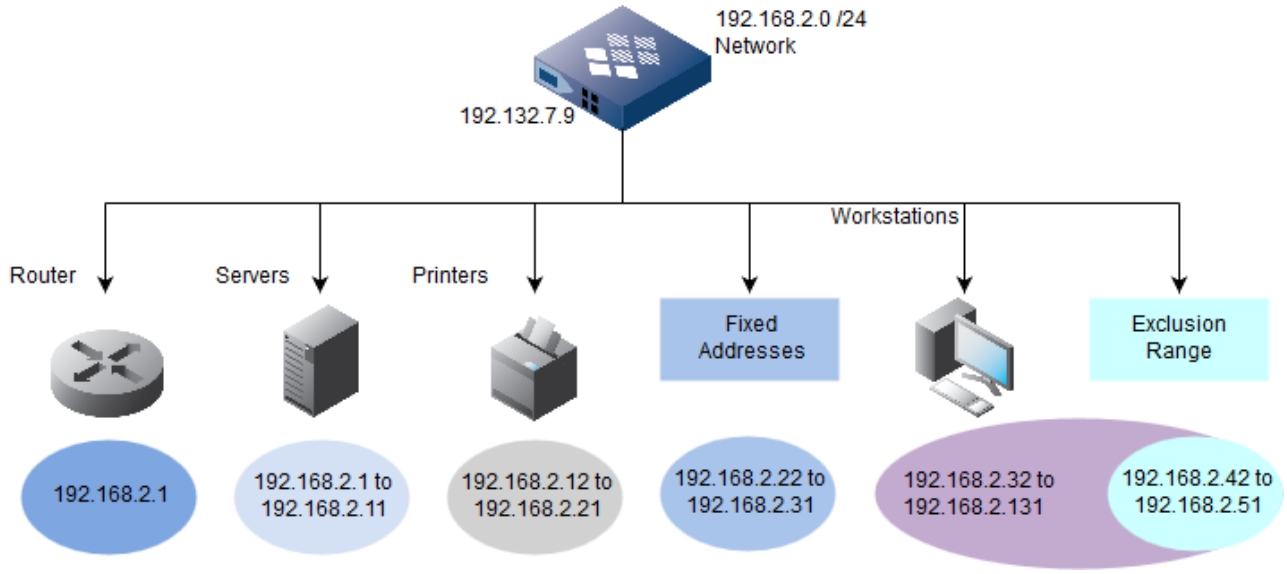
This example describes how to create a /24 network template and how to use the template to create a 192.168.2/24 network with the following configurations:

- First address 192.168.2.1 is reserved for the router
- Next 10 addresses (192.168.2.2 to 192.168.2.11) reserved for servers
- Next 10 addresses (192.168.2.12 to 192.168.2.21) reserved for printers
- Next 10 addresses (192.168.2.22 to 192.168.2.31) assigned as fixed addresses

- 100 addresses (192.168.2.32 to 192.168.2.131) reserved for workstations. The appliance assigns these dynamically.
- 10 addresses (192.168.2.42 to 192.168.2.51) are in an exclusion range. If you assigned static addresses to certain hosts in the middle of an address range template, you can exclude the addresses from the address range template so the appliance does not assign these IP addresses to clients

The below figure illustrates the configurations of the 192.168.2/24 network using the network template you create:

Creating a Network Using a Template



Use the following steps to create the sample network template (shown in the above figure).

1. Create the following DHCP range templates. For information, see Adding IPv4 Range Templates above.
    - Server template with the following values:
        - **Name:** Servers
        - **Offset:** 2
        - **Number of Addresses:** 10
        - **Comment:** Address range 2 to 11 for Servers
    - Printer template with the following values:
        - **Name:** Printers
        - **Offset:** 12
        - **Number of Addresses:** 10
        - **Comment:** Address range 12 to 21 for printers.
    - Workstation template with the following values:
        - **Name:** Workstations
        - **Offset:** 32
        - **Number of Addresses:** 100
        - **Comment:** Address range 32 to 131 for DHCP on workstations
    - Exclusion range with the following values. You must modify the *Workstations* template to add the exclusion range. For information, see Modifying IPv4 Range Templates above.
        - **Name:** Exclusion
        - **Offset:** 42
        - **Number of Addresses:** 10
        - **Comment:** Excluding addresses 42 to 51 from the DHCP range 32 to 131.
2. Create a fixed address/reservation template with the following values. For information, see Adding IPv4 Fixed Address/Reservation Templates above.
    - **Name:** Router
    - **Comment:** Fixed address template
    - **Offset:** 1
    - **Number of Addresses:** 1

3. Create a fixed address/reservation template with the following values. For information, see Adding IPv4 Fixed Address/Reservation Templates above.
    - **Name:** myFixedAddress
    - **Comment:** Fixed address template
    - **Offset:** 22
    - **Number of Addresses:** 10
4. Create a network template with the following values. For information, see Adding IPv4 Network Templates above.
    - **Name:** myNetworkTemplate
    - **Netmask**: Select /24 as the fixed subnet mask for the network
    - **Comment:** Network template for /24 network
    - **Automatically create are verse-mapping zone:** Select this so that the NIOS appliance automatically creates the corresponding reverse-mapping zone for the network.
5. Add the DHCP range templates *Servers*, *Printers*, and *Workstations* to the network template.
6. 6. Add the fixed address/reservation template *myFixedAddress* to the network template.
7. Add a fixed address with the following values:
8. Create a network using the network template *myNetworkTemplate* with the following values. For information, see *Adding IPv4 Networks*.
    - **Address:** Enter the IP address 192.168.2.0 of the network that you want to create using the template.
    - **Select template:** Select the network template *myNetworkTemplate*.
9. To verify your configuration, from the **Data Management** tab, select the **DHCP** tab -> **Templates** tab. Select *myNetworkTemplate* and click the Edit icon. In the *Network Template* editor, click the **Templates** tab. The Grid Manager displays the DHCP range templates and fixed address templates.
10. Click **Restart** to restart services.

About IPv6 DHCP Templates

You can use templates to create DHCP IPv6 ranges, fixed addresses, roaming hosts, and networks. You can create the following IPv6 templates:

- A DHCP range template that specifies an offset and the total number of addresses in a range. You can add a DHCP range template to a network template. For more information, see *About IPv6 Range Templates*.
- A fixed address template, containing information for creating fixed addresses and roaming hosts. You can add a fixed address template to a network template. For information, see *About IPv6 Fixed Address Templates*.
- A network template, containing basic network properties for creating networks. It is also a container that holds your DHCP range templates and fixed address/reservation templates. When you create a network using a network template, the network inherits the properties of the range and fixed address/reservation templates. You can create a network in any network view using a network template. For information, see *Adding IPv6 Network Templates*.

Because you can potentially add DHCP range and fixed address/reservation templates to a network template, create the DHCP range and fixed address/reservation templates before you create a network template.

About IPv6 Range Templates

You can create range templates to specify an offset and the number of addresses allocated to a range. Note that you cannot create templates for prefix-delegated ranges because the start or end prefix can be outside of the subnet address boundary.
After you create a DHCP range template, you can configure additional properties such as exclusion ranges and DHCP properties, as described in Modifying IPv6 Range Templates below. Then when you use the template to create a DHCP range, the range inherits the properties of the template. You can also include a DHCP range template in a network template to automatically create a DHCP range when you use that network template.
If you have deployed the Cloud Network Automation license on the Grid Master, you can configure range templates for cloud delegation. If you select a default Cloud Platform Appliance for a template, all ranges you create using this template will delegate authority to the same Cloud member. Note that when a Cloud member is removed from the Grid, the delegation will also be removed from the template. For information about Cloud Network Automation, see *Deploying Cloud Network Automation*.

> **Note**
>
> Infoblox does not support global IPv6 prefix delegation for IPv6 range templates.

Adding IPv6 Range Templates

To create an IPv6 range template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab.
2. Click the drop-down menu of the Add icon and select **IPv6 Range Template**.
3. In the *Add IPv6 Range Template* wizard, complete the following:
   - **Name:** Enter a name that helps identify the IPv6 DHCP range template.
   - **Offset:** An offset in a DHCP range template determines the starting IP address of the range. The appliance adds the offset value you enter here to the start IP address of the network in which you create a DHCP range using this template. That IP address becomes the start IP address of the DHCP range. For example, you specify an offset value of 10 for the 2001:db8:1263:/48 network using the DHCP range template, the appliance creates a range with the start address 2001:db8:1263:0:0:0:0:a.
   - **Number of Addresses:** Enter the total number of IPv6 addresses to be included in the DHCP range.
   - **Comment:** Optionally, enter additional information about the template.

     The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*. To configure this template for cloud delegation, complete the following:

     Use for cloud delegation: Select this checkbox to enable cloud delegation for this template.

     Delegate authority from the Grid Master
   - **Delegate To**: In a non-cloud API request, this parameter defines the default member to which authority is delegated. In a cloud API request, the appliance ignores this parameter, which allows you to use this template to create an object on different Cloud Platform Appliances. Click **Select** to choose the default Cloud Platform Appliance to which you want to delegate authority. The *Member Selector* displays only Cloud Platform Appliances in the Grid. Click the member, and Grid Manager displays the member name next to this field.
4. Click **Next** and select one of the following to provide DHCP services for the range:
   - **None (Reserved Range)**: Select this if you want to reserve this address range for static hosts. Addresses in this range cannot be allocated as dynamic addresses. You can allocate the next available IP from this range to a static host. This is selected by default.
   - **Grid Member:** Click Select and choose a Grid member from the drop-down list.
5. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attribute*.
6. Save the configuration.

Modifying IPv6 Range Templates

You can modify the properties of a DHCP range template and define an exclusion range. For the exclusion range in the template, the start and end addresses are determined by the number of offsets in the DHCP range template's start address and the number of IP addresses in the exclusion range. For more information about exclusion ranges, see *About DHCP Ranges*.
To modify a DHCP range:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab -> *template* checkbox, and then click the Edit icon.
2. The *IPv6 DHCP Range Template* editor contains the following tabs from which you can modify data:
   - **General**: Modify general information as described in Adding IPv6 Range Templates above.
   - **Member Assignment**: Change the Grid member that provides DHCP services for ranges created from this template. For information, see Adding IPv6 Range Templates above.

- **Extensible Attributes**: Add and delete extensible attributes that are associated with this template. You can also modify the values of the extensible attributes. For information, see *Using Extensible Attributes.*
- **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *About Administrative Permissions*.

3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify data:
   - **Exclusion Ranges**: Configure a range of IP addresses that the appliance does not use for dynamic address assignments. **Exclusion Ranges**: Configure a range of IP addresses that the appliance does not use for dynamic address assignments. Complete the following:
     - **Offset:** An offset for an exclusion range determines the start IP address of the exclusion range. The appliance adds the offset value you enter here to the start IP address of the DHCP range created using this template. That IP address becomes the start IP address of the exclusion range.
     - **Number of Addresses:** Enter the number of IP addresses to be included in the exclusion range.
     - **Comment:** Enter useful information about the exclusion range.
     Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.
4. Save the configuration.

About IPv6 Fixed Address Templates

A fixed address template is useful when you want to create multiple fixed addresses in a network. When you create a fixed address template, you specify the offset value and number of fixed addresses to be created. You can also specify additional properties for the fixed addresses.
Note that you can use the template to create address-based fixed addresses. You cannot specify prefixes in the template because a fixed address could use a prefix that is not part of the subnet to which the fixed address belongs. You can enter prefixes when you create the individual fixed address objects using the template.
If you have deployed the Cloud Network Automation license on the Grid Master, you can configure fixed address templates for cloud delegation. When you configure a template for cloud delegation, all fixed addresses you create using this template will inherit authority delegations from their parent objects. For information about Cloud Network Automation, see *Deploying Cloud Network Automation*.

Adding IPv6 Fixed Address Templates

To create an IPv6 fixed address template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab.
2. Click the drop-down menu of the Add icon and select **IPv6 Fixed Address Template**.
3. In the *Add IPv6 Fixed Address Template* wizard, enter the following:
   - **Name:** Enter a name that helps identify the IPv6 fixed address template. For example, you can enter **HP Printer** when you create a template that contains settings for assigning fixed addresses or reservations to HP printers.
   - **Comment:** Optionally, enter additional information about the template.
   - **Use for cloud delegation**: When you select this checkbox, all fixed addresses you create using this template inherit authority delegation from their parent objects.
     In the **Optional Settings For Range of Objects** section, do the following:
   - **Offset:** An offset in a fixed address template determines the IP address of the first fixed address created from the template. The appliance adds the offset value you enter here to the start IP address of the network in which you create objects using this template, and that IP address becomes the IP address of the object. For example, you specify an offset value of 50 for the 2001:db8:1263:/48 network, when you create a fixed address using the fixed address template, the appliance assigns it the address 2001:db8:1263:0:0:0:0:32.
   - **Number of Addresses:** Enter the number of IP addresses to be used as fixed addresses or roaming hosts. Note that the appliance uses the offset and number of addresses only when this template is used in a network template.
4. Click **Next** to configure or override DHCP options as described in *Defining General IPv6 Properties*.
5. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
6. Save the configuration.

Modifying IPv6 Fixed Address Templates

To modify a fixed address template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab -> *template* checkbox, and then click the Edit icon.
2. The *IPv6 Fixed Address Template* editor contains the following tabs from which you can modify data:
   - **General**: Modify general information for the template as described in Adding IPv6 Fixed Address Templates above.
   - **IPv6 DHCP Options**: Keep the inherited DHCP options or override them and enter unique settings for the template. For information, see *Defining General IPv6 Properties*.
   - **Extensible Attributes**: Add and delete extensible attributes that are associated with the template. You can also modify the values of the extensible attributes. For information, see *Using Extensible Attributes*.
   - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *About Administrative Permissions*.
3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify data:
   - **IPv6 DDNS**: Keep the inherited DDNS settings or override them and enter unique settings for the template. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
   - **Filters**: You can keep the inherited IPv6 logic filters or override them and add a new IPv6 logic filter. For information, see *Applying Filters to DHCP Objects*.
     Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.
4. Save the configuration.

About IPv6 Network Templates

You can create IPv6 network templates to facilitate network configuration. You can use network templates to create networks in any network view. When you create a network template, you do not specify a network address. You enter the network address when you create an actual network from the template. You can specify a netmask or allow the user to define the netmask when they create the actual network.
A network template is useful for setting up a network with fixed addresses and DHCP ranges already defined. You can add DHCP range or fixed address templates to a network template.

> **Note**
>
> You cannot configure the following DHCP options in an IPv6 network template: server-id (Option 2), preference (option 7), and unicast (Option 12). These options are valid only for a DHCP member.

When you enable support for RIR updates, you can create IPv6 network templates specific for RIR associated networks. For information about RIR updates, see *RIR Registration Updates*.
You can also configure network templates for cloud delegation if you have deployed the Cloud Network Automation on the Grid Master. If you select a default Cloud Platform Appliance for a template, all networks you create using this template will delegate authority to the same Cloud member. Note that when a Cloud member is removed from the Grid, the delegation will also be removed from the template. For information about Cloud Network Automation, see *Deploying Cloud Network Automation*.

Adding IPv6 Network Templates

To create a network template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab.
2. Click the drop-down menu of the **Add** icon and select **IPv6 Network Template**.
3. In the *Add IPv6 Network Template* wizard, do the following:
   - **RegionalInternetRegistry**: This section appears only when support for RIR updates is enabled. For information about RIR, see *RIR Registration Updates*. Complete the following to create a network template for an RIR IPv6 network container or network:

- **Internet Registry**: Select the RIR from the drop-down list. The default is **RIPE**. When you select **None**, the network is not associated with an RIR organization.
- **Organization ID**: Click **Select Organization** and select an organization from the *RIR Organization Selector* dialog box.
- **Registration Status**: The default is **Not Registered**. When using this template to add an RIR allocated network, you can change this to **Registered** and select the **Do not update registrations** checkbox below. Note that when you select **API** as the communication method, the registration status will be updated automatically after the registration update is completed. However, when you select **Email** as the communication method, the registration status will not be automatically updated. If you are creating a new network and the registration update is completed successfully, the status will be changed to **Registered**. If the update fails, the status will be changed to **Not Registered**.
- **Registration Action**: Select the registration action from the drop-down list. When you select **Create**, the appliance creates the IPv4 network and assigns it to the selected organization. When you select **None**, the appliance does not send registration updates to RIPE. When you use this template to add an existing RIR allocated network to NIOS, select **None**. When you use this template to add networks to an RIR allocated network (a parent network), select **Create**. Ensure that the parent network associated with an RIR organization already exists.
- **Do not update registrations**: Select this checkbox if you do not want the appliance to submit RIR updates to RIPE. By default, the appliance sends updates to the RIR database based on the configured communication method.

- **IPv6 Prefix:** If you are adding a template for a previously defined global IPv6 prefix, you can select it from the drop-down list.
- **Name:** Enter a name that helps identify the network template.
- **Netmask**: Select one of the following options:
  - **Fixed**: Select this and adjust the netmask slider to a fixed netmask for this network template. When you select this option, users cannot specify another netmask when they use this template to create a network. For example, if you select /24 as the fixed netmask, all networks created using this template have a /24 netmask. The slider moves to the CIDR value associated with the selected prefix when you choose a global IPv6 prefix.
  - **Allow User to Specify Netmask**: Select this to allow users to specify the subnet mask when creating networks using this template.
- **Comment:** Enter useful information about the template.
- **Automatically create a reverse-mapping zone:** This function is enabled if the fixed netmask of the template is a multiple of 4 (4, 8, 24, and so on), or if you select the **Allow User to Specify Netmask** option. Select this if you want the appliance to automatically create the corresponding reverse-mapping zone for the networks created using this template. These zones are created in the DNS view assigned to receive dynamic DNS updates at the network level.

  The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*. To configure this template for cloud delegation, complete the following:
  Use for cloud delegation: Select this checkbox to enable cloud delegation for this template.

  Delegate authority from the Grid Master

  Delegate To: In a non-cloud API request, this parameter defines the default member to which authority is delegated. In a cloud API request, the appliance ignores this parameter, which allows you to use this template to create an object on different Cloud Platform Appliances. Click **Select** to choose the default Cloud Platform Appliance to which you want to delegate authority. The *Member Selector* displays only Cloud Platform Appliances in the Grid. Click the member, and Grid Manager displays the member name next to this field.

4. Click **Next** to assign Grid members to this network template. Ensure that you include members that are associated with other templates that you plan to add to this network template. You can assign one or multiple members to this template. However, you cannot assign a combination of NIOS Grid members and vNIOS Grid members to the template.
   - Click the Add icon to add a Grid member as a DHCP server for the networks created using this template. Select the Grid member from the *Member Selector* dialog box. Keep in mind, DHCP properties for the

network are inherited from this member. Networks created using this template can be served by multiple members, but a member can serve networks in one network view only.

5. Click **Next** to associate Active Directory Sites with the network. For more information, see *Associating Active Directory Sites with Networks*.
6. Click **Next**, and then click the Add icon to include DHCP range and fixed address templates in the network template. Choose the template that you want to include in this network template. Use SHIFT+click and CTRL+click to select multiple templates.
   You can remove a template from the list by selecting the template and clicking the Delete icon.
7. Click **Next** to configure or override DHCP options as described in *Defining General IPv6 Properties*.
8. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
   If you are adding an RIR network, the RIR network attribute table appears. For information about these attributes and how to enter them, see *RIR Network Attributes*.
9. Save the configuration.

Modifying IPv6 Network Templates

To modify and set the properties of a network template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab -> *template* checkbox, and then click the Edit icon.
2. The *Network Template* editor contains the following tabs from which you can modify data:
   - **General**: Modify general information described in Adding IPv6 Network Templates above.
   - **Member Assignment**: Change the Grid members that provide DHCP services for networks created from this template. For information, see *Adding IPv6 Networks*.
   - **Templates**: Add or delete DHCP range and fixed address templates. For information, see *Adding IPv6 Range Templates* and *Adding IPv6 Fixed Address Templates*.
   - **IPv6 DHCP Options**: Keep the inherited DHCP options or override them and enter unique settings for the template. For information, see *Defining General IPv6 Properties*.
   - **RIR Registration**: Modify RIR network information. This tab appears only when support for RIR updates is enabled. For information, see *Modifying RIR Network Data*.
   - **Extensible Attributes**: Add and delete extensible attributes that are associated with the template. You can also modify the values of the extensible attributes. For information, see *Using Extensible Attributes*.
   - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions*.
3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify data:
   - **IPv6 DDNS**: Keep the inherited DDNS settings or override them and enter unique settings for the template. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
   - **Filters**: You can keep the inherited IPv6 logic filters or override them and add a new IPv6 logic filter. For information, see *Applying Filters to DHCP Objects*.
     Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.
4. Save the configuration.

Viewing and Deleting Templates

You can view a list of all IPv4 and IPv6 DHCP templates and delete the templates that are not required.

Viewing Templates

To view a list of all IPv4 and IPv6 DHCP templates:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab.
2. Grid Manager displays the following information:
   - **Name**: The name of the template.
   - **Type**: The template type, such as **IPv4 Network Template** or IPv6 Network Template.
   - **Comment**: The information you entered about the template.

- **Site**: The site to which the template belongs. This is one of the predefined extensible attributes.

You can select predefined and user defined extensible attributes for display. You can also do the following in this panel:

- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- Sort the displayed data in ascending or descending order by column.
- Delete a selected template or multiple templates. For information, see Deleting Templates below.
- Use filters and the **Goto** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Goto** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Select an object and edit its information.
- Print or export the data in the panel.

Deleting Templates

To delete a template:

1. From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab -> *template* checkbox, and then click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes**.

Managing IPv6 DHCP Data

This section explains how to configure and manage IPv6 DHCP data. It contains the following topics:

Configuring IPv6 Networks

To configure DHCP services for an IPv6 network and the resources in the network, perform the following tasks:

1. To facilitate network creation, you can specify the IPv6 global prefixes for the Grid. For more information, see *Defining Global IPv6 Prefixes*.
2. Create a network and assign it to Grid members. For information, see *Managing IPv6 Networks* and *About IPv6 Shared Networks*.
3. Optionally, configure DHCP properties for the network. You can override properties set at the Grid or member level and enter unique values for the network and fixed addresses. For information, see *Configuring DHCPv6 Properties* and *Configuring DHCP IPv4 and IPv6 Common Properties*.
4. Optionally, assign zones to a network. For information, see *Associating Networks with Zones*.
5. Add a DHCP range to the network and assign it to a member. For information, see *Configuring IPv6 Address Ranges*.
6. Optionally, add exclusions to the DHCP range for addresses that are not used for dynamic allocation. For information, see *Modifying IPv6 Address Ranges*.
7. Optionally, configure DHCP properties for the address range. You can override properties set at an upper level and enter unique values for the address range. For information, see *Modifying IPv6 Address Ranges*.

8. Optionally, add fixed addresses to the network and configure DHCP properties for them. A fixed address may also be associated with a device port through a Port Reservation. For information, see *Configuring IPv6 Fixed Addresses*.
9. Start the DHCP service and the IPv6 DHCP service. For more information, see *Starting DHCP Services on a Member*.

Defining Global IPv6 Prefixes

To simplify network creation, you can define IPv6 prefixes that are used for networks served by the Grid members. If your organization is assigned IPv6 prefixes, you can enter them globally at the Grid level, and then just select the appropriate IPv6 prefix when you define the network and network templates. You can create multiple global prefixes. When you define an IPv6 network and network templates, you must adjust the slider to the desired netmask as per the CIDR in the prefix. Use the netmask slider to select /64 as the CIDR, if an IPv6 prefix is unavailable for an IPv6 network.

To add global IPv6 prefixes:

1. From the **Data Management** tab, select the **DHCP** tab.
2. Expand the Toolbar and click **Grid DHCP Properties**.
3. In the *Grid DHCP Properties* editor, select the **IPv6 Global Prefixes** tab.
4. Click the Add icon and enter a name for the prefix and the prefix. Select the **Default** checkbox to specify a default IPv6 prefix for the Grid.
5. Save the configuration.

Managing IPv6 Networks

You can create an IPv6 network from scratch or create a network template and then use that template to create one or more networks. Using a network template facilitates creating multiple IPv6 networks with similar properties. You can also create an IPv6 network from the Tasks Dashboard. For information about the Tasks Dashboard, see *Tasks Dashboard*.
An IPv6 network inherits its DHCP options & DDNS settings from its shared network, if it is part of a shared network, or from the member to which it is assigned.
If you have enabled support for RIR (Regional Internet Registry) updates and are adding an RIR IPv6 network container or network to NIOS, Grid Manager displays an RIR section in the *Add IPv6 Network* wizard. You must enter RIR related information in this section in order for NIOS to associate the newly added network with an RIR organization. For more information about RIR address allocation and updates, see *RIR Registration Updates*.

Adding IPv6 Networks

To add an IPv6 network:

1. Select the **Data Management** tab.
2. If you have more than one network view in the system, select the network view in which you want to add the network.
3. Select the **DHCP** tab -> **Networks** tab.
4. In the **Networks** section, expand the **Toolbar** and click the **Add** drop-down list and select **Network**-> **IPv6** or click the Add icon drop-down list and select **IPv6 Network**.
5. In the *Add IPv6 Network* wizard, select one of the following and click **Next**:
    - **Add IPv6 Network:** Click this to add an IPv6 network from scratch.
    - **Add IPv6 Network using Template:** To use a template, click this, and then click **Select Template** and select an IPv6 network template. For information about network templates, see *About IPv6 Network Templates*. When you use a template to create a network, the configurations of the template apply to the new network. The appliance populates the template properties in the wizard when you click **Next**. You can then edit the pre-populated properties. If the template specified a fixed netmask, you cannot edit the netmask.
6. Complete the following and click **Next**:
    - **Regional Internet Registry**: This section appears only when support for RIR updates is enabled. For information about RIR, see *RIR Registration Updates*. Complete the following to create an RIR IPv6 network container or network:

- **Internet Registry**: Select the RIR from the drop-down list. The default is **RIPE**. When you select **None**, the network is not associated with an RIR organization.
- **Organization ID**: Click **Select Organization** and select an organization from the *RIR Organization Selector* dialog box.
- **Registration Status**: The default is **Not Registered**. When adding an RIR allocated network, you can change this to **Registered** and select the **Do not update registrations** checkbox below. Note that when you select **API** as the communication method, the registration status will be updated automatically after the registration update is completed. However, when you select **Email** as the communication method, the registration status will not be automatically updated. If you are creating a new network and the registration update is completed successfully, the status will be changed to **Registered**. If the update fails, the status will be changed to **Not Registered**. The updated status and timestamp are displayed in the **Status of last update** field in the *IPv6 Network Container* or *IPv6 Network* editor.
- **Registration Action**: Select the registration action from the drop-down list. When you select **Create**, the appliance creates the IPv4 network and assigns it to the selected organization. When you select **None**, the appliance does not send registration updates to RIPE. When you are adding an existing RIR allocated network to NIOS, select **None**. When you are adding networks to an RIR allocated network (a parent network), select **Create**. Ensure that the parent network associated with an RIR organization already exists.
- **Do not update registrations**: Select this checkbox if you do not want the appliance to submit RIR updates to RIPE. By default, the appliance sends updates to the RIR database based on the configured communication method.

- **Netmask**: Use the netmask slider to select the appropriate number of subnet mask bits for the network. Select /64 as the CIDR, if an IPv6 prefix is unavailable for an IPv6 network. When the prefix is available, you must adjust the slider to the desired netmask as per the CIDR in the prefix.
- **Networks**: Do one of the following to add new networks:
  - Click the Add icon to enter a new network. If you are adding a network for a previously defined global IPv6 prefix, you can select the prefix from the **IPv6 Prefix** drop-down list. The default is **None**, which means that you are not creating an IPv6 network for a previously defined subnet route. If you have defined a global prefix at the Grid level, the default is the global prefix value. Click **Add** and Grid Manager adds a row to the table. Enter the network address in the **Network** field. When you enter an IPv6 address, you can use double colons to compress a contiguous sequence of zeros. You can also omit any leading zeros in a four-hexadecimal group. For example, the complete IPv6 address 2001:0db8:0000:0000:0000:0000:0102:0304 can be shortened to 2001:db8::0102:0304. Note that if there are multiple noncontiguous groups of zeros, the double colon can only be used for one group to avoid ambiguity. The appliance displays an IPv6 address in its shortened form, regardless of its form when it was entered. Click **Add** again to add another network. You can also select a network and click the **Delete** icon to delete it.
    or
    Click the Next Available icon to have the appliance search for the next available network. Complete the following in the Next Available Networks section:
    - **Create new network(s) under**: Enter the network container in which you want to create the new network. When you enter a network that does not exist, the appliance adds it as a network container. When you enter a network that is part of a parent network, the parent network is converted into a network container if it does not have a member assignment or does not contain fixed addresses and host records that are served by DHCP. You can also click **Select Network** to select a specific network in the *Network Selector* dialog box. For information about how the appliance searches for the next available network, see *Obtaining the Next Available*.
    - **Number of new networks**: Enter the number of networks you want to add to the selected network container. Note that if there is not enough network space in the selected network to create the number of networks specified here, Grid Manager displays an error message. The maximum number is 20 at a time. Note that when you have existing networks in the table and you select one, the number you enter here includes the selected network.
    - Click **Add Next** to add the networks. Grid Manager lists the networks in the table. You can click **Cancel** to reset the values.

      You must click **Add Next** to add the network container you enter in the Next Available

Networks section. If you enter a network in the Next Available Networks section and then use the Add icon to add another network, the appliance does not save the network you enter in the Next Available Networks section until you click **Add Next**.

- **Comment**: Enter additional information about the network, such as the name of the organization it serves.
- **Automatically Create Reverse-Mapping Zone**: This function is enabled if the netmask of the network is a multiple of four, such as 4, 8, 12 or 16. Select this to have the appliance automatically create reverse-mapping zones for the network. A reverse-mapping zone is an area of network space for which one or more name servers have the responsibility for responding to address-to-name queries. These zones are created in the DNS view assigned to receive dynamic DNS updates at the network view level.
- **Disable for DHCP:** Select this if you do not want the DHCP server to provide DHCP services for this network at this time. This feature is useful when you are in the process of setting up the DHCP server. Clear this after you have configured the server and are ready to have it serve DHCP for this network. Note that disabling an IPv6 network may take a longer time to complete depending on the size of the data.
- The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*. To delegate authority for this network, complete the following:
  Delegate authority from the Grid Master
- **Delegate To**: This field indicates whether the authority for the network you want to create has already been delegated to a Cloud Platform Appliance. Click **Select** to choose the Cloud Platform Appliance to which you want to delegate authority. The *Member Selector* displays only Cloud Platform Appliances in the Grid. Click the member, and Grid Manager displays the member name next to this field. This cloud member now assumes authority for this network, and the Grid Master does not have authority any more. You can also click **Clear** to remove authority delegation from the selected Cloud Platform Appliance and return authority back to the Grid Master.

