  - Accept: The response is an Access-Accept packet.
  - Reject: The response is an Access-Reject packet.
- Whether the Access-Accept packet contains an error. The Infoblox DHCP server expects certain RADIUS VSAs in the Access-Accept packet. An error occurs when any of the RADIUS VSAs are missing. For information about the Access-Accept packet and the RADIUS VSAs, refer to the documentation for the specified RADIUS server.

        - Yes: The Access-Accept packet does not include one or more RADIUS VSAs.
        - No: There are no errors in the Access-Accept packet.
    - A compliance state: unknown, non-compliant, compliant or partially compliant.
    - A RADIUS server user class.

When the member DHCP server receives an address request, it checks the DHCP ranges in their priority order. For information about the order of DHCP ranges, see *Listing DHCP Ranges*.
For each DHCP range, it checks if the request matches any MAC filters, relay agent filters, or DHCP option filters that apply to the range. (For information about these filters, see *Configuring IPv4 DHCP Filters*.) If any of those filters match, then the member either grants or denies a lease to the DHCP client, based on the filter. If none of those filters match and there are NAC filters defined, then the member tries to send an authentication request to a server in the RADIUS authentication server group.
If you want the member DHCP server to grant leases to specific DHCP ranges in case the RADIUS authentication server group is considered disabled (server state = disabled) or if all RADIUS servers are down (server state = failure), create a NAC filter for each situation and apply it to the appropriate range.
Note that when you create a NAC filter, you do not have to include rules that specify prerequisite conditions. For example, when you create a filter that specifies a RADIUS server compliance state or user class, you do not have to include rules that specify the following: server state=success, server response=accept, and server error = no.

Defining NAC Filters

To define a NAC filter:

1. From the **Data Management** tab, select the **DHCP** tab -> **Filters** tab, and then expand the Toolbar and click **Add** -> **IPv4 NAC Filter**.
   or
   From any panel in the **DHCP** tab, expand the Toolbar and click **Add** -> **IPv4 NAC Filter**.
2. In the *Add Filter* Wizard, complete the following and click **Next**:
    - **Name:** Enter a name for the filter. You can enter a maximum of 255 characters. The name must be unique within a specific network. If you want to specify option settings in the filter, the name must be unique among all NAC filters.
    - **Comment:** Optionally, enter additional information about the NAC filter.
3. Create a rule as follows:
    - In the first drop-down list, select one of the following criterion: **Compliance State**, **Server Error**, **Server Response**, **Server State** or **User Class**.
    - In the second drop-down list, select an operator: **equals** or **does not equal**.
    - The selections in the third drop-down list depend on the criterion you selected:
        - **Compliance State**: Select one of the following compliance states: **Unknown**, **Non-compliant**, **Compliant** or **Partially Compliant**.
          Server Error: The Infoblox DHCP server expects certain RADIUS VSAs in the Access-Accept packet. When any of the VSAs are missing, then the DHCP server considers this an error. For information about the Access-Accept packet and the VSAs, refer to the documentation for the specified RADIUS server. Select one of the following:
        - **Yes**: Create a rule that matches when the RADIUS server sends an Access-Accept packet with a missing VSA.
        - **No:** Create a rule that matches when the RADIUS server sends an Access-Accept packet with no errors.

          Server Response: Select one of the following:
        - **Accept:** Create a rule that matches when the server sends back an Access-Accept packet.
        - **Reject:** Create a rule that matches when the server sends back an Access-Reject packet.

          Server State: Select one of the following:
        - **Success:** Create a rule that matches when at least one RADIUS server in the group is up.
        - **Fail:** Create a rule that matches when the MAC address of the DHCP client is not in the cache and all RADIUS servers in the server group are down.
        - **Disable:** Create a rule that matches when the RADIUS authentication server group is disabled, all servers in the group are disable, or the member was not assigned a server group.

User Class: Enter the RADIUS user class value, for example, NACDeny. The member DHCP server does not validate the entry. Therefore, you must make sure that the user class you enter matches the user class name on the RADIUS server.

To add another rule:

- Click **+** to add another rule at the same level.
- Click **|<-** to add an **all** (logical AND) or **any** (logical OR) operator line and a parenthetical rule that is indented one level and above the first rule.
- Click **->|** to add an **all** (logical AND) or **any** (logical OR) operator line and a parenthetical rule that is indented one level.

After you add all the match rules, you can click **Preview** to view the rules or click **Reset** to remove the previously configured rules and start again.

4. Click **Next** and complete the following to define DHCP options:
   - **Option Space**: Select an option space from the drop-down list. This field is not displayed if you do not have custom option spaces. The appliance uses the **DHCP** option space as the default.
   - **Lease Time**: Enter the value of the lease time in the field and select the time unit from the drop-down list. The lease time applies to hosts that meet the filter criteria.

   Options to Merge with Object Options

   Click the Add icon. Grid Manager adds a new row to the table with the default **DHCP** option space and option name displayed. Complete the following:
   - **Option Space**: Click the down arrow and select an option space from the drop-down list. The selected option space contains the corresponding DHCP options.
   - **Option Name**: Click the down arrow and from the drop-down list, select the DHCP option you want to return to the matching client.
   - **Value**: Enter the match value that you want the filter to use for the selected DHCP option. For example, enter the value 172.124.3.0 for the SUNW.SrootIP4 option.

   To add more options to the filter, click the Add icon and repeat the steps.
5. Click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.
6. Save the configuration and click **Restart** if it appears at the top of the screen.

After you add NAC filters, you must then apply them to DHCP ranges, as described in *Applying Filters to DHCP Objects*. You can also list, modify or delete NAC filters, as described in *Managing DHCP Filters*.

Disabling NAC Filters

NAC filters are enabled by default. When you disable them, the appliance bypasses evaluations of all NAC filters for the entire Grid. There are no configuration changes, service restarts, or service down times when you disable the NAC filters. The appliance keeps the filter configurations so you can enable them at a later time.

To disable NAC filters for the Grid:

1. From the **Data Management** tab -> **DHCP** tab, select **Grid DHCP Properties** from the Toolbar.
2. In the *Grid DHCP Properties* editor, click **Toggle Advanced Mode**, select the **General** tab -> **Advanced** tab, and then complete the following in the Common Properties section:
   - **Disable All NAC Filters:** Select this to disable all NAC filters in the Grid. The appliance keeps the filter configurations so you can enable them when needed.

Managing Leases

Historical DHCP lease records complement the real-time DHCP lease viewer by allowing the appliance to store and correlate DHCP lease information over the lifetime of a lease. You can see critical information such as when the appliance issued or freed an IPv4 or IPv6 address, the MAC address or DUID and host name of the device that received the IP address, the Grid member that supplied the lease, and the start and end dates of the lease.

You can view current leases and lease history in the **Data Management** -> **DHCP** -> **Leases** tab in Grid Manager. To view lease history, you must first enable lease logging at the Grid level. For information, see *Configuring DHCP Logging* and *Configuring the Lease Logging Member*. You can also export the DHCP lease history log in CSV format for archival and reporting purposes.

In the **Leases** tab, you can do the following:

- View current leases. For information, see *Viewing Current Leases*.
- View detailed information about a specific lease. For information, see *Viewing Detailed Lease Information*.
- View historical lease records. For information, *Viewing Lease History*.
- Export current leases and lease history logs. For information, see *Exporting Lease Records*.
- Clear leases. For information, see *Clearing Leases*.

You can also use the filter and **Go to** functions in the lease panels to retrieve lease information for specific hosts, MAC addresses, and IP addresses. These capabilities are crucial for security auditing and for meeting new compliance regulations such as SOX and HIPAA. You can also sort the lease information by column.

This section explains how to manage IPv4 and IPv6 leases. It contains the following topics:

Viewing Current Leases

To view current IPv4 and IPv6 leases:

1. From the **Data Management** tab, select the **DHCP** tab -> **Leases** tab -> **Current Leases**.
2. Grid Manager displays the following information:
    - **IP Address**: The IPv4 address or IPv6 prefix or address that the appliance assigned to a DHCP client for this lease.
    - **Protocol:** Indicates whether the lease is for an IPv4 or IPv6 address.
    - **Members/Servers**: The Grid member or Microsoft server (for IPv4 leases only) that granted the lease.
    - **MAC address**: The MAC address of the IPv4 DHCP client that received the lease for an IPv4 address.
    - **DUID:** The DHCP Unique Identifier (DUID) of the IPv6 DHCP client that received the lease for an IPv6 address.
    - **Host Name**: The hostname that the DHCP client sent with its DHCP request. For IPv4 leases, this field displays the hostname of the DHCP client. For IPv6 leases, this field typically displays the FQDN.
    - **Fingerprint**: The name of the DHCP fingerprint or vendor ID of the DHCP client that was identified through DHCP fingerprint detection. This field displays **No Match** for devices that do not have any DHCP fingerprint information. For information about DHCP fingerprints, see *DHCP Fingerprint Detection*.
    - **State**: The binding state of the current lease. The lease state can be one of the following:
        - **Free**: The lease is available for clients to use.
        - **Active**: The lease is currently in use by a DHCP client.
        - **Static**: The lease is a fixed address lease.
        - **Expired**: The lease was in use, but the DHCP client never renewed it, so it is no longer valid.
        - **Released**: The DHCP client returned the lease to the appliance.
        - **Abandoned**: The appliance cannot lease this IP address because the appliance received a response when pinging the address.
    - **End**: The day, date, and time when the state of the lease ends.
    - **Start**: The day, date, and time when the state of the lease starts.
    - **Username**: Displays the name of the user who receives the lease for the IP address. The username enables you to differentiate between guest users and authenticated users. If you log in as an authenticated user, your username is whatever you choose when you log in. If you log in as a guest, your username is First: first_name Last: last_name.
      For example, if your first name is John and last name is Doe and your username is jdoe, when you log in

as an authenticated user, your username is jdoe. If you log in as a guest user, your username is First: John, Last: Doe.

- **Client ID**: The DHCP client identifier (option 61) in an IPv4 lease. The client sends the client identifier as option 61 in the DHCP DISCOVER and REQUEST packets, as described in *RFC2132, DHCP Options and BOOTP Vendor Extensions*. The client identifier is either the MAC address of the network interface card requesting the address or any string uniquely identifying the client. This field is not displayed by default.
  Note that the dates and timestamps in the Leases tab are determined by the time zone setting of the admin account that you use to log in to the appliance.

  You can display the following discovered data for IPv4 leases:
  - **Last Discovered:** The timestamp when the IP address was last discovered. This data is read-only.
  - **OS**: The operating system of the detected host or virtual entity. The OS can be one of the following:
    - **Microsoft** for all discovered hosts that have a non-null value in the MAC addresses using the NetBIOS discovery method.
    - A value that a TCP discovery returns.
    - The OS of a virtual entity on a vSphere server.
- **NetBIOS Name**: The name returned in the NetBIOS reply or the name you manually register for the discovered host.
- **Discovered Name**: The name of the network device associated with the discovered IP address.
- **Discoverer**: Specifies whether the IP address was discovered by a PortIQ or NIOS discovery process.

You can do the following in this tab:

- Sort the data in ascending or descending order by column.
- View the lease detailed information of a current lease by selecting the checkbox of the lease, and then clicking the Open icon.
- Change a current lease state to **Free** by selecting the checkbox of a current lease, and then clicking the Delete icon.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Print and export the data in this tab.

Viewing Detailed Lease Information

You can view detailed information about a specific lease. To view detailed information of a specific lease:

1. From the **Data Management** tab, select **DHCP** tab -> **Leases** -> **Current Leases** -> *lease* checkbox, and then click the **Lease Details** icon.
   or
   From the **Data Management** tab, select the **IPAM** tab, drill down to the IP Map, IP List, or IP address panel, and then click **Lease Details** from the Toolbar.
2. In the *Lease Detailed Information* viewer, Grid Manager displays the following for each type of lease:
   For IPv4 leases, it displays the fields **Member**, **MAC address**, **Host**, **Start**, **End**, **Binding State**, **Username, Binding State**, as described in *Viewing Current Leases*, plus the following information:
   - **Lease Issue**: The date and time when the lease was issued. Displayed in the lease event details report only.
   - **Event**: The action taken. This can be one of the following: **Issued**, **Renewed**, **Freed**, or **Abandoned**. Displayed in the lease event details report only.
   - **Served by**: The member that provides DHCP services to the lease.
   - **Next Binding State**: The subsequent binding state when the current lease expires. The lease state and the next binding state can be one of the following:
     - **Free**: The lease is available for clients to use.
     - **Active**: The lease is currently in use by a DHCP client.
     - **Static**: The lease is a fixed address lease.
     - **Expired**: The lease was in use, but the DHCP client never renewed it, so it is no longer valid.
     - **Released**: The DHCP client returned the lease to the appliance.

    - **Abandoned**: The appliance cannot lease this IP address because the appliance received a response when pinging the address.
- **Billing Class**: The billing class of the lease.
- **Option 82 Agent ID**: The agent ID of the relay agent filter (option 82). A relay agent can append DHCP option 82, relay agent information, to a message that it forwards from a DHCP client to a DHCP server.
- **Option 82 Circuit ID**: The circuit ID of the relay agent filter (option 82).
- **Option 82 Remote ID**: The remote ID of the relay agent filter (option 82).
- **Option 82 Link Selection**: An IP address, provided by the DHCP relay agent, in the subnet from which the DHCP server allocated the leased IP address to the client.
- **Option 82 Server ID Override**: The IP address, provided by the DHCP relay agent, that the DHCP server used as the value in the server identifier option of the response sent to the client.

  For more information about the sub options for Option 82, see *About the DHCP Relay Agent Option (Option 82)*.

  The agent, circuit, and remote IDs for option 82 can be displayed in hexadecimal or plain text format. By default, Grid Manager displays them in hexadecimal format. You can change the logging format, as described in *Defining Logging Format for DHCP Option 82*.
- **Option**: Agent circuit ID and remote ID data sent by a DHCP relay agent in all DHCP options.
- **UID**: (User ID) The client identifier that the DHCP client sends the appliance (in DHCP option 61) when it acquires the lease. Not all DHCP clients send a UID.
- **TSFP**: (Time Sent From Partner) The time — from the point of view of a remote DHCP failover peer — when the current lease state ends.
- **CLTT**: (Client Last Transaction Time) The time of the last transaction with the DHCP client for this lease.
- **TSTP**: (Time Sent To Partner) The time — from the point of view of the local DHCP failover peer — that the current lease state ends.

  For IPv6 leases, it displays most of the same fields as IPv4 leases, plus the following information:
- **DUID:** The DUID of the IPv6 DHCP client that received the lease for an IPv6 address.
- **Prefix Bits:** The prefix length.
- **Preferred Lifetime:** The length of time that a valid address is preferred. A preferred address can be used with no restrictions. When this time expires, the address becomes deprecated.

Viewing Lease History

To view lease history:

- From the **Data Management** tab, select the **DHCP** tab -> **Leases** tab -> **Lease History**.