7. Click **Next** and add one or more Grid members as DHCP servers for the network.
   - Click the **Add** icon and select a Grid member from the *Member Selector* dialog box. Note that, some DHCP properties for the network are inherited from this member. The network can be served by multiple members, but a member can serve networks in one network view only.
8. Click **Next** to associate Active Directory Sites with the network. For more information, see *Associating Active Directory Sites with Networks*.
9. (*Applies only to Network Insight*) Click **Next** to initiate or disable discovery of the new network(s). Discovery settings differ based on whether you are defining one network or multiple networks.
   - **Configuring one network**: discovery settings include the following: **Enable Discovery** and **Immediate Discovery**, selecting a Probe member to perform the discovery; and **Polling Options**, which define how the network will be discovered by the Probe member. By default, all Polling Options discovery settings are inherited from the parent network (or Grid, if no parent exists) unless you click **Override**. Polling Options govern the protocols used to query and collect information about the network devices being discovered.
     or
   - **Configuring more than one network**: If the networks are child networks, they automatically inherit the settings of the parent network, including discovery settings and the discovery member. These settings will not appear in the wizard page. For discovery of multiple networks, you can only enable or disable **Immediate Discovery**. Click **Next** to override the DHCP properties described in *Defining General IPv6 Properties*.
10. Assign VLAN objects to the network. For more information, see *VLAN Management*.
11. As part of creating a network, you can provision the network on an actual device (switch, router, or switch-router), that is discovered and managed through the Grid Manager.
    - Begin by checking the **Enable Network Provisioning** checkbox, and clicking the **Select Device** button. Choose your device from the Device Selector dialog. (Click **Clear** to remove the setting. For more information, see the section *Using the Device Selector*.)
    - If you performed DHCP configuration in the previous step of the Add Network Wizard, the **Router IP** value will automatically be populated with the DHCP Router IP address value. Otherwise, you enter the standard router IP address.
    - If required for the newly provisioned network to ensure that attached devices receive DHCP auto-configuration, enable the **DHCP Forwarding** checkbox. For this setting, if a DHCP Failover was previously configured, the IP addresses defined for DHCP failover are automatically used for the DHCP forwarding configuration.
    - You will also need to choose an interface on the selected device on which to provision the network by selecting it from the **Interface** drop-down menu. Grid Manager ensures that only those interfaces that can

support provisioning, and are available for provisioning (that do not have an **Operation Status** of Up), appear in the drop-down menu.
    - Otherwise, when creating networks and provisioning them on managed devices, you can create a VLAN on which to provision the network by clicking the **Create VLAN** option and entering the **VLAN Name** and **VLAN ID**. Ensure that the **VLAN ID** value you enter is appropriate for the application - don't create a new VLAN and provision a network for a VLAN value that is already actively carrying traffic for another routing domain.
      If a selected device does not support VLANs, the **Create VLAN** option will not appear.
12. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Managing Extensible Attributes*.
    If you are adding an RIR network, the RIR network attribute table appears. For information about these attributes and how to enter them, see *RIR Network Attributes*. You can preview the information before the appliance submits updates to the RIPE database. To preview registration updates, click **Preview RIR Submissions**. For more information, see *Previewing Registration Updates*.

    Note that you cannot leave an optional RIR attribute value empty. If you do not have a value for an RIR attribute, you must delete it from the table. You can enter up to 256 characters for all RIR attributes.

    You need to assign a **Subscriber Member Site** to add subscriber service related extensible attributes in order to populate Subscriber Cache.
13. As the final step in the Add IPv6 Network wizard, you define when Grid Manager creates the new network by scheduling it. You also schedule when the associated port control task executes (if a port configuration has been specified).
    - To create the new network and its associated port configuration immediately, select **Now**. Grid Manager synchronizes the port control task to take place at the same time as the creation of the new network.
    - You can choose to have Grid Manager execute the port control task at a later time by selecting **Later**. Choose a **Selected time** by entering or selecting a **Start Date** (click the calendar icon to choose a calendar date) and a **Start Time**, and choose a **Time Zone**.
14. Choose one of the following from the **Save &...** drop-down button menu:
    - Click **Save & Close** to add the new network and close the wizard (this is the default).
    - Click **Save & Edit** to add the new network and launch the editor.
    - Click **Save & New** to add the new network and launch the wizard again to add another network.

    At any step during the wizard, you can click Schedule for Later to schedule the task. In the Schedule Change panel, enter a date, time, and time zone. For information, see *Scheduling Tasks.*

    After you create a network, you can do the following:

- Add it to a shared network. For more information, see *Adding IPv6 Shared Networks*.
- Use the split network feature to create subnets for the network. For information, see *Splitting IPv6 Networks into Subnets*.
- Use the join networks feature to create a parent network that encompasses multiple subnets into a larger network. For information, see *Joining IPv6 Networks*. You can also create a shared network for subnets that are on the same network segment.
- View a list of networks. For more information, see *Viewing Networks*.

Modifying IPv6 Networks

You can modify existing network settings and override the Grid or member DHCP properties, with the exception of the network address and netmask.
To modify an IPv6 network:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon.
2. The *IPv6 Network* editor contains the following basic tabs from which you can modify data:
    - **General Basic**: You can modify the following fields:
        - **Comment**: The information you entered for the network.

- **Disabled:** This field is displayed only if the selected network is a network without a child network under it. You can disable and enable existing networks instead of removing them from the database, if the selected network does not have a child subnet. This feature is especially helpful when you have to move or repair the server for a particular network. Note that disabling an IPv6 network may take a longer time to complete depending on the size of the data.
  When the Cloud Network Automation license is installed on the Grid Master, Grid Manager displays the following information in the **Cloud** section: **Cloud Usage**, **Owned By**, and **Delegated To**.
  You cannot modify these fields. For more information, see Adding IPv6 Networks above.
  - **Member Assignment**: Add or delete a Grid member that provides DHCP services for this network.
  - **IPv6 DHCP Options**: Keep the inherited DHCP properties or override them and enter unique settings for the network. For information, see *Defining General IPv6 Properties*.
  - **Discovery**: Checking the **Enable Discovery** checkbox informs NIOS to begin discovering the network after you click **Save and Close**. You manage discovery polling settings local to each network from this page. For a complete overview of features on this page, see *Discovering Devices and Networks* and its subsections.
  - **Discovery Exclusions**: IP Addresses and IP ranges can be locally excluded from discovery by clicking the Add icon and selecting **Add IP Address** or **Add IP Range**. These IP addresses or IP ranges are selected from within the chosen network. For related information, see *Excluding IP Addresses from Discovery* and its subsections.
  - **Discovery Blackout**: Define extended time periods and regularly scheduled times when discovery and/or port configuration tasks will not take place on a network. Editing a network under DHCP, blackout settings apply only to the specified network. You also specify the scheduled time when the blackout period begins, and the duration of the blackout period. By default, the network inherits its discovery blackout settings from the Grid level. For related information, see *Defining Blackout Periods* and its subsections.Discovery blackout settings also can be defined for DHCP ranges.
  - **RIR Registration**: Modify RIR network information. This tab appears only when support for RIR updates is enabled. For information, see *Modifying RIR Network Data*.
  - **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific network. You can also modify the values of the extensible attributes. For information, see *Managing Extensible Attributes*.
  - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions*.

3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify advanced data.
   - **General Advanced***:* You can associate zones with a network. For information, see *Associating Networks with Zones*.
   - **IPv6 DDNS**: Keep the inherited DDNS settings or override them and enter unique settings for the network. Note that you must click **Override** and select **Enable DDNS updates** for the DDNS settings you configure in this tab to take effect. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
   - **Filters**: You can keep the inherited IPv6 logic filters or override them and add a new IPv6 logic filter. For information, see *Applying Filters to DHCP Objects*.
     Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.
4. Save the configuration or click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks.*

Deleting IPv6 Networks

When you delete a network, all of its data, including all DHCP records, subnets, and records in its subnets, is deleted from the database. Because of the potentially large loss of data that can occur when you delete a network, the appliance stores the deleted network in the Recycle Bin. You can restore a deleted network from the Recycle Bin, if enabled. You can also disable a network instead of deleting it. For information, see Modifying IPv6 Networks above.
To delete a network:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> *network* checkbox, and then select **Delete** or **Schedule Delete** from the Delete drop-down menu.
2. To delete the network now, in the Delete Confirmation dialog box, click **Yes**. Grid Manager displays a warning message. Click **Yes** to continue or **No** to cancel the process. To schedule the deletion, see *Scheduling Deletions*. You can also choose to export all network data to a CSV file before deleting. To do this, click the **Export & Delete** button. For more information about this option, see *Configuring IPv4 Networks*.

The appliance puts the deleted network in the Recycle Bin, if enabled. Click **Restore** in the Recycle Bin to recover the deleted data. Click **Yes** in the Restore Item dialog box to restore or **No** to cancel the process. Note that deleting and restoring an IPv6 network may take a longer time to complete depending on the size of the data.

> ⚠ Note
>
> You cannot delete a network that has a VLAN object assigned to it. For more information, see *Assigning VLANs to a Network*.

Configuring IPv6 Shared Networks

You can combine two or more contiguous IPv6 networks into a shared network. When you do, the DHCP server allocates IP addresses from both subnets. To create a shared network, create the individual subnets, and then create the shared network and add the subnets to it. For more information about shared networks, see *About Shared Networks*.

Adding IPv6 Shared Networks

To add an IPv6 shared network:

1. Select the **Data Management** tab.
2. If you have more than one network view in the system, select the network view in which you want to add the network.
3. Select the **DHCP** tab -> **Networks** tab.
4. In the **Shared Networks** section, click the **Add** drop-down list and select **Shared Network**-> **IPv6** or or, click the Add icon drop-down list and select **IPv6 Shared Network**.
5. In the *Add IPv6 Shared Network* wizard, do the following:
   - **Name**: Enter the name of the shared network.
   - **Comment:** Enter information about the shared network.
   - **Disabled:** Select this if you want to enable the shared network at a later time. You can disable and enable existing networks instead of removing them from the database. This feature is especially helpful when you have to move or repair the server for a particular network.
6. Click **Next** and do the following to add networks:
   a. Click the Add icon.
   b. In the *Network Selector*, select the networks that you want to include in the shared network. Ensure that the networks are served by the same Grid members to avoid DHCP inconsistencies.
7. Click **Next** to configure DHCP properties described in *Defining General IPv6 Properties*.
8. Click **Next** to enter values for required extensible attributes or add optional extensible attributes for the shared network. For information, see *Using Extensible Attributes*.
9. Save the configuration or click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

For information on viewing shared networks, see *Viewing Shared Networks*.

Modifying IPv6 Shared Networks

To modify a shared network:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Shared Networks** section -> *shared_network* checkbox, and then click the Edit icon.

2. The *IPv6 Shared Network* editor contains the following tabs from which you can modify data:
    - **General**: Modify the fields **Name**, **Comments**, and **Disabled** as described in the previous section, Adding IPv6 Shared Networks.
        - **Networks**: Displays the networks that are currently assigned to the shared network. You can add or delete a network. To add a network, click the Add icon. To delete a network, select the *network* checkbox, and then click the Delete icon.
    - **IPv6 DHCP Options**: Keep the inherited DHCP properties or override them and enter unique settings for the shared network. For information, see *Defining General IPv6 Properties*.
    - **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific network. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.
    - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions*.
3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify advanced data.
    - **IPv6 DDNS**: Keep the inherited DDNS settings or override them and enter unique settings for the shared network. Note that you must click **Override** and select **Enable DDNS updates** for the DDNS settings you configure in this tab to take effect. For information, see *Enabling DDNS for IPv4 and IPv6 DHCP Clients*.
    - **Filters**: You can keep the inherited IPv6 logic filters or override them and add a new IPv6 logic filter. For information, see *Applying Filters to DHCP Objects*.

      Note that Grid Manager displays both the basic and advanced tabs the next time you log in to the GUI.

4. Save the configuration and click **Restart** if it appears at the top of the screen.
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Deleting IPv6 Shared Networks

Though you can delete the networks in a shared network, a shared network must have at least one network in it. To delete a shared network:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Shared Networks** section -> *shared_network* checkbox, and then select **Delete** or **Schedule Delete** from the drop-down menu.
2. To delete the shared network now, in the *Delete Confirmation* dialog box, click **Yes**. To schedule the deletion, see *Scheduling Deletions*.

The appliance puts the deleted shared network in the Recycle Bin, if enabled.

Configuring IPv6 Fixed Addresses

You can configure IPv6 fixed addresses with either an IPv6 address or prefix. You can assign prefix-based fixed addresses to routers so they can advertise the prefixes associated with a link. The fixed addresses also can be bound to interfaces on a network device, such as a switch or a router, that is discovered and managed under IPAM. DHCP hosts, in turn, use these prefixes to generate IP addresses using the stateless autoconfiguration mechanism defined in *RFC 2462, IPv6 Stateless Autoconfiguration*. You can also create IPv6 fixed addresses from the Tasks Dashboard. For information about the Tasks Dashboard, see *Tasks Dashboard*.

> **Note**
>
> IPv6 fixed addresses do not support dynamic DNS updates.

Adding IPv6 Fixed Addresses

> **Note**
>
> At any time during the wizard, you can click **Schedule for Later** to schedule the task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

To add an IPv6 fixed address:

1. Navigate to the network to which you want to add a fixed address, and then select **Fixed Address** from the Add drop down menu.
   or
   From any panel in the DHCP tab, expand the Toolbar and click **Add** -> **Fixed Address** -> **IPv6**.
2. In the *Add Fixed Address* wizard, select one of the following and click **Next**:
   - **Add IPv6 Fixed Address**
     or
   - **Add IPv6 Fixed Address Using Template**

     Click **Select Template** and select the template that you want to use. When you use a template to create a fixed address, the configurations of the template apply to the new address. The appliance automatically populates the fixed address properties in the wizard. You can edit the pre-populated properties.
3. In this panel, the displayed network address can either be the last selected network or the network from which you are adding the fixed address. If no network address is displayed or if you want to specify a different network, click **Select Network**. When there are multiple networks, Grid Manager displays the *Select Network* dialog box. Specify one of the following:
   - Select **Address** to assign an IPv6 address to a fixed address. You can either enter an IPv6 address or select **Next Available IP** to obtain the next available IP address. Note that for Cloud Network Automation, Next Available IP is not available if the fixed address you want to create is within a delegated range.
   - Select **Prefix Delegation** to assign an IPv6 prefix. Enter the prefix and prefix length.
   - Select **Both** to assign an IPv6 prefix and address. Enter the IPv6 address, prefix, and prefix length.

     Complete the following:
   - **DUID:** Specify the DHCP Unique Identifier (DUID) of the DHCP client assigned to this fixed address.
   - **Name:** Enter a name for the fixed address.
   - **Comment:** Optionally, enter additional information.
   - **Disabled:** Select this if you do not want the DHCP server to allocate this IP address at this time.

     The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*. This section displays the following information:
   - **Cloud Usage**: This field indicates whether this object is associated with any specific cloud extensible attributes or within a scope of delegation. It can be one of the following:
     - **Cloud from adapter**: Indicates that this object has been created by a cloud adapter and it may or may not be within a scope of delegation at the moment.
     - **Cloud from delegation**: Indicates that this object is within the scope of delegation or the object itself defines a scope of authority delegation, and it is not created by a cloud adapter.
     - **Used by cloud**: Indicates that this network or network container is associated with the extensible attribute **Is External** or **Is Shared** and the value is set to True, which implies the network is a private or shared network managed by the CMP, and it is not **Cloud from adapter** or **Cloud from delegation**.
     - **Non-cloud**: The object is a regular NIOS object and is not within the scope of any authority delegation nor is it associated with any of these extensible attributes: **Cloud API Owned, Is External** or **Is Shared**. NIOS admin users can modify this object based on their permissions.
   - **Owned By**: A cloud object can be owned by the Grid Master or the cloud adapter. When the object is created by the Grid Master, this shows **Grid**. If the object is created by the cloud adapter, this shows **Adapter**.

Delegate authority from the Grid Master

- **Delegate To**: This field indicates whether the authority for the object you want to create has already been delegated. If so, it displays the name of the delegation.

4. Click **Next** to configure or override DHCP options as described in *Defining General IPv6 Properties*.
5. (*Applies only with Network Insight*) *This step is not required for creating a new Fixed Address*. In the current Wizard step, you can optionally define the following identification values and settings for the new object's port reservation:
   - Choose the **DeviceType**: **Router**, **Switch-Router**, **Switch**, **MSFT** (Microsoft) **Server**, **NetMRI**, **NIOS**, **VNIOS**, or **ESX** (VMware) **Server**.
     The values on this page are not required for defining the actual port reservation in a later wizard step. Certain device types could be descriptively relevant based on the type of object you are creating. As an example, the **MSFT Server** designator helps identify the new object as a Microsoft Hyper-V Host. The **ESX Server** designator can be used to identify the new object as a VMware ESX Host. These values are not required and will not affect the functionality of the object.
   - Choose the **Device Vendor**: **Cisco**, **Juniper**, **Aruba**, **Dell**, **Infoblox**, or **HP**.
   - You can also enter a **Location** and a **Description**. These values are advisory and not required for configuration.
     After you define this group of settings, you will still need to define a device port reservation, which is done in a later step.
6. Click **Next** to initiate or disable discovery of the new Fixed Address. (*Applies only to Network Insight*) *This step is not required for creating a new Fixed Address*.
   a. Choose either **Exclude from Network Discovery** or **Enable Immediate Discovery**. If you choose to Exclude, discovery will not execute on the Fixed Address. If you choose **Enable Immediate Discovery**, discovery will execute on the host after you save your settings. You may also choose to leave both options disabled.
   b. By default, the new fixed address object inherits its SNMP credentials from those defined at the grid level. Should you wish to override them for a local set of credentials, check the **Override Credentials** checkbox and select the **SNMPv1/SNMPv2** or **SNMPv3** option and enter the locally used credentials.
   c. You may also test the entered SNMP credentials by clicking **Test SNMP Credential**.

      For descriptions of SNMP credentials for discovery, see the section *Configuring SNMP1/v2 Credentials for Polling* and *Configuring SNMPv3 Properties*. These Grid-based values are inherited, by default, by each new object you create.
      - For the new object, you can check the **Override CLI Credentials** checkbox to override the inherited set of CLI credentials taken from the Grid level. This set of credentials may be used for the device that is directly associated with the new object in its Port Reservation.
      - You can also click **Test CLI Credentials** to enter and test a set of CLI login credentials against a device based on its IP address.

        Port control operations require CLI credentials for the involved devices. (If you are not using port control for the new object, usage of CLI credentials is optional.) Because some IPAM and DHCP objects will use port control features as part of object creation, CLI credentials are automatically leveraged as part of discovery. Ensure you have the correct sets of CLI credentials for devices in your network. See the section *Configuring CLI Discovery Properties* for related information.
      - SSH is the default for CLI operations. Check the **Allow Telnet** checkbox if you know the device involved in the object assignment may support Telnet but may not support SSH, or if you want Telnet as an option.

        All port control operations require CLI credentials to be entered into Grid Manager. Because some IPAM and DHCP objects will use port control features as part of object creation, CLI credentials are automatically leveraged as part of discovery. Ensure you have the correct sets of CLI credentials for devices in your network.
7. Click **Next** to define the port reservation for the device port that will be associated with the new Fixed Address. *This step is not required for creating a new Fixed Address*. This feature set is also termed *port control* in the NIOS/Grid Manager system. The device to which the new Fixed Address will be associated should already be discovered and managed from the Grid Manager.
   - Begin by checking the **Reserve Port** checkbox. Note that reserving a switch port does not guarantee its availability.

Optionally, you can skip connecting port configuration by clicking **Next**.
Click the **Clear** button to remove the selected device from the configuration.

- Click the **Select Device** button to choose the device for which the port reservation will be associated. You should know the identity of the device to whose interface the new object will be associated before taking this step. For more information, see the section *Using the Device Selector*.
- After choosing the device, choose the **Interface** with which the port reservation will be bound. The drop-down list shows only interfaces that are most recently found to be available by Grid Manager during the last discovery cycle. This list will not include any ports that are Administratively Up and Operationally Up, or that are otherwise already assigned to other networks or objects.
- The Wizard page also shows a list of any VLANs that are currently configured in the chosen device (**The following VLANs are configured**). This Wizard page allows only the assignment of an existing VLAN in the chosen device to the new port reservation.
- Check the **Configure Port** checkbox to define specific port control settings for the port reservation.
- Choose the **Data VLAN** and/or the **Voice VLAN** settings you may need for the port assignment. Depending on the selected device, you may or may not be able to apply VLAN settings.
- Set the **Admin Status** to **Up** if you need to activate the port after assignment in the current task. All port control operations require CLI credentials to be entered into Grid Manager. Because some IPAM and DHCP objects will use port control features as part of object creation, CLI credentials are automatically leveraged as part of discovery and definition of port configurations such as Admin Up/Down status. Ensure you have the correct sets of CLI credentials for devices in your network.
- Enter a **Description** for the port assignment. Infoblox recommends doing so to help other technicians to recognize the port assignment task.

8. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.

   You need to assign a **Subscriber Member Site** to add subscriber service related extensible attribute in order to populate Subscriber Cache.

9. As the final step in the Add Fixed Address wizard, you define when Grid Manager creates the new object by scheduling it. You also schedule when the associated port configuration task executes.
   - To create the new object and its associated port configuration immediately, select **Now**. The port control event is automatically synchronized to take place at the same time as the activation of the new object.
   - You can choose to have Grid Manager execute the port reservation task at the same time as the Fixed Address object creation. To do so, select **At same time as Host**.
   - You can choose to have Grid Manager execute the port reservation task at a later time by selecting **Later**. Choose a **Selected time** by entering or selecting a **Start Date** (click the calendar icon to choose a calendar date) and a **Start Time**, and choose a **Time Zone**.
10. Choose one of the following from the **Save&...** drop-down button menu:
    - Click **Save & Close** to add the new object and close the wizard (this is the default).
    - Click **Save & Edit** to add the new object and launch the editor.
    - Click **Save & New** to add the new object and launch the wizard again to add another Fixed Address object.
11. Save the configuration and click **Restart** if it appears at the top of the screen.

> ⚠ **Note**
>
> At any step during the wizard, you can click **Schedule for Later** to schedule the task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*. You cannot schedule this task when you are creating an object that is within a delegated scope.

For information on viewing IPv6 fixed addresses in a network, see *Viewing IPv4 DHCP Objects*.

Modifying IPv6 Fixed Addresses

To modify a fixed address:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network* -> *fixed_address* checkbox, and then click the Edit icon.

2. The *Fixed Address* editor contains the following basic tabs from which you can modify data:
    - **General**: You can modify all the fields you filled out in the first step of the wizard described in *Adding IPv6 Fixed Addresses.*
    - **Device Information**: You can change advisory Device Information settings for the object's port reservation; settings are described in the section *Configuring IPv6 Fixed Addresses.*
    - **Discovery:** Checking the **Enable Discovery** checkbox informs NIOS to begin discovering the network after you click **Save and Close**. You manage discovery polling settings local to each fixed address from this page. For a complete overview of features on this page, see *Discovering Devices and Networks* and its subsections.
    - **Port Reservation:** Review and edit any device port reservations that may be defined for the current object, or create a new port reservation and schedule it. For a closer look, see the section *Port Control Features in Network Insight*, and steps 5-9 in the section *Configuring IPv6 Fixed Addresses.*
    - **IPv6 DHCP Options**: You can keep the inherited DHCP options or override them and enter unique settings for the fixed address. For information, see *Defining General IPv6 Properties*.
    - **Filters**: You can keep the inherited IPv6 logic filters or override them and add a new IPv6 logic filter. For information, see *Applying Filters to DHCP Objects*.
    - **Discovered Data**: You can view discovered data of this address, if any, in this tab. For information, see *Viewing Discovered Data.*
    - **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific network. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes.*
    - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions*.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

    or

    Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Deleting IPv6 Fixed Addresses

To delete a fixed address, from the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network* -> *fixed_address* checkbox, and then click the Delete icon. You cannot delete multiple fixed addresses at the same time if the authority for one of the fixed addresses is delegated to a Cloud Platform Appliance.

Configuring IPv6 Address Ranges

You can configure IPv6 ranges that are used to delegate IPv6 prefixes only, to assign IPv6 addresses only, or to delegate IPv6 prefixes and assign IP v6 addresses. When you define a DHCP range to delegate prefixes, the prefixes can be outside of the network where they are being defined. IPv6 ranges inherit their properties from their network, so each range in a subnet provides the same set of options to their DHCP clients.
Note that when an Infoblox DHCP server grants IPv4 leases, it starts from the last IP address in the range to the first. When the server grants IPv6 leases, it uses an algorithm based on the DUID of the client.

Adding IPv6 Address Ranges

To add a an IPv6 address range:

1. Navigate to the IPv6 network to which you want to add an address range, and then select **Range** from the Add drop down menu.
   or
   From any panel in the DHCP tab, expand the Toolbar and click **Add** -> **Range** -> **IPv6**.
2. In the *Add IPv6 Range* wizard, select one of the following and click **Next**:
    - **Add IPv6 Range:** Select this to add an address range from scratch.
      or
    - **Add IPv6 Range Using Template**

Click **Select Template** and select the template that you want to use. Note that when you use a template to create a DHCP range, the configurations of the template apply to the new range. The appliance automatically populates the address range properties in the wizard. You can then edit the pre-populated properties. For more information, see *About IPv6 Range Templates*.

3. Complete the following:
   - **Network**: Click **Select Network**. Grid Manager displays the network address here if you have only one network configured. When there are multiple networks, Grid Manager displays the *Select Network* dialog box from which you can select one.

     Specify one of the following:
   - **Address**: Select this if the address range is used to allocate IPv6 addresses only to DHCP clients, and then enter the start and end addresses in the range.
   - **Prefix Delegated**: Select this if the DHCP server uses this address range to delegate IPv6 prefixes only to DHCP clients. Enter the start and end prefixes, and the prefix length.
   - **Both:** Select this if the DHCP server delegates IPv6 prefixes and allocates IPv6 addresses from this range. Enter the start and end addresses in the range, and the start and end prefixes, and the prefix length.

     Complete the following:
   - **Name:** Enter a name for the address range.
   - **Comment:** Enter additional information about the address range.
   - **Disabled for DHCP:** Select this if you want to save the configuration for the address range but do not want to activate the address range yet. You can clear this checkbox when you are ready to allocate addresses from this range.

     The **Cloud** section appears when the Cloud Network Automation license is installed on the Grid Master. For information, see *Deploying Cloud Network Automation*. To delegate authority for this range, complete the following:

     Delegate authority from the Grid Master

     DelegateTo: This field indicates whether the authority for the range you want to create has already been delegated to a Cloud Platform Appliance. Click **Select** to choose the Cloud Platform Appliance to which you want to delegate authority. The *Member Selector* displays only Cloud Platform Appliances in the Grid. Click the member, and Grid Manager displays the member name next to this field. This cloud member now assumes authority for this range, and the Grid Master does not have authority any more. You can also click **Clear** to remove authority delegation from the selected Cloud Platform Appliance and return authority back to the Grid Master.
4. Click **Next** and select one of the following to provide DHCP services for the DHCP range:
   - **None (Reserved Range)**: Select this if you want to reserve this address range for static hosts. Addresses in this range cannot be allocated as dynamic addresses. You can allocate the next available IP from this range to a static host. This is selected by default.
   - **Grid Member:** Select this if you want a Grid member to serve DHCP for this DHCP range. Select a Grid member from the drop-down list. The drop-down list displays only the Grid members that are associated with the network to which the DHCP range belongs.
5. (*Applies only to Network Insight*) Click **Next** to initiate or disable discovery of the new DHCP range.
   - **Configuring one network**: Discovery settings include the following: **Enable Discovery** and **Immediate Discovery**, selecting a Probe member to perform the discovery; and **Polling Options**, which define how the network will be discovered by the Probe member using SNMP and CLI credentials. By default, all Polling Options discovery settings are inherited from the parent network unless you click **Override**. Polling Options govern the protocols used to query and collect information about the network devices being discovered. See the section *Configuring Discovery Properties* for a complete description of discovery Polling Options.
6. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes.*
7. Save the configuration and click **Restart** if it appears at the top of the screen.
   or

Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Setting the Priority of IPv6 Address Ranges

The DHCP server allocates IP addresses from the configured DHCP ranges according to the order in which the ranges are listed. By default, ranges are listed according to their start addresses. You can move the ranges up and down in the list to change their order. For information about viewing DHCP ranges and other objects in a network, see *Viewing IPv6 DHCP Objects*.
To change the order of DHCP ranges in a network:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> *network*.
2. Expand the Toolbar and click **Order DHCP Ranges**.
3. In the *Order DHCP Ranges* dialog box, click the up and down arrows to move ranges up or down on the list. The Priority value changes accordingly. Click **OK** to save the configuration.

Modifying IPv6 Address Ranges

To modify an IPv6 address range:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *addr_range* checkbox, and then click the Edit icon.
2. The *DHCP Range* editor contains the following basic tabs from which you can modify data:
    - **General**: Modify the fields, except the network address, as described in Adding IPv6 Address Ranges above.
      When the Cloud Network Automation license is installed on the Grid Master, Grid Manager displays the following information in the **Cloud** section: **Cloud Usage**, **Owned By**, and **Delegated To**. You cannot modify these fields.
    - **Member Assignment**: Modify the Grid member that provides DHCP services for the DHCP range as described in Adding IPv6 Address Ranges above.
    - **Discovery**: You can enable and change discovery settings for the IPv6 range at any time after creating the range. Discovery settings include the following: **Enable Discovery** and **Immediate Discovery**, selecting a Probe member to perform the discovery; and **Polling Options**, which define how the network will be discovered by the Probe member using SNMP and CLI credentials. By default, all Polling Options discovery settings are inherited from the parent network unless you click **Override**. Polling Options govern the protocols used to query and collect information about the network devices being discovered. See the section *Configuring Discovery Properties* for a complete description of discovery Polling Options.
    - **Discovery Blackout**: Define extended time periods and regularly scheduled times when discovery and/or port configuration tasks will not take place on a network or DHCP range. Editing a network or range under DHCP, blackout settings apply only to the specified network or range. You also specify the scheduled time when the blackout period begins, and the duration of the blackout period. By default, the network inherits its discovery blackout settings from the Grid level. For related information, see *Defining Blackout Periods* and its subsections.
    - **IPv6 DHCP Options**: Keep active leases in a deleted DHCP range. For more information, see *Keeping Leases in Deleted IPv4 and IPv6 Networks and Ranges*.
    - **Extensible Attributes**: You can add and delete extensible attributes that are associated with a specific DHCP range. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.
    - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *Managing Permissions*.
3. Optionally, you can click **Toggle Advanced Mode** to display the following tabs from which you can modify advanced data.
    - **Exclusion Ranges**: Configure a range of IP addresses that the appliance does not use to assign to clients. You can use these exclusion addresses as static IP addresses. For more information, see *About Exclusion Ranges*.
    - **Filters**: You can keep the inherited IPv6 logic filters or override them and add a new IPv6 logic filter. For information, see *Applying Filters to DHCP Objects*.

Note that Grid Manager displays both the basic and advanced mode tabs the next time you log in to the GUI.

4. Save the configuration and click **Restart** if it appears at the top of the screen.
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Deleting IPv6 Address Ranges

To delete an IPv6 address range:

- From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *addr_range* checkbox, and then click the Delete icon.

Viewing IPv6 DHCP Objects

You can view the DHCP objects in an IPv6 network by navigating to the **DHCP** tab -> **Networks** tab -> **Networks** panel, and then clicking the network link. This panel displays the following information about DHCP objects in the selected IPv6 network:

- **IP Address**: The IPv6 address of a DHCP object, such as a DHCP range, fixed address, or host configured for DHCP, or roaming host with an allocated IP address. For a DHCP range, this field displays the start and end addresses of the range. For a host that has multiple IP addresses, each IP address is displayed separately. Note that the appliance highlights all disabled DHCP objects in gray.
- **Type**: The DHCP object type, such as **IPv6 DHCP Range** or **IPv6 Fixed Address**.
- **Name**: The object name. For example, if the IP address belongs to a host record, this field displays the hostname.
- **Comment**: The information you entered for the object.
- **Site**: The site to which the DHCP object belongs. This is one of the predefined extensible attributes. You can select the following additional columns for display:
- **Priority**: Displays the priority of the DHCP range.
- **Disabled**: Indicates whether the network is disabled. You can also do the following in this panel:
- Modify some of the data in the table. Double click a row, and either modify the data in the field or select an item from a drop-down list. Click **Save** to save the changes. Note that some fields are read only.
- Sort the data in ascending or descending order by column.
- Create a bookmark for the object.
- Click **Go to IPAM View** to view information about the object in the **IPAM** tab.
- Delete or schedule the deletion of a selected object or multiple objects.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Print or export the data.

Setting the Prefix Length Mode for DHCPv6

The prefix length mode determines the prefix selection rules employed by the DHCPv6 server when a DHCPv6 client sends an empty prefix with just a prefix length as a hint for the server to specify the required prefix length. This determines the prefix that gets allocated to the DHCPv6 client.

To set the prefix length mode:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
2. In the editor, click the **General** tab -> **Advanced** tab.
3. In the IPv6 Properties area, from the **Prefix Length Mode** drop-down list, select from the following options:

- **Exact**: The DHCP server looks for a prefix with exactly the same length as the length requested by the client. If it cannot find a prefix that has the exact same length as the length requested, the server returns a status indicating that no prefixes are available. If you do not configure the prefix length mode, Exact is the default value.
- **Ignore**: The DHCP server ignores the length requested by the client and offers the first available prefix.
- **Prefer**: The DHCP server looks for prefixes that have the same length as the length requested by the client. If it does not find a prefix of the same length, it offers the first available prefix of any length.
- **Minimum**: The DHCP server looks for a prefix that has the same length as the requested length. If it does not find such a prefix, it returns a prefix whose length is greater than (that is, longer than) the requested value. If it does not even find a prefix of a greater length, it returns a status indicating that no are prefixes available. For example, if the client requests a prefix length of /60, and the DHCP server has prefixes of lengths /56 and /64 available, it offers a prefix of length /64.
- **Maximum**: The DHCP server looks for a prefix that has the same length as the requested length. If it does not find such a prefix, it returns a prefix whose length is less than (that is, shorter than) the requested value. If it does not even find a prefix of a shorter length, it returns a status indicating that no prefixes are available. For example, if the client requests a length of /60, and the server has prefixes of lengths /56 and /64 available, it offers a prefix of length /56.

4. Click **Save & Close**.

Configuring DHCP Failover

This section explains how to configure DHCP failover associations. It contains the following topics:

DHCP Failover

You can create a failover association between two DHCP servers (a primary server and a secondary) and assign the failover association to serve an IPv4 DHCP range. When you set up a failover association, you greatly reduce DHCP service downtime if one of your DHCP servers is out of service. You can better manage IP address requests by making two servers available for DHCP services. You can also configure one of the servers to assume full DHCP services when you know the other server may go out of service for a period of time.

You can configure two NIOS appliances, or one appliance and one external server, to form a failover association. The pairing of a primary and secondary server is called a peer association. The failover peers establish a TCP connection for their communication. They share a pool of IP addresses that they allocate to hosts on their networks based on load balancing. Load balancing is a technique to split the address allocation workload evenly across the two DHCP servers. You can assign a DHCP failover association to serve DHCP ranges in a network. A DHCP failover association can serve DHCP ranges that belong to one network view only. It cannot serve ranges in different network views.

> **Note**
>
> When you assign a failover association to serve DHCP ranges and networks, NIOS denies dynamic BOOTP clients by default, regardless of whether you select or deselect the **Deny BOOTP Requests** option from Grid Manager. However, if the DHCP ranges or networks are assigned to a single DHCP server (not a failover association), NIOS does not automatically deny dynamic BOOTP clients. In this case, you must manually select the **Deny BOOTP Requests** option through Grid Manager to ensure that NIOS denies BOOTP requests to avoid problems such as receiving two IP addresses for the same network device. For information about how to deny BOOTP requests, see *Configuring IPv4 BOOTP and PXE Properties*.

Failover Association Operations

When a host broadcasts a DHCPDISCOVER message, it includes its MAC address. Both the primary and secondary peers receive this message. To determine which server should allocate an IP address to the host, they each extract the MAC address from the DHCPDISCOVER message and perform a hash operation. Each server then compares the result of its hash operation with the configured load balancing split. The split is set to 50% by default to ensure an even split between the two servers. When the split is 50%, the primary server allocates the IP address if the hash result is between 1 and 127, and the secondary server allocates the IP address if the hash result is between 128 and 255. As a server allocates an IP address, it updates its peer so their databases remain synchronized.
As shown in the following figure Load Balancing and IP Addresses Allocation, when a host broadcasts a DHCPDISCOVER message, both the primary and secondary servers receive the message. They perform a hash operation on the MAC address in the DHCPDISCOVER message, and the result is 250. Since the load balancing split is 50% and the hash result is 250, the secondary server responds to the host with a DHCPOFFER message. The secondary peer allocates an IP address from its assigned pool of IP addresses. It then sends a lease update message to the primary server so that the primary server knows how the address is assigned and can properly take over if the secondary server fails.

Load Balancing and IP Addresses Allocation

Configuring DHCP Failover

Configuring Failover Associations

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
2. Click **Toggle Advanced Mode** if the editor is in basic mode. When the additional tabs appear, select the **General Advanced** tab to complete the following:
    - **Failover Port:** You can modify the port number that members use for failover associations. You can use any available port from 519 to 647. The default is 647 for a new installation and 519 for an upgrade.

The following are tasks and guidelines for configuring a DHCP failover:

1. Identify the primary and secondary DHCP servers and ensure that the appliances are set up correctly for the failover association, using the following guidelines:
    - Configure a failover association using two NIOS appliances, or a NIOS appliance and an ISC DHCP compliant server.
    - One of the DHCP servers must be an independent appliance or in an Infoblox Grid.
    - The DHCP servers do not have to be in the same geographic location.
    - The clocks on both servers must be synchronized. This happens automatically when both servers are on the same Grid.
    - Both servers must use the same version of the DHCP configuration file. This happens automatically when both servers are on the same Grid.
    - If you use firewalls on your networks, ensure that the firewalls allow TCP port 647 between the servers, and that TCP port 7911 is open for partner down operations.
    - Each pair of DHCP servers can participate in only one failover association. An appliance can participate in more than one failover association, as long as it is with a different peer.

      Configure the same DHCP properties on the primary and secondary servers, as described in *Configuring General IPv4 DHCP Properties*.
    - Both the primary and secondary servers must have the same operational parameters, and they must be able to receive DHCPDISCOVER messages that hosts broadcast on the networks.
    - If you change any of the DHCP failover parameters for a peer association definition, you must make the same changes on both the primary and secondary servers.

      Note that if both the primary and secondary servers are in a Grid, you configure the properties on the failover association and the configuration applies to both servers.
2. Create a failover association and configure load balancing between the servers. For information, see Adding Failover Associations below.
    - Ensure that you use the same failover association name on both the primary and secondary servers.
    - The appliance assigns default values to the failover timers and triggers. In general, these default values serve the purpose of a failover. Do not change these values unless you understand the ramification of the changes. For example, when one of the peers in a failover association fails, the other peer goes into a COMMUNICATIONS-INTERRUPTED state, and the lease time changes to the MCLT (Maximum Client Lead Time). You should consider how the MCLT affects the lease time when a failover occurs if you want to change this value.
3. Assign the failover association to the DHCP ranges in the same network view. Failover associations can serve only IPv4 DHCP ranges. For information, see *Configuring IPv4 Address Ranges*.
    - If you configure a shared network, and the subnets in the shared network contain ranges served by a DHCP failover association, both the primary and secondary DHCP server must have the same shared networks defined, containing the same networks and DHCP ranges.
      If you have multiple networks that are in a shared network and you plan to use a DHCP failover, you must use the same failover association and specify the same peers on all the networks in the shared network.
4. Enable DHCP on the primary and secondary servers AFTER you complete all the configurations. For information, see *Managing Failover Associations*.

Note

When you set up a failover association for the first time, ensure that both servers are up and running and their databases are synchronized before they can start assigning IP addresses.

When you configure a failover association, the appliance assigns default values for timers and triggers, such as the MCLT and the maximum number of "unacked" packets. A failover may occur when some of the timers expire or when a failover peer goes out of service. When a failover occurs, the functional peer takes over and assigns IP addresses with the lease time set to the MCLT. When the server that is offline comes back online, it synchronizes its database with its peer before it starts allocating IP addresses.

Adding Failover Associations

To add a DHCP failover association, perform the following procedures on both the primary and secondary servers:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **IPv4 Failover Associations** section, and then click the Add icon.
   or
   Expand the Toolbar and click **Add** -> **IPv4 Failover Association**.
2. In the *Add Failover Association* wizard, complete the following:
   - **Name:** Enter a unique name for the failover association. The failover association name is case sensitive. Enter the same name on both the primary and secondary servers. The appliance validates the names on both servers. The names must be exactly the same. If they do not match, the failover association goes into disconnect mode.
   - **DHCP Failover Primary**: Select one of the following. The default is **Grid Member**.
     - **Grid Member:** Click **Select member**. In the *Select Member* dialog box, select the primary server and click the Select icon.
     - **MS Server**: Click **Select Server**. In the *Microsoft Server Selector* dialog box, select the Microsoft server that supports DHCP failover. Note that only certain versions of Microsoft servers support failover. This dialog box also displays the following columns: **IP address**, **Comment**, and **Site**.
       The failover association requires at least two Microsoft servers. NIOS displays an error message when you select **MS Server** if there is only one Microsoft server. When you add or modify a failover association through Grid Manager, the appliance displays a message to ensure the connectivity between two Microsoft servers. If you want a failover association to be in a normal state, you must ensure an end-to-end connectivity. If the connectivity fails, you must re-establish connectivity between the two Microsoft servers and the failover association follows the recovery states based on the DHCP failover protocol.
       You can configure Microsoft primary and secondary servers using this wizard only. You cannot edit Microsoft primary and secondary servers after you configure them. You must delete and reconfigure the primary or secondary Microsoft server for a failover association.
     - **External Server IP Address:** Select this to use an external ISC DHCP compliant server as the primary server. Enter the IP address of the primary server in the field.
     - **DHCP Failover Secondary**: Select one of the of following. The default is **Grid Member**.
       - **Grid Member:** Click **Select member**. In the *Select Member* dialog box, select the secondary server and click the Select icon.
       - **MS Server**: NIOS selects this automatically when you set the **DHCP Failover Primary** to **MS Server**. Click **Select Server**. In the *Microsoft Server Selector* dialog box, select the Microsoft server that supports DHCP failover. Note that only Microsoft Windows Server 2012 or later versions support synchronization of failover relationships. This dialog box also displays the following columns: **IP address**, **Comment**, and **Site**.
         The primary and secondary Microsoft servers that you select in a failover relationship must be in the same network view. For more information, see *About Microsoft DHCP Failover Relationships*.
       - **External Server IP Address:** Select this to use an external ISC DHCP compliant server as the secondary server. Enter the IP address of the secondary server in the field.
         You cannot select **External Server IP Address** for both the primary and secondary servers. One of the servers must be an independent appliance or in an Infoblox Grid.
   - **Comment**: Enter useful information about the failover association.
3. Click **Next** and do the following to control the IP address allocation between the peers and how they switch from one to the other based on the configuration:
   - **Failover mode:** This is valid for Microsoft Management only. Select a failover mode. You can either select **Hot standby** or **Load balancing**. When you select **Hot standby**, the secondary server is set to **Standby** by default and the slider move to the position at 95%. The slider moves to 50% when you set the failover mode to **Load balancing mode**. You can synchronize and manage a failover mode that is operating in **Hot standby** mode. The primary partner is the active server that first creates the relationship if you use the **Load balancing** or the **Hot standby** mode.
     When you configure a failover association, the slider changes its position based on the Failover mode you select. When you edit failover settings, the slider remains in the Balanced position, at 50%, by default. For more information about modifying failover associations, see *Modifying Failover Associations*.

- **Load Balancing Data:** Adjust the slider to determine which server should handle more IP address requests. The default is 50%. When you move the slider all the way to the left, the primary server responds to all IP address requests. The opposite applies when you move the slider all the way to the right. Infoblox recommends that you use the default (50/50) to enable the primary and secondary servers to respond to IP address requests on an equal basis.
- **Lease Deletion:** Select the following to override settings at the Grid and member levels.
  - **Keep leases from deleted ranges until one week after expiration**: When you select this and delete a DHCP range with active leases, the appliance stores these leases up to one week after they expire. When you add a new DHCP range that includes the IP addresses of these active leases, the appliance automatically restores the leases.
- **Secondary role**: This is valid for Microsoft Management only. Note that the secondary role is available only in **Hot standby** mode. The appliance displays **Standby** by default and you cannot edit this value.
- **Maximum client lead time**: Specify the maximum client lead time in minutes or hours. The default is one hour. Select **Minutes** or **Hours** from the drop-down list. This specifies the maximum amount of time the server waits before assuming control.
- **Enable switchover interval:** This is valid for Microsoft Management only. Select this to automatically change the state to partner down after a specified period. NIOS does not support the "partner down" state for Microsoft DHCP failover association.
- **State switchover interval (Minutes)**: This is valid for Microsoft Management only. Specify the amount of time after which the server must change the state. The default is 60 minutes.
- **Enable Authentication**: This is valid for Microsoft Management only. Select this if you want to secure the communication between failover partners.
- **Shared Secret**: This is valid for Microsoft Management only. Enter a shared secret that can be used to authenticate the communication between failover partners. You can specify a shared secret only if you enable authentication.

4. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Best Practices for Restoring Microsoft DHCP Server Data

When you synchronize two Microsoft servers in read/write mode for a Microsoft DHCP failover association, the appliance might override new data. For example, assume that you are synchronizing data from one Microsoft server, which has latest data. But after the restore operation, the appliance will synchronize data from a Microsoft server that has old data. If you synchronize old data, it might override new data. Infoblox recommends that you follow the steps mentioned below to prevent new data being replaced with the old one:

1. Disable DHCP synchronization for the Microsoft server before you restore data to the Microsoft server.
2. Restore the Microsoft DHCP server.
3. From the Microsoft server, which has the latest data, replicate its DHCP failover association and scopes to the restored Microsoft server. This ensures that both Microsoft servers have the same latest data.
4. Re-enable DHCP synchronization for the restored Microsoft server. NIOS will resynchronize with the Microsoft server.

Managing Failover Associations

After you establish a failover association, you can monitor its status periodically to ensure that it is functioning properly. You can also delete a failover association when it is not assigned to any DHCP range.
See the following sections on how to manage failover associations:

- *Modifying Failover Associations*
- *Monitoring Failover Associations*
- *Deleting Failover Associations*
- *Setting a Peer in the Partner-Down State*
- *Performing a Force Recovery*
- *Recovering DHCP Failover Associations*

Under special circumstances, you can manually adjust the configuration of a failover association. For example, when you know in advance that a peer will be out of service for an extended period of time, you can manually set the functional peer in a PARTNER-DOWN mode. This allows the functional partner to assume all leases and be able to allocate addresses to client requests in full capacity. In addition, when you suspect the databases in a failover association are not synchronized, you can consider doing a force recovery (after you consult with Infoblox Technical Support or your Infoblox representative) so the secondary server can completely rebuild its lease table with updates from the primary server. See the following sections on how to set a peer to the partner-down mode and perform a force recovery:

- Setting a Peer in the Partner-Down State
- Performing a Force Recovery

Modifying Failover Associations

To modify a failover association:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Failover Associations** -> *failover_association* checkbox, and then click the Edit icon.
2. The *DHCP Failover Association* editor contains the following tabs from which you can modify data:
    - **General**: In the **Basic** tab, modify the fields as described in *Adding Failover Associations*.
      In the **Advanced** tab, complete the following to modify the port number you use for the failover association:
        - **Failover Port:** Click **Override** to enter a port number for the failover association. You can use any available port from 1 to 63999. The default is 647 for a new installation and 519 for an upgrade.
    - **Triggers**: Before editing the triggers and timers, ensure that you understand the ramification of the changes. Improper configuration of the triggers can cause the failover association to fail. For information about the fields in the **Basic** tab, see *Adding Failover Associations*. The following are the triggers in the **Advanced** tab:
        - **Max Response Delay Before Failover(s):** Specifies the maximum duration of time (in seconds) before a failover enters the Communications-Interrupted state after failing to hear from its peers. The duration must be long enough to prevent frequent connections and disconnections from the DHCP failover peers, yet short enough so that the transient network failure will not keep the peers out of contact for an extended duration. The recommended default is 60 seconds.
        - **Max Number of Unacked Updates:** Specifies the number of "unacked" packets the server can send before a failover occurs. The default is 10 messages.
        - **Max Client Lead Time (s):** Specifies the length of time that a failover peer can renew a lease without contacting its peer. The larger the number, the longer it takes for the peer to recover IP addresses after moving to the **PARTNER-DOWN** state. The smaller the number, the more load your servers experience when they are not communicating. The default is 3600 seconds.
        - **Max Load Balancing Delay (s):** Specifies the cutoff after load balancing is disabled. The cutoff is based on the number of seconds since a client sent its first **DHCPDISCOVER** message. For instance, if one of the failover peers gets into a state where it is busy responding to failover messages but is not responding to other client requests, the other peer responds to the client requests when the clients retry. This does not cause a failover. The default is three seconds.
    - **Failover Settings:** This is valid for Microsoft Management only. Modify failover association settings. For information, see *Configuring Failover Associations*.
      If you modify failover settings from secondary Microsoft server settings, the appliance does not update failover settings on NIOS for the following reasons:
        - When DHCP synchronization is disabled for primary Microsoft server, you must enable DHCP synchronization for primary Microsoft server to reflect the settings on NIOS.
        - The primary synchronization interval must be completed. For example, consider that you are modifying failover settings from secondary Microsoft server settings where the synchronization interval for primary server is five minutes, and the time interval for the secondary server is one minute. In this case, failover settings are updated on NIOS only after the primary server synchronization interval, which is five minutes.
    - **Extensible Attributes**: Add and delete extensible attributes that are associated with a failover association. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.

Monitoring Failover Associations

After you configure a failover association, the peers establish a TCP connection for communication. In a normal operational state, they send keepalive messages and database updates every time they grant a lease. However, there are times when the failover association experiences problems and goes into a state other than **NORMAL**. You can monitor the overall state of a failover association and the individual status of the peers to verify that the servers are operating and communicating properly.

Both peers in a failover association maintain the same DHCP fingerprinting state (enabled or disabled) even when one of the peers fails or becomes operational again. Note that both peers must be in the same Grid for the fingerprinting state to stay the same. For information about DHCP fingerprinting, see *About DHCP Fingerprints*.

In this panel, you can also modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.

To monitor the failover association status:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **IPv4 Failover Associations** section. Grid Manager displays the list of failover associations and their overall status.
2. To view detailed information about a failover association, select the *failover_association* checkbox, and then click the Show Status icon.
3. In the *Failover Association Status* dialog box, Grid Manager displays the overall status of the failover association and the status of both the primary and secondary servers.
   The failover association can be in one of the following states:
   - **OK** (green): The failover association is functioning properly.
   - **DEGRADED** (yellow): The failover association is degraded when one of the peers is giving out limited addresses.
   - **FAILURE** (red): The failover association is not functioning, may be because it is not completely configured. The peers are not assigning IP addresses.
     For each peer, Grid Manager displays the hostname or IP address, the status, and event date. The peer can be in one of the following states:
   - **STARTUP**: The server is starting up.
   - **NORMAL**: The server is in a normal operational state in which it responds to its load balancing subset of DHCP clients.
   - **PAUSED**: This state allows a peer to inform the other peer that it is going out of service for a short period of time so the other peer can immediately transition to the **COMMUNICATIONS-INTERRUPTED** state and start providing DHCP service to DHCP clients.
   - **COMMUNICATIONS-INTERRUPTED**: The servers are not communicating with each other. Both servers provide DHCP service to DHCP clients from which they receive DHCP requests.
   - **PARTNER-DOWN:** The server assumes control of the DHCP service because its peer is out of service.
   - **RECOVER**: The server is starting up and trying to get a complete update from its peer and discovers that its peer is in the **PARTNER-DOWN** state.
   - **RECOVER-WAIT**: The server has got a complete update from its peer and is waiting for MCLT period to pass before transitioning to the **RECOVER-DONE** state.
   - **RECOVER-DONE:** The server completed an update from its peer.
   - **POTENTIAL-CONFLICT:** The peers are not synchronized due to an administrative error or an incorrect state transition. Check the failover configuration and correct the error.
   - **CONFLICT-DONE:** This is a temporary state that the primary server enters after it received updates from the secondary server when it was in the **POTENTIAL-CONFLICT** state.
   - **RESOLUTION-INTERRUPTED**: The server responds to DHCP clients in a limited way when it is in this state.
   - **UNKNOWN**: The DHCP server is in an unknown state. The failover association is not functioning properly, may be because it is configured improperly. For example, failover association is not assigned to any DHCP range.
   - **SHUTDOWN**: This state allows a peer to inform the other peer that it is going out of service for a long period of time so the other peer can immediately transition to the **PARTNER-DOWN** state and completely assume control of the DHCP service.

Note

NIOS does not support **PARTNER-DOWN** and Force Recovery for a Microsoft DHCP failover association.

Deleting Failover Associations

You cannot delete a failover association if it is currently assigned to a DHCP range. If you want to delete a failover association, ensure that it is not assigned to any DHCP range.
To delete a failover association:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Failover Associations** -> *failover_association* checkbox, and then click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes**.
   The appliance puts the failover association in the recycle bin, if enabled.

Setting a Peer in the Partner-Down State

If one of the peers in a failover association is out of service for an extended period of time, you should consider putting the functional peer in the **PARTNER-DOWN** state. When you place the functional peer in the **PARTNER-DOWN** state, it assumes full DHCP services for the networks. Since the functional server may not receive all the updates from its peer, it extends all the leases on the MCLT. Once the following conditions are met, the functional peer provides DHCP services autonomously:

- It has reclaimed all the leases that belonged to its peer.
- The MCLT has passed.

When the peer that is offline comes back online, it synchronizes with the functional peer and reestablishes the communication before it provides DHCP services to the clients.

Warning
*Before you put a peer in the **partner-down** state, ensure that the other peer is indeed out of service. If both the primary and secondary servers are operational when you place one of them in the partner-down mode, both servers may stop issuing leases for a minimum of time defined in the MCLT.*

To set a peer in the **PARTNER-DOWN** state:

1. From the **Data Management** tab, select the **DHCP** tab ->**Members** tab- > **Failover Associations** -> *failover_association* checkbox.
2. Expand the Toolbar and click **Set Partner Down**.
3. In the *Set Failover Association Partner Down* dialog box, select one of the following:
   - **Primary**: Select this if the secondary server is out of service.
   - **Secondary**: Select this if the primary server is out of service.
4. Click **OK**.

Note
You cannot place the functional peer in the **PARTNER-DOWN** state for a Microsoft DHCP failover in NIOS.

Performing a Force Recovery

When the primary and secondary peers are not synchronized, you can perform a force recovery to set the primary server in the **PARTNER-DOWN** state while putting the secondary server in the **RECOVER** state. During a force recovery, all leases in the databases are resynchronized. When you perform a force recovery, the secondary server does not serve any DHCP leases for a minimum of the MCLT while it resynchronizes with the primary server. Before you perform a force recovery, consult with Infoblox Technical Support or your Infoblox representative to ensure that the force recovery is appropriate for the situation.
To perform a force recovery:

1. From the **Data Management** tab, select the **DHCP** tab-> **Members** tab-> **Failover Associations** -> *failover_association* checkbox.
2. Expand the Toolbar and click **Force Recovery State**.
3. In the *Force Secondary Peer Recovery State* dialog box, click **OK**.

The appliance synchronizes the databases on the primary and secondary servers.

> ⚠ Note
> You cannot place the functional peer in the **PARTNER-DOWN** state for a force recovery in NIOS.

Recovering DHCP Failover Associations

During a conflict resolution, when the primary peer of the DHCP failover association is in the **CONFLICT-DONE** state and the secondary peer in the **POTENTIAL-CONFLICT** state, the secondary peer might experience problems (such as restarting, network outage, etc.) and goes into an invalid state. This results in a deadlock state for the failover association, causing a DHCP service outage. When the failover association is in a deadlock state, you can perform a recovery for the failover association. You can run the recovery for one failover association at a time and when the primary member is in the **CONFLICT-DONE** state. This feature is supported for Infoblox appliances only and not for any other external DHCP servers.

> ⚠ Note
> When the failover recovery is in progress, the DHCP service on both peers are disabled and you cannot enable the DHCP service until the failover recovery is successfully completed. You can view the logs of the failover recovery process in the syslog and infoblox.log file.

To recover a DHCP failover association:

1. From the **Data Management** tab, select the **DHCP** tab-> **Members** tab -> **Failover Associations** -> *failover_association* checkbox.
2. Expand the Toolbar and click **Recovery from Deadlock State**.
3. In the *Failover Recovery Progress* dialog box, click **Start** to start the recovery of the failover association from the deadlock state.
4. In the confirmation dialog box, click **Yes**.

> ⚠ Note
> After you start the failover recovery, you cannot revert the changes.

Grid Manager starts the failover recovery and you can view the following information in the *Failover Recovery Progress* dialog box:

- **Failover association**: The name of the failover association.
- **Primary**: The hostname or IP address of the primary server.
- **Secondary**: The hostname or IP address of the secondary server.
- **Number of leases to be processed**: The total number of leases to be processed.
- **Number of leases processed**: The number of leases that have been processed.
- **Current Status**: Displays the current status of the failover recovery process. The current status can be one of the following:
    - **Pending**: The failover recovery is initiated for a failover association and the recovery process will start soon.
    - **Calculating**: The appliance calculates the total amount of leases to be processed.
    - **Applying**: The appliance looks for conflicts and tries to resolve the conflicts.
    - **Completed**: The failover recovery is completed successfully.
    - **Failed**: The failover recovery fails.

Grid Manager also displays the reason for the failure if that happens.

After successful completion of the failover recovery, you must restart both the primary and secondary peers to bring them back to the **CONFLICT-DONE** state.

You can stop the failover recovery operation by clicking **Stop** in the *Failover Recovery Progress* dialog box before the recovery process is complete.

> ⚠ Note
> If for any reasons the recovery is blocked when the operation is in progress, you can cancel the current operation and start the recovery for the failover association again.

Configuring DHCP Filters

To control how the appliance allocates IPv4 or IPv6 addresses, you can define DHCP filters and apply them to Grid, members, DHCP ranges, range templates, IPv4 network containers, IPv4 networks, shared networks, IPv4 / IPv6 network templates, IPv4 / IPv6 fixed addresses, IPv4 / IPv6 fixed address templates, IPv4 / IPv6 reservations, IPv4 / IPv6 reservation templates, and IPv4 / IPv6 host addresses. You can override filters set at an upper level and apply a new logic filter. Depending on your configuration, DHCP filters screen requesting clients by matching MAC addresses, relay agent identifiers, DHCP options, or DHCP fingerprints you define in the filters. If you configure DHCP servers in the Grid to send authentication requests to a RADIUS authentication server group, you can also filter requests by matching the authentication results. (For information about this feature, see *Authenticated DHCP*.)

When you define DHCP filters, you classify DHCP clients based on the information provided by the clients or by the RADIUS server. When you apply filters to an address range, the appliance responds to your address requests based on your configuration. The appliance also decides which DHCP options to return to the matching clients based on how you apply the filters. For more information, see *Applying Filters to DHCP Objects*.
You can use filters to control address allocation based on your network requirements. For example, you can use DHCP filters to screen unmanaged hosts on a network by denying their address and option requests. If you have multiple DHCP address ranges on the same network and you want to assign IP addresses from specific address ranges to specific clients, you can use filters to screen the address assignments. For information, see *IP Address Allocation*.
The appliance supports the following filters:

- **MAC address filters**: Use MAC addresses as matching criteria for granting or denying address requests. For information, see *Configuring MAC Address Filters*.
- **Relay agent filters**: Identify remote hosts by matching the relay agent identifiers in the DHCPDISCOVER messages. For information, see *About Relay Agent Filters*.
- **Option filters**: Classify hosts by matching the DHCP options and values sent by the requesting hosts. For information, see *Configuring Option Filters*.
- **DHCP fingerprint filter:** Identify remote clients by matching the option number sequence or vendor ID sent in option 55 and 60 of the DHCP request against the DHCP fingerprints cached on the system. For information about DHCP fingerprint filters, see *Configuring DHCP Fingerprint Filters*. For information about DHCP fingerprint detection, see *DHCP Fingerprint Detection*.
- **NAC filters**: Use authentication results from a RADIUS authentication server group as matching criteria for granting or denying address requests. For information, see *Authenticated DHCP*.

You can use MAC, option, and NAC filters to define DHCP options that matching clients can receive. Depending on how you apply a filter, all DHCP clients with matching criteria can receive all or some of the DHCP options defined in the filter. DHCP options defined for a matching filter supersede those defined at the Grid, member, network, and DHCP range levels. Options defined for a filter that is in the Class Filter List of an address range supersede those defined in the Logic Filter List. For more information about how the appliance returns options and how to apply DHCP filters, see *Applying Filters to DHCP Objects*.