Grid Manager displays a table of historical leases that have been archived in the system. You can export the information in the lease history table. You can also search by the IP address or MAC address of the lease. Grid Manager displays the following read-only information:

- **Lease Issue**: The date and time when the lease was issued.
- **Protocol**: Indicates whether the lease is for an IPv4 or IPv6 address.
- **IP Address**: The IPv4 address or IPv6 prefix or address of the lease.
- **MAC Address**: The MAC address of the IPv4 lease.
- **DUID**: The DUID of the DHCP client that received the lease for an IPv6 address.
- **Fingerprint**: The name of the DHCP fingerprint or vendor ID of the DHCP client that was identified through DHCP fingerprint detection. This field displays **No Match** for devices that do not have any DHCP fingerprint information. For information about DHCP fingerprints, see *DHCP Fingerprint Detection*.
- **Host Name**: The host name that the DHCP client sent to the appliance.
- **Action**: This can be one of the following: Issued, Renewed, Freed, or Abandoned.
- **User Name**: The name of the user who received the lease for the IP address.
- **Start**: The start date of the lease.
- **Stop**: The end date of the lease.
- **Member/Server**: The DHCP member or Microsoft server that granted the lease.
- **Member IP Address**: The IP address of the DHCP member that granted the lease. You can do the following in this section:

- View the lease event detailed information of a historical lease by selecting the checkbox of a lease, and then clicking the Open icon.
- Print or export the information in this section.

Viewing Lease Event Detailed Information

You can view detailed information about a historical lease record by clicking the lease in the **Data Management** tab -> **DHCP** tab -> **Leases** tab -> **Lease History**. Grid Manager displays the event, the date and time when the event occurred, plus detailed information about the historical lease record. For information about the fields, see *Viewing Detailed Lease Information*.

You can also export and print the information in this panel. For information, see *Exporting Lease Records*.

Exporting Lease Records

The DHCP lease history log holds a maximum of 100,000 entries. After that maximum is reached, the appliance begins deleting entries, starting with the oldest. To archive DHCP lease history logs, you can export them and save them as CSV (comma separated variables) files. You do not need to export the entire log. You can selectively export a section of the log, such as the lease events for a single day.
As a conservative approach to archiving DHCP lease data, Infoblox recommends exporting the log on a daily basis, perhaps through API (application programming interface) scripting. By exporting the daily log entries every day over a certain period of time and then opening the exported files with a spreadsheet program, you can see the number of entries for each day. You can then estimate how often you need to export the log to ensure that you save all of the entries before the log fills up (at 100,000 entries). As a result, you might discover that you need to export the log more or less frequently than once a day to archive all the records.
A limited-access admin group can view and export the DHCP lease history if it has read-only permission to the DHCP lease history. For information on setting permissions for the DHCP lease history, see *Administrative Permissions for the IPv4 and IPv6 DHCP Lease Histories*. In addition, you can export the displayed DHCP current lease information or you can export them to a CSV file.
To export displayed current lease information:

1. From the **Data Management** tab, select the **DHCP** tab -> **Leases** tab -> **Current Leases**.
2. Click the Export icon and select **Export visible data**. For more information on how to export, see *Exporting Displayed Data*.

To export DHCP current lease information to a CSV file:

1. From the **Data Management** tab, select the **DHCP** tab -> **Leases** tab -> **Current Leases**.
2. Click the Export icon and select **Export data in Infoblox CSV Import format**. For more information on how to export, see *Exporting Data to Files*.

To export a lease history log:

1. From the **Data Management** tab, select the **DHCP** tab -> **Leases** tab -> **Current Leases** or **Lease History**.
2. Click the Export icon and select.
3. In the *Export* dialog box, click **Start**
4. Click **Download** when the export is complete. Ensure that you turn off the pop-up blocker in your browser.
5. In the *File Download* dialog box, select the appropriate action to either open or save the CSV file.

Clearing Leases

You can clear active leases for which you have read/write permission. When you clear an active lease, its IP address becomes available and its status changes to "Free". To clear an active lease:

1. From the **Data Management** tab, select the **DHCP** tab -> **Leases** tab -> **Current Leases**.
2. Click the checkboxes beside the IP addresses of the leases you want to clear, and then click the Clear Lease icon.

Grid Manager clears the selected leases. You can view information about a cleared lease, by selecting it in the Lease History panel and clicking the Edit icon.

Configuring Microsoft Windows Servers

This section describes how you can centrally manage Microsoft Windows® DNS and DHCP servers from Grid Manager. You can synchronize your DNS and DHCP data from the Microsoft servers to the Grid, and then use IPAM tools to facilitate DHCP and DNS configuration and data management. This section includes the following topics:

- *Managing Microsoft Windows Servers*
- *Managing Microsoft DNS Services*
- *Managing Microsoft DHCP Services*

Managing Microsoft Windows Servers

This section explains how to configure Grid members to manage Microsoft Windows DNS and DHCP servers from Grid Manager. It includes the following topics:

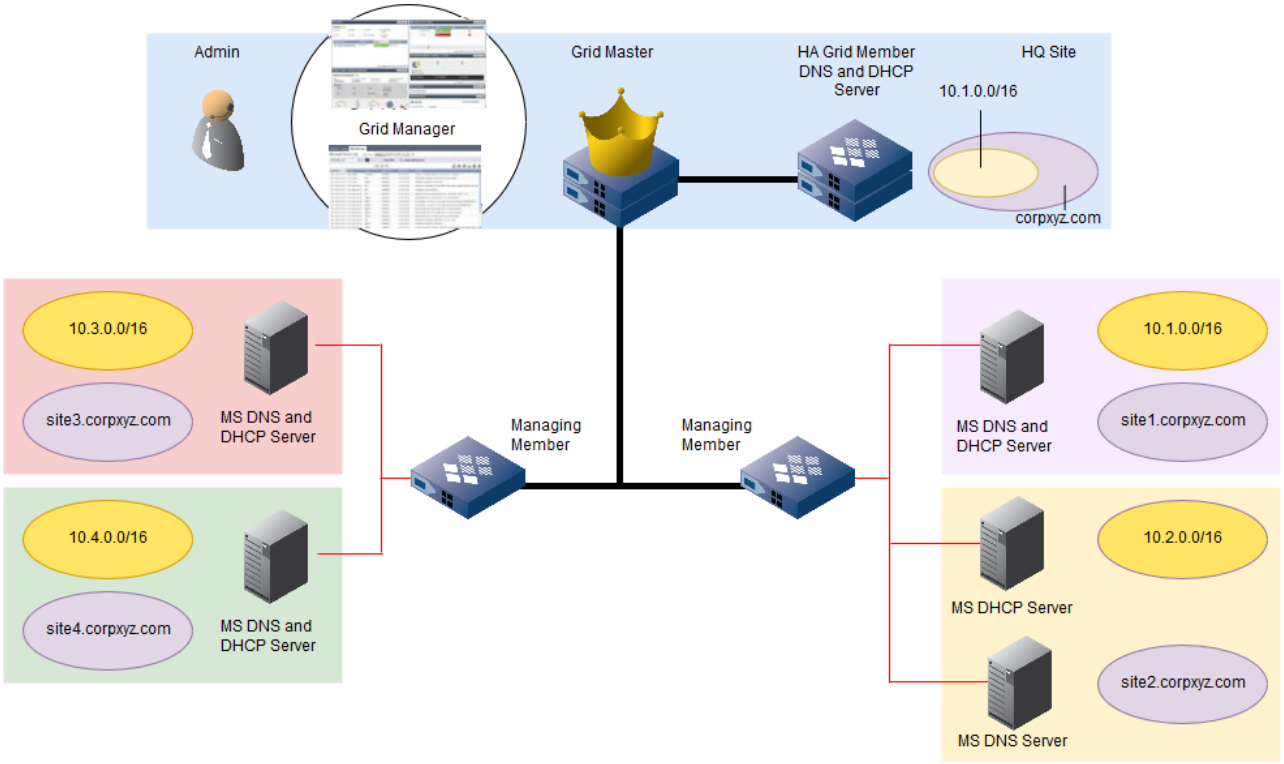
- *About Managing Microsoft Windows Servers*
- *Configuring Members to Manage Microsoft Servers*
- *Configuring Grid Properties for Managing Microsoft Servers*
- *Managing Microsoft Servers*
- *Configuring Active Directory Sites and Services*
- *Configuring Active Directory Sites and Associated Networks*
- *Managing Active Directory Sites*
- *Managing Active Directory Sites and Associated Networks*
- *Configuring Identity Mapping*
- *Monitoring Managed Microsoft Servers*

About Managing Microsoft Windows Servers

You can configure Grid members to manage Microsoft Windows DNS and DHCP servers, and synchronize their DNS and DHCP data to the Grid database, so you can view and optionally, manage the data from Grid Manager. After the data is synchronized, you can use the IPAM tools of Grid Manager to simplify DNS and DHCP configuration and troubleshooting. You can use Smart Folders to organize your data, and monitor your networks and Microsoft servers from the Dashboard. In addition, you can control the DNS and DHCP services of the Microsoft servers from Grid Manager and configure server properties as well. You can use the Identity Mapping feature to get visibility of user interaction with their environments. For more information about the Identity Mapping feature, see *Configuring Identity Mapping*.

The below figure illustrates a Grid that includes a member that provides DNS and DHCP services, and two other members that manage multiple Microsoft DNS and DHCP servers. Assuming the admin has the appropriate permissions, the admin can centrally manage the Microsoft DNS and DHCP servers and Infoblox DNS and DHCP server from a single interface, Grid Manager.

Managing Microsoft and Infoblox DNS and DHCP Servers from the Grid Master



You do not have to configure or install any application on the Microsoft servers for the Grid members to communicate with the servers. Infoblox uses MS-RPC (Microsoft Remote Procedure Calls) to manage Microsoft servers.

A Grid member can manage a Microsoft server in either of two modes, Read-only or Read/Write. In Read-only mode, the Grid member synchronizes data from the Microsoft server to the Grid so admins can use Grid Manager to view the synchronized data, but not update it. Read/Write mode allows admins to update the synchronized data as well.

Updates from Grid Manager are then synchronized to the Microsoft server, and updates from the Microsoft server are synchronized to the Grid.
Configuration changes and data synchronized from the Grid to the Microsoft server apply immediately after the synchronization. You do not have to restart the Microsoft server or for DNS, reload the zones.

Note that due to a field length limit set on the Microsoft DHCP server, after you synchronize DHCP data on the Microsoft server, the "Comment" and "Description" fields for a fixed address and reservation can display only up to 128 characters even though NIOS allows up to 256 characters for these fields.

> **Note**
>
> A Grid member must have a Microsoft Management license installed to manage a Microsoft server. The license allows the member to synchronize data with Microsoft servers. It also activates the tabs, dialog boxes and other elements in Grid Manager that you need to manage a Microsoft server. If you do not see the Microsoft Servers tab after you add a member that has a Microsoft Management license, you might have to restart the Grid Master to view the tab and to manage Microsoft DNS and DHCP servers in the Grid.

Supported Windows Versions

Infoblox Grid members can manage Microsoft servers that support the following Windows versions:

OS	Levels	Platforms
Microsoft Windows 2003 Standard and Datacenter	SP2	32 bits
Microsoft Windows 2003 R2 Standard and Datacenter	Initial Release	32 bits, 64 bits
Microsoft Windows 2008 Standard and Datacenter	SP2	32 bits, 64 bits
Microsoft Windows 2008 R2 Standard and Datacenter	Initial Release	64 bits
Microsoft Windows 2012 Standard and Datacenter	Initial Release	64 bits
Microsoft Windows 2012 R2 Standard and Datacenter	Initial Release	64 bits
Microsoft Windows 2016 Standard and Datacenter	Initial Release	64 bits
Microsoft Windows 2019 Standard and Datacenter	Initial Release	64 bits

Infoblox supports the following SMB (Server Message Block) protocol versions for Microsoft Windows servers: SMB version 1 (SMBv1), SMB version 2.x (SMBv2.x), and SMB version 3.x (SMBv3.x).

Grid members check the Windows version of the Microsoft servers before each synchronization. If a Microsoft server reports an unsupported version before a synchronization, the member logs an error and the synchronization fails. Note that some Windows versions require certain updates and hotfixes installed, so the Microsoft server can synchronize with the Grid member. Following are the current requirements:

- Windows Server 2003, Enterprise x64 Edition requires the installation of security update 935966.
- Windows Server 2008 R2 requires the hotfix referenced in the Knowledge Base article 981776.
- Windows Server 2008-based DNS servers might not display delegations for reverse lookup zones. For information about this issue, including the available hotfix, refer to Knowledge Base article 958190.

For information about the updates, enter their IDs in the Search field of the Microsoft Support website at *http://support.microsoft.com*.

Administrative Permissions

By default, only superusers can configure Grid members to manage Microsoft servers. Superusers can give limited-access users Read-only or Read/Write permission to Microsoft servers. Read-only permission allows admins to view the properties and data of a Microsoft server from Grid Manager. Write permission is required to configure Grid members to manage Microsoft servers, edit their properties, and start or stop their DNS and DHCP services. For additional information, see *Administrative Permissions for Microsoft Servers*.
Note that to view and manage the DNS and DHCP data synchronized from Microsoft servers, admins must have permissions to the applicable DNS and DHCP resources. For example, to view DNS zones synchronized from Microsoft servers, admins must have Read-only permission to zones, and to edit the zones, admins need Read/Write permission to them. Similarly, to view DHCP ranges synchronized from Microsoft servers, admins must have Read-only permission to DHCP ranges, and to edit the DHCP ranges, admins need Read/Write permission to the DHCP ranges. For information, see *Administrative Permissions for DNS Resources* and *Administrative Permissions for DHCP Resources*.
The administrative permissions on the Grid are different from those on the Microsoft server. These permissions are independent of each other and are not synchronized.

Deployment Guidelines

Following are some recommendations and considerations when configuring Grid members to manage Microsoft servers:

- Infoblox recommends that you schedule the initial synchronization at a time when your network is less busy, especially if you are synchronizing a large amount of data. In addition, if a Microsoft server reconnects after being disconnected for a long period of time, it could synchronize a significant amount of data and this could impact the Grid Master performance.
- vNIOS Grid members and Grid members running on Infoblox-250, Trinzic 100, and Trinzic 810 appliances do not support being configured as managing members.
- The managing member must be close, in terms of network hops, latency and bandwidth, to the Microsoft servers that it manages. This will help reduce the synchronization time and potential retries due to network delays.
- Although a Grid member that manages Microsoft servers can run other protocols and services, to optimize performance, Infoblox recommends that you configure one or more members solely for managing Microsoft servers.
- Grid members connect to Microsoft servers using RPC calls over TCP/IP. You must adjust your firewall policies to allow traffic between the managing Grid member and its assigned Microsoft servers. Grid members use the VIP as their source port. In Windows Server 2003, RPC uses the dynamic port range 1025-5000, by default. In Windows Server 2008, RPC uses the dynamic port range 49152-65535, by default. You can reduce the number of available ports as follows:
    - In Windows Server 2003, use the rpccfg.exe tool. For information, refer to *http://support.microsoft.com/kb/908472*.
    - In Windows Server 2008 and later, use the netsh tool. For information, refer to *http://support.microsoft.com/kb/929851*.