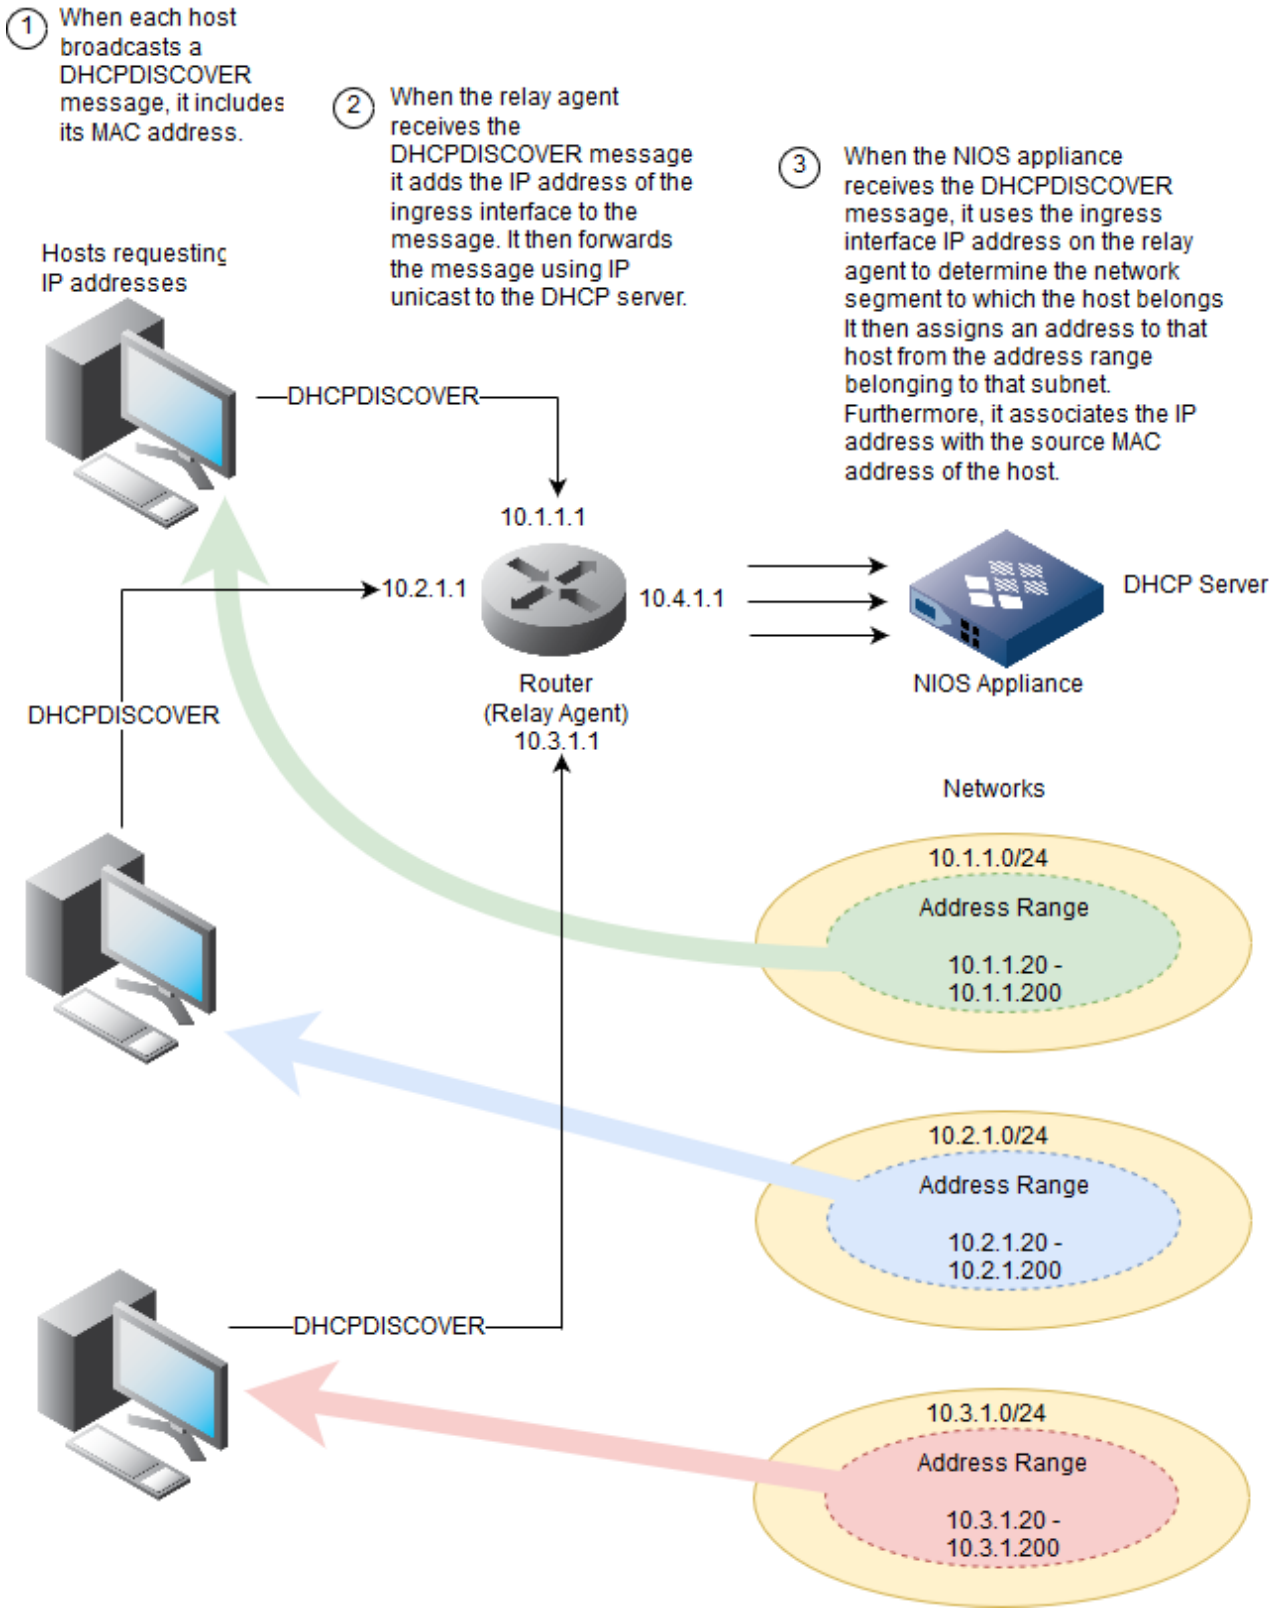
This section explains how to configure IPv4 DHCP filters. It contains the following topics:

- *Applying Filters to DHCP Objects*
- *Managing DHCP Filters*

IP Address Allocation

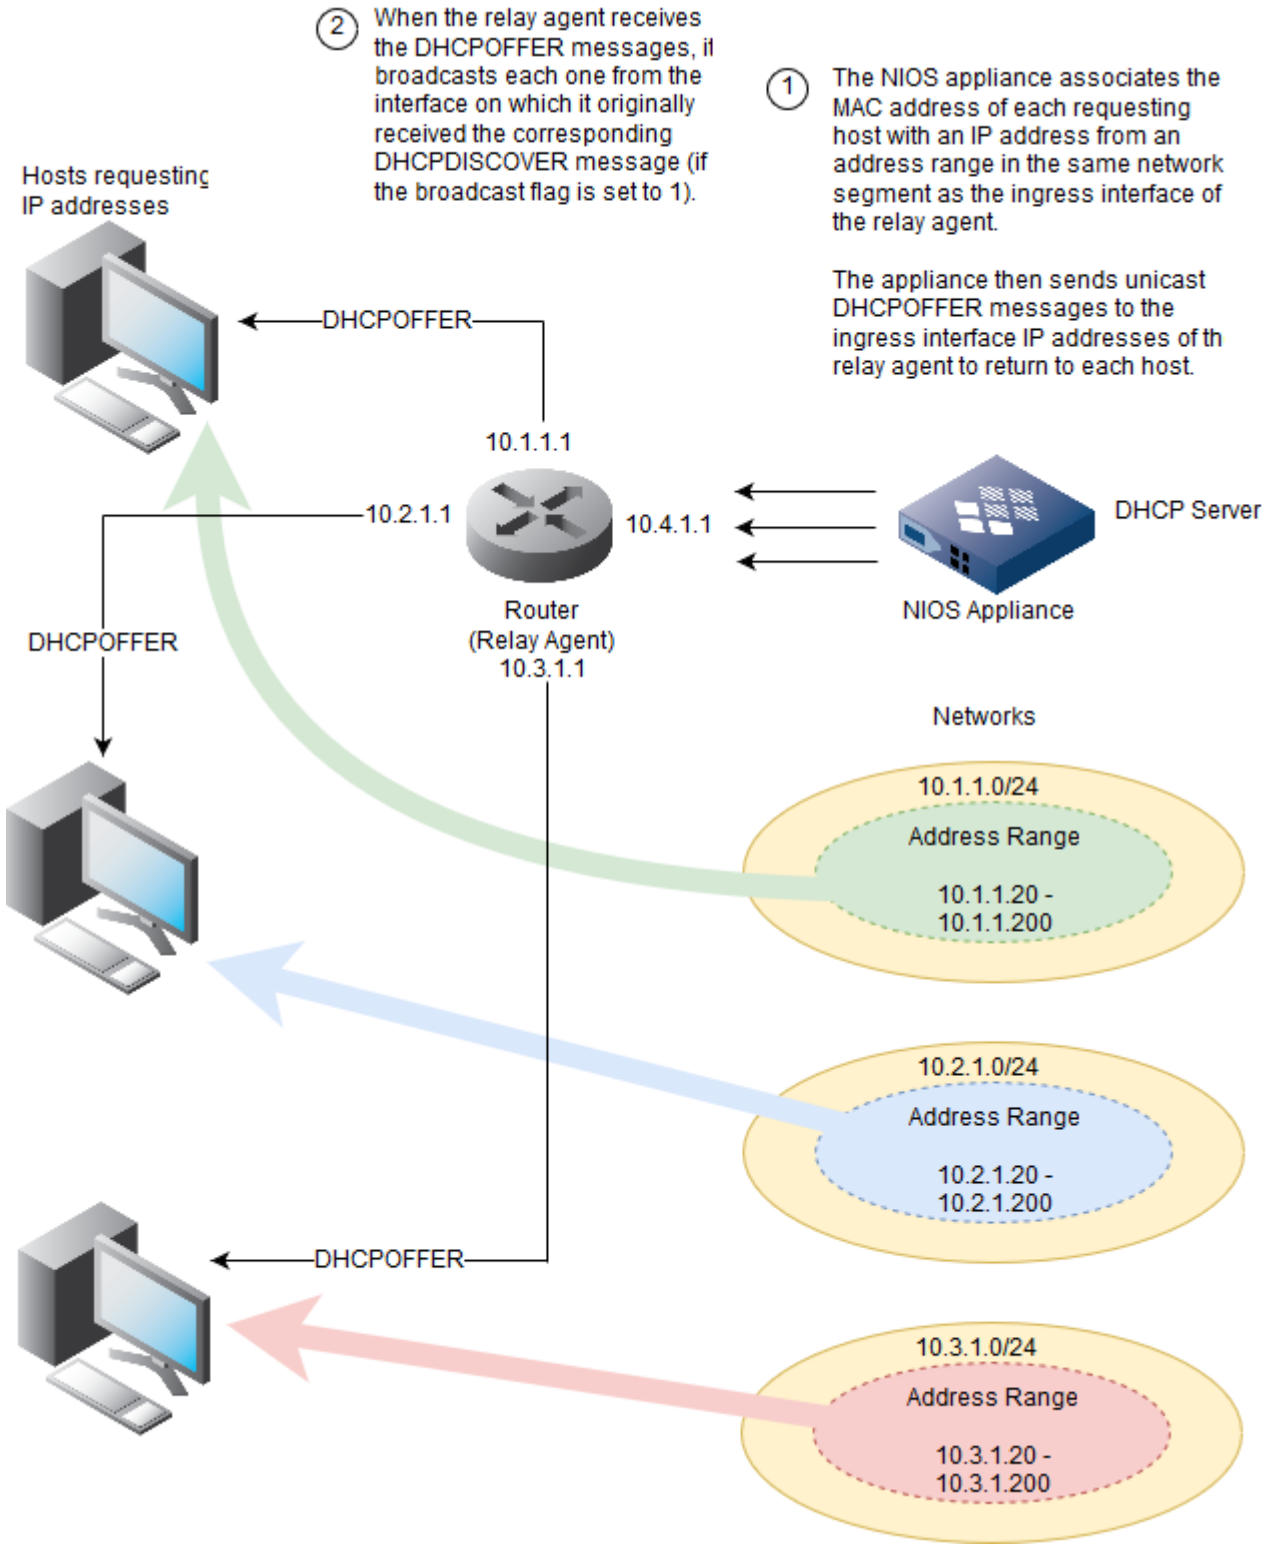
When a DHCP client requests an IP address, the NIOS appliance draws an address from an address range associated with the network segment for that client. Because you define that range, you can thereby control the IP address (within the defined range) and the associated TCP/IP settings that the client receives.
In the following figure Requesting Addresses – DHCPDISCOVER Messages, three hosts — each in a different subnet — request an IP address. Each one broadcasts a DHCPDISCOVER message, which includes its MAC address. When the router, which also functions as a DHCP relay agent, receives the message, it adds the IP address of the interface on which the message arrives and forwards the message to the DHCP server — or servers — previously configured on the router. When the NIOS appliance receives the message, it uses the ingress interface IP address of the router to determine the network segment to which the host belongs and associates the MAC address of the requesting host with an IP address from an address range for that network.

Requesting Addresses – DHCPDISCOVER Messages



The NIOS appliance replies to DHCPREQUEST messages by sending DHCPOFFER messages through the relay agent to the requesting hosts, as shown in the following figure Requesting Addresses – DHCPOFFER Messages.

Requesting Addresses – DHCPOFFER Messages

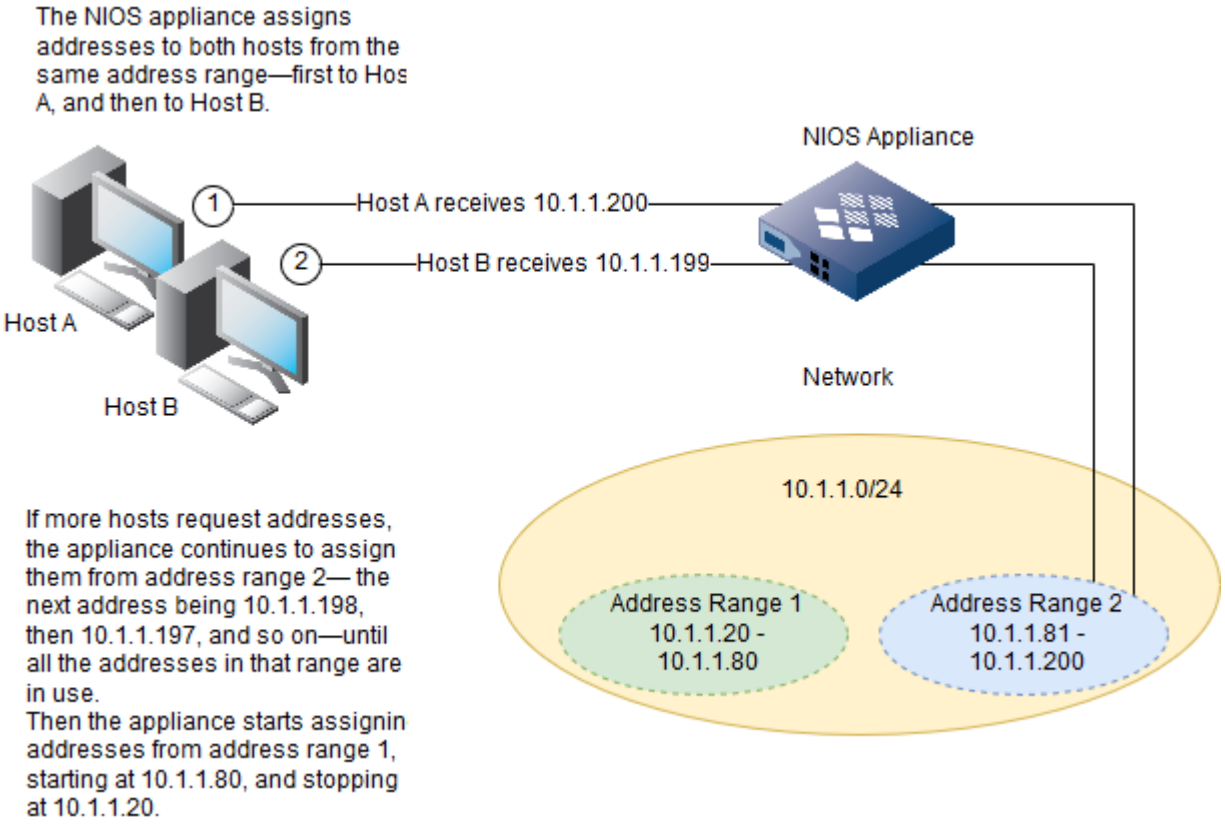


The addressing scheme depicted in the figures Requesting Addresses – DHCPDISCOVER Messages and Requesting Addresses – DHCPOFFER Messages above, is fairly simple: each network has a single address range. Consequently,

address assignments are fairly straightforward. However, if you have multiple address ranges in the same network and you want to assign addresses from specific address ranges to specific hosts, you must screen the address assignments through the use of filters.

> **Note**
>
> After the DHCP server runs for a while, it assigns leases based on when it last used addresses, and not just on their positions in the range.

Multiple Address Ranges without Filters



IP Address Allocation Using Filters

To control the assignment of addresses from specific address ranges to specific hosts, the NIOS appliance provides the following filters:

- A MAC address filter to which you add MAC addresses as filter criteria. For information, see *Configuring MAC Address Filters*.
- A relay agent filter with configured circuit ID and remote ID as specified by the relay agent (DHCP option 82). For information, see *About Relay Agent Filters*.
- An option filter in which you specify DHCP options and matching values. For information, see *Configuring Option Filters*.
- A NAC filter in which you specify authentication results from a RADIUS authentication server group as filter criteria. For information, see *About NAC Filters*.

When the appliance receives an address request, it checks if the request matches a filter. If it does not, the appliance assigns an address from the address range with the highest available IP address. If the request matches at least one class filter for a range, the appliance applies the following rules:

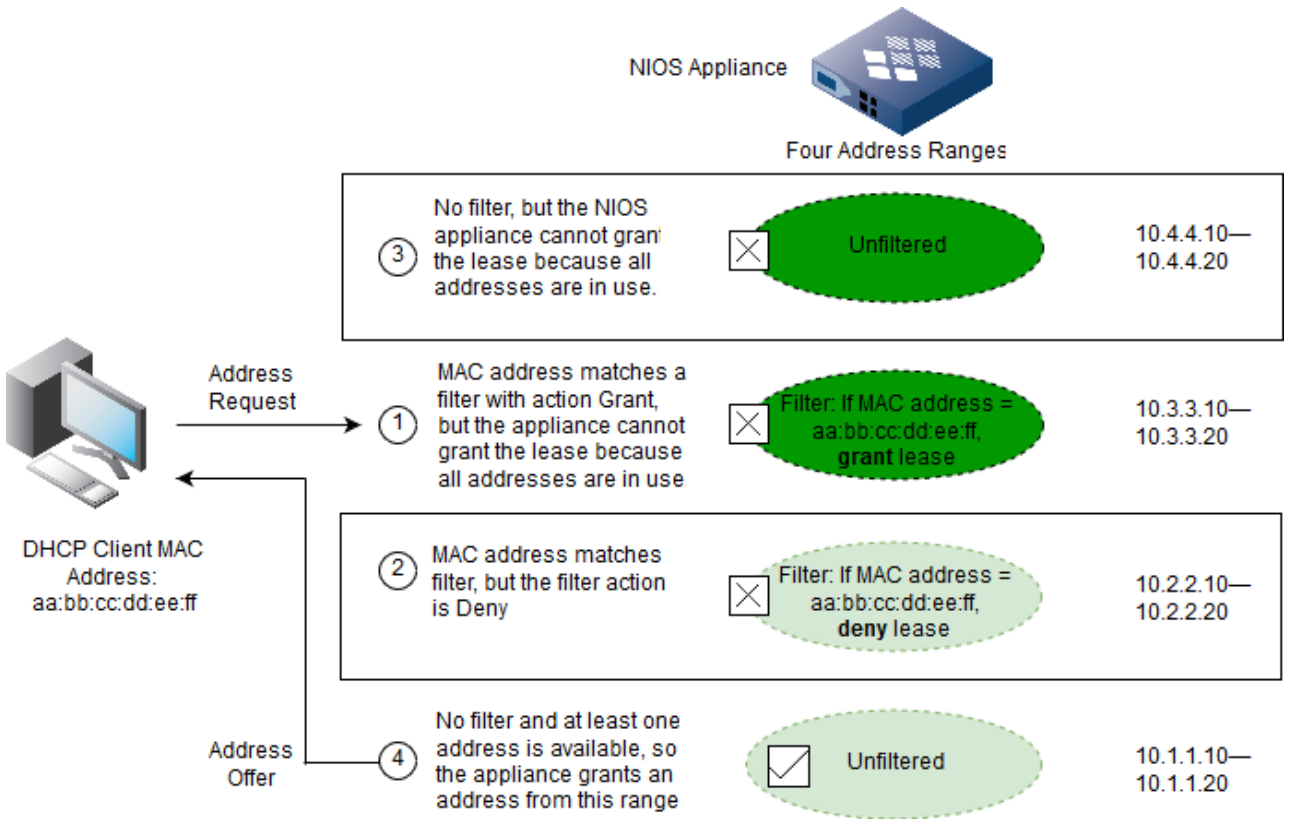
- If there are grant address filters applied to that range, the request must match one of the class filters or the appliance does not grant an address from that range.
- If there are deny address filters applied to that range, the request must not match any of the filters. If the request matches a deny filter, the appliance does not grant an address from that range.
- If an address range has a combination of grant and deny filters, the request must:
    - Match a grant filter
    - Not match a deny filter

Two rules govern the behavior of the appliance in relation to DHCP filters:

1. Depending on your filter configuration, the appliance checks if any data in an address request (such as the MAC address of the client, DHCP options 77 and 82, etc.) matches any filters applied to an address range.
2. The appliance checks for available addresses in the address ranges containing the highest addresses first. ("Highest" means closest to 255.255.255.255, and "lowest" means closest to 0.0.0.0.)

These two rules can work in coordination. For example, when the appliance receives an address request, it first checks if the request matches any filter. If it matches more than one filter assigned to different address ranges, the appliance first applies the filter that belongs to the range with the highest IP addresses. If that address does not grant an address lease (because the filter action is Deny or all address leases in that range are already in use), the appliance then applies the matching filter for the range with the next higher set of IP addresses. If the appliance still has not granted a lease from the address ranges whose filters match data in the request and there are unfiltered address ranges, the appliance attempts to assign an address from one of these ranges, again beginning with the range having the highest IP addresses. The figure DHCP Address Assignment with Multiple Filters below presents an example illustrating the sequence in which the appliance assigns addresses when a request matches a MAC address filter. For information about MAC address filters, see *Configuring MAC Address Filters*.

Figure 31.4 DHCP Address Assignment with Multiple Filters



if	then
the appliance receives a request that matches a filter for one address range,	it applies the action specified in the filter for that address range. If it does not assign an address from that range (the action is deny or the action is grant but all addresses in that range are in use), the appliance then checks if it can assign an address from an unfiltered address range (if there are any), starting with the range with the highest addresses first, as shown in *IP Address Allocation*.
the same filter applies to multiple address ranges and the appliance receives an address request matching that filter,	it checks the address range with the highest IP addresses matching that filter. If the appliance does not assign an address from that range, it checks the filtered address range with the next highest IP addresses, and so on. If it still has not assigned an address, the appliance starts checking unfiltered address ranges (if there are any), again beginning with the range with the highest address first.
multiple filters for the same address range conflict with each other (one filter grants a lease and another denies it) and a requesting client matches both filters,	the filter denying the lease takes precedence. For example, if a requesting client matches both a MAC address filter (granting a lease) and a user class filter (denying a lease) for the same address range, the appliance denies the lease. When faced with a choice to either allow or deny a lease based on equal but contradictory filters, the appliance takes the more secure stance of denying it.

Configuring MAC Address Filters

The appliance can filter an address request by the MAC address of a requesting host. Depending on how you apply the MAC filter, the appliance can grant or deny the address request if the requesting host matches the filter criteria. You can also define DHCP options that you want to return to the matching client if the options are so configured. The client can also request specific options to be returned through DHCP option 55. The appliance returns DHCP options to matching clients based on how you apply the filters. For information, see *Applying Filters to DHCP Objects*.
You can configure a MAC address filter or specific MAC addresses within a filter to expire after a certain amount of time has passed. Filter expiration is useful in situations where you want to keep filters running against updated MAC addresses. The permission to use the MAC addresses assigned to an IP address may become invalid after a certain period of time. For example, you can use a MAC address filter to restrict the right to use MAC addresses assigned to IP addresses for visiting guests or temporary workers. You can avoid removing invalid addresses from address filters manually by configuring the appliance to expire filters or to expire specific addresses within filters.
To apply a MAC address filter to an address range:

1. Define a MAC address filter. For information, see Defining MAC Address Filters below.
2. Add a MAC address to the filter. For information, see Adding MAC Address Filter Items below.
3. Apply the filter to a DHCP address range or range template, and specify that if the MAC address of a requesting host matches the filter definition, the appliance either grants or denies the address assignment. For information, see *Applying Filters to DHCP Objects*.

Defining MAC Address Filters

To define a MAC address filter:

1. From the **Data Management** tab, select the **DHCP** tab ->**Filters** tab, and then expand the Toolbar and click **Add** -> **IPv4 MAC Address Filter**.
   or
   From any panel in the **DHCP** tab, expand the Toolbar and click **Add** -> **IPv4 MAC Address Filter**.
2. In the *Add IPv4 MAC Filter* wizard, complete the following:
   - **Name**: Enter a meaningful name for the filter. For example, if you want to filter address requests by department, you can name one filter "Marketing", another "Finance", and so on. The name must be unique within a specific network. If you want to specify option settings in the filter, the filter name must be unique among all MAC filters.
   - **Comment**: Enter useful information about the filter.
3. Click **Next** and complete the following to define the DHCP options to return to the matching client:
   - **Option Space**: Select an option space from the drop-down list. This field is displayed only when you have custom option spaces. The appliance uses the **DHCP** option space as the default.

- **Lease Time**: Enter the value of the lease time in the field and select the time unit from the drop-down list. The lease time applies to hosts that meet the filter criteria.

  Options to Merge with Object Options
  Click the Add icon. Grid Manager adds a new row to the table with the default **DHCP** option space and option name displayed. Complete the following:
- **Option Space**: Click the down arrow and select an option space from the drop-down list. The selected option space contains the corresponding DHCP options.
- **Option Name**: Click the down arrow and from the drop-down list, select the DHCP option you want to return to the requesting host.
- **Value**: Enter the value that you want the filter to return for the selected DHCP option. For example, enter the value 255.255.255.0 for the subnet-mask option.
  To add more options to the filter, click the Add icon and repeat the steps.

4. Click **Next** and complete the following to configure the expiration setting:
   - **Default MAC Address Expiration**
   - Select one of the following to configure the expiration setting for the filter:
     - **Never Expires**: Select this if you want the MAC address filter to never expire. This is selected by default.
     - **Automatically Expires in**: Select this if you want the filter to expire after a specific time frame. You can specify the time in seconds, minutes, hours, or days.
       The filter expiration time you configure here affects how long the DHCP server grants a lease to a client. It has an upper limit of 15 minutes on the lease time you configure for the Grid. For example, if both the filter expiration time and the lease time are less than 15 minutes, the appliance uses the lease time. If both the filter expiration time and lease time are greater than 15 minutes, the appliance uses the filter expiration time. If the filter expiration time is less than 15 minutes and the lease time is greater than 15 minutes, the DHCP server grants a lease for 15 minutes. If the filter expiration time is greater than 15 minutes and the lease time is less than 15 minutes, the appliance uses the lease time.
     - **Enforce Expiration Times** : Select this to enable the expiration setting.
     - **Enabled**: The filter is enabled by default. Clear the checkbox box to disable this filter.
5. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
6. Save the configuration and click **Restart** if it appears at the top of the screen.

Adding MAC Address Filter Items

To add a MAC address to a MAC address filter:

1. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab, and then expand the Toolbar and click **Add** -> **IPv4 MAC Address Filter Item**.
   or
   From any panel in the **DHCP** tab, expand the Toolbar and click **Add** -> **IPv4 MAC Address Filter Item**.
2. In the *Add IPv4 MAC Address Filter Item* wizard, complete the following:
   - **MAC Address Filter**: Click **Select Filter**. In the *DHCP Filter Selector* dialog box, select the MAC address filter to which you want to add a MAC address, and then click the Select icon. If you are adding a MAC address to a filter that you have selected in the *Filters* panel, Grid Manager displays the selected filter in this field.
   - **MAC Address**: Enter the MAC address in one of the following formats: aa:bb:cc:dd:ee:ff, aa-bb-cc-dd-ee-ff, aabb.ccdd.eeff, aabbcc-ddeeff, and aabbccddeeff. The appliance displays the address in the AA:BB:CC:DD:EE:FF format. You can also enter a vendor prefix in the three hexadecimal format using the same separators supported in the MAC address format. For example, you can enter aa.bb.cc as the vendor prefix. The appliance displays AA:BB:CC.
   - **Comment**: Enter useful information about the filter item.
   - **Expiration Time**: MAC addresses in a filter stay valid until you explicitly configure them to expire. You can enable expiration for specific MAC addresses in the filter. Select one of the following:
     - **Never Expires**: Select this if you want the MAC address to never expire. This is selected by default.
     - **Expires on**: Select this and specify the **Date** and **Time** for the expiration. The fields display the current date and time. If you have already configured an expiration time for the filter, the appliance

displays the time here by adding the filter expiration time to the current time. For example, if the expiration time for the filter is two days and the current date is June 6, 2009, the appliance displays June 8, 2009 in the **Date** field.

3. Click **Next** and select one of the following to configure user registration (optional):
   - **Register as User**: Select this and enter a username in the field.
   - **Register as Guest**: Select this and enter the first name, middle name, last name, email address, and phone number of the guest user.
     The appliance displays the information you enter here in the lease viewers.
4. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

After you define a MAC address filter and add MAC addresses to it, you can assign the filter to a DHCP range. The appliance filters IP address requests based on the filter criteria. For information, see *Applying Filters to DHCP Objects*.