  The minimum number of ports required in the range is 255.
  Note that TCP ports 135 and 445 must be open on the Microsoft server, in addition to the dynamic port range. Ports 135 and 445 are used by the port mapper interface, which is a service on the Microsoft server that provides information to clients on which port to use to connect to a specific service, such as the service that allows the management of the DNS service.
- The capacity of the managing member must be greater than or equal to the sum of all its assigned Microsoft servers.
- The capacity of the Grid Master must be greater than or equal to the sum of all managed Microsoft servers
- A Microsoft server can synchronize its data to only one network view, and for DNS data, only one DNS view.
- Multiple Microsoft servers can synchronize their data into the same network view and DNS view, unless there is a conflict in their data. For example, two Microsoft servers in different locations could serve the same private IP address space, such as 10.1.0.0/16, or serve reverse-mapping zones with the same name, such as 10.in-addr.arpa. Synchronizing their data to the same network view and DNS view would cause conflicts which result in the Grid member synchronizing the data of only one Microsoft server and logging an error for the other Microsoft server. In such situations, Infoblox recommends that you synchronize each Microsoft server to a different network view and DNS view to ensure that data from both servers are synchronized.
- This release supports the following Microsoft IPAM enhancements:
    - Monitor and control settings for DNS and DHCP services for Microsoft servers
    - Synchronization of IP addresses with invalid MAC addresses
    - Output destination for Microsoft server log messages in the syslog
    - Synchronization and configuration of Microsoft DHCP failover relationships
    - RPC (Remote Policy Call) timeout setting
    - Maximum concurrent connections for Microsoft servers
    - Enabling and Disabling DNS zone synchronization
    - The ability to allow GSS-TSIG based DDNS updates from multiple clients in a single forest or multiple forests using keys that are appropriate for their respective domains.

  Earlier NIOS releases do not support these features. When you modify settings related to these features on Microsoft servers assigned to Grid members running a NIOS release earlier than NIOS 6.11, the NIOS appliance displays an error message.

Limitations for Scheduling Full Upgrades

When you schedule a full upgrade to NIOS 6.11 and later, you can set the RPC (Remote Procedure Calls) timeout settings and maximum concurrent connections immediately on any member as soon as you upgrade the Grid Master. When you disable the synchronization of a DNS zone, NIOS displays an error message if any Microsoft server that is a potential synchronization master, which is assigned to a Grid member, has not been upgraded to NIOS 6.11.0 or later

versions.
The following happens if a DHCP failover configuration exists:

- Any Microsoft server configured to manage DHCP and assigned to a Grid member, which has not been upgraded, synchronizes the DHCP configuration without any failover related data.
- You cannot assign a Microsoft server that is assigned to a Grid member, which has not been upgraded, to any Microsoft failover relationship.
- NIOS manages any DHCP scope that is identified to be part of a Microsoft failover relationship but is managed by a Grid member that has not been upgraded, in Read-only mode.

Configuring Members to Manage Microsoft Servers

You can manage Microsoft DNS and DHCP servers on any Grid member. To avoid performance issues, Infoblox strongly recommends that you do not configure Microsoft DNS and DHCP servers on the Grid Master and Grid Master candidate. When an HA pair manages Microsoft servers, the active node handles synchronization. If an HA failover occurs during a synchronization, the failing node immediately aborts the synchronization. The new active node resumes the next synchronization. Changes that occurred on the Grid since the end of the last synchronization are lost.
For Microsoft DHCP failover, NIOS supports both the hot standby and load sharing modes in both Read/Write and Read-only modes on DHCP servers running Microsoft Windows 2012 and 2012 R2. For more information about Microsoft DHCP failover, refer to the Microsoft documentation.
Complete the following tasks to configure a Grid member to manage a Microsoft server:

1. On the Microsoft server, create a user account for the Grid member. For information, see Setting Microsoft Server Credentials below.
2. On the Grid Master, configure the managing member, as described in Configuring a Managing Member below.

Setting Microsoft Server Credentials

To enable a Grid member to synchronize data with a Microsoft server and control DNS and DHCP services, you must do the following on the Microsoft server:

1. Create a user account for the Grid member.
2. Grant the user account the necessary permissions.

You can either add the user account to the Administrators Group or add the user account to specific groups and explicitly set only the permissions necessary to access the DHCP and DNS services of the Microsoft server. The following sections provide general instruction on each method.

Adding User Account to the Administrators Group

Adding the user account of the Grid member to the Administrators Group provides total control over the Active Directory Domain. Do one of the following:

- If the managed Microsoft server is a standalone server or a member server in a domain, open **Computer Management**, click **Groups**, and add the user account to the Administrators Group.
- If the managed Microsoft server is a domain controller, open **Active Directory Users and Computers**, select the domain name, click **Builtin**, and add the user account to the Administrators Group.

Setting Specific Group Memberships and Permissions

If your security policy precludes adding user accounts to the Administrators group, you can add the user account to individual groups and grant only the required permissions. For guidelines and more information, see the following:

http://support.microsoft.com/kb/325349

http://support.microsoft.com/kb/914392

To add the user account of the Grid member to individual groups and grant specific permissions:

- To enable the member to synchronize DNS data with the Microsoft server, add its user account to the DnsAdmins Group.
- To enable the member to synchronize DHCP data with the Microsoft server, add its user account to the Dhcp Administrators Group.
- To enable the Grid member to monitor, start, and stop the DNS and DHCP services, grant the user account permissions on the Service Control Manager (SCM), as follows:
    a. Grant permissions to the SCM on each managed Microsoft server. For more information, refer to the section *DNS Server Service Permissions* at *http://technet.microsoft.com/en-us/library/gg638675.aspx*.
    To find additional information, you can also search for "Least Privilege Setup" on the Microsoft sites.
    b. Grant permissions to the DNS and/or DHCP service on each managed server by doing one of the following:
        - Use the `sc` command line utility to remotely configure each managed DNS or DHCP server. Note that you need to know the SID of the user account and its current permissions. You can retrieve the SID of the user account by using the `dsquery` and `dsget` commands.
        - Use the Domain Controller Policy editor to define a global policy that applies to all DNS or DHCP services running in a domain or on domain controllers. For additional information, refer to *http://support.microsoft.com/kb/324802.*

Configuring a Managing Member

When you configure a member to manage Microsoft servers, you must specify the following:

- The management mode of the Microsoft server. For information, see Setting the Management Mode in the next section.
- A network view, if there is more than one in the Grid, and a DNS view, if there is more than one in the network view. For information, see Synchronizing to a Network View and DNS View below.

For the steps on configuring the managing member, see Assigning Grid Members to Microsoft Servers below.

Setting the Management Mode

A Grid member can manage a Microsoft server in Read-only mode, which is the default, or in read-write mode. In Read-only mode, the Grid member copies the DNS and DHCP data from the Microsoft server to the Grid so Grid Manager admins can view the synchronized data. They cannot update the data, control the DNS and DHCP service of the Microsoft server, or configure any properties.

When you select Read-only mode for Active Directory sites, you can view the sites and networks that are present on the Microsoft server through Grid Manager. Note that you cannot manage the Active Directory sites and networks directly from the Grid, but you can manage an object within the Grid that is associated with a Read-only Active Directory Site or an Active Directory network. The synchronization process is Read-only and you cannot write into the Microsoft server in this mode. For more information, see Assigning Grid Members to Microsoft Servers below.

In Read/Write mode, Grid Manager admins are allowed to update the data of the Microsoft server. Therefore during each synchronization, the Grid member applies changes from the Grid to the Microsoft server and vice versa. Read/Write mode also allows admins to control DNS and DHCP services of the Microsoft server and configure some of their properties.

When you select Read/Write mode for Active Directory Sites, you can view and manage the sites and networks that are present on the Microsoft server through Grid Manager. When you update an object that is associated with the Active Directory Site or an Active Directory network, the changes reflect on the Microsoft server. For more information, see Assigning Grid Members to Microsoft Servers below.

Note that the management mode of a Microsoft server is separate from the admin permissions that the appliance requires to access the Microsoft servers and DNS and DHCP resources. An admin must still have the applicable permissions to the Microsoft servers and DNS and DHCP resources they want to access.

Synchronizing to a Network View and DNS View

A Microsoft server can synchronize its data only to a single network view and a DNS view. Grid Manager automatically assigns Microsoft servers to the default view when a Grid contains only the default network view and DNS view. If a Grid has more than one network view, you must select a network view for the Microsoft server to synchronize its data; and if there are multiple DNS views, you must select a DNS view as well.

You cannot modify the assigned network view or DNS view of a Microsoft server after its data has been synchronized. Instead, you must remove the Microsoft server and then add it again. For information about removing a server, see *Removing a Managed Microsoft Server*.

Microsoft servers do not support network views and DNS views. Therefore, network view and DNS view properties have no effect on the DNS and DHCP data that are synchronized from Microsoft servers.

Assigning Grid Members to Microsoft Servers

To configure a Grid member to manage one or more Microsoft servers:

1. **Grid**: From the **Grid** tab -> **Microsoft Servers** tab -> **Servers** tab, click the Add icon.
   Standalone appliance: From the **System** tab -> **Microsoft Servers** tab -> **Servers** tab, click the Add icon.
2. In the *Add Microsoft Server(s)* wizard, complete the following:
   - **Which features do you want to configure?**: This section appears only when you have selected the **Enable MS AD feature** checkbox for mapping network users. For more information, see *Enabling Identity Mapping*. You can select multiple options in this section:
     - **Network Users**: Select this checkbox to enable the Grid member to synchronize user information with the managed Microsoft servers.
     - **DNS and DHCP Services**: Select this checkbox to enable the Grid member to synchronize DNS and DHCP services with the Microsoft servers.
     - **Active Directory Sites**: Select this checkbox to enable the Grid member to synchronize Active Directory sites.
   - In the **General Settings** section, complete the following:
     - **Managing Member:** Click **Select Member** and select the Grid member that manages Microsoft servers.
       Select **None** if you do not want to associate a Microsoft server with a Grid member.
     - **Credentials to Connect to the Microsoft Server(s):** Enter the login name and password that the appliance uses to connect to the Microsoft servers. These must be the same as those you specified when you created the user account for the Grid member on the Microsoft servers. Note that you must specify the domain name and the user name in the following format: *domain_name**user_name.*
     - **Manage Server(s) in:** Select the management mode, which is either **Read-only** or **Read/Write**. You can choose to manage the DNS and DHCP synchronization services in either **Read-only** or **Read/Write** mode. For more information, see *Setting the Management Mode*.
     - **Minimum Synchronization Interval (min)**: The default synchronization interval is two minutes. This is the time between the completion of one synchronization and the start of a new one.
       Synchronizing large data sets could take longer than the synchronization interval, causing a delay in the start of the next synchronization. For example, if the synchronization interval is two minutes but a synchronization takes five minutes, the time between the start of the first synchronization and the start of the next one is approximately seven minutes.
       Note that the synchronization of Microsoft DHCP servers running Microsoft Windows 2012 or later includes the synchronization of DHCP failover relationships. Note that the DNS and DHCP failover synchronization rules do not have an impact on the Microsoft servers running a Windows version that is earlier than 2012.
   - **Logging Level**: Select a logging level for the Microsoft server log from the drop-down list: **Low**, **Normal**, **High**, and **Debug**. NIOS logs the messages based on the logging level you set.
     - **Low:** Logs only error messages.
     - **Normal:** Logs warning and error messages.
     - **High:** Logs warning, error and information messages.
     - **Debug:** Logs messages about all events associated with synchronization.

- See *Viewing Synchronization Logs* for a description of each level.
- **Logging output destination**: From the drop-down list, select an output destination to which the appliance saves log messages for Microsoft servers. When you select **Microsoft Log**, the appliance logs the messages that are generated for the respective Microsoft server in the existing Microsoft log. This is selected by default. For more information, see *Viewing Synchronization Logs*. When you select **Syslog**, NIOS logs the messages that are generated for the respective Microsoft server in the syslog. For more information about the syslog, see *Viewing the Syslog*.
- **Synchronize Data into Network View:** This field appears only when there is more than one network view in the Grid. Specify to which network view the data from the Microsoft servers is synchronized.
- **Synchronize DNS Data into DNS View:** This field appears only when there is more than one DNS view in the network view. Specify to which DNS view the data from the Microsoft servers is synchronized.
- **Comment:** You can enter additional information about the servers.
- **Disable Synchronization:** Select this to disable the Microsoft servers. This allows you to preprovision the Microsoft servers and then enable them at a later time.

3. Click **Next**.
   Depending on your configuration in the **Which features do you want to configure?** section, the Add Microsoft Server(s) wizard displays the Microsoft server setting options.
4. Complete the following:
   - If you have selected the **Network Users** checkbox, complete the following in the **Select your across-server settings for Network Users** page:
     - **Use General credentials (from first page of wizard)**: Select this checkbox if you want to use the same credentials that you specified for connecting the Microsoft servers.
     - **Credentials for synchronizing Network User service information**: Specify a username and password to synchronize user information from Active Directory domain controllers. The username you specify here must belong to the Domain User group and Event Log Reader group in Microsoft. For information, see *Prerequisites on the Microsoft Server*.
     - **Use General synchronization interval (from first page of wizard)**: Select this checkbox to use the same synchronization interval that you specified in the **Minimum Synchronization Interval** for synchronizing the user and device mapping information from the Microsoft Active Directory authentication logs.
     - **Minimum synchronization interval**: The default synchronization interval is two minutes. This is the time between the completion of one synchronization and the start of a new one. Specify an interval to synchronize user information from the Microsoft Active Directory authentication logs.
   - If you have selected the **DNS and DHCP Services** checkbox, complete the following in the **Select your across-server settings for DNS and DHCP Services** page:
     - **Use General credentials (from first page of wizard)**: Select this checkbox if you want to use the same credentials that you specified for connecting the Microsoft servers.
     - **Credentials to connect to DNS and DHCP Services**: Specify a username and password to synchronize DNS and DHCP services. You must use the same username and password that you specify here when the appliance prompts for credentials during DNS or DHCP synchronization.
     - **Use General synchronization interval (from first page of wizard)**: Select this checkbox to use the same synchronization interval that you specified in the **Minimum Synchronization Interval** for synchronizing the DNS and DHCP services as well.
     - **Minimum Synchronization interval**: The default synchronization interval is two minutes. This is the time between the completion of one synchronization and the start of a new one. Specify an interval to synchronize the DNS and DHCP data from the Microsoft server.
     - **Manage DNS and DHCP services in**: Select a value from the drop-down list. You can choose to manage the DNS and DHCP synchronization services in either **Read-only** or **Read/Write** mode. For more information, see Setting the Management Mode above.
   - If you have selected the **Active Directory Sites** checkbox, complete the following in the **Select your across-server settings for Active Directory Sites** page:
     - **Use General credentials (from first page of wizard)**: Select this checkbox if you want to use the same credentials that you specified for connecting the Microsoft servers. Clear the checkbox to specify a new username and password for managing Active Directory sites.
     - **Credentials for synchronizing Active Directory information:** Specify a username and password to synchronize Active Directory sites. You must specify the same username and password that you specify here when the appliance prompts for credentials while synchronizing Active Directory sites.

- **Use General synchronization interval (from first page of wizard)**: Select this checkbox to use the same synchronization interval that you specified in the **Minimum Synchronization Interval** for synchronizing Active Directory sites.
- **Minimum Synchronization interval**: The default synchronization interval is two minutes. This is the time between the completion of one synchronization and the start of a new one. Specify an interval to synchronize the Active Directory sites.
- **Manage Active Directory sites in**: Select a value from the drop-down list. You can choose to manage the Active Directory Site in either **Read-only** or **Read/Write** mode. For more information, see Setting the Management Mode above.
- **Encryption**: You can encrypt the network traffic between the Grid member and the managed Microsoft server using SSL. Select a value, **None** or **SSL**, from the drop-down list. Infoblox strongly recommends that you select **SSL** from the drop-down list to ensure the security of all communications between the NIOS appliance and the Active Directory server. When you select **SSL**, the appliance automatically updates the TCP port to 636. When you select this option, you must specify the FQDN of the Microsoft server instead of the IP address and you must upload a CA certificate from the Active Directory server. Click **CA Certificates** to upload the certificate. In the *CA Certificates* dialog box, click the Add icon, and then navigate to the certificate to upload it.
- **TCP port for LDAP connections**: The appliance displays the port number by default based on the encryption type that you select. When you select **None**, the appliance automatically updates the TCP port to 389.

5. Click **Next** and do the following in the Managed Servers table:
   - **Name or IP Address:** Enter either the FQDN or IP address of the Microsoft server. In order for the member to resolve the FQDN of a Microsoft server, you must define a DNS resolver for the Grid member in the **DNS Resolver** tab of the *Member Properties* editor. Note that if the IP address of the Microsoft server is specified, then the DNS resolver must resolve it when the member and Microsoft server synchronize DHCP data only.
   - **DNS Sync:** Select this option to enable the Grid member to manage the DNS service and synchronize DNS data with this server. Clearing this checkbox disables DNS service management and data synchronization. This allows you to pre-provision specific Microsoft servers and then enable them at a later time.
   - **DHCP Sync**: Select this option to manage the DHCP service of the Microsoft server and synchronize DHCP data with this server. Clearing this checkbox disables DHCP service management and data synchronization. This allows you to pre-provision specific Microsoft servers and then enable them at a later time.
   - **Active Directory Sites:** Select this option to manage Active Directory sites and synchronize Active Directory Sites and networks with the Grid.
   - **DNS Monitor & Control**: Click **Override** to override the setting inherited from the Grid. To inherit the same settings as the Grid, click **Inherit**. Select this to enable monitoring and the ability to control DNS service for the Microsoft server. For more information, see *Setting Grid Properties for Managing Microsoft Servers*.
   - **Synchronize DNS Reporting Data**: Click **Override** to override the settings that are inherited from the Grid. To retain the same settings as the Grid, click **Inherit**. Select this to synchronize DNS reporting data from the Microsoft server. For more information, see *Synchronizing DNS Reporting Data*.
     Note that synchronization of DNS reporting data is effective only when **DNS Sync** option is enabled for the Microsoft server.
   - **DHCP Monitor & Control**: Click **Override** to override the setting inherited from the Grid. To inherit the same settings as the Grid, click **Inherit**. Select this to monitor and control DHCP service for the Microsoft server. For more information, see *Setting Grid Properties for Managing Microsoft Servers*.

     Note that you cannot start or stop a DNS or DHCP service on a specific Microsoft server if you disable the monitor and control setting for the respective service. You can control and monitor DNS and DHCP services at the Grid level and override the settings at the Microsoft server level. Each monitor and control setting applies only to the DNS or DHCP service and the respective Microsoft server.
   - **Synchronize Network Users**: Click **Override** to override the settings inherited from the Grid. To inherit the same settings as the Grid, click **Inherit**. Select this to enable the identity mapping for the Microsoft server. For information, see *Enabling Identity Mapping*.
     You can assign multiple Microsoft servers to a Grid member and test their connection to the Grid member. Click the Add icon to add another Microsoft server.

6. Select a Microsoft server and click the Test Microsoft Server icon, or click the Action icon ☰ next to the respective Microsoft server and select **Test Microsoft Server** from the menu to verify whether the appliance can successfully connect to the Microsoft server. The appliance displays the test results in the *Test Microsoft Server Results* dialog box.
7. Save the configuration and click **Restart** if it appears at the top of the screen.

   or

   Click **Next:** Continue to the next step and define extensible attributes for the Microsoft servers. For information, see *Managing Extensible Attributes*.

After you configure a Grid member to manage a Microsoft server, the member automatically connects to the Microsoft server and starts synchronizing data. You can then do the following:

- View the status of the servers in the *Microsoft Servers* panel, as described in *Monitoring Managed Microsoft Servers*. Newly added servers first display a status of **Connecting** as the Grid member contacts the Microsoft servers. The status changes to **OK** after the Grid member successfully connects to the Microsoft server.
- View the data synchronized from the Microsoft servers. To view DNS data, navigate to the DNS view you specified. For information, see *Viewing Zones*. To view DHCP data, navigate to the **Networks** tab of the network view that you specified. For information, see *Managing IPv4 DHCP Data*.

  Network conditions and the amount of data can affect the synchronization time. Therefore, you might not be able to view all of the synchronized data immediately.

- Use Smart Folders to organize the Microsoft servers and their data. For example, you can create a folder for DNS zones and another folder for DHCP scopes synchronized from a Microsoft server. For information about Smart Folders, see *Smart Folders*.
- Update the synchronized data. For information, see *Managing Microsoft DNS Services,* and *Managing Microsoft DHCP Services*.

You can also use Global Search to search for synchronized data, such as zones and IP addresses. For information, see *Using Global Search*.

Configuring Grid Properties for Managing Microsoft Servers

You can configure the following Grid properties for Microsoft servers that are managed by a Grid member:

- Monitor and control settings for DNS and DHCP services. For information, see Defining Monitor and Control Settings for DNS and DHCP Services below.
- Use the identity mapping feature to get visibility of user interaction with their environments. For information, see *Configuring Identity Mapping*.
- Output destination for Microsoft server log messages. For information, see Output Destination for Log Messages below.
- Simultaneous connections for Microsoft servers. For information, see Maximum Simultaneous Connections for Microsoft Servers below.
- Maximum connection timeout setting. For information, see Configuring RPC Timeout Settings below.
- Forward WINS packets to dedicated Microsoft Windows DNS and DHCP servers. For information see Forwarding WINS Packets to Microsoft Servers below.

For more information about configuring other Grid properties for Microsoft servers, see Setting Grid Properties for Managing Microsoft Servers below.

Defining Monitor and Control Settings for DNS and DHCP Services

You can enable or disable monitor and control settings of DNS and DHCP services for a specific Microsoft server. The appliance enables this by default when you add a Microsoft server. When you upgrade the existing Microsoft servers, the managed member inherits values from the Grid. You can monitor and control the DNS and DHCP services on a Microsoft service only if both the management setting of the respective service and the monitor and control settings of the corresponding Microsoft server for the selected service are enabled. To know more about how to enable monitor and control settings, see Setting Grid Properties for Managing Microsoft Servers below.

> **Note**
>
> The original setting that controls the overall management of a given service is referred to as the management setting. It controls whether the synchronization of the corresponding service is enabled or not, with no change to the existing synchronization behavior. Note that synchronization does not depend on the value of the monitor and control setting for the Microsoft server.

You can configure Microsoft server settings at the Grid level. Note that Microsoft servers inherit these settings by default, and you can override these settings at the Microsoft server level.

When you enable monitor and control settings for DNS and DHCP services, the managing member verifies the corresponding service status on the Microsoft server every 30 seconds. The Grid Master is notified of the status through Grid replication.

When you disable monitor and control setting for DNS and DHCP services, the managing member stops verifying the service status. NIOS administrators cannot start or stop DNS or DHCP service on the Microsoft server. When you try to start or stop these services through the Infoblox API, the appliance generates an error message. The pending service control requests made before disabling the monitor and control settings are sent to the Microsoft server.

For information about the displayed status, see *Viewing DNS and DHCP Service Status on Microsoft Servers*.

Synchronizing DNS Reporting Data

You can enable synchronization of DNS reporting data from the Microsoft server and view both NIOS and Microsoft services data in a single view in the supported DNS reports. This feature is enabled by default when you add a Microsoft server to the Grid. This feature is supported for Microsoft Windows 2012 R2 and Microsoft Windows 2016 versions, and you must disable this feature for all previous versions of Microsoft Windows servers. When you upgrade the Grid to NIOS 8.2 or later, this feature is disabled. For information about how to enable synchronization of DNS reporting data, see Setting Grid Properties for Managing Microsoft Servers below.

You can enable the synchronization of DNS reporting data at the Grid level. The Microsoft servers inherit these settings by default, and you can override these settings at the Microsoft server level. The synchronization of DNS reporting data is effective only if a valid Reporting license is installed on the Grid and when **DNS Sync** is enabled for the Microsoft server to synchronize the DNS data. For information about how to enable **DNS Sync**, see *Assigning Grid Members to Microsoft Servers*.

> **Note**
>
> You must enable DNS logging feature on the Microsoft server for this feature to function properly. To enable DNS logging feature on Microsoft servers, refer to *https://technet.microsoft.com/en-us/library/dn800669#some*.

When you enable the synchronization of DNS reporting data, the appliance performs the reporting data synchronization from the Microsoft server based on the specified time interval. The default synchronization interval is 15 seconds. You can change the synchronization interval using the CLI command `set ms_dns_reports_sync_interval`. For information, refer to the *Infoblox CLI Guide*. The collection of reporting data is dependent on the synchronization intervals set for the Microsoft server. Hence, there would be differences in the Microsoft services data updated in the reports as compared to the NIOS reporting data. Note that only events that are logged in the Microsoft event log are displayed in the Microsoft DNS reports. For a list of DNS reports that display data from both NIOS and the Microsoft server when this feature is enabled, see *Reports with Data Synchronized from Microsoft Servers*.

Microsoft provides enhanced DNS logging and diagnostics for Microsoft Windows Server 2012 R2 and later versions. This includes DNS analytic events logging which enables activity tracking on the DNS server. An analytic event is logged each time the server sends or receives DNS information. In order to install enhanced DNS logging and diagnostics feature in Microsoft Windows Server 2012 R2 and later versions, you must apply the query logging and change auditing hotfix. Click the following link to apply the query logging and change auditing hotfix: *https://support.microsoft.com/en-us/help/2956577/update-adds-query-logging-and-change-auditing-to-windows-dns-servers*.

Note that DNS analytic events logging is not enabled by default on Microsoft servers. To install and enable DNS analytic events logging feature on Microsoft servers, refer to *https://technet.microsoft.com/en-us/library/dn800669#some*.

Output Destination for Log Messages

You can configure an output destination for Microsoft server log messages at the Grid level and override it at the Microsoft server level. You can choose to save log messages related to Microsoft synchronization in the syslog or Microsoft log. For information, see *Viewing the Syslog*.
When you change the setting, the Grid Master notifies the managing member about the new setting through Grid replication and sends log messages to the selected destination. The new setting takes effect for synchronization only after the managing member is notified. The synchronization, which is already in progress continues to log messages to the destination based on the old setting. To know more about how to select output destination for log messages, see Setting Grid Properties for Managing Microsoft Servers below.

Maximum Simultaneous Connections for Microsoft Servers

You can specify a maximum number of simultaneous RPC connections that can be configured for the respective Microsoft server, which are managed by the Grid. You can override this value at the Microsoft server level. To know more about how to define maximum simultaneous connections for Microsoft servers, see Setting Grid Properties for Managing Microsoft Servers below.

> **Note**
>
> When you increase the maximum number of simultaneous connections above the recommended setting for a given Microsoft server, it may consume additional bandwidth, memory, and CPU usage.

Configuring RPC Timeout Settings

You can specify an RPC (Remote Procedure Call) timeout value to control network connectivity for Microsoft servers. You can configure an RPC timeout value at the Grid level and override it for each Microsoft server. The default value at the Grid level is ten seconds and the member inherits this value from the Grid. You can specify a value between one and 60 seconds. To know more about how to configure RPC timeout settings, see the next section, Setting Grid Properties for Managing Microsoft Servers.

Setting Grid Properties for Managing Microsoft Servers

To configure Grid properties for managing Microsoft servers, complete the following:

1. **Grid**: From the **Grid** tab -> **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**. Select **Microsoft Sync Settings** tab in the *Grid Properties Editor* wizard.
   Microsoft Server: From the **Grid** tab -> **Microsoft Servers** tab -> **Servers** tab, select a Microsoft server and click the **Edit** icon, or click the Action icon ☰ next to the respective Microsoft server and select **Edit** from the menu. In the Microsoft server editor, click the **General** tab.
   Standalone appliance: From the **System** tab -> **System Manager** tab, expand the Toolbar and click **System Properties** -> **Edit**.
2. Complete the following in the **Basic** tab:
   - **Logging output destination**: From the drop-down list, select an output destination to which the appliance saves log messages for Microsoft servers. When you select **Microsoft Log**, the appliance logs the messages that are generated for the respective Microsoft server in the existing Microsoft log. This is selected by default. For more information, see *Viewing Synchronization Logs*. When you select **Syslog**, NIOS logs the messages that are generated for the respective Microsoft server in the syslog. For more information about the syslog, see *Viewing the Syslog*. Click **Override** to select an output destination to save the log messages at the member level.
   - **Monitor DNS and DHCP Services**: You can enable monitoring and control services for DNS and DHCP services at the Grid level and override the settings for each service at the Microsoft server level. This is

enabled, by default. Each monitoring and control setting applies only to the corresponding service and is applicable to the respective Microsoft server only.
    - **Monitor and control DNS Services**: Select this to enable monitoring and the ability to control DNS service for the Microsoft server.
    - **Synchronize DNS Reporting Data**: Select this to synchronize DNS reporting data from the Microsoft server. Clearing this checkbox disables DNS reporting data synchronization.
    - **Monitor and control DHCP Services**: Select this to enable monitoring and the ability to control a DHCP service for the Microsoft server.
3. Optionally, select the **Microsoft Server Settings** tab in the *Grid Properties Editor* wizard and complete the following in the **Advanced** tab or click the **Advanced** tab in the **General** tab in a Microsoft server editor:
    - **Maximum simultaneous connections**: Specify a maximum number of simultaneous RPC connections that can be configured for the respective Microsoft server, which are managed by the Grid. The default is five. You can specify a value between two and 40.
      You can click **Override** at the member level to specify a new value. The **Override** button changes to **Inherit**. Click **Inherit** to inherit the value from the Grid.
    - **RPC timeout**: Specify the RPC timeout value in seconds to control the network communication timeout. The default is ten seconds. You can specify a value between one and 60.
      You can click **Override** at the member level to specify a new value. The **Override** button changes to **Inherit**. Click **Inherit** to inherit the value from the Grid.
4. Save the configuration.

Forwarding WINS Packets to Microsoft Servers

If your Infoblox Grid includes legacy Microsoft DNS and DHCP servers, you can configure NIOS to forward WINS packets to dedicated Microsoft servers. Infoblox provides the set wins_forwarding and show wins_forwarding CLI commands you can use to perform this task. For detailed information about these commands, see *Using the NIOS CLI*.
When you enable port redundancy in NIOS, the LAN1 and LAN2 ports are grouped into one logical interface. They share one IP address and appear as one interface to the network. If a link to one of the ports fails or is disabled, the appliance fails over to the other port, avoiding a service disruption. When you enable port redundancy, WINS packet forwarding is not supported on the LAN2 interface. You must use the LAN1 interface.

> **Note**
>
> Ensure that port 137 is not used for any services in your Grid; otherwise you will not be able to configure the appliance to forward WINS packets to Microsoft DNS and DHCP servers. Likewise, if you have enabled this feature, you will not be able to configure port 137 for any other services in your Grid.