Guidelines for Associating MAC Address Filters with DHCP Objects

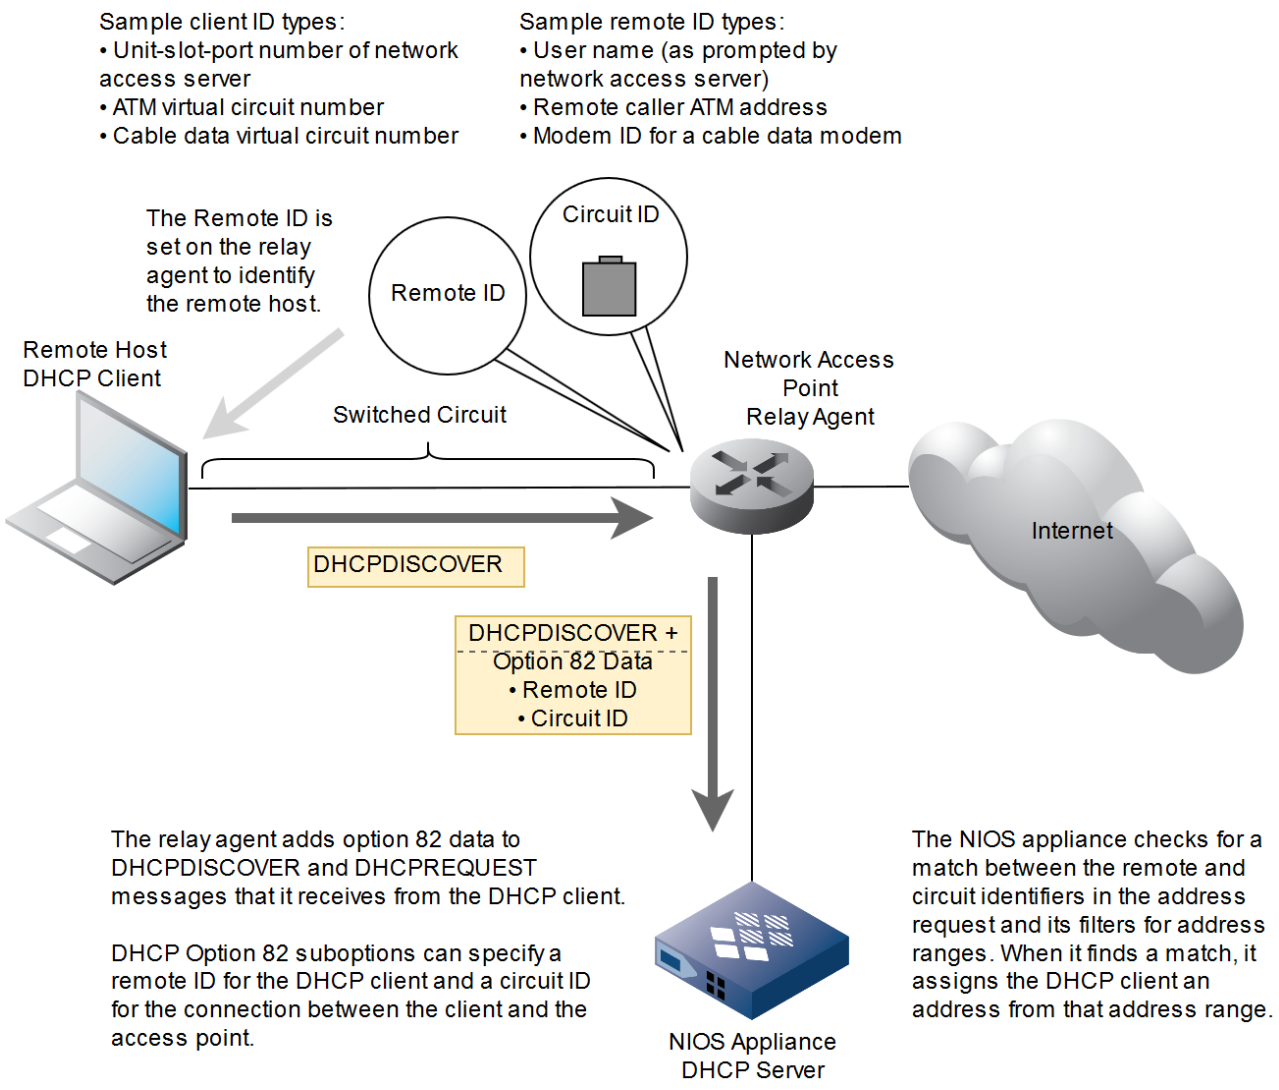
The following is a list of guidelines for associating MAC Address Filters with DHCP objects:

- Associating a MAC address filter with a DHCP range on a DHCP member or failover association requires a DHCP service restart.
- Associating the same MAC address filter to a different DHCP range on the same member does not require a DHCP service restart.
- Making further changes to a MAC address filter already assigned to a range (such as changing a MAC filter policy on the range from the grant lease to the deny lease) does not require a service restart.
- A restart is required only when:
  - You add a new MAC address filter (new to the DHCP member) is added to a range on a specific DHCP member or failover association.
  - Remove a specific MAC address filter from the last range it was associated with, on a specific DHCP member or failover association.
- Changes are propagated seamlessly to the the dhcpd process memory without a service restart and the dhcpd.conf file is not updated until you restart the service.

About Relay Agent Filters

The NIOS appliance can filter an address request by the circuit ID and remote ID of a requesting host. The filter instructs the appliance either to grant or deny an address request if the requesting host matches the filter. For information about the DHCP relay agent option, see as described in *About the DHCP Relay Agent Option (Option 82)*.
Option 82 assists the agent in forwarding address assignments across the proper circuit. When a relay agent receives a DHCPDISCOVER message, it can add one or two agent IDs (circuit ID or remote ID) in the DHCP option 82 suboption fields to the message, as illustrated in the figure Relay Agent Filtering below. If the agent ID strings match those defined in a relay agent filter applied to a DHCP address range, the appliance either assigns addresses from that range or denies the request based on the configured parameters.

Relay Agent Filtering



To apply a relay agent filter to an address range:

1. Define a relay agent filter. For information, see Defining Relay Agent Filters below..
2. Apply the filter to a DHCP address range or range template, and specify that if the circuit ID or remote ID of a requesting host matches the filter definition, the appliance either grants or denies the address assignment. For information, see *Applying Filters to DHCP Objects*.
3. Define the access privileges of limited-access admin group for relay agent filters. For information, see *Managing Administrators*.

Defining Relay Agent Filters

To define a relay agent filter:

1. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab, and then expand the Toolbar and click **Add** -> **IPv4 Relay Agent Filter**.
   or
   From any panel in the **DHCP** tab, expand the Toolbar and click **Add** -> **IPv4 Relay Agent Filter**.
2. In the *Add IPv4 Relay Agent Filter* wizard, complete the following:
   - **Name**: Enter a meaningful name for the filter. For example, you can enter the IP address or the name of the router acting as the relay agent. The name must be unique within a specific network.

- **Comment**: Enter useful information about the filter.

3. Click **Next** to define the relay agent ID type. If you apply both ID types, the relay agent must provide both identifiers when submitting a DHCP address request.
   Select one of the following for both **Circuit ID** and **Remote ID:**
   - **Any**: Select this and the filter matches any of the circuit identifiers for remote hosts. You cannot select this for circuit ID and remote ID at the same time.
   - **Not Set**: Select this and no circuit identifier is set for remote hosts.
   - **Matches Values**: Select this and enter the circuit ID or remote ID in the field. You can enter the ID in hexadecimal format, such as 1f:cd, ab, or ef:23:56, or in string format, such as abcd or aa:gg. The appliance matches the value you enter here with the value sent by the DHCP client in counted octet sequence format. This field supports wildcard characters and regular expressions. You can also select to have an exact match or a substring match, as follows:
     - **Exact Match**: Select this to match the exact value sent by the DHCP client that contains the value you entered in the **Matches Values** field.
     - **Substring**: Select this to match a substring of the value sent by the DHCP client. Enter the **Offset** and **Length** values for the substring match, as follows:
       - **Offset**: Enter the number of characters at which the match value for the substring starts. Enter 0 to start at the beginning of the value, enter 1 for the second position, and so on. For example, when you enter 2 and have a substring value of AFTR, the appliance matches the value AFTR starting at the third character of the match value.
       - **Length**: Enter the length of the substring value. For example, if the match value is AFTR, the length is 4.
4. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

After you define a relay agent filter, you can assign it to a DHCP range. The appliance responds to address requests based on the filter criteria. For information, see *Applying Filters to DHCP Objects*.

Configuring Option Filters

You can use option filters to classify DHCP clients and decide which DHCP options each group of clients can receive. By default, regardless of the networks in which the DHCP clients reside and whether an option filter is applied to a DHCP range or range template, all DHCP clients that match the filter criteria receive the DHCP options and values you define in the filter. You can change this configuration so the appliance does not use the filter to classify DHCP clients. For information about how to configure this, see Defining Option Filters below.
You can add DHCP options and the Hardware Operator option to an option filter. (For information about the Hardware Operator option, see DHCP Hardware Operator below.) Depending on whether the options you add to the filter are also defined at the Grid, member, network, and DHCP range levels, and whether you add the filter to the Class Filter List or Logic Filter List, the appliance either appends them to the existing options or overwrites the option values before returning them to the matching clients. For more information about how the appliance returns DHCP options, see *Adding Filters to the Logic Filter List*.
The appliance can filter an address request by the options (such as root-server-ip-address or user-class) of the requesting host. Depending on how you apply an option filter, the appliance can grant or deny an address request if the requesting host matches the filter criteria. You can also create complex match rules that use the AND and OR logic to further define the filter criteria. When you select match rules in Grid Manager, you can preview the rules before committing them to the filter. Grid Manager provides an expression builder that automatically builds the rules after you define them.
To define an option filter and apply it to an address range:

1. Define an option filter based on either the predefined or custom DHCP options.
2. Apply the filter to a DHCP address range or range template in the Class Filter List or Logic Filter List. For information, see *Applying Filters to DHCP Objects*.

After you define an option space and add options to it, you can set up option filters and define option values. For example, to handle two different client classes, you can define two option filters (vendor-class_1 and vendor-class_2) and send different option values to different clients based on the vendor-class-identifier options that you obtain from the clients.

DHCP Hardware Operator

You can define the Hardware Operator option and add it as a match rule to an option filter. This option enables the appliance to match the hardware type and MAC address of the DHCP client, which it derives from the hardware type, hlen (hardware length) and chaddr (client hardware address) fields of the client's DHCP Discover and Renew packets. To add Hardware Operator to an option filter, fill in the fields as follows:

- In the first drop-down list, select **Hardware Operator**. Note that because it is not a DHCP Option, it does not have an actual option number.
- In the second drop-down list, select one of the following operators: **equals**, **does not equal**, **substring equals** and **substring does not equal.**
  If the operator is **substring equals** or s**ubstring does not equal**, specify the offset and length.
- In the text field, enter the string that represents the hardware type and MAC address to match. For example, the htype value is 1 for the Ethernet hardware type. The hardware types (hrd) are defined at *http://www.iana.org/assignments/arp-parameters/arp-parameters.xml.*

This filter rule assumes that the values exist in the DHCP packets.
The following table provides examples of rules that include the Hardware Operator option. The entry in the first drop-down list for all rules is **Hardware Operator**.
Hardware Operator Sample Rules

Rule Description	Second Drop-Down List (operator)	Text Field (string)	Offset	Length
Match a hardware type and MAC address.	equals	01:00:C0:B0:AA:BB:CC		
Match hardware type only.	substring equals	01	0	1
Match the vendor MAC prefix (first three bytes of MAC address).	substring equals	00:C0:B0	1	3

Defining Option Filters

To define an option filter:

1. From the **Data Management** tab, select the **DHCP** tab ->**Filters** tab, and then expand the Toolbar and click **Add** -> **IPv4/IPv6 Option Filter**.
2. or
   From any panel in the **DHCP** tab, expand the Toolbar and click **Add** -> **IPv4/IPv6 Option Filter**.
3. In the *Add IPv4 Option Filter* wizard, complete the following:
   - **Name**: Enter a meaningful name for the option filter. For example, you can enter Linux if you plan to use this option filter to screen Linux systems. The name must be unique within a specific network. If you want to specify option settings in the filter, the filter name must be unique among all option filters.
   - **Comment**: Enter useful information about the filter.
   - **Apply this filter as a global DHCP class**: This checkbox is selected by default. When you select this checkbox, the appliance defines a global class statement in the dhcpd configuration file for members that have DHCP enabled, regardless of whether the filter is applied to a DHCP range or range template. All DHCP clients that belong to this class receive the DHCP options and values you define in the filter. When you clear this checkbox, you cannot apply this filter to the Class Filter List of a range or range template. You cannot clear this checkbox if the filter is currently applied to a range or range template. The appliance displays an error message when you try to save this configuration.
4. Click **Next** and complete the following to add match rules:
   - In the first drop-down list, select a DHCP option.
     For example,

- If you are adding an IPv4 option filter, select **user-class(77)** for a specific user class, such as mobile users.
- If you are adding an IPv6 option filter, select **dhcp6.fqdn (39) string** for a specific domain name. The following DHCP options are not supported for IPv6 option filter:
  - dhcp6.bcms-server-a
  - dhcp6.bcms-server-d
  - dhcp6.domain-search
  - dhcp6.name-servers
  - dhcp6.nis-domain-name
  - dhcp6.nisp-domain-name
  - dhcp6.nis-servers
  - dhcp6.preference (7) 8-bit unsigned integer
  - dhcp6.rapid-commit (14) boolean
  - dhcp6.server-id (2) string
  - dhcp6.sip-servers-addresses
  - dhcp6.sip-servers-names(21) domain-list
  - dhcp6.sntp-servers
  - dhcp6.unicast(12)ip-address

- In the second drop-down list, select an operator.
  If you select **equals** or **does not equal**, enter the value of the selected option you want the filter to match in the field.
  If your operator and match value include a substring of an option value, enter the offset and length of the substring based on the following definitions:
  - **Offset**: Enter the number of characters at which the match value substring starts in the option data. Enter 0 to start at the beginning of the option data, enter 1 for the second position, and so on. For example, when you enter 2 and have a match value of MSFT, the appliance matches the value MSFT starting at the third character of the option data.
  - **Length**: Enter the length of the match value. For example, if the match value is MSFT, the length is 4.

  You can do the following and repeat the filter selection steps to add another rule:
- Click **+** to add another rule at the same level.
- Click **|<-** to add an **all** (logical AND) or **any** (logical OR) operator line and a parenthetical rule that is indented one level and above the first rule.
- Click **->|** to add an **all** (logical AND) or **any** (logical OR) operator line and a parenthetical rule that is indented one level.

  After you add all the match rules, you can click **Preview** to view the rules that are written to the dhcpd configuration file or click **Reset** to remove the previously configured rules and start again. For information about how to use match rules, see Using Match Rules in Option Filters below.

5. Click **Next** and complete the following to define which DHCP options to return to the matching client:
   - **Option Space**: For an **IPv4 or IPv6 option filter** select an option space from the drop-down list. This field is not displayed if you do not have custom option spaces. The appliance uses the **DHCP** option space as the default.
   - **Lease Time**: Enter the value of the lease time in the field and select the time unit from the drop-down list. The lease time applies to hosts that meet the filter criteria.

     Options to Merge with Object Options
     Click the Add icon. Grid Manager adds a new row to the table with the default **DHCP** option space and option name displayed. Complete the following:
   - **Option Space**: Click the down arrow and select an option space from the drop-down list. The selected option space contains the corresponding DHCP options that you can use as filter criteria.
   - **Option Name**: Click the down arrow and from the drop-down list, select the DHCP option you want to use as filter criteria.
   - **Value**: Enter the match value that you want the filter to use for the selected DHCP option. To add more options to the filter, click the Add icon and repeat the steps.
6. Click **Next** to define extensible attributes. For information, see *Managing Extensible Attributes*.
7. Save the configuration and click **Restart** if it appears at the top of the screen.

Using Match Rules in Option Filters

Each match rule you define in an option filter further defines the filter criteria of a matching client. You can add multiple match rules to an option filter. The appliance writes these rules to the dhcpd configuration file. You can also create complex match rules that use the AND and OR logic to further define the filter criteria. After you define the match rules, you can preview the rules before committing them to the filters.
For example, you can define the following rules in an option filter:

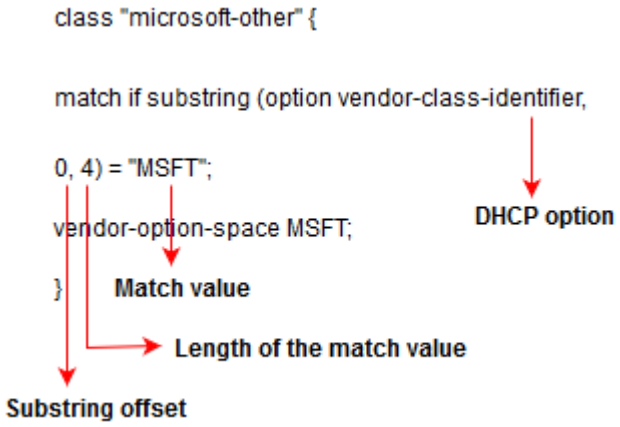
DHCP option = `vendor-class-identifier`

Substring offset = `0` (the match value starts at the beginning of the option data received from the client)

Substring length = `4` (the length of the match value MSFT)

Match value = `MSFT`

The appliance generates the following rules in the dhcpd configuration file:



You can also define more complex rules using the AND and OR logic as follows:

DHCP option = `vendor-class-identifier`

Match value = i `nfoblox2000a`

OR

DHCP option = v `endor-encapsulated-options`

Substring offset = `0` (the match value starts at the first character of the option data received from the client)

Substring length = `8` (the length of the match value infoblox)

Match value = `infoblox`

AND

DHCP option = `vendor-encapsulated-options`

Substring offset = `10` (the match value starts at the ninth character of the option data received from the client)

Substring length = `5` , the length of the match value `2000a`

Match value = `2000a`

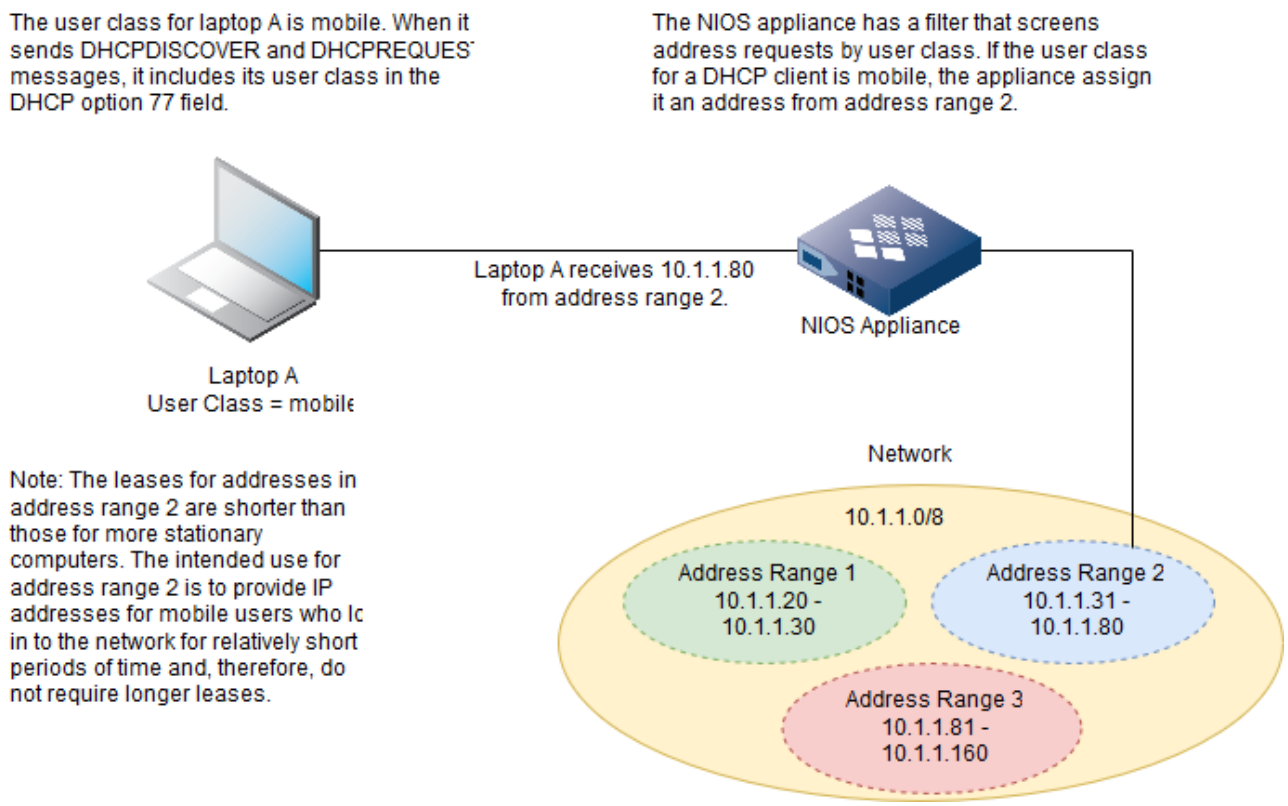
The appliance generates the following rules in the dhcpd configuration file:

```
class "infoblox" {
match if (option vendor-class-identifier=infoblox2000a:) or
((substring(option vendor-encapsulated-options,0,8)="infoblox") and
(substring(option vendor-encapsulated-options,10,5)="2000a")); vendor-option-space DHCP
}
```

Configuring User Class Filters

The NIOS appliance can filter DHCP address requests by user class filters. A user class indicates a category of user, application, or device of which the DHCP client is a member. User class identifiers are configured on DHCP clients and are sent during a DHCP address request operation. The client includes the user class identifier in DHCP option 77 when sending DHCPDISCOVER and DHCPREQUEST messages.
By using user class identifiers, a DHCP server can screen address requests and assign addresses from select address ranges based on the different user class identifiers it receives. For example, if you assign a user class filter named mobile to a range of addresses from 10.1.1.31–10.1.1.80, the appliance selects an address from that range if it receives an address request that includes the user class name mobile and there are still addresses available in that range. You might want mobile users to receive these addresses because you have given them shorter lease times than other, more stationary DHCP clients. See the below figure.

Applying User Class Filtering



If the NIOS appliance receives address requests with the user class mobile and there are no available addresses in address range 2 but there are available addresses in ranges 1 and 3, the appliance begins assigning addresses from address range 3 (because its addresses are higher than those in range 1). Then, if all addresses in range 3 are in use, the appliance begins assigning addresses from address range 1. If you want the appliance to assign addresses to mobile users (that is, those identified with the user class mobile) exclusively from address range 2, then you must apply user class filters for "mobile" to address ranges 1 and 3 that deny lease requests matching that user class.

Configuration Example: Using Option Filters

The following example shows you how to create an option space, add custom options to it, create an option filter, and a match rule to filter the options so that the NIOS appliance can filter an address request by the vendor options of the requesting hosts. It can grant or deny an address request if the requesting host matches the filter.

1. Add an option space called MSFT, and then add the following options to it. For information, see *Applying DHCP Options*.

Option name	Code	Type
root-mount-options	1	Text
root-server-ip-address	2	IP address
root-server-host-name	3	Text
root-server-path-name	4	Text

Option name	Code	Type
swap-server-ip-address	5	IP address
swap-file-path-name	6	Text
boot-file-path-name	7	Text
posix-timezone-string	8	String
boot-read-size	9	16-Bit unsigned integer

2. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab and click the Add icon.

3. In the *AddIPv4Filter* wizard, enter the filter name i86pc, and then select **Options** as the filter type.

4. Select **MSFT** as the option space, select an option, specify a value for it, and then add it to the i86pc option filter. You can select multiple options. Add the following options to the i86pc option filter:

Option name	Code	Type
root-server-ip-address	2	IP address
root-server-host-name	3	Text
root-server-path-name	4	Text
boot-file-path-name	7	Text

5. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab -> *filter_name*, and then click the Add icon.

6. In the *AddIPv4MatchRule* wizard, select **i86pc** as the option filter, select **vendor-class-identifier(60)** as the matching option, and then enter **MSFT** as the matching value.

7. Add a DHCP range to the network. For information, see *Configuring IPv4 Address Ranges*.

8. Apply the i86pc option filter to the DHCP address range. For information, see *Applying Filters to DHCP Objects*.

9. Click **Restart** to restart services.

Configuring DHCP Fingerprint Filters

The appliance can filter an address request by the DHCP fingerprint of a requesting client. Depending on how you apply DHCP fingerprint filters, the appliance can grant or deny the address request if the requesting client matches the filter criteria. Note that only superusers can add, modify, and delete DHCP fingerprint filters. Limited-access users cannot perform any DHCP fingerprint filter related tasks, though with the correct permissions they can apply DHCP fingerprint filters to DHCP ranges and range templates. For information about how to apply filters to DHCP ranges, see *Applying Filters to DHCP Objects*.

You can define a DHCP fingerprint filter by selecting one or multiple DHCP fingerprints from the existing list of DHCP fingerprints, and then assign a grant or deny permission to the filter. You can then apply the filter to a DHCP address range, if DHCP fingerprint detection is enabled. For information about how to enable DHCP fingerprint detection, see *Enabling and Disabling DHCP Fingerprint Detection*.

Note that once you apply a DHCP fingerprint filter to an address range, you cannot disable DHCP fingerprint detection or disable individual DHCP fingerprints that have been included in the filter. You must first delete or disable the DHCP fingerprint filter that you have applied to the address range before you can disable any fingerprint related tasks. For

information about how to delete a DHCP fingerprint filter, see *Deleting Filters*.
On lease renewals, requesting clients must send the same DHCP fingerprint information in order for the appliance to properly grant or deny leases based on the configured DHCP fingerprint filters. For example, if a client sends option 55 in the original request but does not send the same information in the renewal request, and you have configured a DHCP fingerprint filter to grant a lease to this client, the appliance may not be able to properly grant a lease to this client.
To apply a DHCP fingerprint filter to an address range:

1. Define a DHCP fingerprint filter. For information, see Defining DHCP Fingerprint Filters below.
2. Apply the filter to a DHCP address range or range template, and specify that if the DHCP fingerprint of a requesting host matches the filter definition, the appliance either grants or denies the address assignment. For information, see *Applying Filters to DHCP Objects*.

Associating a DHCP fingerprint filter with a DHCP range on a DHCP member or a failover association does not require a DHCP service restart. Changes are propagated seamlessly to the the dhcpd process memory without a service restart and the dhcpd.conf file is not updated until you restart the service.

Defining DHCP Fingerprint Filters

To define a DHCP fingerprint filter:

1. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab, and then expand the Toolbar and click **Add** -> **IPv4 Fingerprint Filter**.
   From any panel in the **DHCP** tab, expand the Toolbar and click **Add** -> **IPv4 Fingerprint Filter**.
2. In the *Add IPv4 Fingerprint Filter* wizard, complete the following:
   - **Name**: Enter a meaningful name for the filter. For example, if you want to filter address requests by a specific device class, you can name one filter "Gaming Console," another "Android Phones," and so on. The filter name must be unique among all DHCP fingerprint filters.
   - **Comment**: Enter useful information about the filter.
3. Click **Next** and then click the Add icon in the Select Fingerprints table. In the *Fingerprint Selector* dialog box, select the DHCP fingerprint you want to include in this filter. Click Add icon to select another DHCP fingerprint. When you select **No Match**, the appliance applies the filter to all requesting clients that do not send option 55 and option 60 or to clients that send values in option 55 and 60 that do not match any existing DHCP fingerprints.
4. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
5. Save the configuration.

Applying Filters to DHCP Objects

To further control how the appliance allocates IPv4 or IPv6 addresses to DHCP client requests, you can apply DHCP filters to determine the following:

- The class statements
- The address ranges from which it assigns leases
- When to grant or deny leases to the matching clients
- Which DHCP options to return to the matching clients

You can apply IPv4 or IPv6 logic filters at the Grid DHCP or Member DHCP. You can choose to keep the inherited properties or override them when you edit the IPv4 / IPv6 networks, IPv4 / IPv6 network containers, IPv4 / IPv6 network templates, IPv4 / IPv6 shared networks, IPv4 / IPv6 DHCP ranges, IPv4 / IPv6 DHCP range templates, IPv4 / IPv6 fixed addresses, IPv4 / IPv6 reservations, IPv4 / IPv6 fixed address templates, IPv4 / IPv6 reservation templates, or IPv4 / IPv6 host addresses.

Adding Filters to the Class Filter List

You can apply any DHCP filter to the Class Filter List of a DHCP range or range template. The appliance uses the matching rules of these filters to select the address range from which it assigns a lease. You can define permissions for these filters to instruct the appliance whether to grant or deny a lease to the matching client. When you add a filter with a grant permission, the client must match the filter criteria to receive a lease. When you define a filter with a deny permission, clients that do not match the filter criteria still receive leases. Only the client that matches the filter criteria is

denied a lease.
Filters in the Class Filter List correspond to the class statement generated in the dhcpd configuration file, which is a classification of the client packet. All DHCP clients that match the option filter and relay agent filter criteria become members of the same class and are eligible to receive DHCP options for that class, regardless of the networks in which the clients reside. However, a client can only become a member of the MAC or NAC filter class when it is granted a lease from the DHCP range based on the filter criteria. Whether a client receives specific options and option values depends on the hierarchy of the options and how you apply the filters. For information about how the appliance returns DHCP options, see *Adding Filters to the Logic Filter List*.

Adding Filters to the Logic Filter List

The filters you add to the Logic Filter List correspond to the match rules that are written to the dhcpd configuration file. The appliance uses these filters to identify DHCP options and values to return to the matching clients. You can apply option, MAC, and NAC filters to the Logic Filter List. Note that a DHCP client is eligible to receive DHCP options defined in a filter if it matches the filter criteria. Whether the client receives specific options and their corresponding values depends on the hierarchy of the options and the list of options requested by the client through DHCP option 55. You can configure the appliance to ignore the option list requested by a matching client and return all the options that the client is eligible to receive. For information about how to ignore the option list requested by a client, see *Configuring General IPv4 DHCP Properties*.

⚠ Notes

- The appliance allows you to add an empty IPv4 logic filter at the end of the logic filter list, which means that you can add an IPv4 logic filter without defining DHCP options in it. In addition, you can change the order of the filters in the logic filter list.
- When a range has multiple class filters assigned to it, if any of the filters deny a lease to a client, then the client will not get a lease even if another class filter allows it.

The appliance decides which options and values to return to a client based on the following:

- If you have different DHCP options defined in a range and any DHCP filters in the Class Filter and Logic Filter lists, and these options do not overlap, the appliance merges and returns all options to the matching client. For example, a DHCP client obtains a lease from a DHCP address range (R) through an option filter in the Class Filter List (CF), which contains an option statement (O1) with a value of (S1). The appliance then matches a filter in the Logic Filter List (LF) that contains an option statement (O2) with a value of (S2). In this case, option statements O1 and O2 and their values S1 and S2 are merged and returned to the matching client.
- If there are overlapping DHCP options in a range and any DHCP filters in the Class Filter and Logic Filter lists, the values defined in the Class Filter List filters take precedence over those defined in the range and filters in the Logic Filter List. The appliance returns the option value defined in the class filters to the matching client. For example, a DHCP client obtains a lease from a DHCP address range (R) through an option filter in the Class Filter List (CF), which contains an option statement (O1) with a value of (S1). The appliance then matches a filter in the Logic Filter List (LF) that contains the same option statement (O1) with a value of (S2). In this case, the option value S1 defined in the option filter in the Class Filter List takes precedence and is returned to the DHCP client.
- When you apply option, MAC, and NAC filters to the Logic Filter List, the appliance translates their match rules into a DHCP if/elseif/else statement using the match rules of the first filter on the list as the "if" expression in the statement. Match rules in subsequent filters are translated into the "elseif" statements, and the last filter that does not contain any match rules is translated into the "else" statement. Note that a filter without any match rules can only be added as the last filter in the Logic Filter List.

For more information about how the appliance grants and denies leases to requesting clients and determines which DHCP options to return to the matching clients, see Configuration Example: Using the Class and Logic Filter Lists below.
To apply filters:

1. **Grid:** From the **Data Management** tab **-> DHCP** tab**,** select **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox -> Edit icon.
   Network: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network*

checkbox, and then click the Edit icon.
DHCP Range: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* ->*addr_range* checkbox, and then click the Edit icon
Fixed Address: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *fixed_address* checkbox, and then click the Edit icon.
IPv4 Reservation: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *reservation* checkbox, and then click the Edit icon.
Host Address: From the **Data Management** tab, select the **DHCP** *tab -> **Networks** tab -> **Networks** -> network -> host_record* checkbox, and then click the Edit icon. Select the host IP address, and then click the Edit icon.
IPv4 Network or Fixed Address Template: From the **Data Management** tab, select the **DHCP** tab -> **Templates** tab -> (*IPv4 network or fixed address) template* checkbox, and then click the Edit icon.

2. In the editor, click **Toggle Advanced Mode**, and then select the **Filters** tab.
3. **Logic Filter List**: You can keep the inherited IPv4 logic filters or override them. To override the value that has been inherited from the upper level, click **Override**. Click the Add icon to add a filter to match a client based on the match rules defined in the filter.
   If you have only one configured DHCP filter, the appliance displays the filter in the table. Otherwise, in the *DHCP Filter Selector* dialog box, click the filter you want to add. Use SHIFT+click and CTRL+click to select multiple filters.
4. Complete the following to add the **Class Filter** to a DHCP address range:
   - Click the Add icon to add a filter to identify the class of a matching client, and to grant or deny a lease to a client. For more information, see Adding Filters to the Class Filter List above.

     If you have only one configured DHCP filter, the appliance displays the filter in the table. Otherwise, in the *DHCP Filter Selector* dialog box, click the filter you want to add. Use SHIFT+click and CTRL+click to select multiple filters.
     For each filter you add, click the **Action** column and select one of the following from the drop-down list:
   - **Grant lease**:
     For MAC address filters: Select this to assign an IP address from the address range to a requesting host whose MAC address matches the MAC address in the filter.
     For relay agent filters: Select this to assign an IP address from the address range when one or both of the relay agent identifiers of the requesting host match the filter criteria.
     For option filters: Select this to assign an IP address from the address range to a requesting host whose DHCP options match the DHCP options and match rules defined in the filter.
     For NAC filters: Select this to assign an IP address from the address range to a requesting host based on the authentication results from a RADIUS authentication server group.
     For DHCP fingerprint filters: Select this to grant a lease from the address range to a requesting host based whose DHCP fingerprint matches the DHCP fingerprint in the filter.
   - **Deny lease**:
     For MAC address filters: Select this to deny an address request from a host whose MAC address matches a MAC address in the filter.
     For relay agent filters: Select this to deny an address request when one or both relay agent identifiers match the filter criteria in the filter.
     For option filters: Select this to deny an address request from a host whose DHCP options match the options and match rules in the filter.
     For NAC filters: Select this to deny an address request from a host based on the authentication results from a RADIUS authentication server group.
     For DHCP fingerprint filters: Select this to deny a lease request when the DHCP fingerprint of the requesting host matches the DHCP fingerprint in the filter.
     The appliance uses filters in both the Class Filter and Logic Filter lists to determine the DHCP options and values it returns to the matching clients.

> ⚠ Note
>
> You can only add a filter that does not contain any match rules as the last filter in the Logic Filter List.

5. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuration Example: Using the Class and Logic Filter Lists

The following example shows you how to define DHCP filters and apply them to the class and logic filter lists. It also shows you the DHCP configuration file that is generated based on the configuration.
In this example, you first define a MAC filter, two option filters (one without match rules), and a NAC filter, and then apply the MAC filter to the Class Filter List and the other filters to the Logic Filter List of the address range 10.34.34.6 - 10.34.34.55.

1. Configure and save a MAC filter as follows. For more information, see *Defining MAC Address Filters*.
    a. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab, and then expand the Toolbar and click **Add** -> **IPv4 MAC Address Filter**.
    b. In the *Add IPv4 MAC Filter* wizard, complete the following:
        - **Name**: Enter **MAC1**.
    c. Click **Next** and complete the following to define the DHCP options to return to the matching client:
        - **Lease Time**: Enter **1234** and select **seconds** from the drop-down list.
          Options to Merge with Object Options: Click the Add icon. Grid Manager adds a new row to the table with the default DHCP option space and option name displayed. Complete the following:
        - **Option Name**: Click the down arrow and select **log-server(7)** from the drop-down list.
        - **Value**: Enter **10.34.34.3** as the value for the log-server option that is sent to the client in the OFFER/ACK message.
    d. Save the configuration.
2. Add a MAC address filter item as follows. For more information, see *Adding MAC Address Filter Items*.
    a. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab, and then expand the Toolbar and click **Add** -> **IPv4 MAC Address Filter Item**.
    b. In the *Add IPv4 MAC Address Filter Item* wizard, complete the following:
        - **MAC Address Filter**: Click **Select Filter**. In the *DHCP Filter Selector* dialog box, click **MAC1**.
        - **MAC Address**: Enter `AB:DE:CC:DD:EE:01` as the MAC address.
    c. Save the configuration.
3. Configure and save an option filter with match rules as follows. For more information, see *Defining Option Filters*.
    a. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab, and then expand the Toolbar and click **Add** -> **IPv4 / IPv6 Option Filter**.
    b. In the *AddIPv4OptionFilter* wizard, complete the following:
        - **Name**: Enter `Option1`.
    c. Click **Next** and complete the following to add match rules:
        - In the first drop-down list, select `vendor-class-identifier.`
        - In the second drop-down list, select `substring equals`, and then enter the following:
            - **Offset**: Enter `0` to match the value starting at the first character of the option data.
            - **Length**: Enter `4`.
            - Enter `MSFT` as the matching value.

              Click **Preview** and the appliance displays the expression: `(vendor-class-identifier,0,4="MSFT")`.
    d. Click **Next** and complete the following to define the DHCP options to return to the matching client:
       Options to Merge with Object Options: Click the Add icon. Grid Manager adds a new row to the table with the default DHCP option space and option name displayed. Complete the following:
        - **Option Name**: Click the down arrow and from the drop-down list, select `time-server(4)`.
        - **Value**: Enter `10.34.34.2` as the value for the time-server option that is sent to the client in the OFFER/ACK message.
    e. Save the configuration.
4. Configure and save another option filter without match rules as follows:
    a. In the *AddIPv4OptionFilter* wizard, complete the following:

- **Name**: Enter **Option2**.

b. Click **Next**. Do not define any match rules.
c. Click **Next** again and complete the following to define the DHCP options to return to the matching client:
Options to Merge with Object Options: Click the Add icon. Grid Manager adds a new row to the table with the default DHCP option space and option name displayed. Complete the following:
   - **Option Name**: Click the down arrow and from the drop-down list, select `domain-name(6).`
   - **Value**: Enter `www.infoblox.com.`

d. Save the configuration.

5. Configure and save a NAC filter as follows. For more information, see *Defining NAC Filters*.
   a. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab, and then expand the Toolbar and click **Add** -> **IPv4 NAC Filter**.
   b. In the *AddFilter* Wizard, complete the following and click **Next**:
      - **Name:** Enter `NAC1` .
   c. Create a rule as follows:
      - In the first drop-down list, select **Compliance State**.
      - In the second drop-down list, select **equals**.
      - In the third drop-down list, select **Compliant**.

      Click **Preview** and the appliance displays the expression:
      (`Sophos.ComplianceState="Compliant"`).
   d. Click **Next** and complete the following to define DHCP options:
      - **Lease Time**: Enter **1000** and select `seconds` from the drop-down list.

      Options to Merge with Object Options: Click the Add icon. Grid Manager adds a new row to the table with the default DHCP option space and option name displayed. Complete the following:
      - **Option Name**: Click the down arrow and from the drop-down list, select `cookies-servers(8)` .
      - **Value**: Enter **10.34.34.5**.

   e. Save the configuration.
6. Apply the filters to the address range as follows.
   a. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> **10.34.34.6-10.34.34.55** checkbox, and then click the Edit icon.
   b. In the *DHCP Range* editor, click **Toggle Advanced Mode**.
   c. Click the **Filters** tab and complete the following:
   Class Filter List: Click the Add icon and add **MAC1** as a class filter. Click the **Action** column and select **Grant lease** from the drop-down list.
   Logic Filter List: Click the Add icon and add **Option1**, **NAC1**, and **Option2** respectively as logic filters
   d. Save the configuration.
   The appliance generates the following information in the DHCP configuration file based on the filter configuration in this example:

```
# MAC filter "MAC1"
class "MAC1" {
    default-lease-time 1234;
    min-lease-time 1234;
    max-lease-time 1234;
option log-servers 10.34.34.3;
```

```
}
# NAC filter "NAC1"
    {option sophos.compliance
    state="compliant"
}
 subnet 10.34.34.0 netmask 255.255.255.0 {
    pool {
        infoblox-range 10.34.34.6 10.34.34.55;
        range 10.34.34.6 10.34.34.55;
        option routers 10.34.34.1;
        # INFOBLOXMACFILTERDEBUGINFO: allow members of "MAC1";
     if (substring(option vendor-class-identifier,0,4)="MSFT") {
        # Option filter "Option1"
        option time-servers 10.34.34.2;
}
elsif (option Sophos.ComplianceState="Compliant") {
    # NAC filter "NAC1"
    default-lease-time 1000;
    min-lease-time 1000;
    max-lease-time 1000;
    option cookie-servers 10.34.34.5;
}
else {
    # Option filter "Option2"
    default-lease-time 2500;
    min-lease-time 2500;
    max-lease-time 2500;
    option domain-name "www.infoblox.com"; }
```

```
}
```

Depending on client requests and the matching criteria, the following scenarios can happen in this example:

If the requesting client matches the MAC1 and Option1 filters, the appliance returns the following:

- Lease time = 1234 seconds (from the MAC filter)
- Returned options:
  - Router(3) with a value of 10.34.34.1 (from the address range)
  - Log-server(7) with a value of 10.34.34.3 (from the MAC filter MAC1)
  - Time-server(4) with a value of 10.34.34.2 (from the option filter Option1)

If the requesting client matches the MAC1 and NAC1 filters, the appliance returns the following:

- Lease time = 1234 seconds (from the MAC filter MAC1)Returned options:
  - Router(3) with a value of 10.34.34.1 (from the address range)
  - Log-server(7) with a value of 10.34.34.3 (from the MAC filter MAC1)
  - Cookie-server(8) with a value of 10.34.34.5 (from the NAC filter NAC1)

If the client matches the MAC1 filter, but not the Option1 or NAC1 filters, the appliance returns the following:

- Lease time = 1234 seconds (from the MAC filter)
- Returned options:
  - Router(3) with a value of 10.34.34.1 (from the address range)
  - Log-server(7) with a value of 10.34.34.3 (from the MAC filter MAC1)
  - Domain-name(6) with a value of www.infoblox.com (from the option filter Option2)

If the requesting client does not match the MAC1 filter, no lease is granted.

Managing DHCP Filters

You can do the following to manage DHCP filters:

Modifying DHCP Filters

To modify a filter:

1. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab -> *filter_name* checkbox, and then click the Edit icon.
2. For a MAC address filter, the *DHCP MAC Filter* editor provides the following tabs from which you can modify information:
   - **General**: Modify the fields as described in *Defining MAC Address Filters*.
   - **DHCP Options**: Add or delete DHCP options. For information, see *Defining MAC Address Filters*.
   - **Extensible Attributes**: Add or delete extensible attributes that are associated with a specific DHCP range. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.
   - **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *About Administrative Permissions*.
   - For a relay agent filter, the Relay Agent Filter editor provides the following tabs from which you can modify information:
     - **General**: Modify the fields as described in *Defining Relay Agent Filters*.

        - **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific DHCP range. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.

    - For an option filter, the Option Filter editor contains the following tabs from which you can modify information:
        - **General**: Modify the fields as described in *Defining Option Filters*.
        - **Rules**: Modify the match rules as described in *Defining Option Filters*.
        - **DHCP Options**: Modify option spaces and DHCP options in the **Basic** tab as described in *Defining Option Filters*. You must define the **PXE Lease Time** in the **Advanced** tab.
        - **BOOTP**: Modify BOOTP settings as described in *Configuring IPv4 BOOTP and PXE Properties*.
        - **Extensible Attributes**: Add or delete extensible attributes that are associated with a specific DHCP range. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.

    - For a DHCP fingerprint filter, the Add IPv4 Fingerprint Filter editor provides the following tabs from which you can modify information:
        - **General**: Modify general information, such as the name and device class, as described in *Defining DHCP Fingerprint Filters.*
        - **Fingerprints**: Add or delete DHCP fingerprints as described in *Defining DHCP Fingerprint Filters*..
        - **Extensible Attributes**: Add and delete extensible attributes that are associated with the DHCP fingerprint filter. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.

    - For a NAC filter, the NAC Filter editor contains the following tabs from which you can modifying information:
        - **General**: Modify the name and comment.
        - **Rules:** Modify the rules as described in *Defining NAC Filters.*
        - **DHCP Options**: Add or delete DHCP options. For information, see *Defining NAC Filters*.
        - **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific DHCP range. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes.*

3. Save the configuration and click **Restart** if it appears at the top of the screen.

You can modify the MAC address filter items and match rules for corresponding MAC address filters and option filters. For information, see ModifyingMACAddressFilterItems and ViewingDHCPFilters below.

Modifying MAC Address Filter Items

To modify a MAC address filter item:

1. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab -> *filter_name* -> *mac_filter* checkbox, and then click the Edit icon.
2. The *MAC Address Filter Item* editor contains the following tabs from which you can edit data:
    - **General**: Modify the fields as described in *Adding MAC Address Filter Items*.
    - **Registration**: Modify registration settings as described in *Adding MAC Address Filter Items*.
    - **Extensible Attributes**: Add or delete extensible attributes that are associated with a specific DHCP range. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Viewing DHCP Filters

To view DHCP filters:

1. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab.
2. Grid Manager displays the following for each filter:
    - **Name**: The name of the filter.
    - **Filter Type**: The filter type.
    - **Comment**: The information about the filter.

- **Site**: The location to which the filter belongs. This is one of the predefined extensible attributes.

Viewing MAC Address Filter Items

To view a list of MAC addresses in a specific MAC address filter:

1. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab -> *filter_name*.
2. Grid Manager displays the following:
   - **MAC Address**: The DHCP fingerprint information of client's device. This field is displayed only when users use captive portal for authentication. MAC address assigned to the filter.
   - **Username**: Grid Manager displays the username to which the MAC address belongs in the lease viewers.
   - **Comment**: The information you entered about the filter item.
   - **Expiration Time**: The expiration time you configured for the MAC address.
   - **Fingerprint**: The DHCP fingerprint information of client's device. This field is updated when users use Captive Portal for authentication.
   - **Site**: The location to which the filter belongs. This is one of the predefined extensible attributes.

Deleting Filters

You can delete a filter that is not currently assigned to a DHCP range. You can also remove a filter from a DHCP range, and then delete the filter if it is not in use.
To delete a filter:

1. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab -> *filter_name*, and then click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes**.

The appliance puts the deleted filters in the Recycle Bin, if enabled. You can later restore the filter if needed.

To schedule this task, click the Delete icon -> **Schedule Delete**. In the *Schedule Deletion* dialog box, click **Delete Later**, and then specify a date, time, and time zone.

Authenticated DHCP

This feature provides the ability to control access to your IPv4 networks. (This feature does not support IPv6 networks.) You can divide a network into segments for unauthenticated, authenticated and guest users, and the DHCP server assigns clients to the appropriate segment based on their MAC addresses and authentication credentials.

For example, you can divide a network into one or more production segments for valid employees and systems, a guest segment with access only to the Internet and/or limited public servers, and a quarantine segment with access to a captive portal only. A captive portal is a web page that can provide an option to register as an authenticated user or as a guest.

On a member DHCP server, configure DHCP ranges for each access level — quarantine, authenticated, and guest — and create MAC address filters for the DHCP ranges. You can use DHCP options and Access Control Lists (ACLs) on your routers and firewall policies to define the appropriate services for each access level. On another Grid member, configure the captive portal and specify the authentication server group that authenticates the users. You can configure an authentication server group for external servers running RADIUS, LDAP, or Active Directory (AD).

When a DHCP client first sends a request for an IP address, the DHCP server offers an IP address from the quarantine range and directs the client to the captive portal, where the user can register either as an authenticated user or as a guest. When users sign in as guests or are successfully authenticated, the member automatically adds their MAC addresses to the appropriate MAC address filters and assigns addresses out of the appropriate address range.

This section includes the following topics:

- *Defining MAC Address Filters*
- *Using the Captive Portal Wizard*
- *Adding and Modifying the Filters and Associations*
- *Monitoring DHCP Authentication*
- *Configuration Example: Configuring Authenticated DHCP*
- *NAC Integration*
- *Configuring NAC with RADIUS Servers*
- *About Authentication Servers*
- *Configuring DHCP Ranges*
- *About NAC Filters*

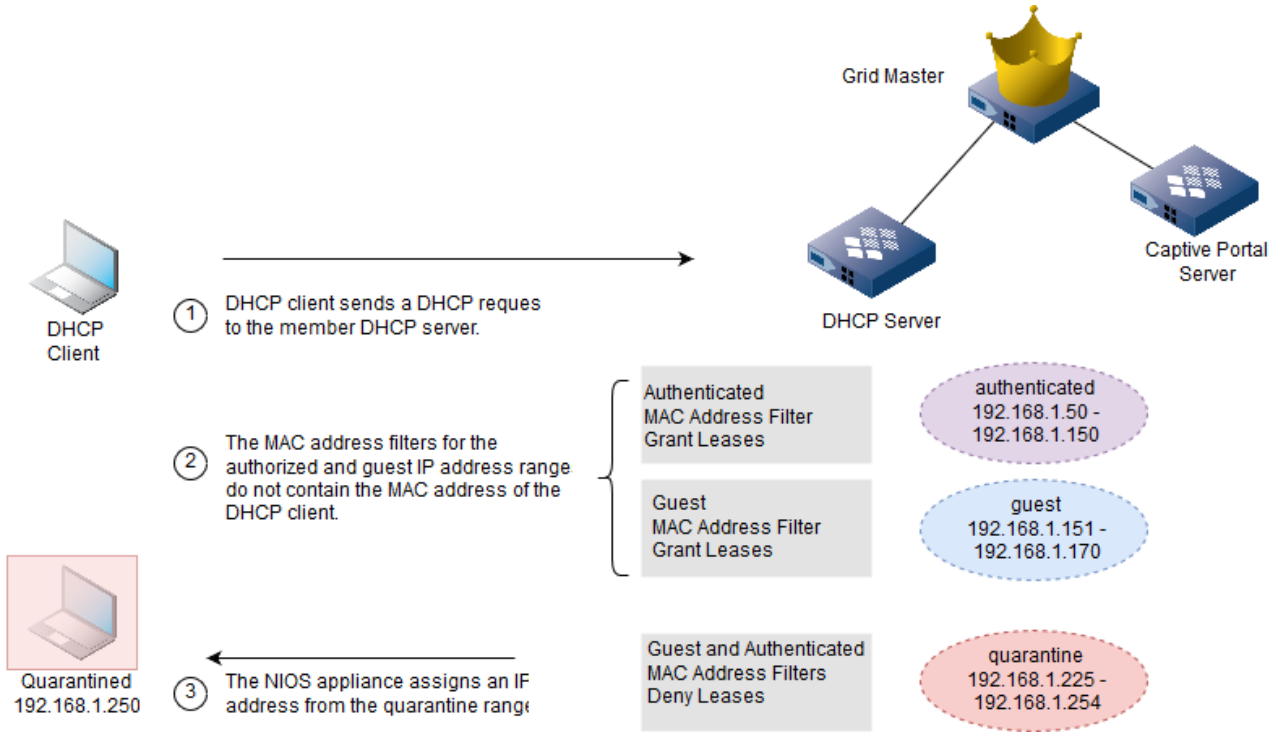
DHCP Authentication Process

DHCP Authentication Process

This section illustrates the DHCP authentication process. As illustrated in the following figure Quarantining an Unauthenticated DHCP Client, the DHCP authentication process begins when a DHCP client attempts to connect to the network. The member DHCP server checks if the MAC address of the DHCP client matches a MAC address in the guest or authenticated MAC address filters. If the member does not find a match, it assigns an IP address from the quarantine range to the DHCP client. When the client tries to access a web site, it is redirected to the captive portal page.

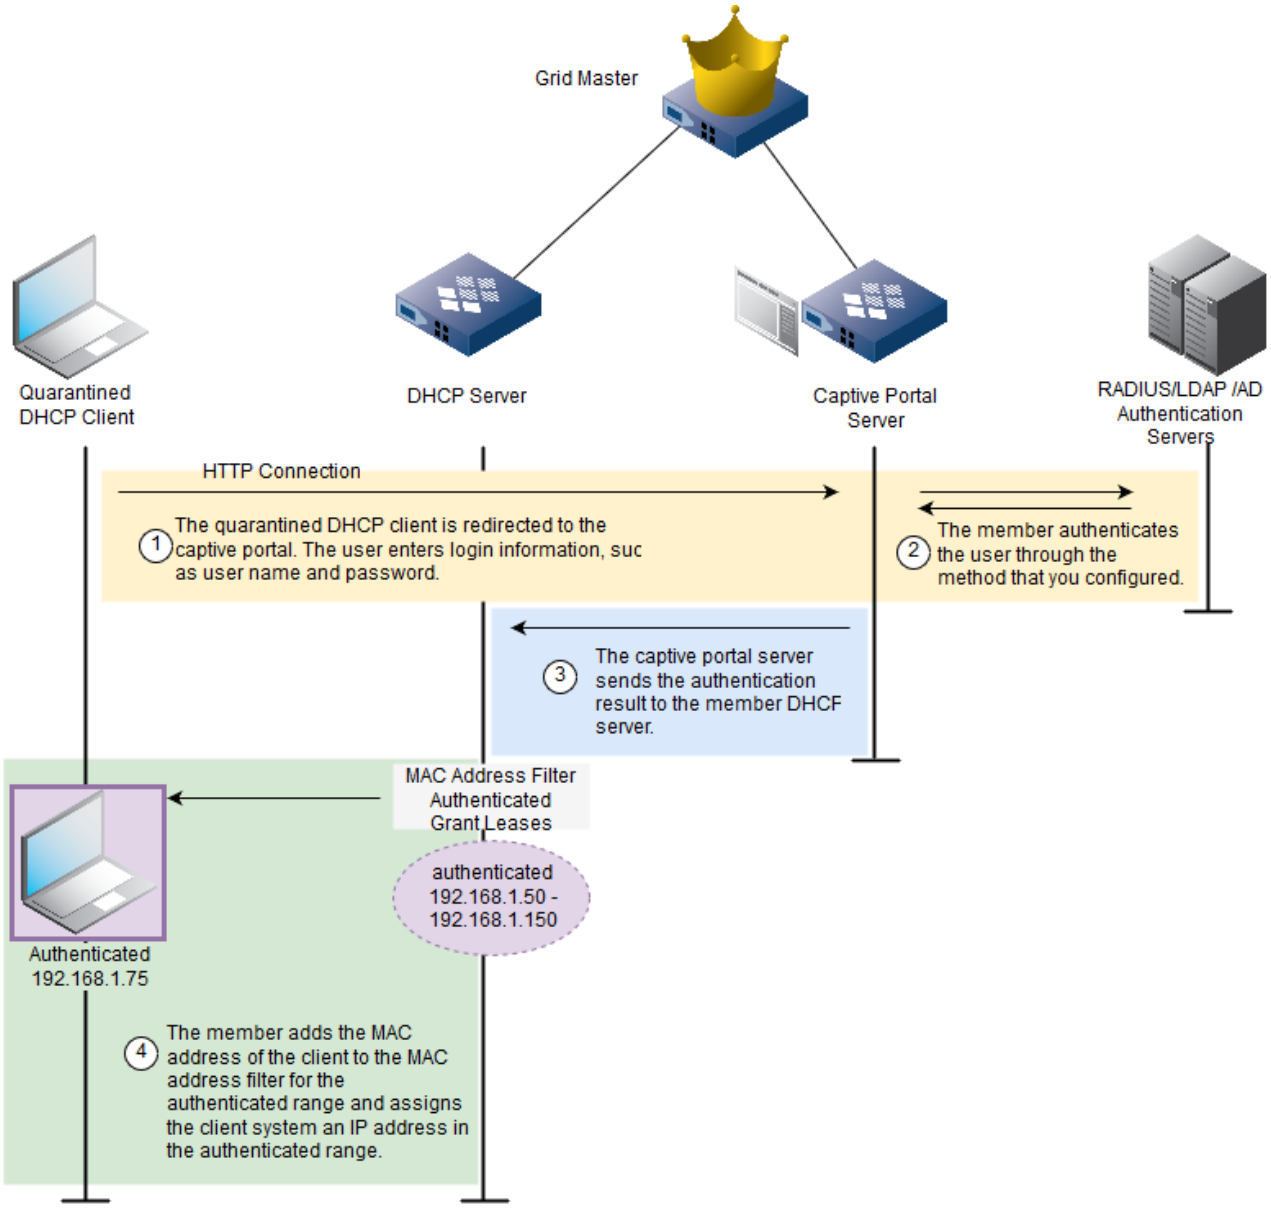
Stage 1: Quarantining an Unauthenticated DHCP Client



Note that the quarantine range in the figure Quarantining an Unauthenticated DHCP Client above contains MAC address filters to deny leases in the quarantine range to DHCP clients with MAC addresses that match those in the Guest and Authenticated MAC address filters.
When the client connects to the captive portal IP address through its web browser, the user can register and continue the

authentication process to obtain an IP address from the authenticated DHCP range, or register as a guest and obtain an IP address from the guest DHCP range.
If the user chooses to continue the authentication process, as shown in Authenticating the User below, the member authenticates the user with the authentication service that you configured, which can be RADIUS, LDAP, or AD.

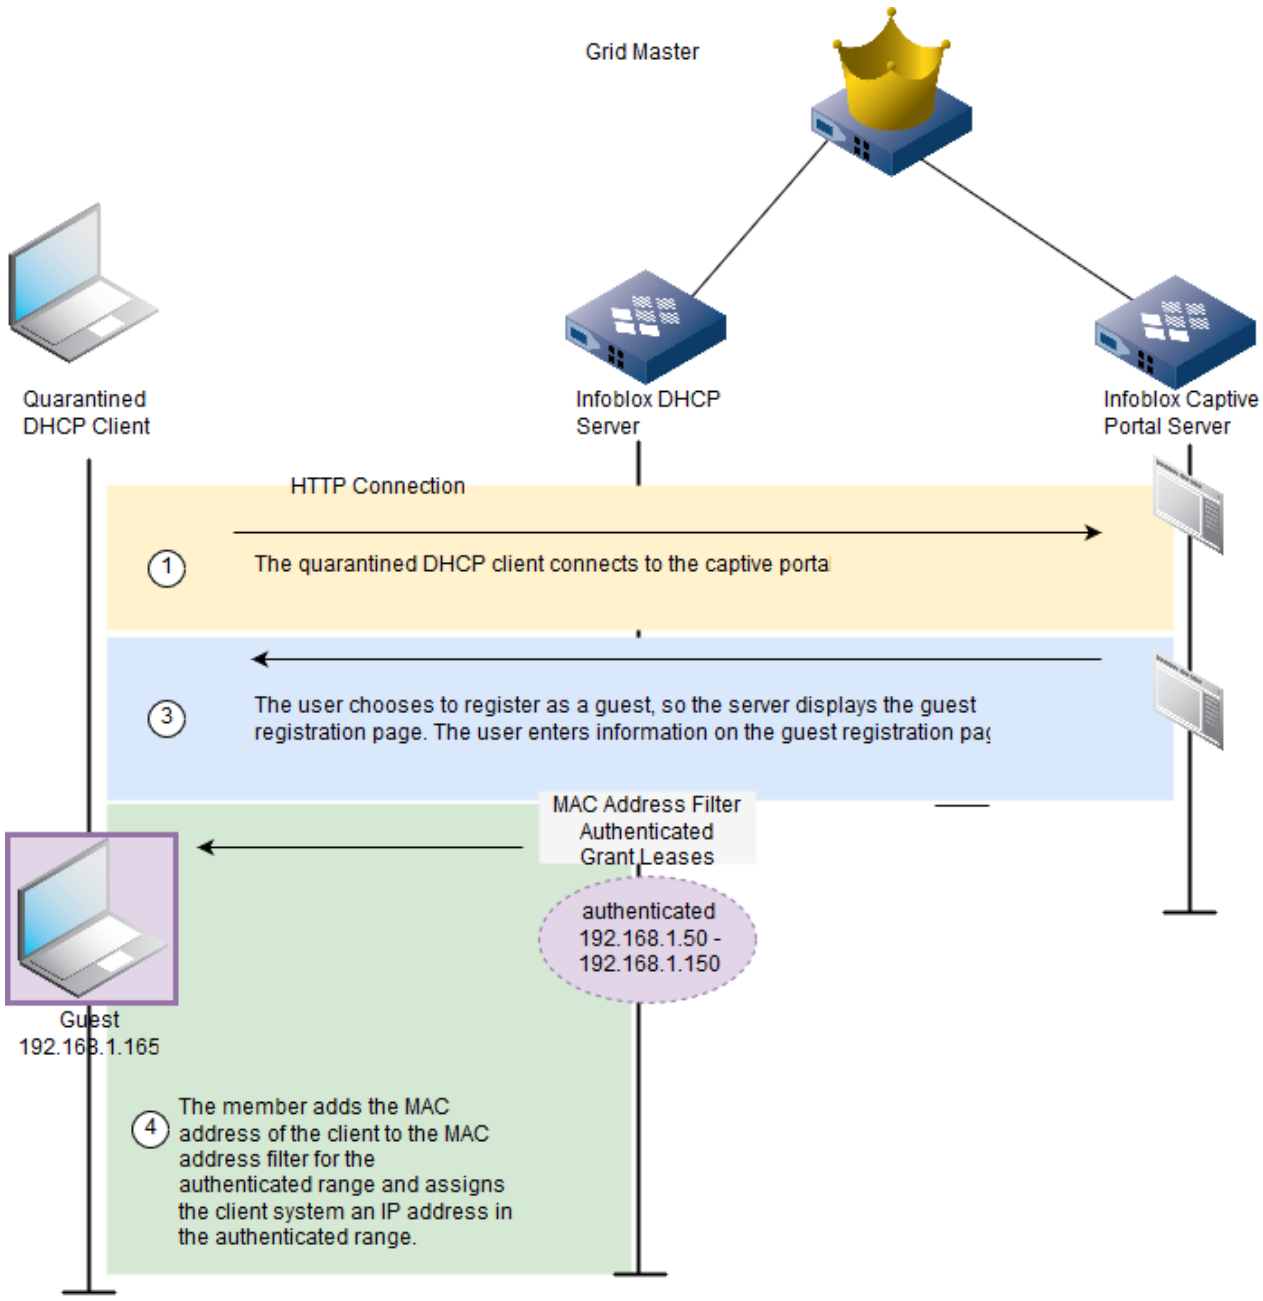
Stage 2a: Authenticating the User



After the client successfully passes the authentication stage, the appliance stores the MAC address of the client in the MAC address filter for the authenticated range. When the client tries to renew its IP address, it receives a new IP address from the authenticated DHCP range.
Note that if the MAC address filter has an expiration period, the member automatically deletes expired MAC addresses from the filter. Therefore, if a DHCP client tries to renew its IP address after the expiration period, the client is redirected to the captive portal because its MAC address is no longer in the MAC address filter. For more information, see *Defining MAC Address Filters*.