Managing Microsoft Servers

After you configure Grid members to manage Microsoft servers, you can set certain properties and manage the servers as follows:

- Set server properties, as described in the next section, Setting Microsoft Server Properties.
- Change the managing member or the management mode, as described in Changing the Managing Member or Management Mode below.
- Back up the synchronized data, as described in Backing Up Synchronized Data below.
- Disable synchronization with a Microsoft server, as described in Disabling Synchronization below.
- Remove a Microsoft server, as described in Removing a Managed Microsoft Server below.

Setting Microsoft Server Properties

You can modify any of the Microsoft server properties you previously configured, except for the network view and DNS view. You can also set certain properties, including the logging level, extensible attributes, and administrative permissions. Extensible attributes and permissions apply to the data only when they are managed from Grid Manager. Extensible attributes and permissions are not synchronized to the Microsoft server.
To set the properties of a Microsoft server:

1. From the **Grid** tab, select the **Microsoft Servers** tab -> **Servers** tab, select a Microsoft server and click the Edit icon, or click the Action icon ☰ next to the respective Microsoft server and select **Edit** from the menu.
2. In the *Microsoft Server Properties* editor, you can set properties in the following tabs:
    - **General:** Modify the settings described in *Assigning Grid Members to Microsoft Servers*.
    - **Services (DNS/DHCP)**: Modify DNS and DHCP synchronization settings. For more information, see *Assigning Grid Members to Microsoft Servers*.
    - **Active Directory Domain/sites:** Modify Active Directory Site settings. For more information, see *Assigning Grid Members to Microsoft Servers*.
    - **Extensible Attributes**: Define extensible attributes for the server. For information, see *Managing Extensible Attributes*.
    - **Permissions:** Define administrative permissions that apply to the server. For information see *About Administrative Permissions*.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

You can edit the General and Logging properties of multiple Microsoft servers at the same time by selecting the Microsoft servers and clicking the Edit icon. When Grid Manager displays the *Microsoft Server Properties* editor, it displays the values that the Microsoft servers have in common. If a property has multiple values, it indicates this. You can then change any of the values and when you click **Save**, Grid Manager applies your changes to all the selected Microsoft servers.

Changing the Managing Member or Management Mode

You can change the managing member and the management mode of a Microsoft server.
If you change the managing member, the previous member aborts any ongoing synchronization, and the newly assigned member resumes the synchronization process.
Note that if you switch the managing member or change the management mode of a Microsoft server from Read/Write to Read-only, the Grid member reverts any changes that were made from Grid Manager since the last synchronization. For example, an admin adds a network and DHCP range for a scope. If another admin changes the management mode of the Microsoft server to Read-only before the next synchronization, the Grid member deletes the network and DHCP range at the next synchronization.
To change the member or management mode:

1. From the **Grid** tab, select the **Microsoft Servers** tab -> **Servers** tab, select a Microsoft server and click the Edit icon, or click the Action icon next to the respective Microsoft server and select **Edit** from the menu.
2. In the *Microsoft Server Properties* editor, select the **General** tab and do any of the following:
    - **Managing Member:** Click **Select Member** and select another Grid member.
    - **Manage Server(s) in:** Select either **Read-only** or **Read/Write**.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Backing Up Synchronized Data

When you back up the Grid, it includes all managed Microsoft data. If you restore a backup, the data is restored on the Grid only. It is not synchronized to the Microsoft servers. When the Grid member synchronizes the data after the restore operation, it overrides the data on the Grid with the data from the Microsoft servers. For information about backing up and restoring data, see *Backing Up and Restoring Configuration Files*.

Disabling Synchronization

When you set the disable option, the Grid member completes any on-going synchronization and does not start a new one. Setting this option only affects data synchronization and does not affect the operations of the Microsoft server. Synchronization resumes when the Microsoft server is re-enabled.
To disable a Microsoft server:

1. From the **Grid** tab, select the **Microsoft Servers** tab -> **Servers** tab, select a Microsoft server and click the Edit icon, or click the Action icon next to the respective Microsoft server and select **Edit** from the menu.
2. In the **General** tab, select the **Disable Synchronization** option.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Removing a Managed Microsoft Server

When you remove a Microsoft server from the Grid, the managing member stops any on-going synchronization and does not start a new one. If the Microsoft server served DNS, the synchronized DNS data remains unchanged in the Grid. If the Microsoft server served DHCP, then Grid Manager deletes all the DHCP ranges, leases, and fixed addresses associated with the server. It also deletes networks that were assigned only to the Microsoft server. It does not delete a network if it was assigned to other Microsoft servers as well.

Removing a managed Microsoft server from the Grid does not affect the operations of the Microsoft server.

To remove a managed server:

1. From the **Grid** tab, select the **Microsoft Servers** tab -> **Servers** tab, select a Microsoft server and click the Delete icon, or click the Action icon next to the respective Microsoft server and select **Delete** from the menu.
2. When the *Delete Confirmation* dialog box appears, click **Yes**.

For information about how removing a Microsoft server affects the synchronized DNS and DHCP data, see *Disabling and Removing Microsoft DNS Servers* and *Disabling and Removing Microsoft DHCP Servers*.

Configuring Active Directory Sites and Services

An Active Directory Site represents physical or logical sites that are defined on a Microsoft server. Each Active Directory Site is associated with an Active Directory Domain. A Microsoft administrator can associate multiple sites and networks with an Active Directory Domain. You cannot associate the same network with multiple Active Directory Sites. For more information about adding an Active Directory Site, see *Monitoring Managed Microsoft Servers*.
You can synchronize Active Directory Sites, along with the associated networks, from the Active Directory server. The networks that synchronize from the Active Directory server appears in NIOS as a network or a network container. The Active Directory Site to which the network belongs is displayed as an extensible attribute and associated with the respective network. For more information, see *Managing Extensible Attributes and Associated Networks*. When you create a new Active Directory Site on NIOS, the appliance synchronizes new Active Directory Sites and associated networks with the Active Directory server.
The appliance uses LDAP to communicate with the Microsoft server. For more information, see as described in *Configuring Microsoft Server and LDAP Connections*. You can specify a site link for a given Active Directory Site. For more information, see *Configuring Server Site Links*.
You can assign relevant permissions for Active Directory Domains at the Grid level, network view level, or at the object level. For more information, see Configuring and Managing Server Permissions below.
For more information on supported versions, see *Supported Windows Versions*.

Best Practices for Configuring Active Directory Sites and Services

- A Grid member configured to synchronize Active Directory Sites and networks of a Microsoft server uses system resources, CPU, memory, network, etc. The amount of consumed resources depends on the number of Microsoft servers that are managed by the Grid member, the amount of data for synchronization and the synchronization frequency. Infoblox recommends that the managing Grid member should not serve other protocols.
- The Grid Master might also be affected by the initial synchronization. The first synchronization replicates all Active Directory Sites and networks from the managing Grid member to the Grid Master.
- The Grid member always initiates the connection to the Microsoft server. Infoblox recommends that you use an encrypted LDAP connection between the Grid member and the Microsoft server. The appliance displays a warning message when you use a non-encrypted connection.
- During a scheduled full upgrade, the synchronization of a Microsoft server is deactivated until the managing Grid member completes its upgrade.
- Microsoft Windows 2003 does not support IPv6 networks. Hence, the appliance prevents you from performing the following operations on the NIOS appliance, which might result in a synchronization failure on the Microsoft server:
    - Assigning an Active Directory Site to an IPv6 network if the site belongs to an Active Directory Domain that is managed by a Windows 2003 server.

- Creating an IPv6 network from an IPv6 network template in which an Active Directory Site belonging to an Active Directory Domain managed by a Windows 2003 server is defined.
- Moving one or more IPv6 networks when the destination Active Directory Site belongs to an Active Directory Domain that is managed by a Windows 2003 server.

Synchronizing Active Directory Domains on a Domain Controller

The top level container in the Active Directory is called a Forest. Each forest can contain one or more Active Directory domains. All these domains share the same sites and networks. To avoid any inconsistency within NIOS, the appliance synchronizes only the root Active Directory domain of the forest into the Grid. For example, if the Microsoft server points to a domain controller of xyz.abc.com domain, the appliance synchronizes abc.com domain in NIOS.

An Active Directory user with the Domain User privilege (configured for synchronizing domains, sites, and their associated subnets) can read data from Active Directory and the same user with complete privileges on sites can write data from NIOS to Microsoft. However, these privileges are not enough to read deleted subnet associations of a site, when the delete operation occurs on the Microsoft server. For example. if you delete 10.x.x.0/24 from a Microsoft site and add 10.x.x.0/25 and 10.x.x.128/25 to the same site, after a synchronization, Grid Manager reflects all three subnets on the site.

NIOS performs incremental LDAP queries to search for the `uSNChanged` attribute on objects. This fetches the newly added or modified objects but does not fetch deleted objects. To find these objects, a query must be run against the Deleted Objects container. Only users with the Domain Admin privilege can read from the Deleted Objects container using LDAP queries.

Configuring and Managing Server Permissions

You can define permissions for Active Directory Sites on both the NIOS and Microsoft servers, but there is no relationship between these two sets of permissions and they are not synchronized. You must have relevant permissions on the Microsoft server to synchronize an Active Directory server. If you do not have permissions, the operation fails and the appliance logs the message into the Microsoft log. The synchronization process fails until appropriate permissions are granted.
On the Active Directory Sites, make sure that you set the following permissions in the *Permission Entry for Sites* dialog box:

- In the **Permissions** section, select all the checkboxes.
- In the **Properties** section, select the **Read All Properties** and **Write All Properties** checkboxes.

An administrator can define relevant permissions on the Active Directory Site and associated networks to prevent them from accidental deletion. However, you can modify such Active Directory Sites and networks. For example, you can rename an Active Directory Site.
You can define permissions for an Active Directory Domain at the following levels:

- Grid level: When you assign Grid level permission, it is applicable to the objects that are associated with the Active Directory Domains that you have defined. When you assign Grid permissions, you can assign either **Read/Write**, **Read-only**, or **Deny** permissions for **All Active Directory Domains** resource. For more information about how to define Grid level permission, see *Defining Global Permissions*.
- Network view level: When you assign permission at the network view level, the permission is applicable to all the Active Directory Domains within the selected network view. For more information, see *Administrative Permissions for Network Views*.
- Permission on the Active Directory Domain. For more information, see *Defining Object Permissions*.

You must have the following permissions on the Active Directory Domain to perform the relevant operations:

- Read-only permission on the Active Directory Domain to view the Active Directory Domain and associated Sites.
- Read/Write permission on the Active Directory Domain to add, update or delete an associated Active Directory Site.
- Read/Write permission on the Active Directory Domain to associate or dissociate an Active Directory Site from or to the network.

- Note that the **All Active Directory Domains** permission will only support two modes: **Read-Only** and **Read/Write**. If you do not define permissions explicitly, the appliance sets Read-only permission for Active Directory Domains and Sites.
- Note that the extensible attributes are used to represent Active Directory Domains and Sites. As extensible attributes are generic and they do not support permissions, you can always retrieve Active Directory Domains and Sites for a given network if you have Read-only permission.

Configuring Active Directory Sites and Associated Networks

An Active Directory Domain is a collection of Active Directory Sites and associated networks. Each Active Directory Site can have multiple networks associated with it. The synchronization process ignores a network which is not assigned to an Active Directory Site. You can create and modify Active Directory Sites and networks on the NIOS appliance.
You can use Active Directory Sites and services to synchronize sites and networks from the Active Directory server. After synchronization, the appliance displays these as networks or network containers in the appliance.
The Active Directory Sites that are associated with a network are displayed as extensible attributes, which is a combination of the Active Directory Domain and Site name, for the respective networks on the appliance.
To add Active Directory Sites, you must have Read/Write permission on the respective Active Directory Domain with which it is associated. For more information about permissions, see *Configuring and Managing Server Permissions*.

To create Active Directory Sites and associate networks:

1. From the **Grid** tab, select the **Microsoft Servers** tab -> **Active Directory Domains** tab and click the respective Active Directory Domain name.
2. Click the Add icon in the *New Active Directory sites* wizard and specify a name for the Active Directory Site. You can associate multiple sites with an Active Directory Domain.

   Note

   You can specify a name up to 63 bytes and it is not case-sensitive, but it cannot contain spaces and the following special characters: | { } ~ [ ] ' : ; < > = ? @ ! " # $ % ^ & ` ( ) + / \ , * .

   You can select an Active Directory Site and click the Delete icon to delete it.
3. Click **Next** to associate networks with an Active Directory Site. Select an Active Directory Site and click the Add icon to associate networks with the respective site.
4. Click **Cancel** to close the wizard without saving your settings. You can click **Save and Close** to save the settings and close the wizard or click **Save and Edit** to save the settings and edit the properties. The application will close the wizard and open the *Active Directory Site Properties* editor. Click **Save and New** to save the Active Directory Sites in the list and open a new wizard.

Managing Active Directory Sites

You can manage Active Directory Sites and networks that you defined earlier and modify their information. You can do the following:

- View Active Directory Domains and sites, as described in Viewing Active Directory Domains and Sites.
- Modify Active Directory Sites and networks, as described in *Monitoring Managed Microsoft Servers*.
- Delete Active Directory Sites. For more information, see Associating Active Directory Sites with Networks below.
- Move networks that are associated with an Active Directory Site to another. For more information, see Moving Networks Between Active Directory Sites below.

Viewing Active Directory Domains and Sites

You can view Active Directory Domains that are associated with the Microsoft server. You can also view Active Directory Sites and networks that are associated with the Active Directory Domains.
To view Active Directory Domains and sites:

1. From the **Grid** tab, select the **Microsoft Servers** tab -> **Active Directory Domains** tab.

2. Grid Manager displays the following information:
    - **Name**: The name of the Active Directory Domain. You can click the name to view the Active Directory Sites below it.
    - **NetBIOS Name**: The name returned in the NetBIOS format.
    - **MS Sync Server**: The Microsoft synchronization server that is associated with the Active Directory Domain.
    - **Network View**: The network view that is associated with the Active Directory Domain.

    You can do the following in the **Active Directory Domains** tab:
        - Sort the Active Directory Domains in ascending or descending order by column.
        - Use filters and the search function to look for specific values.
        - Export and print the information in the table.
3. To view Active Directory Sites associated with an Active Directory Domain, click the domain name that is displayed as a hyperlink. The appliance displays the list of Active Directory Sites that are associated with the respective Active Directory Domain in the **Active Directory Domains Home** table.

You can do the following in the **Active Directory Domains Home** table:

- Sort the Active Directory Sites in ascending or descending order by column.
- Use filters and the search function to look for specific values.
- Export and print the information in the table.

Modifying Active Directory Sites and Networks

You can edit the name of an Active Directory Site and associate networks with the respective site. You can also add additional networks or remove associated networks from the Active Directory Site.
To edit an Active Directory Site:

1. From the **Grid** tab, select the **Microsoft Servers** tab -> **Active Directory Domains** tab and click respective Active Directory Domain name.
2. In the **Active Directory Domains Home** table, select an Active Directory Site name and click the Edit icon, or click the Action icon ☰ next to the respective Active Directory Site name and select **Edit** from the menu.
3. In the *Active Directory Site Properties* editor, you can do the following:
    - **Name**: The name of the Active Directory Site. You can edit the name.
    - **Networks**: The networks that are associated with the Active Directory Site. You can click the Add icon to associate new networks with the Active Directory Site.

      To delete an associated network, select the checkbox adjacent to the network address, and click the Delete icon.
4. You can either click **Save and Close** or **Save** to save your settings. Click **Cancel** to close the editor without saving your settings.

Deleting Active Directory Sites

You can delete Active Directory Sites that are associated with an Active Directory Domain. You cannot delete an Active Directory Site from the Active Directory Domain if the respective Active Directory Site has networks associated with it. You must first delete the associated networks to delete an Active Directory Site.
To delete Active Directory Sites:

1. From the **Grid** tab, select the **Microsoft Servers** tab -> **Active Directory Domains** tab and click the respective Active Directory Domain name.
2. In the **Active Directory Domains Home** table, select an Active Directory Site and click the Delete icon, or click the Action icon next to the respective Active Directory Site name and select **Delete** from the menu.
3. The appliance displays a confirmation message. Click **Yes** to delete the sites or click **No** to cancel the operation.

Moving Networks Between Active Directory Sites

You can move networks from an Active Directory Site to another using either the **Microsoft Servers** or the **IPAM tab**. You can use the **Microsoft Servers** tab to move networks only when you select an Active Directory Site.
You can add multiple networks from various Active Directory Sites and move them simultaneously to an Active Directory Site. When the Active Directory Site synchronizes, it always maps to a certain network view. You can only select

networks from a network view to which the Active Directory Domain belongs.
To move networks within Active Directory Sites, complete the following:

1. **Microsoft Servers tab**: From the **Grid** tab, select the **Microsoft Servers** tab -> **Active Directory Domains** tab and click respective Active Directory Domain name. In the **Active Directory Domains Home** table, click the Action icon next to the respective Active Directory Site name and select **Move Networks** from the menu.
   OR
   IPAM tab: From the **Data Management** tab, select the **IPAM** tab, select networks that you want to move and click **Move Networks** from the Toolbar.
2. In the *Move Networks* wizard, complete the following:
   - **Destination Active Directory Site**: Click **Select Site** to select the destination Active Directory Site. The appliance displays the *Microsoft Sites Selector* dialog box listing all the Active Directory sites in the Grid. It also displays the smart folders, if any. You can use the filter and **Go to** functions to find a specific Active Directory site. To select an Active Directory site, click the site name.
   - **Networks**: You can select networks that you want to move to another Active Directory Site.
     - **Go to**: Specify an IP address of the network that you want to move to another destination and click **Go**.
     - Click the Add icon to add networks. To delete a network from the list, select the checkbox next to the network and click the Delete icon.
3. Click **Move** to move networks or click **Close** to exit.

Moving Multiple Networks to an Active Directory Site

You can move multiple networks to a given Active Directory Site in a single operation. The following rules are applicable:

- Only a super-user can move multiple networks to an Active Directory Site.
- The destination site must belong to an Active Directory Domain that is synchronized in Read/Write mode.
- The appliance assigns the destination Active Directory Site to a network in either of the following cases:
  - If the network is currently assigned to another Active Directory Site within the same Active Directory Domain.
  - If the network is currently not assigned to any Active Directory Site within the Active Directory Domain.
  - The Active Directory Sites associated with an Active Directory Domain is different from the destination Active Directory Site.

Associating Active Directory Sites with Networks

You can associate an Active Directory Site with an IPv4 or IPv6 network or an IPv4 and IPv6 network template. The appliance does not check the synchronization mode of the associated Active Directory Domain when you create or modify a template, but it verifies only when you use the template to create a network.
To assign Active Directory Sites to networks, complete the following:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab.
2. In the **Networks** section, select either **IPv4 Network** or **IPv6 Network** from the **Add** drop-down menu and complete the details as mentioned in *Adding IPv4 Networks* and *Adding IPv6 Networks* respectively, and complete the following to assign Active Directory Sites to networks:
   - **No Active Directory Site**: Select this if you do not want to associate an Active Directory Site with the network.
   - **Assign these Active Directory Domains/sites**: Select this to assign multiple Active Directory Sites to a network, but note that each Active Directory Site must be associated with a different domain. You cannot add an Active Directory Site, if you have already assigned a domain from the same Active Directory Site. When you select this option, the appliance enables the following:
     - **Active Directory Domain**: The Active Directory Domains that are synchronized from the Microsoft server. Click an Active Directory Domain that you want to associate.
       To search for a particular Active Directory Domain, specify the respective name and click **Go**.
     - **Active Directory Sites**: The Active Directory Sites that are associated with the selected Active Directory Domain. Click an Active Directory Site that you want to associate.
       To search for a particular Active Directory Site, specify the respective name and click **Go**.
     - **Add >**: Click this to add the selected Active Directory Sites to the network.

        - **<Remove**: Click this to remove an Active Directory Site, which you have already added, from the network.
        - **<<Remove all**: Click this to remove Active Directory Sites, which you have already added, from the list.
    - **Assign the same domains/sites as the selected network**: Click **Select Network** to assign Active Directory Sites, which are associated with the selected network, to the new network that you are configuring. Select a network from the *Network Selector* dialog box. The appliance displays the Active Directory Domains and Sites that are associated with the selected network, but you cannot make any changes and the fields are greyed out. Click **Clear** to clear the entry.
3. You can either click **Save and Close** to save the settings and close the wizard or click **Save and New** to save your settings and open a new wizard or click **Cancel** to close the wizard without saving your settings.

Managing Extensible Attributes and Associated Networks

The appliance creates an extensible attribute for each Active Directory Domain that is synchronized with the Grid. Note the following about extensible attributes:

- The appliance generates a name for the extensible attribute. The appliance displays an error message if you have already created an extensible attribute with the same name.
- Extensible attributes are Read-only and does not support inheritance.
- You can define a single value only and there are no default values.
- The appliance restricts an extensible attribute to IPv4 network and IPv6 network objects.
- You can specify a value for each extensible attribute and it is optional.

Configuring Microsoft Server and LDAP Connections

Active Directory is a distributed directory service that authenticates network users. Active Directory uses LDAP (Lightweight Directory Access Protocol) to access other network services. This protocol is also used when an Active Directory Service entry is configured under Authentication Server Groups. For an Active Directory, the Grid member uses LDAP to communicate with the Microsoft server. Note that the managed Microsoft server must be a part of an Active Directory Domain and it must be a domain controller for the respective domain. The appliance logs an error message in the Microsoft log each time the synchronization happens if the Microsoft server is not a part of the Active Directory Domain or if it is not the domain controller for the respective domain. You can define an LDAP timeout value at the Grid level and override it at the Microsoft server level.
To configure LDAP timeout settings, complete the following:

1. **Grid**: From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar. Select the **Microsoft Sync Settings** tab in the *Grid Properties Editor* wizard and click the **Advanced** tab.
   Microsoft Server: From the **Grid** tab -> **Microsoft Servers** tab -> **Servers** tab, select a **Microsoft server** and click the Edit icon. In the Microsoft server editor, select the **General** tab and click the **Advanced** tab.
2. Complete the following:
    - **LDAP timeout**: Specify the LDAP connection timeout value. The default is 10 seconds. You can specify a value between one and 60 seconds.
      You can click **Override** to override the LDAP timeout value at the Microsoft server level. To inherit the settings from the Grid, click **Inherit**.
3. Save the configuration.

Configuring Server Site Links

You must choose a site link when you create an Active Directory Site on the Microsoft server. The site link describes how the replication occurs between the sites and the protocol, either IP (Internet Protocol) or SMTP (Simple Mail Transfer Protocol), which is used for communication.
The appliance uses the default object DEFAULTIPSITELINK when you create an Active Directory Site from the NIOS appliance. If you want to change the site link for a given Active Directory Site, which is already created, you must create the Active Directory Site on the Microsoft server or modify it on the Microsoft server after you create it using the NIOS appliance.
You must first configure site links on the Microsoft server. When you create Active Directory sites, the appliance automatically associates them with the default IP site link. The value that you specify for default IP site link must exist on the Microsoft server. Note that the appliance does not display any error message when you create a site with a site link

that does not exist on the Microsoft server.
To configure server site links, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar.
   Microsoft Server: From the **Grid** tab -> **Microsoft Servers** tab -> **Servers** tab, select a **Microsoft server** and click the Edit icon. In the Microsoft server editor, select the **General** tab and click the **Advanced** tab.
2. Select the **Microsoft Sync Settings** tab in the *Grid Properties Editor* wizard and complete the following in the **Advanced** tab:
   - **Default IP site link**: Specify the default IP site link in the form of a string. The appliance does not validate it against the Windows server during configuration. The appliance displays an error message during synchronization, if the site link for IP does not match the configured name on the Windows server.
     You can click **Override** to override the default IP site link value at the Microsoft server level. To inherit the settings from the Grid, click **Inherit**.
3. Save the configuration.

Managing Active Directory Sites and Associated Networks

You can manage Active Directory Sites and networks using either the Microsoft servers or the NIOS appliance.

Managing an Active Directory Site from the Microsoft server

You can create, modify, or delete an Active Directory Site from the Microsoft server in both Read-only and Read/Write synchronization modes. When you create an Active Directory Site from the Microsoft server, it is created on the NIOS appliance. This site appears as an Active Directory Site under the corresponding Active Directory Domain and in the respective extensible attribute.
When you make changes on the Microsoft server, the synchronization process ignores any other modifications that you make, but replicates only the name changes to the Grid. When you rename an Active Directory Site, the change reflects:

- in the Active Directory Site and in the respective extensible attribute.
- on all the networks that are associated with the Active Directory Site.

When you delete an Active Directory Site from the Microsoft server, it deletes the Active Directory Site object and removes corresponding extensible attributes. The appliance removes the value from all the network objects that are associated with it.

Managing an Active Directory Site from NIOS

You can create, modify, or delete an Active Directory Site from the appliance in Read/Write synchronization mode only. The appliance displays an error message if you perform any of these operations in Read-only mode.
When you rename an Active Directory Site and the associated networks, the changes reflect on the Microsoft server. The appliance displays an error message when you delete an Active Directory Site that is associated with networks. You must first remove the networks that are associated with the site.
You cannot resize or split a network with an associated site in Read-only synchronization mode. You cannot join two networks if any of the involved networks or network containers are associated with a site irrespective of the synchronization mode.

Managing Network Operations from Microsoft server

Note that you can perform network operations, such as create, modify or edit networks, in both Read-only and Read/Write synchronization modes. When you create a network, the synchronization process ignores the network if it is not assigned to a Active Directory Site. When the network is attached to the site, the appliance finds a matching network or network container in the configured network view. If it does not exist, the appliance creates a new network or a network container depending on the objects existing in the database. The new network or network container is set as unmanaged and a new extensible attribute is attached to the object to store the site.
Note the following about managing networks:

- When you update a site that is associated with a network, the change is visible on the corresponding network or network container.

- Synchronization process ignores the changes when you update a network. Note that it does not ignore the changes when you modify the Active Directory Site or change an IP address or a CIDR.
- When you delete a network, the appliance removes the extensible attribute that is representing the associated site from the corresponding network or network container.
- If the status is set as managed, it indicates that the network is used for another purpose inside the Grid. The appliance does not remove it from the Grid.
- If the status is set as unmanaged, the appliance deletes the network if there is no other site coming from another Active Directory Domain, which is associated with the network. Otherwise the appliance does not remove the network from the Grid.

Converting Unmanaged Networks to Managed Status

When you synchronize a network from the Active Directory server, the network created in NIOS is considered to be unmanaged. You can neither associate a NIOS member or a Microsoft server to manage it nor edit permissions, and other fields. You can only edit extensible attributes and Active Directory sites on the unmanaged network. To perform certain operations on Unmanaged networks, you must first convert them to Managed networks.
The IPAM main page lists all networks that are created during Active Directory synchronization as unmanaged, highlighted in yellow. You can explore unmanaged networks through IPAM's **IP Map** and **IP List** views.
Unmanaged networks can be converted at the IPAM main page and at the device level under **Data Management –> Devices**, selecting a device and opening the **Networks** page.

Managing Network Operations from NIOS

The appliance denies the operation when you create a network, which is associated with a site, if the respective site belongs to an Active Directory Domain that is synchronized in Read-only mode. Otherwise the appliance creates it on the Microsoft server that is associated with the respective site.

Restoring Server Data

When you restore a database backup, the appliance performs the following operations after the standard restore procedure is complete:

- The appliance deletes the cached data that is used for synchronization.
- Synchronization for all configured Microsoft servers starts in Read-only mode. Note that these rules are applicable during upgrade also.

Configuring Identity Mapping

You can enable Identity Mapping on the NIOS appliance to provide Active Directory domain user information if the NIOS appliance is connected to a Microsoft server. This feature supports Active Directory domains whose domain controller is running the supported Windows server. For more information on supported windows versions, see *Supported Windows Versions*.
Note that Identity Mapping is not supported for the Windows 2003 server and earlier editions. Note that Identity Mapping is not supported on the IB-VM-810 and IB-VM-820 appliances.
Each network user being mapped can use different devices to access the Windows environment. So using the identity mapping feature and synchronizing all Microsoft servers on the Infoblox appliance provide visibility of user interaction with their environments. By enabling this feature, you can monitor Active Directory domain users, the IP addresses they log on to, the login status, and the time duration of their current status in the **IPAM** tab.
To view user information, you must first enable this feature at the Grid level. You can enable this feature even when you have not installed an **MS Management** license on the appliance. However, you cannot configure DNS, DHCP, and Active Directory sites synchronization unless you install an **MS Management** license on the appliance.
When you enable this feature, the appliance remotely communicates with all synchronized Microsoft servers (Domain Controllers, an Exchange server, or a domain member) to pull event logs. The identity mapping information displayed is as accurate as these event logs are available in the Microsoft authentication logs. Therefore, it is necessary to assign Grid members to Microsoft servers to collect user information from Windows event logs. For information, see *Assigning Grid Members to Microsoft Servers*.

> **Note**
>
> The identity mapping information displayed on NIOS completely depends on live event logs that are available on the Microsoft servers. The appliance pulls event logs incrementally. So subsequent requests pull only the latest logs since the last successful synchronization. To avoid data loss, depending on the expected activities, you must consider the size of the event log file on the Microsoft server and how often you want to synchronize the data with the appliance before the event log file rolls over.

Prerequisites on the Microsoft Server

You must enable event logs on the Microsoft server for the Identity Mapping feature to function properly. To enable event logging on Microsoft servers, refer to *https://technet.microsoft.com/en-us/library/dd941595%28v=ws.10%29.aspx*.
The identity mapping information is collected successfully only when the Microsoft users belonging to a Domain User group and Event Log Reader group start a RPC session and access MS-EVEN6. The synchronization process is successful when they have this permission. The synchronization process fails unless appropriate permissions are granted. The failed operations are logged in the Microsoft logs. The NIOS appliance tries to collect user information again in the next synchronization.