If the user chooses to sign in as a guest, as shown in Registering as a Guest below, the user can fill in the guest registration page provided by the captive portal.

Stage 2b: Registering as a Guest



After the user signs in as a guest, the appliance stores the MAC address of the client in the MAC address filter for the guest range. When the DHCP client tries to renew its IP address, it receives a new IP address from the guest DHCP range, unless the MAC address of the client expired and was removed from the filter. In this case, the DHCP client is redirected to the captive portal.

Authenticated DHCP

Configuring DHCP Authentication

Following are the tasks to configure the DHCP Authentication feature:

1. Configure the authentication server group which the captive portal uses to authenticate DHCP clients. For more information, see *About Authentication Server Groups*.
   If the captive portal is used to register guest users and does not authenticate users, then you do not have to configure an authentication server group.
2. Configure the captive portal properties and associate the captive portal with the authentication server group. For more information, see *Configuring Captive Portal Properties*.
3. Optionally, customize the captive portal interface and guest registration page, as described in *Customizing the Captive Portal Interface*. Additionally, if you enabled SSL encryption, upload the required certificates, as described in *Managing Captive Portal Certificates*.
4. Enable the captive portal, as described in *Starting the Captive Portal Service*.
5. Configure the network and a DHCP range for quarantine DHCP clients. Configure DHCP ranges for authenticated and guest DHCP clients, depending on whether you are allowing either one or both types of users to access your network. For information about configuring these DHCP ranges, see *Defining the IPv4 Network and DHCP Ranges*.
6. Run the *Captive Portal* wizard to create MAC address filters for the quarantine range and for the authenticated, and guest DHCP ranges, if configured; and to associate the captive portal server with the member that serves the DHCP ranges. To accomplish these tasks and set other properties, see *Using the Captive Portal Wizard*. Alternatively, you can perform these tasks separately or modify the configured properties, as described in *Adding and Modifying the Filters and Associations*.
7. Enable the DHCP service. For more information, see *Starting DHCP Services on a Member*.

For information about monitoring the captive portal and the DHCP service, see *Monitoring DHCP Authentication*.

Configuring Authentication Server Groups

Create an authentication server group if you want the captive portal server to authenticate users when they register. You can create an authentication server group with RADIUS servers, LDAP servers, or Active Directory servers, and then associate the group with the member that runs the captive portal and sends the authentication requests. You can associate an authentication server group with multiple captive portals, but you can associate a captive portal with only one authentication server group.
The following sections provide instructions for creating a RADIUS authentication server group, an AD authentication server group and an LDAP server group:

- *Configuring a RADIUS Authentication Server Group*
- *Configuring an Active Directory Authentication Server Group*
    - *Managing Multiple Domain Controllers*
- *Configuring an LDAP Server Group*

Configuring a RADIUS Authentication Server Group

You can add multiple RADIUS servers to an authentication server group and prioritize them. When the member sends an authentication request, it always selects the first RADIUS server in the list. It only sends authentication requests to the next server on the list if the first server goes down.
To configure the RADIUS authentication server group to which a captive portal server sends authentication requests:

1. From the **Administration** tab, click the **Authentication Server Groups** tab.

2. Expand the Toolbar and click **Add** -> **RADIUS Service**.
3. In the *Add RADIUS Authentication Service* wizard, complete the following:
    - **Name:** Enter the name of the server group.
    - **RADIUS Servers:** Click the Add icon and enter the following:
        - **Server Name or IP Address:** Enter the RADIUS server FQDN or IP address.
        - **Comment:** You can enter additional information about the server.
        - **Authentication Port**: The destination port on the RADIUS server. The default is 1812.
        - **Authentication Type:** Select the authentication method of the RADIUS server from the drop-down list. You can specify either PAP (Password Authentication Protocol) or CHAP (Challenge Handshake Authentication Protocol). The default is PAP.
        - **Shared Secret:** Enter the shared secret that the member DHCP server and the RADIUS server use to encrypt and decrypt their messages. This shared secret must match the one you entered on the RADIUS server and must be between 4 and 64 characters (inclusive) in length.
        - **Connect through Management Interface:** Select this to enable the member to use its MGMT port to communicate with just this server.
        - **Disable server:** Select this to disable the RADIUS server if, for example, the connection to the server is down and you want to stop the DHCP server from trying to connect to this server.
        - Click **Test** to validate the configuration and check that the Grid Master can connect to the RADIUS server. Before you can test the configuration though, you must specify the authentication and accounting timeout and retry values.
          If the Grid Master connects to the RADIUS server using the configuration you entered, it displays a message confirming the configuration is valid. If it is unable to connect to the RADIUS server, the appliance displays a message indicating an error in the configuration.
        - Click **Add** to add the RADIUS server to the group.

      When you add multiple RADIUS servers to the list, you can use the up and down arrows to change the position of the servers on the list. The member DHCP server connects to the RADIUS servers in the order they are listed.

    - **Authentication Timeout:** The time that the member DHCP server waits for a response from a RADIUS server before considering it unreachable. You can enter the time in milliseconds or seconds. The maximum is 10 seconds.
    - **Retries:** The number of times the member DHCP server retries connecting to a RADIUS server before it considers the server unreachable. The default is five.
    - **Accounting Timeout:** The time that the member DHCP server waits for a response from a RADIUS server before considering it unreachable. You can enter the time in milliseconds or seconds. The maximum is 10 seconds.
    - **Retries:** The number of times the member DHCP server retries connecting to a RADIUS server before it considers the server unreachable. The default is five.
    - **Recovery Interval:** Specifies the duration of time a RADIUS server stays inactive after being down, before becoming eligible to have RADIUS requests sent to it. The recovery interval starts when a RADIUS server is first discovered to be down.
    - **Comment**: You can enter additional information about the server group.
    - **Disable**: Select this to disable the authentication server group.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring an Active Directory Authentication Server Group

1. From the **Administration** tab, click the **Authentication Server Groups** tab.
2. Click the **Active Directory Services** subtab and click the Add icon.
3. In the *Add Active Directory Authentication Service* wizard, complete the following:
    - **Name:** Enter a name for the service.
    - **Active Directory Domain**: Enter the AD domain name.
    - **Domain Controllers**: Click the Add icon and complete the following to add an AD domain controller:
        - **Server Name or IP Address:** Enter the FQDN or the IP address of the AD server that is used for authentication.
        - **Comment:** Enter additional information about the AD server.
        - **Authentication Port**: Enter the port number on the domain controller to which the member sends authentication requests. The default is 389.

- **Encryption:** Select **SSL** from the drop-down list to transmit through an SSL (Secure Sockets Layer) tunnel. When you select SSL, the appliance automatically updates the authentication port to 636. Infoblox strongly recommends that you select this option to ensure the security of all communications between the member and the AD server. If you select this option, you must upload a CA certificate from the AD server. Click **CA Certificates** to upload the certificate. In the *CA Certificates* dialog box, click the Add icon, and then navigate to the certificate to upload it.
- **Connect through Management Interface:** Select this so that the member uses the MGMT port for administrator authentication communications with just this AD server.
- **Disable server:** Select this to disable an AD server if, for example, the connection to the server is down and you want to stop the Grid member from trying to connect to this server.
- Click **Test** to test the configuration. If the Grid member connects to the domain controller using the configuration you entered, it displays a message confirming the configuration is valid. If it is unable to connect to the server, the appliance displays a message indicating an error in the configuration.
- Click **Add** to add the domain controller to the group.

- **Timeout(s):** The number of seconds that the Grid member waits for a response from the specified authentication server. The default is 5.
- **Comment:** Enter additional information about the service.
- **Disable**: Select this to retain an inactive AD authentication service profile.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing Multiple Domain Controllers

You can create multiple domain controllers on the Microsoft server and associate it with a single Active Directory Domain, which is synchronized by multiple Grid members within the same Grid:

- Synchronization happens from only one Grid member that is a Microsoft server, which is referred as the master, at a time in a given network view.
- If the master Microsoft server fails the synchronization three times in a row, it loses its master status.
- The Grid Master will periodically ensure that for each Active Director Domain there is one Microsoft server with the master status. Otherwise, the appliance selects a new master, based on the following:
  - Microsoft server that has been designated as the Grid Master for the longest time previously.
  - Microsoft server configured in read/write synchronization mode.
- The master server is indicated within the Active Directory Domain object.
- Synchronization mode changes based on the master.
- When synchronization happens in two separate network views, respective Grid members synchronize data simultaneously.

Configuring Captive Portal

The captive portal can be used to register users for authentication, guest users, or both types of users. When a DHCP client attempts to connect to the network and its MAC address is not in any of the configured MAC filters, the member DHCP server assigns it an IP address in the quarantine range. When the quarantined client tries to reach any web site, it is redirected to the captive portal. The captive portal runs a limited DNS server that is used solely to redirect queries to the captive portal web interface.

You can enable the captive portal as a service on any Grid member, except the Grid Master or Grid Master candidate. The Grid member that runs the captive portal cannot run any other service, such as DHCP and DNS. Note that the limited DNS service that the captive portal runs is different from the full-scale DNS service on an Infoblox appliance. The full-scale DNS service must be explicitly disabled on the member that runs the captive portal. For information on disabling DNS service, see *Starting and Stopping the DNS Service*.

You can configure one or more captive portals in the Grid. You can also configure one or more member DHCP servers to use a captive portal to register users. For example, if your organization has two sites, you can configure a captive portal for each site and configure the DHCP servers in each site to use their respective captive portals to authenticate users.

In order for clients to reach the captive portal, you must specify a route to the captive portal. In a network where all IP addresses are on the same subnet, you can configure Option 33 for the quarantine DHCP range. For additional information, see *Quarantine DHCP Range*. On a routed network, you must configure a default route on the router for the subnet.

Following are the tasks to configure a captive portal:

1. Select the Grid member that runs the captive portal and configure its properties, as described in the next section, Configuring Captive Portal Properties.
2. Optionally, customize the captive portal and registrati.
3. If you enabled SSL, generate the CA certificate, as described in Managing Captive Portal Certificates below.
4. Start the captive portal, as described in Starting the Captive Portal Service below.

Configuring Captive Portal Properties

When you configure the captive portal properties of a member, you specify if it is used to register users for authentication, guests, or both. If it is used to register guests only, then do not associate it with an authentication server group.
You can specify the VIP address of the Grid member or configure an additional IP address on the loopback interface as the captive portal IP address. Alternatively, if the Grid member supports the LAN2 port and it is enabled, but the NIC failover feature is disabled, you can use the IP address of the LAN2 port as the captive portal IP address. To configure an IP address on the loopback interface, see *Configuring IP Addresses on the Loopback Interface*. For information on the LAN2 port, see *Using the LAN2 Port*.
In addition, you can configure the port on which the appliance listens for authentication requests redirected from the captive portal. When a user logs in to the captive portal, the member sends an authentication request to its associated authentication server group. The member determines future DHCP replies to client requests based on the authentication result.
To configure the properties of the captive portal:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Captive Portal**.
   Grid Manager lists all the members, except for the Grid Master and Grid Master candidate.
2. Select the member that runs the captive portal and click the Edit icon.
3. In the **General Basic** tab of the *Member Captive Portal Properties* editor, complete the following:
   - **Use This Authentication Server Group for Authenticating Captive Portal Users:** Select the authentication server group that authenticates users for this captive portal. For information about authentication server groups, see *Configuring Authentication Server Groups*.
   - **Captive Portal User Types:** Specify whether the captive portal is used to register **Authenticated** users only, **Guest** users only, or **Both**.
   - **Portal IP Address:** Select the IP address of the captive portal server. The appliance lists the VIP address and the IP addresses of the loopback interface and the LAN2 port, if enabled. You can select any of these addresses as the portal IP address.
   - **Enable SSL on Portal:** Select this to support encrypted web traffic through SSL/TLS. If you select this option, you must upload a certificate or generate a self-signed certificate. For information about creating and uploading a certificate for the captive portal, see Managing Captive Portal Certificates below.
   - Network View: This field displays if there are multiple network views configured. Select the network view in which the authenticated, quarantine, and guest DHCP ranges belong.
   - **Log Registration Success:** Select to enable the member to log successful registrations in syslog, and then select the logging level from the drop-down list.
   - **Log Registration Failure:** Select to enable the member to log failed registrations in syslog, and then select the logging level from the drop-down list.
4. In the **General Advanced** tab of the editor, you can specify the port on which the member listens for authentication requests redirected from the captive portal. The default port is 4433. Depending on your firewall and network policies, you can configure an unused port greater than 1 and less than 63999.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Customizing the Captive Portal Interface

You can customize the captive portal, and if configured, the guest registration page as well. You can upload image files to the appliance and display your own logo, header and footer. In addition, you can upload the acceptable use policies that are displayed on the captive portal and guest registration page.

Following are guidelines for each item you can customize:

- **Logo Image**: The maximum size is 200 pixels wide by 55 pixels high, and the images can be in JPEG, GIF, or PNG format. It displays on top of the header image.
- **Header Image:** The optimal size is 600 pixels wide by 137 pixels high. The image can be in JPEG, GIF, or PNG format. The header displays at the top of the page.

- **Footer Image:** The optimal size is 600 pixels wide by 20 pixels high. The image can be in JPEG, GIF, or PNG format. The footer displays at the bottom of the page.
- **Acceptable Use Policy:** The policy must be saved as a UTF-8 encoded file. It appears below the welcome message in the captive portal. Users can scroll through the policy when they review it. This is used in the captive portal and guest registrati characters, including white space.

If any of the customizable fields are not configured, then the factory defaults are displayed. To customize the captive portal:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Captive Portal**.
2. Select the member that is running the captive portal and click the Edit icon.
3. Select the **Customization** tab of the *Member Captive Portal Properties* editor.
4. In the **General Captive Portal Customization** section, complete the following:
    - **Company Name:** Enter the name of your company. The company name displays on the title bar of the browser. You can enter a maximum of 256 characters.
    - **Welcome Message:** Type the message that displays on the captive portal. The message can contain a maximum of 300 characters.
    - **Help Desk Message:** Type a message that provides Helpdesk information, such as contact information for technical assistance. The message can contain a maximum of 300 characters.
    - **Logo Image**, **Header Image**, **Footer Image**, **Acceptable Use Policy**: To display the image files and the acceptable use policy on the captive portal, click **Select** beside the item you want to upload. In the *Upload* dialog box, click **Select File** and navigate to the image or text file. Select the file you want to display and click **Upload**. Note that these files have size requirements, as listed earlier in this section.
5. In the **Guest Users Web Page Customization** section, complete the following:
    - The appliance displays certain fields on the guest registration page. Select the checkboxes of the fields that users are required to complete: Re**quire First Name, Require Middle Name, Require Last Name, Require Email,** and **Require Phone**.
    - **Custom Field 1 — Custom Field 4**: You can display up to four additional fields on the guest registration page. To add a field to the guest registration page, enter a label for that field. The label can have a maximum of 32 characters. Select **Require** to require users to complete the field.|
      Users can enter a maximum of 128 characters in each of the fields in the captive portal login page and the guest registration page.
6. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing Captive Portal Certificates

When you enable support for encrypted web traffic sent over SSL/TLS, you can do any of the following:

- Generate a self-signed certificate and save it to the certificate store of your browser.
- Request a CA-signed certificate. When you receive the certificate from the CA, upload it on the member running the captive portal.

Generating Self-Signed Certificates

You can generate a self-signed certificate for the captive portal. When you generate a self-signed certificate, you can specify the hostname and change the public/private key size, enter valid dates and specify additional information specific to the captive portal. If you have multiple captive portals, you can generate a certificate for each captive portal with the appropriate hostname.

To generate a self-signed certificate:

1. From the Grid tab, select the Grid Manager tab, and then click Captive Portal.
2. Select the member that is running the captive portal, and then click HTTPS Cert -> Generate Self-signed Certificate from the Toolbar.
3. In the Generate Self-signed Certificate dialog box, complete the following:
    - Secure Hash Algorithm and Key Size: You can select SHA-1 and a RSA key size of 1024 or 2048. SHA-256 (SHA-2) can be selected together with a RSA key size of 2048 or 4096. The default value is SHA-256 2048.
    - **Days Valid:** Specify the validity period of the certificate.
    - **Common Name:** Specify the domain name of the captive portal.

- **Organization:** Enter the name of your company.
- **Organizational Unit:** Enter the name of your department.
- **Locality:** Enter a location, such as the city or town of your company.
- **State or Province:** Enter the state or province.
- **Country Code:** Enter the two-letter code that identifies the country, such as US.
- **Admin E-mail Address:** Enter the email address of the captive portal administrator.
- **Comment:** Enter additional information about the certificate.

4. Click **OK**.

Generating Certificate Signing Requests

You can generate a CSR (certificate signing request) that you can use to obtain a signed certificate from your own trusted CA. Once you receive the signed certificate, you can import it in to the Grid member that runs the captive portal, as described in the next section, Uploading Certificates.
To generate a CSR:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Captive Portal**.
2. Select the member that is running the Captive Portal, and then click **HTTPS Cert** -> **Create Signing Request** from the Toolbar.
3. In the *Create Signing Request* dialog box, enter the following:
   - **Secure Hash Algorithm and Key Size:** You can select SHA-1 and a RSA key size of 1024 or 2048. SHA-256 (SHA-2) can be selected together with a RSA key size of 2048 or 4096. The default value is SHA-256 2048.
   - **Common Name**: Specify the domain name of the captive portal.
   - **Organization**: Enter the name of your company.
   - **Organizational Unit**: Enter the name of your department.
   - **Locality**: Enter a location, such as the city or town of your company.
   - **State or Province**: Enter the state or province.
   - **Country Code**: Enter the two-letter code that identifies the country, such as US.
   - **Admin E-mail Address**: Enter the email address of the captive portal administrator.
   - **Comment**: Enter information about the certificate.
4. Click **OK**.

Uploading Certificates

When you upload a certificate, the NIOS appliance finds the matching CSR and takes the private key associated with the CSR and associates it with the newly uploaded certificate. The appliance then automatically deletes the CSR.
If the CA sends an intermediate certificate that must be installed along with the server certificate, you can upload both certificates to the appliance. The appliance supports the use of intermediate certificates to complete the chain of trust from the server certificate to a trusted root CA.
To upload a certificate:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Captive Portal**.
2. Select the member that is running the captive portal, and then click **HTTPS Cert** -> **Upload Certificate** from the Toolbar.
3. In the **Upload** dialog box, click **Select File**, navigate to the certificate location, and click **Open**.

The appliance imports the certificate . When you log in to the appliance again, it uses the certificate you imported.

Downloading Certificates

You can download the current certificate or a self-signed certificate so users can install it in their browsers. To download a certificate:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Captive Portal**.
2. Select the member that is running the captive portal, and then click **HTTPS Cert** -> **Download Certificate** from the Toolbar.
3. Navigate to where you want to save the certificate and save it.

Starting the Captive Portal Service

Before you start the captive portal service, ensure that the member is not running any other service. To start the captive portal service:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Captive Portal**.
2. Select the member that is configured to run the captive portal service and click the Start icon.

Defining IPv4 Network and DHCP Ranges

First define the IPv4 network that uses DHCP authentication, and then define the DHCP ranges and services for each access level that you want to provide on the network:

- Quarantine
- Authenticated
- Guest

For information about configuring DHCP IPv4 networks, ranges and services, see *Managing IPv4 DHCP Data*, and *Configuring DHCP Properties*.

Quarantine DHCP Range

You must configure a DHCP range for the quarantine level so the member DHCP server can assign IP addresses within that range to unauthenticated DHCP clients. An unauthenticated client is allowed to access the captive portal only and must successfully pass the authentication process before it can receive an IP address from the authenticated range. Infoblox recommends 30-second leases for addresses in the quarantine DHCP range. This provides enough time for the user authentication process, so when the client attempts to renew the lease at the midpoint of its lease time, the member can then assign the client a new IP address, depending on the result of the authentication process.
When you configure the quarantine DHCP range, you must specify the captive portal IP address as the DNS server for the address range. The captive portal runs a limited DNS server that resolves all queries with the IP address assigned to the web interface on the captive portal.
Note that you can run the *Captive Portal* wizard to automatically set the lease time of the quarantine range to 30 seconds and to add the captive portal IP address as the DNS server. For information about the *Captive Portal* wizard, see *Using the Captive Portal Wizard*. Alternatively, you can set the lease time and the DNS server IP address in the **DHCP** tab of the *DHCP Range* editor. For information about the *DHCP Range* editor, see *Configuring IPv4 Address Ranges*.
To ensure that clients can reach the captive portal, you must specify a route to the captive portal. On a network where all systems can reach each other without going through a router, that is, all IP addresses are on the same subnet, you must configure Option 33 for the quarantine DHCP range. This option specifies a list of static routes that the client should install in its routing cache. The routes consist of a list of IP address pairs. For clients to reach the captive portal, specify the portal IP address first (destination address), and the LAN address of the NIOS appliance second. When the appliance assigns an IP address from the quarantine DHCP range, it also includes the static route that you specified in option 33. For information about configuring DHCP options, see *Configuring IPv4 DHCP Options*. On a routed network, you must configure a default route via the router on the subnet.

Authenticated DHCP Range

Configure a DHCP range for authenticated users if you want the Grid member to assign IP addresses within that range to authenticated DHCP clients. Users that receive an IP address in this range typically are allowed full access to the network.
When a client successfully passes authentication, the member automatically stores its MAC address in the corresponding MAC address filter. When the client attempts to renew the lease at the midpoint of its lease time, the member matches the source MAC address in the request with a MAC address in the filter for the authenticated DHCP address range. The member then assigns the client a new IP address from the authenticated DHCP range.

Guest DHCP Range

Configure a guest DHCP range if you want to provide guest access privileges. You can configure and customize a guest registration page when you configure the captive portal. For information about this feature, see *Customizing the Captive Portal Interface*.

Defining MAC Address Filters

After you configure the network and DHCP ranges, you must then configure the MAC address filters and add them to the appropriate DHCP ranges. If you configured DHCP ranges for authenticated and guest users, you must configure MAC address filters for each range with an action of Allow. You must also add those filters to the quarantine range with an action of Deny, to ensure that the member does not allocate an address from the quarantine range to a host whose MAC address matches an entry in the MAC filters for the authenticated and guest DHCP ranges.
When you create the filters, you also specify whether the MAC address entries expire. The member automatically deletes expired MAC address entries from the filter. If a client that registered earlier attempts to renew its IP address or to register after its MAC address has expired, it is redirected to the captive portal because its MAC address is no longer in the filter.
You can run the *Captive Portal* wizard to automatically create the MAC address filters, as described in the next section, *Using the Captive Portal Wizard*, or you can configure each filter as described in *Defining MAC Address Filters*.

Using the Captive Portal Wizard

After you configure the captive portal and the DHCP ranges for each access level, you can use the *Captive Portal* wizard to accomplish the following tasks:

- Associate the captive portal member with the member that serves the DHCP ranges you configured.
- Create MAC address filters and add them to the appropriate DHCP ranges. The wizard allows you to create MAC address filters for the quarantine DHCP range, and for the authenticated and guest DHCP ranges, depending on whether the captive portal is used to register users for authentication, guests, or both. This was specified, when you configured the captive portal properties, described in *Configuring Captive Portal Properties*. For example, if you indicated that the captive portal is used for authenticated users only, then the wizard allows you to create a MAC filter for the authenticated DHCP range only.
    - If the captive portal is used to register users for authentication, the wizard allows you to create a MAC address filter for the authenticated range. The wizard then automatically adds the filter to the authenticated DHCP range with an action of Allow. It also adds the filter to the quarantine range with an action of Deny. This ensures that the member does not allocate an address from the quarantine range to a host whose MAC address matches an entry in the MAC filter.
    - If the captive portal is used to register guest users, the wizard allows you to create a MAC address filter for the guest range. The wizard then automatically adds the filter to the guest DHCP range with an action of Allow. It also adds the filter to the quarantine range with an action of Deny. This ensures that the member does not allocate an address from the quarantine range to a host whose MAC address matches an entry in the MAC filter.
- Add the captive portal IP address as the DNS server for the quarantine address range.
- Set the lease time of the quarantine range to 30 seconds.

To use the *Captive Portal* wizard to complete the tasks for the DHCP authentication feature:

1. From the **Data Management** tab, select the **DHCP** tab, or from the **Grid** tab, select the **Grid Manager** tab.
2. Expand the Toolbar and click **Configure Captive Portal**.
3. In the *Captive Portal* wizard, complete the following and click **Next**:
    - **Member DHCP:** Select the member DHCP server that uses this captive portal to authenticate users.
    - **Captive Portal:** Select the member that runs the captive portal. Note that the member that runs the captive portal cannot run any other service, such as DHCP or DNS, and cannot be the Grid Master or Grid Master candidate.
4. This panel allows you to create MAC filters for the authenticated and guest DHCP ranges. The MAC filters you can create depend on your entry in the Captive Portal properties of the Grid member. For example, if you

indicated that the captive portal is used for authenticated users only, then this panel allows you to create a MAC filter for the authenticated DHCP range only.
You can also specify existing MAC filters, if you want to apply them to the authenticated and guest DHCP ranges. Complete the following and click **Next**:
    - **Authenticated MAC Filter:** Specify a name for the MAC filter that is used for authenticated users.
    - **Expiration Time:** Specify how long a MAC address is stored in the MAC address filter for authenticated users.
        - **Never**: Select this option to store MAC addresses in the MAC address filter until they are manually removed.
        - **Expires in**: Select this option to store MAC addresses in the MAC address filter for the specified period of time.
    - **Guest MAC Filter:** Specify a name for the MAC filter that is used for guest users.
    - **Expiration Time:** Specify how long a MAC address is stored in the MAC address filter for guest users.
        - **Never**: Select this option to store MAC addresses in the MAC address filter until they are manually removed.
        - **Expires in**: Select this option to store MAC addresses in the MAC address filter for the specified period of time.
5. In this panel, you specify the network and address ranges, so the wizard can apply the MAC address filters to the appropriate ranges. Complete the following:
    - **Network:** Select the network that uses DHCP authentication.
    - **Authenticated Range:** Select the IP address range that the appliance uses for authenticated users. The wizard applies the authenticated MAC address filter you specified in the preceding step to this DHCP range with an action of Allow. This effectively allows the member to assign an IP address from the address range to a requesting host whose MAC address matches the MAC address in the filter.
    - **Guest Range:** Select the IP address range that the appliance uses for guest users. The wizard applies the guest MAC address filter you specified in the preceding step to this DHCP range with an action of Allow. This effectively allows the member to assign an IP address from the address range to a requesting host whose MAC address matches the MAC address in the filter.
    - **Quarantine Range:** Select the IP address range that the appliance uses for quarantined addresses. The wizard applies the authenticated and guest MAC address filters to the quarantine DHCP range with an action of Deny. This effectively denies an address request from a host whose MAC address matches an entry in the MAC filters for the authenticated and guest DHCP ranges.
6. Save the configuration and click **Restart** if it appears at the top of the screen.

Adding and Modifying the Filters and Associations

The *Captive Portal* wizard simplified the configuration process by accomplishing a number of tasks simultaneously. To accomplish each task separately, or to modify the filters or associations after you have run the wizard:

- To define the MAC address filters for each range, see *Defining MAC Address Filters*.
- To bind each filter to the appropriate DHCP range, see *Applying Filters to DHCP Objects*.
- To specify the DNS server IP address for the quarantine range and set the lease time to 30 seconds, see *Configuring General IPv4 DHCP Properties*.
- To associate a member DHCP server with a captive portal and specify the MAC filters for the authenticated and guest DHCP ranges:
    a. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox -> Edit icon.
    b. In the *Member DHCP Properties* editor, click the **IPv4 Authenticated DHCP** tab and complete the following:
        - **Use this Captive Portal for Infoblox Authenticated DHCP:** Select this checkbox and select the captive portal that you want to associate with the member.
        - **Authenticated User MAC Filter:** Select the MAC filter used for authenticated users. To change your section, click **Clear** and click **Select** again.
        - **Guest User MAC Filter:** Select the MAC filter for guest users. To change you selection, click **Clear** and click **Select** again.
    c. Save the configuration and click **Restart** if it appears at the top of the screen.