Administrative Permissions

Only superusers can view identity mapping information. Limited-access admin groups can view identity mapping information only if they have network permissions. For example, if the users have permissions to only DNS zones, they may not be able to view identity mapping information because they do not have network permissions. The appliance does not display a warning message if admins do not have correct permissions. For information about network permissions, see *Administrative Permissions for IPv4 and IPv6 Networks and Shared Networks.*

About User Sessions

A user session is an abstract concept to specify a single user logging with a network address for a finite period of time. A user session starts when a Kerberos account authentication event or login event is received and ends when a logout is received, although such an event may never be received. In such cases, a session is considered to be timed out. Network user associations are unique for a finite period of time. A single login involves a number of login and logout events. In order to consolidate and improve system performance, Infoblox uses the concept of consolidation window. If a login event or Kerberos service ticket is received within the consolidation window, then that session is considered as an extension from the previous session. If a login event is received outside this window, it is considered as a new session. The number of network users you see depends on the length of the consolidation window.
For example, consider the following sample events occurred on the Microsoft server when the consolidation window is set to 10 minutes:

```
Kerberos Authentication Request: 10:00:00
Kerberos Service Ticket Request: 10:00:01
Account Logon: 10:00:02
Account Logoff: 10:00:03
Account Logon: 10:00:05
Account Logoff: 10:00:07
Account Logon: 10:00:10
Account Logoff: 10:00:11
```

The sample user session for the above events:

User Name	IP Address	First Seen Time (UTC)	Last Seen Time (UTC)
John	10.10.10.10	10:00:00 AM (UTC)	10:00:11 AM (UTC)

If another login request is received at 10:30 AM (10 minutes after the last seen event), then it is considered as a different session:

User Name	IP Address	First Seen Time (UTC)	Last Seen Time (UTC)
John	10.10.10.10	10:00:00 AM (UTC)	10:00:11 AM (UTC)
John	10.10.10.10	10:30:00 AM (UTC)	

If a Kerberos service ticket is received instead of a login event, then the previous session is extended and is updated as **Last Seen Time** in the first user session.

User Name	IP Address	First Seen Time (UTC)	Last Seen Time (UTC)
John	10.10.10.10	10:00:00 AM (UTC)	10:30:00 AM (UTC)

The appliance displays separate entries (counts) for the following scenarios:

- Multiple users logging in from the same IP address. For example, User 1 logged in with 10.10.10.10 address counts as one network user and User 2 logged in with 10.10.10.10 address counts as another network user.
- Same user logging in from multiple IP addresses. For example, a single user can log in to multiple workstations, each with a different IP address.
- Same user logging from the same IP address at different time intervals.

Network User Count Displayed for Different Login Scenarios

If you are configuring multiple Domain Controllers belonging to different organizations, then you must configure them in different network views. For example, if the same user logs in to multiple Domain Controllers with the same IP, it creates multiple entries for each login. In this case, there is a chance of overwriting an entry by subsequent events. If Domain Controllers are configured in different views, then separate entries are displayed for different network views. You can configure multiple Domain Controllers within the same network view if they serve the same organization, possibly using a load balancing method.

> **Note**
>
> The appliance displays user information only for the managed networks.

The following table illustrates how the appliance displays counts for different login scenarios:
Network User Count Displayed for Different Login Scenarios

Login Scenarios	Appliance Displaying User Mapping Information
Mobile user logging in to the Microsoft Exchange server	Note that you must first synchronize both the Domain Controller and Microsoft Exchange server with the appliance to get user mapping information for this scenario. For this example, two entries are displayed. 1. User name and IP address of the Microsoft Exchange server on the Domain Controller. 2. User name and IP address of the mobile device on the Microsoft Exchange server.
Multiple users from the same IP address	Appliance displays separate entry (user name and IP address) for each user.
Same user from multiple IP address	Appliance displays separate entry (user name and IP address) for each user.

Login and Logout Timestamps

Note that all timestamps are displayed in the time zone of the admin account that you use to log in to the appliance. There is a possibility of missing the login and logout events as described in the following cases:

- There is a chance of missing a login event when NIOS retrieves event logs from the Microsoft server after a user logs in and the event log has already rolled over.
- There is a possibility of missing a logout or session end notifications when the user shuts down the workstation or leaves the system. In such cases, the Microsoft event log does not specifically indicate a logout. The logout events that are missed on the Domain Controller or Exchange server are missed on NIOS as well.

To maintain accuracy, the login timestamp is estimated as logout timestamp minus (-) the idle timeout. However, when a login or Kerberos Authentication event is received, the login timestamp is updated to the value available in the Kerberos authentication event or the login event.
To maintain accuracy of the logout time data, the appliance allows you to configure the length of idle time in the *Grid Properties Editor* wizard. After this time interval, the status of the user changes to **Timed Out**. For information about how to set timeout length, see *Configuring Active User Timeout Session*.

> **Note**
>
> The **Timed Out** and **Logged Out** user information is periodically removed from the database.

Viewing Active Directory User Information

To view Active Directory user information, you must first enable identity mapping feature at the Grid level. For information about enabling Identity Mapping feature, see *Enabling Identity Mapping*. After you enable the identity mapping feature, you must synchronize the appliance with all Microsoft servers in order for the appliance to gather user and device mapping information from the Microsoft servers. You can view Active Directory user information in the **Network Users** tab. For more information, see *Viewing Active Network Users*.
To synchronize the appliance with Microsoft servers:

1. From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar.
2. Select the **Microsoft Integration** tab in the *Grid Properties Editor* wizard, and complete the following:
   - **Synchronize Network Users with all MS servers**: Select this checkbox to synchronize users with all Microsoft servers that are managed by the Grid in order for the appliance to gather user and device mapping information from the Microsoft server authentication logs. You can override this value at the Microsoft server level.

> **Note**

On an Infoblox appliance,
the **Enable Network Users Feature** and **Synchronize Network Users with all MS servers** options are disabled by default for all new installations.

3. Save the configuration.

Monitoring Managed Microsoft Servers

You can monitor the status of managed Microsoft servers from the Dashboard and from various panels in the **Grid** tab. Grid Manager also maintains a log for each managed Microsoft server. You can monitor Microsoft servers and their services as follows:

- You can view the *Microsoft Servers Status* widget on the Dashboard. For information, see *Microsoft Servers Status Widget*.
- You can view the status of Microsoft servers. For information, see Viewing DNS and DHCP Service Status on Microsoft Servers below.
- You can view the logs of the Microsoft servers. For information, see Viewing Synchronization Logs below.

Viewing DNS and DHCP Service Status on Microsoft Servers

Each Microsoft server reports the following statuses:

- **Service status** (**DNS** and **DHCP**): Displays the status of the service on the actual Microsoft server, based on the latest polling of the service by the managing member. The monitor and control setting has an effect only on the service status, and therefore can affect the overall status.
- **Overall status:** Displays the service status for each service that is enabled for synchronization with the Microsoft server. The overall status ignores any service status for which the monitor and control setting is disabled.
- **Synchronization status:** Displays the synchronization status for each service that is enabled for synchronization on the respective Microsoft server. The synchronization status is not affected by the monitor and control setting.

> ⚠ **Note**
>
> When you disable monitor and control settings, Grid Manager displays **unknown** using gray color for such services. When you enable monitor and control setting of a given service, Grid Manager displays the last known status that is obtained before the setting was first disabled. The appliance later updates to the latest status as soon as the monitoring resumes and Grid Manager displays the new status.

You can view details about the managed Microsoft servers by navigating to the **Grid** tab -> **Microsoft Servers** tab -> **Servers** tab. For each Microsoft server, the panel displays the following by default:

- **Name:** The FQDN of the Microsoft server.
- **Status:** The connection status, which can be one of the following:
  - **Running:** The Grid member is connected to the Microsoft server.
  - **Connecting:** The Grid member is connecting to the Microsoft server.
  - **Error:** The Grid member failed to connect to the Microsoft server. Check the Microsoft log for any messages to determine the reason for the failure.
  - **Unknown:** The Microsoft server is disabled. The Grid member does not try to connect to disabled servers.
- **IP Address:** The IP address of the Microsoft server.
- **DNS:** The status of the DNS service on the Microsoft server. When you disable DNS synchronization, NIOS does not display any status icon. The status icon can be one of the following:

Icon	Color	Meaning
	Green	The DNS service is functioning properly.
	Red	The Microsoft server is unavailable.
	Yellow	The DNS service is starting or stopping.
	Gray	The DNS service is stopped or management of the Microsoft DNS server is disabled.

- **DHCP:** The status of the DHCP service on the Microsoft server. When you disable DHCP synchronization, NIOS does not display any status icon. The status icon can be one of the following:

Icon	Color	Meaning
	Green	The DHCP service is functioning properly.
	Red	The Microsoft server is unavailable.
	Yellow	The DHCP service is starting or stopping.
	Gray	The DHCP service is stopped or management of the Microsoft DHCP server is disabled.

- **Comment:** Displays any comments that were entered for the Microsoft server.
- **Site:** Displays any values that were entered for this pre-defined attribute. You can add the following columns for display:
- **Version:** The Windows version of the managed server.
- **Managing Member:** The hostname of the Grid member that manages the server.
- **Synchronization Status:** Displays the synchronization status as follows:
    - **Running:** The Microsoft server is synchronizing data with the Grid member.
    - **Connecting**: The Grid member is trying to connect to the server.
    - **Error:** Synchronization failed between the member and server. You can check the messages in the Microsoft server log to determine the reason for the failure.

- **Last Changed:** Displays information about when the status was last updated for Microsoft DNS and DHCP services. It corresponds to the last time information was exchanged with the server.
- **AD Domain:** Displays the AD domain of the Windows server. This is displayed only if the Windows server belongs to an Active Directory domain.
- **Root AD Domain:** Displays the root AD domain of the Windows server. This is displayed only if the Windows server belongs to an Active Directory domain.

You can also do the following:

- Add Microsoft servers.
    - Click the Add icon.
- Edit the properties of a Microsoft server.
    - Click the checkbox beside a server and click the Edit icon, or click the Action icon ☰ next to the respective Microsoft server and select **Edit** from the menu. For information, see *Setting Microsoft DHCP Server Properties*.
- Delete a Microsoft server.
    - Click the checkbox beside a server and click the Delete icon, or click the Action icon next to the respective Microsoft server and select **Delete** from the menu. For information, see *Removing a Managed Microsoft Server*.
- Manage DNS and DHCP services of a Microsoft server.
    - Click the checkbox beside a server and click the Manage Server Services icon, or click the Action icon next to the respective Microsoft server and select **Manage Server Services** from the menu to view the service status. You can mouse over the DNS and DHCP service icons and click the Start/Stop service icon to start or stop a service, or click the Edit Service icon to edit the service properties. For information about setting DHCP server properties, see *Setting Microsoft DHCP Server Properties*. For information about setting DNS server properties, see *Specifying Forwarders for Microsoft Servers*.
- View detailed server status information, as described in the next section Viewing Detailed Status Information.
- Click **Test MS Server** to test the Microsoft server connection. The appliance validates the Microsoft server and displays the test code and the test result data for services that you have enabled. To test the Microsoft server, click the checkbox beside a server and click the Test Microsoft Server icon, or click the Action icon next to the respective Microsoft server and select **Test Microsoft Server** from the menu. For more information, see *Assigning Grid Members to Microsoft Servers*.
- View extensible attributes associated with the Microsoft server.
  Click the Action icon next to the respective Microsoft server and select **Extensible Attributes** from the menu. For information, see *Assigning Grid Members to Microsoft Servers*.
- Define permissions for Microsoft servers.
  Click the Action icon next to the respective Microsoft server and select **Permissions** from the menu.
- Use filters and the **Go To** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Sort the displayed data in ascending or descending order by column.
- Export the list of Microsoft servers to a .csv file.
    - Click the Export icon.
- Print the list of Microsoft servers.
    - Click the Print icon.

Viewing Detailed Status Information

You can view more status information by selecting a server from the Microsoft servers panel and clicking the Action icon next to the respective Microsoft server and selecting **Detailed Status** from the menu or clicking the Detailed Status icon. The **Detailed Status** panel displays the following information:

- **Synchronization Status**: The status icon indicates the synchronization status as follows:
    - Green: The Microsoft server is synchronizing data with the Grid member.
    - Red: Synchronization failed between the member and server. You can check the messages in the Microsoft server log to determine the reason for the failure.
- **DNS Service Status**: For information about the status icons, see Viewing DNS and DHCP Service Status on Microsoft Servers above.

- **DNS Service Status Last Updated**: The date and time of the last DNS service status update from the Microsoft DNS server.
- **DHCP Service Status**: For information about the status icons, see Viewing DNS and DHCP Service Status on Microsoft Servers above.
- **DHCP Service Status Last Updated**: The date and time of the last DHCP service status update from the Microsoft DHCP server.
- **Active Directory Sync Status**: The Active Directory Site is synchronizing data with the Grid member when the status icon is green.
- **Active Directory sync status last updated**: The date and time of the last Active Directory Site update from the Microsoft server.

Note the following guidelines about status information:

- Grid Manager does not display any status information if there is no synchronization between DHCP and DNS.
- If the appliance has not received any information when the services are enabled, then the Synchronization Status icon is displayed in red, whereas the DNS and DHCP status icons are displayed in grey.

Viewing Synchronization Logs

Grid Manager maintains a synchronization log file for each Microsoft server managed by a Grid member. It logs events related to the synchronization process, depending on the logging level that you configured in the **Logging** tab of the *Microsoft Server Properties* editor described in *Setting Microsoft Server Properties*.
The log files are rotated and compressed once they reach 40MB. To view the log file of managed Microsoft server:

1. From the **Administration** tab, select the **Logs** tab -> **Microsoft Logs** tab.
2. If there is more than one managed server in the Grid, you can select the Microsoft server whose logs you want to view.
3. The log file contains information related to the synchronization of the Microsoft DNS and DHCP data, as follows:

- **Timestamp**: The date and time of the log message. The time zone is the time zone configured in the User Profile.
- **Source**: Identifies the event that generated the message, such as a server synchronization or zone synchronization.
- **Level**: Indicates the severity of the message, which can be one of the following:
    - **Debug:** Provides information about all events associated with synchronization.
    - **Information:** The Grid member is synchronizing with the Microsoft server and these messages provide normal status information.
    - **Warning:** The Grid member synchronized the data, but there was an issue, which is detailed in the Message section.
      If the Grid member encounters an error during the synchronization, it skips the object with the error, logs the error in the Microsoft log, and continues to synchronize the rest of the data. The Grid member logs the error at each synchronization until you resolve the issue and it can synchronize the object successfully.
    - **Error:** The Grid member failed to synchronize an object, such as a DNS zone or DHCP scope, due to the error described in the Message section.
- **Object Type**: The type of object that corresponds to the entry, such as FQDN or ADDRESS.
- **Object Name**: The name of the object that corresponds to the entry.
- **Message**: Detailed information about the event.

You can also do the following in the log viewer:

- Toggle between the single line view and the multi-line view.
- Navigate to the next or last page of the file using the paging buttons.
- Refresh the view.
- Click the Follow icon to have the appliance automatically refresh the log every five seconds.
- Download the log.
- Clear the contents of the log.
- Sort the data in ascending or descending order by column.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Export or print the content of the log.

Managing Microsoft DNS Services

After you configure a Grid member to manage a Microsoft DNS server, the Grid member connects to the Microsoft server and starts synchronizing DNS data from the Microsoft server to its database. First, it synchronizes the Microsoft server properties and its list of zones. Then it synchronizes each zone individually, including its properties and resource records.

The synchronization time varies, depending on different factors, such as the number of managed Microsoft servers and the amount of data being synchronized. The synchronized data is then replicated to the Grid Master through the Grid replication process.
If the server is managed in read/write mode, admins can update the synchronized DNS data, control the DNS service of the server, and specify forwarders for it as well.

This section provides guidelines for using Grid Manager to manage Microsoft DNS servers and for synchronizing DNS data between Microsoft servers and the Grid. It discusses some features of the Microsoft DNS servers only as they relate to the synchronization of data. Please review the Microsoft documentation for complete information about Microsoft DNS servers and their features.

In addition, if you encounter technical issues with your Microsoft DNS servers, contact Microsoft Technical Support or consult the Microsoft Support site at *http://support.microsoft.com/*. Some Windows versions require certain updates and hotfixes installed, so the Microsoft server can synchronize with the Grid member. For information about these requirements, see *Supported Windows Versions*.

The topics in this section include:

Synchronizing DNS Data

Managing members synchronize the properties and resource records for the following types of DNS zones:

- Authoritative forward-mapping zones
- IPv4 and IPv6 reverse-mapping zones
- Stub zones
- Delegations
- Active Directory-integrated zones

Grid members synchronize most of the resource records supported by Microsoft servers, except for WINS, WINSR, and ATMA records. They synchronize all the resource records supported by Infoblox DNS servers, as well as unsupported records, such as ISDN and X25 records. You can view the unsupported records in Grid Manager and delete them, but you cannot edit them. Note that Grid Manager and Microsoft DNS servers display some resource records, such as SIG records, in a different format. You can enable and disable zone synchronization for individual Microsoft DNS zones. For information, see *Enabling and Disabling DNS Zone Synchronization*.
Grid members do not synchronize the following DNS zones supported by Microsoft servers:

Infoblox Terminology	Microsoft Terminology
Forwarding zones	Conditional forwarders
Cached zones	Stub zones

Infoblox Terminology	Microsoft Terminology
Root zone	Root zone (Dot zone)
0.in-addr.arpa	0.in-addr.arpa (0.0.0.0)
127.in-addr.arpa	127.in-addr.arpa (127.0.0.1 - loopback)
255.in-addr.arpa	255.in-addr.arpa (255.255.255.255 - broadcast)
TrustAnchors	Trust Anchors

You cannot use Grid Manager to create the unsupported zones and assign them to a Microsoft server. Any zone on the Grid that has the same name as a forwarding, cached or root zone on the Microsoft server is not synchronized. In addition, Grid members do not synchronize the contents of a zone if the Microsoft server is a secondary server.
Subdomains defined within a Microsoft DNS zone are not synchronized unless they contain at least one resource record. For example, in the corpxyz.com zone, any resource record defined in a subdomain of the corpxyz.com zone is synchronized. If the subdomain sub.corpxyz.com zone has no resource record, it is not synchronized.
The following zones and resource records are supported on Microsoft servers running Windows Server 2008 only. Therefore, Grid members can only synchronize these DNS zones and resource records with Microsoft servers running Windows Server 2008.

- IPv6 reverse-mapping zones
- Global Names zones
- DNAME records
- NAPTR records
- DNSSEC records

Synchronizing with Multiple Servers

Because a Grid member can manage multiple Microsoft servers, it could potentially manage multiple servers assigned to the same zone. For example, a Grid member could manage a Microsoft server that is the primary server of a zone and one or more Microsoft servers that are secondary servers of the same zone. It could also manage multiple Microsoft servers that are secondary servers for the same zone.

If a Grid member manages the primary server and at least one secondary server of a zone, the Grid member always synchronizes DNS data with the primary server only. It never synchronizes data with the secondary server, even if the primary server fails.

If a Grid member manages several Microsoft servers that are secondary servers of the same zone, it synchronizes DNS data as follows:

- If each Microsoft server is assigned to a different DNS view, the Grid member synchronizes data with each one.
- If the Microsoft servers are synchronized to the same DNS view, the Grid member selects a principal server for synchronization purposes, as follows:
    - The first Microsoft server that is assigned as the DNS secondary server is designated principal server.
    - If the secondary servers are managed in read-only and read/write modes, the Grid member always selects a server that is managed in read/write mode.
    - If a Microsoft server fails three successive synchronizations, it loses its principal server status. The Grid Master checks the date that each server last became a principal server and selects the server that has not been the designated principal server the longest.

Note that a Grid member could fail to synchronize with a Microsoft server due to errors, such as a disabled account or an expired password. In these situations, the failure count is reset and is not increased. This prevents the Microsoft server from losing its master status to another Microsoft server that could experience the same errors.
When a zone is served by multiple Microsoft servers, the **MS Sync Server** column of the **Zones** tab shows which Microsoft server is actually performing the synchronization of that zone with the Grid.

Enabling and Disabling DNS Zone Synchronization

You can enable and disable synchronization for a DNS zone that is assigned to a Microsoft server. Zone synchronization setting is valid for the selected zone in the DNS view for which it is defined. When you disable the synchronization for a DNS zone, the NIOS appliance stops synchronizing data with the zone but it does not disable the zone. In addition, the zone synchronization setting takes effect regardless of the role of the zone (primary, secondary, or stub), synchronization mode, and permission (read-only or read-write).
Users who have permissions to edit zone properties can enable or disable zone synchronization. Note that you can enable and disable zone synchronization for Microsoft zones only and when you add Microsoft primary or secondary servers.
To configure Microsoft zone synchronization:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *zone* checkbox, and then click the Edit icon.
2. In the *Authoritative Zone* editor, click **Name Servers**.
3. Select **Use this set of name servers**, and enter the details as specified in *Assigning Zone Authority to Name Servers*.
    - **Disable Zone Synchronization**: Select this to disable zone synchronization for the selected zone. Zone synchronization is enabled when you clear the checkbox.
4. Save the configuration.

Enabling and Disabling DNS Zone Synchronization for Multiple Zones

You can enable or disable Microsoft zone synchronization for multiple zones:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab, and select the *zone* checkboxes. You can either select a single zone or multiple zones.
2. Expand the Toolbar and click the arrow beside **MS Zone Synchronize** to select an option.
    - **Enable**: Click **Enable** to enable zone synchronization for the selected zones. Click **Yes** in the *Enable MS Zone Synchronization* dialog box to enable synchronization or click **No** to cancel the process.
    - **Disable:** Click **Disable** to disable zone synchronization for the selected zones. Click **Yes** in the *Disable MS Zone Synchronization* dialog box to disable synchronization or click **No** to cancel the process.

Considerations about Zone Synchronization

Before you enable and disable zone synchronization for a Microsoft DNS zone, consider the following:

- Zone synchronization is enabled by default.
- A zone must be synchronized at least once before you can disable synchronization.
- Zones defined on a Microsoft DNS server are listed in the NIOS appliance, regardless of whether they are synchronized or not.
- When you delete a zone on the Microsoft server, it is automatically deleted from NIOS, irrespective of its synchronization setting.
- When you create a zone on the NIOS appliance and disable zone synchronization, the zone is not created on the Microsoft server until you enable zone synchronization.
- When you disable zone synchronization, you can perform operations for which you have access rights on the NIOS appliance. This includes changes made directly to the zone or as a result of changes made in another zone. Examples: delegation creations and editing name servers.
- When you disable synchronization for a zone and perform certain operations on the respective zone, the outcomes of those operations are not replicated on any Microsoft servers assigned to the zone. For Microsoft primary servers, any resource records or zone properties (including name servers) that you create, modify, or delete on the NIOS appliance are not copied to the Microsoft server. For Microsoft secondary servers and stub servers, any zone properties (including name servers and masters) that you create, modify, or delete on the NIOS appliance are not copied to the Microsoft server.
- When you disable synchronization for a zone, the zone retains the Microsoft server that was last selected as the master before synchronization was disabled. The master retains its role when you enable synchronization again.
- When you disable synchronization, NIOS completes the ongoing process. The synchronization effectively stops at the end of the synchronization. NIOS resumes the synchronization of the zone as soon as the member assigned to the master MS server is notified through Grid replication that the zone is no longer disabled for

synchronization and the zone is overdue for synchronization. This is based on the last time the zone was successfully synchronized and the synchronization interval at the time of re-enabling the synchronization.
- Note that the zones that are disabled for synchronization are not accounted in the overall synchronization status.
- NIOS retains the zone synchronization disable setting when you enable or disable the DNS synchronization setting of any MS server that is assigned to the zone.

IDN Support for Synchronized DNS Data

Infoblox Grid supports IDNs for synchronized DNS data between the appliance and Microsoft servers. For more information about IDNs, see *Managing Internationalized Domain Names*.
The appliance stores IDNs in punycode and Microsoft server stores IDNs in \xyz format. Due to this difference at the DNS protocol level, IDNs are not allowed in a zone name when you configure NIOS (primary or secondary) and Microsoft (primary or secondary) servers. For information, see IDN Support Limitations for Synchronized Data below. If synchronized data between NIOS and Microsoft servers contain IDNs, the IDNs are preserved on the primary server. When a Microsoft server is the secondary server for a zone, MMC (Microsoft Management Console) displays the zone content that contains IDNs in punycode only. Make sure that you use a zone name that complies with the DNS protocol when manually configuring an authoritative zone.
A Microsoft server serves a resource record that contains an IDN in \xyz format when it is configured as the primary server and NIOS as the secondary server. For example, use the \xyz\xyz\xyz.com representation on NIOS for 网络 .com, a zone added on the Microsoft server.
You can add resource records that contain IDNs for the following configurations:

- NIOS is the primary server and Microsoft server is the secondary server: You can add records in IDNs or punycode. The appliance preserves IDNs and does not encode punycode to IDNs. Note that you cannot add a resource record that contains an IDN on the Microsoft server when it is configured as the secondary server.
- Microsoft server is the primary server and NIOS is the secondary server: You can add records on both NIOS and Microsoft servers. You can use IDNs or punycode. You can add IDN records on both servers in this scenario.

The following table summarizes how the servers display resource records that contain IDNs after synchronization:

Primary Server	Input	Secondary Server	Input	NIOS displays records in...	Microsoft server displays records in...
NIOS	Punycode	Microsoft	NA	Punycode	Punycode
NIOS	IDN	Microsoft	NA	IDN	Punycode
Microsoft	Punycode	NIOS	Punycode	Punycode	Punycode
Microsoft	IDN	NIOS	IDN	IDN	IDN

IDN Support Limitations for Synchronized Data

You cannot configure an authoritative zone and stub zone that contains IDNs for the following configurations:

- When NIOS is the primary server and Microsoft server is the secondary server.
- When Microsoft server is the primary server and NIOS is the secondary server.

Managing Synchronized DNS Data

When Grid members are configured to manage Microsoft servers in read/write mode, you can use Grid Manager to view, edit and delete the DNS data of those servers. You can add new zones and assign them to a Microsoft server. You can modify the properties of zones synchronized from the Microsoft server and edit their resource records as well. All updates are synchronized to the Microsoft servers at regular intervals.
The following sections provide guidelines for managing the zones and resource records served by Microsoft servers:

- *Adding Zones to Microsoft Servers*
- *Setting Zone Properties*
- *Deleting and Restoring Synchronized Zones*
- *Managing Resource Records in Synchronized Zones*

Synchronized zones also support the following features:

- You can import data to zones synchronized with Microsoft servers. Note that the import fails if you try to import unsupported records to a Microsoft zone. For information about importing records, see *Importing Zone Data*.
- You can copy records to and from zones synchronized with Microsoft servers. When copying records to a Microsoft zone, you can copy only those records that are supported by Microsoft servers. For information about copying records, see as decribed in *Defining a Match Destinations List*.

Adding Zones to Microsoft Servers

From Grid Manager, you can create zones and assign Microsoft servers as their primary or secondary servers. The managing Grid member then synchronize these zones to the appropriate Microsoft servers.
From Grid Manager, you can add the following types of zones to Microsoft servers:

- Authoritative forward- and reverse-mapping zones — For information, see *Configuring Authoritative Zones*.
- Forward- and reverse-mapping stub zones — For information, see *Configuring Stub Zones*.
- Delegations — For information, see *Configuring a Delegation*.

Note that you cannot add a zone on a Microsoft server and configure it to be served by an Infoblox Grid member. For example, on the Microsoft server, you cannot add a zone and assign a Grid member as its primary server and the Microsoft server as the secondary server. You must add such a zone from Grid Manager.
Following are guidelines for adding zones to a Microsoft server:

- The primary or secondary server of the zone must be a Microsoft server.
- If the primary server is a domain controller, you can enable the option to store the zone in Active Directory, making it an AD-integrated zone. Note that you can enable Active Directory integration only after the Microsoft server has been synchronized at least once because its AD ability is not known before the synchronization.
- You do not have to assign a Grid member as the primary or a secondary server of the zone. For example, a zone can have a Microsoft server as its primary server and an external secondary server.
- The zone must be in the same DNS view to which the DNS data of the Microsoft server was synchronized. You cannot add a zone served by the Microsoft server to a different DNS view.
- The zone does not inherit the properties from the Grid or from the DNS view. It uses the Infoblox-defined defaults. You can change the property values, as described in Setting Zone Properties below.
- You can set certain zone properties that are not supported and synchronized to the Microsoft server. For example, you can define extensible attributes and administrative permissions. When you set these properties, they apply to the zones only when they are managed from Grid Manager.
- Infoblox does not support all the zone properties of a Microsoft DNS server. When a Grid member synchronizes zones that were created on Grid Manager to the Microsoft server, the zones contain default values for all unsupported properties.
- If you set the Disable option, the zone status is set to "Paused" on the Microsoft server. A zone in a "Paused" status is not served to DNS clients, nor is it available for zone updates.
- Setting the Disable option does not stop synchronization. Grid members synchronize disabled zones.
- The member learns the Windows version of the Microsoft server after its first successful synchronization. Certain zones and resource records are dependent on a specific Windows version. You cannot assign these zones to Microsoft servers whose versions are unknown or insufficient.
- If the member is a secondary server for a zone with a Microsoft primary server, the member obtains the zone data through DNS zone transfers from the Microsoft primary server; not through synchronizations. This ensures that the zone data is always current on the Infoblox secondary server, as it does not have to wait for synchronizations to update its data.

Setting Zone Properties

When the primary server of a zone is a Microsoft server, it does not inherit its properties from the Grid. Zones that are synchronized from a Microsoft server retain their original properties. Zones that Grid Manager admins create assume the

Infoblox-defined default values.
To modify the properties of a synchronized zone:

1. From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *DNS_view* -> *zone* checkbox and click the Edit icon.
2. In the *Authoritative Zone* editor, you can do the following in each tab:
    - **General:** You can add or edit comments, and set the Disable and Lock options. Setting the Disable option sets the status of the zone to "Paused" on the Microsoft server. Grid members synchronize disabled zones to Microsoft servers.
    - **Name Servers:** You can modify the name servers assigned to the zone. For information, see *Assigning Zone Authority to Name Servers*.
    - **Settings:** If the zone was synchronized from a Microsoft server, this tab displays the original settings from the Microsoft server. If the zone was created using Grid Manager, then it inherits the TTL values from the Grid. Note that these values might be different from those on the Microsoft server. To change any of these values, see *Configuring DNS Service Properties*.
    - **Zone Transfers:** In this tab, you specify the servers to which zone transfers are allowed. For information about zone transfers, see *Enabling Zone Transfers*. Set the following parameters, depending on whether the primary or secondary servers of the zone are Infoblox or Microsoft DNS servers:
        - If the primary server is an Infoblox, Microsoft or external primary and the secondary servers are both Infoblox and Microsoft DNS servers, this tab displays two separate tables where you can specify zone transfer settings for the Infoblox DNS servers and