Monitoring DHCP Authentication

You can monitor the status of the captive portal service, as described in *Monitoring Services*. You can check its status in the *Grid Status* widget and the *Member Status* widget on the Dashboard. For information about these widgets, see *Dashboards*.
You can also view the MAC addresses that were added to each MAC address filter, as described in *Viewing MAC Address Filter Items*.

Viewing DHCP Ranges and Filters

To view the newly created MAC address filters:

1. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab**.** Grid Manager lists all the configured filters.
2. You can select a filter and view or configure its properties, such as extensible attributes.

For more information about the filters and editing their properties, see *Managing DHCP Filters*.
To view the DHCP ranges and the newly added filters:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network .*
2. Select the DHCP range you want to view and click the Edit icon.
3. If the editor is in Basic mode, click **Toggle Expert Mode**.
4. Click the **Filters** tab to view the filters.

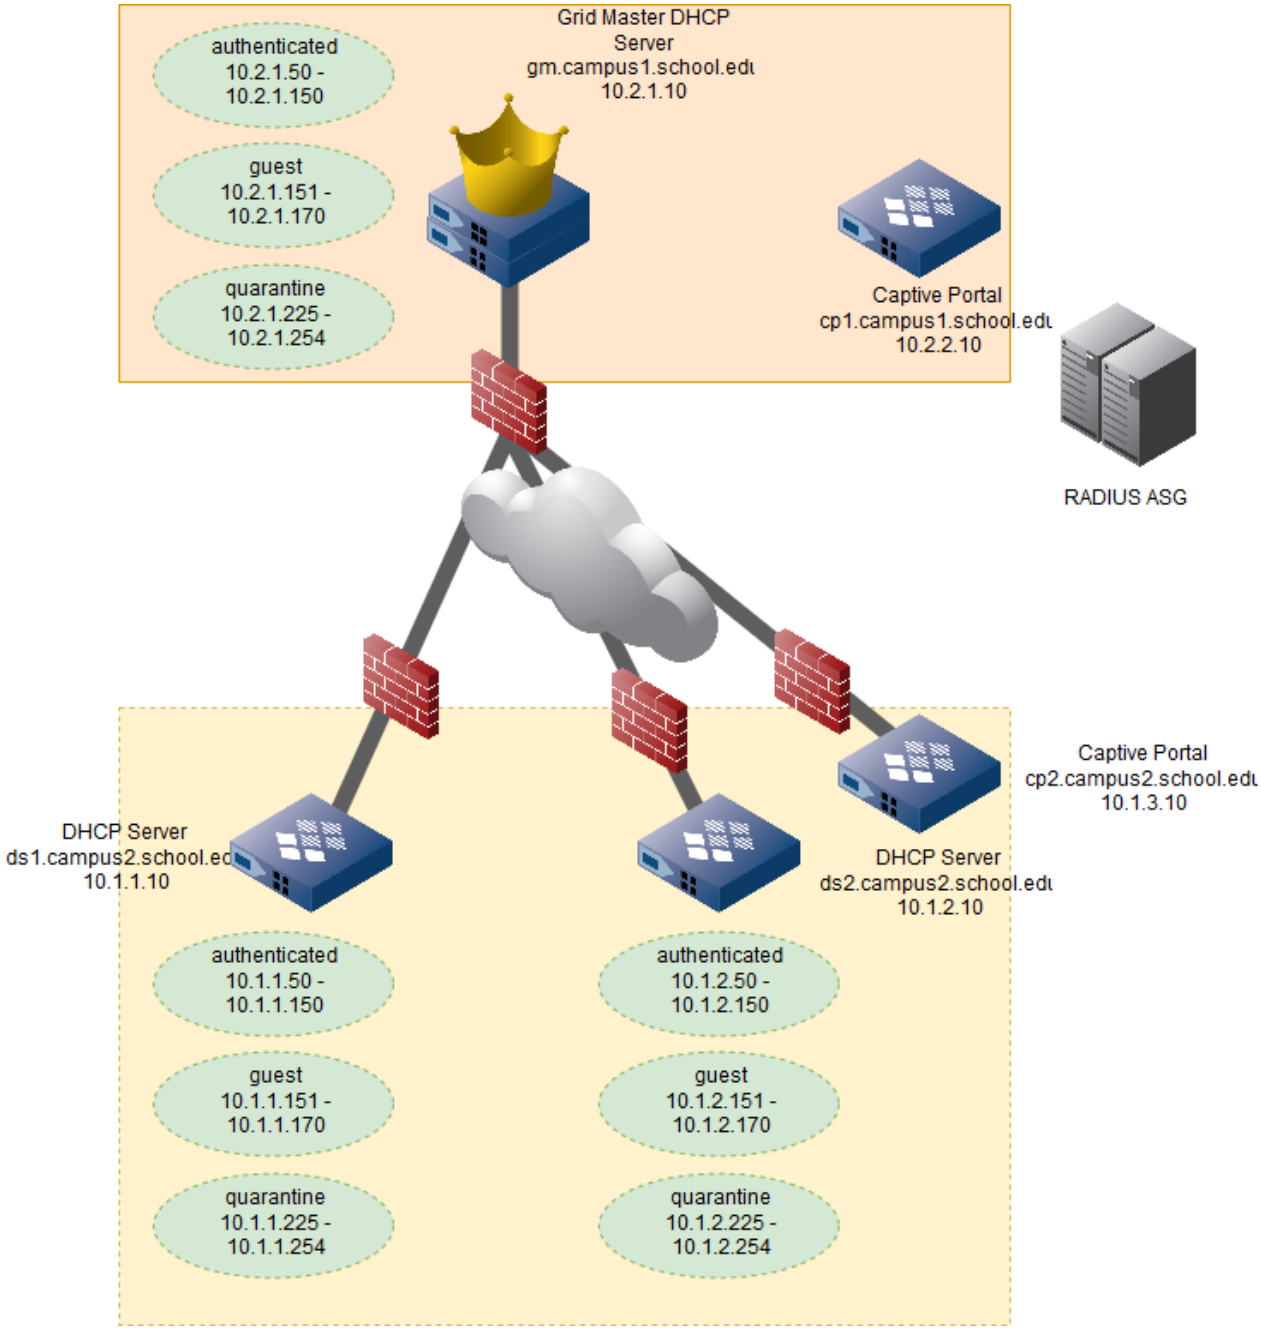
To verify that the captive portal is the DNS server in the quarantine range:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section -> *network.*
2. Select the quarantine DHCP range and click the Edit icon.
3. In the *DHCP Range* editor, click the **DHCP** tab.

The captive portal IP address is listed in the DNS Servers table.

Configuration Example: Configuring Authenticated DHCP

In this example, a school (school.edu) has two locations, its main campus, campus1.schoool.edu, and a satellite campus, campus2.school.edu. It has a captive portal server in each location. In the main campus, the Grid Master also functions as a DHCP server and uses a captive portal server to register DHCP clients. In the satellite campus, two members serve DHCP and use the same captive portal server. The captive portal servers use the same RADIUS authentication server group to authenticate users.



Create the RADIUS Authentication Server Group

Create the RADIUS authentication server group and add two RADIUS servers to the group.

1. From the **Administration** tab, click the **Authentication Server Groups** tab.
2. Expand the Toolbar and click **Add** -> **RADIUS Service**.
3. In the *Add RADIUS Authentication Service* wizard, complete the following:
    - **Name:** Enter **RADIUS ASG**.
    - **RADIUS Servers:** Click the Add icon and enter the following:
        - **Server Name or IP Address:** Enter the RADIUS server FQDN, which is **rs1.school.edu**.
        - **Authentication Port**: Accept the default port (1812).
        - **Authentication Type:** Select the PAP authentication method.

        - **Shared Secret:** Enter **no1nose**.
    - **Authentication**
        - **Timeout:** Enter 5 seconds.
        - **Retries:** Accept the default, which is five.
    - **Accounting**
        - **Timeout:** Enter 5 seconds.
        - **Retries:** Accept the default, which is five.
        - Click **Test** to validate the configuration and check that the Grid Master can connect to the RADIUS server.
          Grid Manager displays a message confirming the configuration is valid.

          Click **Add** to add another RADIUS server to the group, and then enter the following:
        - **Server Name or IP Address:** Enter the RADIUS server FQDN, which is **rs2.school.edu**.
        - **Authentication Port**: Accept the default port (1812).
        - **Authentication Type:** Select the PAP authentication method.
        - **Shared Secret:** Enter **no1nose**.
    - **Authentication**
        - **Timeout:** Enter 5 seconds.
        - **Retries:** Accept the default, which is five.
    - **Accounting**
        - **Timeout:** Enter 5 seconds.
        - **Retries:** Accept the default, which is five.
        - Click **Test** to validate the configuration and check that the Grid Master can connect to the RADIUS server.
          Grid Manager displays a message confirming the configuration is valid.
4. Click **Save & Close.**

Configure the Captive Portal Properties

Configure the captive portal properties of cp1.campus1.school.edu.

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Click the **Captive Portal** tab **-> Services tab.**
3. Select the member **cp1.campus1.school.edu** and click the Edit icon.
4. In the **General Basic** tab of the *Member Captive Portal Properties* editor, complete the following:
    - **Use This Authentication Server Group for Authenticating Captive Portal Users:** Select **RADIUS ASG**.
    - **Captive Portal User Types:** Select **Both**.
    - **Portal IP Address:** Select **10.2.2.10**.
    - **Enable SSL on Portal:** Select this option.
    - **Log Registration Success:** Select **Informational**.
    - **Log Registration Failure:** Select **Informational**.
5. Click **Save & Close.**

Configure the captive portal properties of cp2.campus2.school.edu.

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Click the **Captive Portal** tab **-> Services tab.**
3. Select the member cp2.campus2.school.edu and click the Edit icon.
4. In the **General Basic** tab of the *Member Captive Portal Properties* editor, complete the following:
    - **Use This Authentication Server Group for Authenticating Captive Portal Users:** Select **RADIUS ASG**.
    - **Captive Portal User Types:** Select **Both**.
    - **Portal IP Address:** Select **10.1.3.10**.
    - **Enable SSL on Portal:** Select this option.
    - **Log Registration Success:** Select **Informational**.
    - **Log Registration Failure:** Select **Informational**.
5. Click **Save & Close.**

Customize the Captive Portals

Customize the captive portal cp1.campus1.school.edu.

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Click the **Captive Portal** tab**-> Services tab.**
3. Select **cp1.campus1.school.edu** and click the Edit icon.
4. Select the **Customization** tab of the *Member Captive Portal Properties* editor.
5. In the **General Captive Portal Customization** section, complete the following:
    - **Company Name:** Enter **School**.
    - **Welcome Message:** Type the following: **Welcome to School. Please sign in.**
    - **Help Desk Message:** Type: **To reach the Helpdesk, call (408) 111-2222 or email helpdesk@school.edu.**
    - **Logo Image**: Click **Select** beside the logo file and upload it.
6. In the **Guest Users Web Page Customization** section, complete the following:
    - Select the checkboxes beside **Require First Name**, **Require Last Name**, **Require Email**.
7. Click **Save & Close.**

Select the other captive portal server, cp2.campus2.school.edu, and enter the same information.

Generate a Self-Signed Certificate and Upload It

To generate a self-signed certificate for cp1.campus1.school.edu:

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Click the **Captive Portal** tab from the **Services tab.**
3. Select **cp1.campus1.school.edu**, and then click **HTTPS Cert** -> **Generate Self-signed Certificate** from the Toolbar.
4. In the *Generate Self-signed Certificate* dialog box, complete the following:
    - **Secure Hash Algorithm and Key Size:** You can select SHA-1 and a RSA key size of 1024 or 2048. SHA-256 (SHA-2) can be selected together with a RSA key size of 2048 or 4096. The default value is SHA-256 2048.
    - **Days Valid:** Enter **60 days**.
    - **Common Name:** Enter **cp1.campus1.school.edu**.
5. Click **OK**.
6. Click **Save & Close.**

To generate a self-signed certificate for the captive portal cp2.campus2.school.edu:

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Click the **Captive Portal** tab from the **Services tab.**
3. Select **cp2.campus2.school.edu**, and then click **HTTPS Cert** -> **Generate Self-signed Certificate** from the Toolbar.
4. In the *Generate Self-signed Certificate* dialog box, complete the following:
    - **Secure Hash Algorithm and Key Size:** You can select SHA-1 and a RSA key size of 1024 or 2048. SHA-256 (SHA-2) can be selected together with a RSA key size of 2048 or 4096. The default value is SHA-256 2048.
    - **Days Valid:** Enter **60 days**.
    - **Common Name:** Enter **cp2.campus2.school.edu**.
5. Click **OK**.
6. Click **Save & Close.**

Start the Captive Portal Service

1. From the **Grid** tab, select the **Grid Manager** tab.
2. Click the **Captive Portal** tab from the **Services** tab**.**
3. Select **cp1.campus1.school.edu** and **cp2.campus2.school.edu**, and then click the Start icon.

Configure the Networks and DHCP Ranges

Configure the network on the Grid Master.

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section.

2. Click the Add drop-down list and select **IPv4 Network**.
3. In the *Add IPv4 Network* wizard, select one of the following and click **Next**:
    - **Add Network:** Click this.
4. Complete the following and click **Next**:
    - **Address**: Enter **10.2.1.0/24**.
5. Complete the following to assign the network to the Grid Master:
    - **Add Infoblox Membe**r: Select **gm.campus1.school.edu**.
6. Click **Save & Close.**

Configure the ranges on the Grid Master. To create the authenticated range:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** section.
2. Click the 10.2.1.0/24 network link, and then click the Add drop-down list and select **DHCP Range**.
3. In the *Add IPv4 Range* wizard, select **Add DHCP Range** and click **Next**:
4. Complete the following:
    - **Network**: Click **Select Network** and select **10.2.1.0/24**.
    - **Start:** Enter **10.2.1.50**.**End:** Enter **10.2.1.150**.
    - **Name**: Enter **authenticated range**.
5. Click **Next** and complete the following:
    - **Grid Member:** Select this option and select **gm.campus1.school.edu**.
6. Click **Save & Close.**

To create the guest range:

1. Click the 10.2.1.0/24 network link, and then click the Add drop-down list and select **DHCP Range**.
2. In the *Add IPv4 Range* wizard, select **Add DHCP Range** and click **Next**:
3. Complete the following:
    - **Network**: Click **Select Network** and select 10.2.1.0/24.
    - **Start:** Enter **10.2.1.151**.
    - **End:** Enter **10.2.1.170**.
    - **Name**: Enter **guest range.**
4. Click **Next** and complete the following:
    - **Grid Member:** Select this option and select **gm.campus1.school.edu**.
5. Click **Save & Close.**

To create the quarantine range:

1. Click the 10.2.1.0/24 network link, and then click the Add drop-down list and select **DHCP Range**.
2. In the *Add IPv4 Range* wizard, select **Add DHCP Range** and click **Next**:
3. Complete the following:
    - **Network**: Click **Select Network** and select 10.2.1.0/24.
    - **Start:** Enter **10.2.1.225**.
    - **End:** Enter **10.2.1.254**.
    - **Name**: Enter **quarantine range.**
4. Click **Next** and complete the following:
    - **Grid Member:** Select this option and select **gm.campus1.school.edu**.
5. Click **Save & Close.**

Create the network and DHCP ranges for the DHCP servers ds1.campus1.school.edu and ds2.campus2.school.edu.

Run the Captive Portal Wizard

Run the *Captive Portal* wizard to associate the Grid Master with its captive portal, and to configure the MAC address filters:

1. From the **Data Management** tab, select the **DHCP** tab, or from the **Grid** tab, select the **Grid Manager** tab.
2. Expand the Toolbar and click **Configure Captive Portal**.
3. In the *Captive Portal* wizard, complete the following and click **Next**:
    - **Member DHCP:** Select the Grid Master, **gm.campus1.school.edu**.
    - **Captive Portal:** Select **cp1.campus1.school.edu**.
4. Complete the following and click **Next**:
    - **Authenticated MAC Filter:** Enter **Auth_MAC_Filter**.

- **Expiration Time:** Select **Never**.
- **Guest MAC Filter:** Enter **Guest_MAC_Filter**.
- **Expiration Time:** Select **Never.**

5. Complete the following:
   - **Network:** Select **10.2.1.0/24**.
   - **Authenticated Range:** Select **10.2.1.50 - 10.2.1.150**.
   - **Guest Range:** Select **10.2.1.151 - 10.2.1.170**.
   - **Quarantine Range:** Select **10.2.1.225 - 10.2.1.254**.
6. Click **Save & Close**.

Run the *Captive Portal* wizard to associate ds1.campus2.school.edu with the captive portal server cp2.campus2.school.edu, and then run it again to associate ds2.campus2.school.edu with the same captive portal server.

Start the DHCP Service

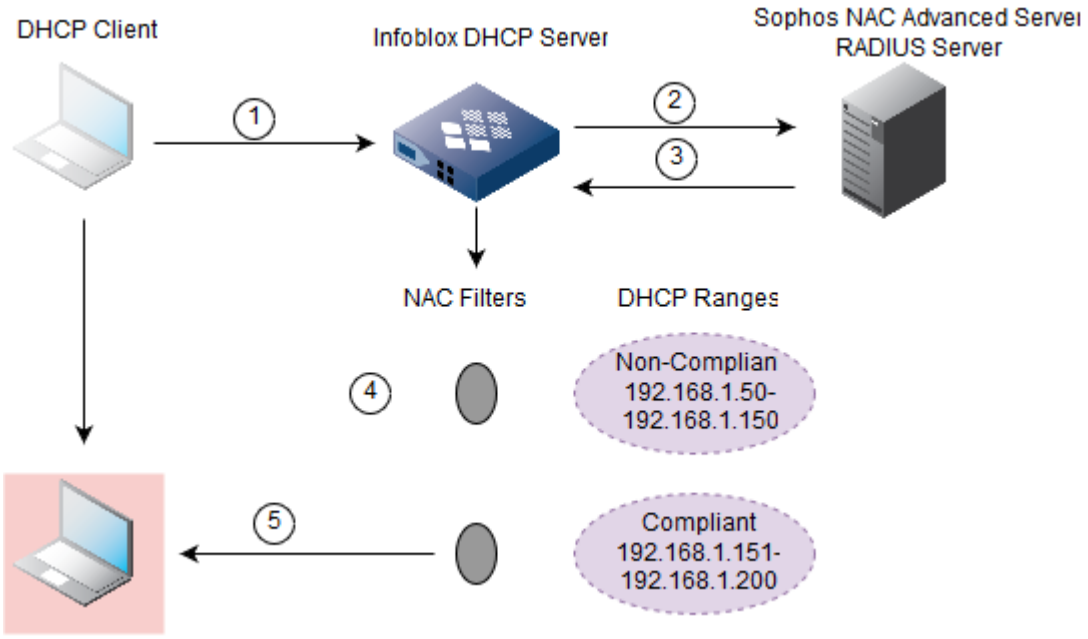
To start the DHCP service on the Grid Master:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab.
2. Select the Grid Master gm.campus1.school.edu, and the two members, ds1.campus2.school.edu and ds2.campus2.school.edu.
3. Expand the Toolbar and click **Start**.
4. In the *Start Member DHCP Service* dialog box, click **Yes**.
5. Grid Manager starts DHCP services on the Grid Master and on the selected members.

NAC Integration

You can configure member DHCP servers to send authentication requests to RADIUS servers and to allocate addresses based on the authentication results. This allows you to place DHCP clients into separate network segments.
You can divide your network into different segments by configuring address ranges and applying NAC filters to them. NAC filters use authentication results from RADIUS servers as matching criteria for granting or denying address requests.
When a DHCP client requests a lease, the member DHCP server can query a remote backend RADIUS server such as the Sophos NAC Advanced server to determine if the DHCP client is authorized to access the network. A Sophos NAC Advanced server is an access-control and compliance server that supports the RADIUS protocol.
The RADIUS server then checks its database and provides the compliance state and user class, if configured, of the DHCP client. The member DHCP server matches the response with the configured NAC filters, and grants a lease to the appropriate network segment.

The following figure presents an example illustrating the authentication process and how a member DHCP server matches the response with NAC filters to determine whether to grant or deny a lease. In the example, there are two DHCP ranges configured, each with a NAC filter that specifies RADIUS compliance state of DHCP clients allowed in each range.



The following steps relate to the above figure.

1. A DHCP client sends a DHCPDISCOVER, DHCPREQUEST, or DHCPINFORM to the Infoblox DHCP server.
2. The DHCP server sends the RADIUS server a RADIUS Access-Request packet that includes RADIUS VSAs (Vendor Specific Attributes) with the MAC address and DHCP transaction ID of the DHCP client.
3. When the RADIUS server receives the Access-Request packet, it does the following:
    a. It looks up the MAC address in its database to retrieve the associated compliance state and user class.
    b. The RADIUS server sends back a RADIUS Access-Accept packet that includes RADIUS VSAs with the compliance status and user class.
4. The DHCP server receives the Access-Accept packet and tries to match the response with a NAC filter.
5. The DHCP server matches the response with the NAC filter for compliant DHCP clients and sends the DHCP client a DHCPOFFER that contains an IP address from the corresponding DHCP range. The server also provides the configuration and options associated with that range.

Configuring NAC with RADIUS Servers

Complete the following tasks to configure the RADIUS server and the member DHCP server. On an already functioning RADIUS server:

- Add the member DHCP server as a RADIUS client. Make sure that the shared secret you enter on the RADIUS server matches the shared secret that you specify when you add the server to the authentication server group in Grid Manager.
  Note that on Grid Manager, you can enter only one shared secret for each RADIUS server. Therefore, on a RADIUS server, you must define the same shared secret for all Grid members that connect to it.
  For information about adding RADIUS clients, refer to the documentation for the RADIUS server.
- Add the Infoblox Grid Master as a RADIUS client, even if it is not going to perform NAC authentication. This enables you to test the connection to the RADIUS server.

On the member DHCP server:

1. Configure the authentication server group for the RADIUS servers. For information, see *Adding a Server Group*.
2. Associate the authentication server group with the Grid member. For information, see *Associating a Server Group with a Member*.
3. Configure the network and the DHCP ranges. For information, see *Configuring DHCP Ranges*.

4. Configure the NAC filters, as described in *About NAC Filters*.
5. Apply the NAC filters to the DHCP ranges, as described in *Applying Filters to DHCP Objects*.
6. Enable the DHCP service. For information, see *Starting DHCP Services on a Member*.

Optionally, you can do the following:

- Manage the authentication cache, as described in *Clearing the Authentication Cache*.

About Authentication Servers

You can create a RADIUS authentication server group for Sophos NAC Advanced servers, and then associate the group with the member DHCP server that sends authentication requests. The member DHCP server tries to connect to each Sophos NAC Advanced server in the group using one of the following methods: Ordered List or Round Robin.
In the Ordered List method, the member DHCP server always selects the first Sophos NAC Advanced server in the list when it sends an authentication request. It only sends authentication requests to the next server on the list if the first server goes down.
In the Round Robin method, the member DHCP server selects the first Sophos NAC Advanced server for the first request, the second server for the next request, and so on until it selects the last server in the list. Then it starts with the first server in the list and continues the same selection process.
Each member DHCP server can have only one RADIUS server group assigned, but a RADIUS server group can be assigned to multiple member DHCP servers.

Adding a Server Group

To create a RADIUS authentication server group for Sophos NAC Advanced servers:

1. From the **Administration** tab, click the **Authentication Server Groups** tab.
2. Expand the Toolbar and click **Add** -> **RADIUS Service**.
3. In the *Add RADIUS Authentication Service* wizard, complete the following:
    - **Name:** Enter the name of the server group.
    - **RADIUS Servers:** Click the Add icon and enter the following:
        - **Server Name or IP Address:** Enter the Sophos NAC Advanced server FQDN or IP address.
        - **Comment:** You can enter additional information about the server.
        - **Authentication Port**: The destination port on the Sophos NAC Advanced server. The default is 1812.
        - **Authentication Type:** Select the authentication method of the RADIUS server from the drop-down list. You can specify either PAP (Password Authentication Protocol) or CHAP (Challenge Handshake Authentication Protocol). The default is PAP.
        - **Shared Secret:** Enter the shared secret that the member DHCP server and the Sophos NAC Advanced server use to encrypt and decrypt their messages. This shared secret must match the one you entered on the Sophos NAC Advanced server.
        - **Enable Accounting**: Leave this blank. RADIUS accounting is not supported.
        - **Connect through Management Interface:** Select this so that the NIOS appliance uses the MGMT port for communications with just this server.
        - **Disable server:** Select this to disable the Sophos NAC Advanced server if, for example, the connection to the server is down and you want to stop the DHCP server from trying to connect to this server.
        - Click **Test** to validate the configuration and check that the Grid Master can connect to the Sophos NAC Advanced server. Before you can test the configuration though, you must specify the authentication and accounting timeout values.
          If the Grid Master connects to the Sophos NAC Advanced server using the configuration you entered, it displays a message confirming the configuration is valid. If it is unable to connect to the Sophos NAC Advanced server, the appliance displays a message indicating an error in the configuration.
        - Click **Add** to add the Sophos NAC Advanced server to the server group.

      When you add multiple Sophos NAC Advanced servers to the list, you can use the up and down arrows to change the position of the servers on the list. The member DHCP server connects to the Sophos NAC Advanced servers in the order they are listed.

- **Authentication**
- **Timeout:** The time that the member DHCP server waits for a response from a Sophos NAC Advanced server before considering it unreachable. You can enter the time in milliseconds or seconds.
- **Retries:** The number of times the member DHCP server retries connecting to a Sophos NAC Advanced server before it considers the server unreachable. The default is five.
- **Mode:** Specifies how the member DHCP server selects the first Sophos NAC Advanced server to contact.
    - **Ordered List:** The member DHCP server always selects the first Sophos NAC Advanced server in the list when it sends an authentication request. It queries the next server only when the first server is considered down. This is the default.
    - **Round Robin:** The member DHCP server selects the first Sophos NAC Advanced server for the first request, the second server for the next request, and so on. If the last server is reached, then the DHCP server starts with the first server in the list, and so on.
- **Enable Authentication Cache:** The member DHCP server automatically caches authentication results for 120 seconds. When you enable this option, you can override this default in the **Cache Time to Live** field. You must enable this option to clear the cache, as described in Clearing the Authentication Cache below.
- **Cache Time to Live:** Specifies the duration of time an authentication result is stored. The default is one hour. The maximum is 259200 seconds (3 days).
- **Recovery Interval:** Specifies the duration of time a Sophos NAC Advanced server stays inactive after being down, before becoming eligible to have RADIUS requests sent to it. The recovery interval starts when a Sophos RADIUS server is first discovered to be down.
- **Comment**: You can enter additional information about the server group.
- **Disable**: Select this to disable the authentication server group.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Associating a Server Group with a Member

To associate an authentication server group with a member DHCP server:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox box, and click the Edit icon.
2. If the *Member DHCP Properties* editor is in Basic mode, click **Toggle Expert Mode**.
3. Select the **IPv4 Authenticated DHCP** tab.
4. Click the **Use this Authentication Server Group for Sophos/RADIUS Authenticated DHCP** checkbox, and then select a group from the drop-down list.
5. Save the configuration and click **Restart** if it appears at the top of the screen.

Managing Server Groups

To view the list of authentication server groups, from the **Administration** tab, click the **Authentication Server Groups** tab and expand the **RADIUS Service** subtab. For each server group, you can view the server group name, comments, and whether the group is available or disabled. You can then select a server group to modify or delete it.
To modify a server group, select it and click the Edit icon. You can modify any of its properties, and add or delete servers from the group. When you delete a Sophos NAC Advanced server from a group, the appliance permanently deletes it.
To delete a server group, select it and click the Delete icon. When you delete an authentication server group, the appliance permanently deletes it.

Clearing the Authentication Cache

The authentication cache can store authentication results for up to 20,000 DHCP clients. When the cache reaches its limit, the DHCP member logs a message in syslog. To clear the entire cache or the cache entry of a specific MAC address, you must enable the authentication cache in the RADIUS Service wizard or editor.
To clear the entire authentication cache:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox.
2. Expand the Toolbar and select **Clear** -> **Authentication Cache**.
3. When the **Clear Authentication Cache** confirmation dialog appears, click **Purge**.

To delete a specific entry:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> *member* checkbox.

2. Expand the Toolbar and select **Clear** -> **Authentication Record**.
3. In the **Clear Authentication Record** dialog box, enter the DHCP client MAC address, and then click **Purge**.

Configuring DHCP Ranges

Create the IPv4 network and DHCP ranges as described in *Managing IPv4 DHCP Data*. You can create multiple DHCP ranges and apply one or more NAC filters to each of them.

Listing DHCP Ranges

By default, DHCP ranges are listed according to their start addresses. You can reorder them according to the order in which you want the member DHCP server to evaluate the ranges.
Consider the following sample DHCP ranges:

- 10.20.30.100-10.20.30.199 (NAC filter that allows leases for compliant DHCP clients)
- 10.20.30.0-10.20.30.99 (No filters)

If the DHCP range with the NAC filter is listed before the range with no filters, then the DHCP server consults the Sophos NAC Advanced server and applies the NAC filter before it grants a lease. It grants leases from the range with no filters only if no NAC filters matched or after all leases from the first range are exhausted. If the first range is the production range and the second range is for the quarantine group, then the server applies the NAC filters for the production range, before it grants leases to the quarantine range.
To change the order of DHCP ranges in a network:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> *network*.
2. Expand the Toolbar and click **Order DHCP Ranges**.
3. In the *Order DHCP Ranges* dialog box, click the up and down arrows to move ranges up or down on the list. The Priority value changes accordingly.
4. Click **OK**.

You can view the DHCP objects in a network, including its DHCP ranges by navigating to the **DHCP** tab -> **Networks** tab -> **Networks** panel, and then clicking the network link. You can select the Priority column for display to view the order of the DHCP ranges. For information about editing the columns, see *Customizing Tables*.

About NAC Filters

You can define NAC filters that specify authentication results from a remote, backend RADIUS server such as the Sophos NAC Advanced server. You can then apply each filter to a DHCP range or range template and indicate whether the DHCP server grants or denies a lease when the authentication result matches the filter. You can apply NAC filters to any DHCP range and DHCP range template.
NAC filters are enabled by default. When necessary, you can disable them for the entire Grid so you can perform maintenance on your RADIUS server. When you disable NAC filters, no service interruptions, service down times, configuration changes, or server restarts are required. For information about how to disable NAC filters, see Disabling NAC Filters below.
In a NAC filter, you can define rules that specify the following:

- The status of the RADIUS authentication server group:
  - Success: At least one of the servers in the RADIUS authentication server group is up.
  - Fail: The MAC address in the DHCP request is not in the authentication cache and all servers in the server group are down.
  - Disabled: The RADIUS authentication server group is disabled, all the servers in the group are disabled, or the member is not assigned a server group.
- The response from the RADIUS server:
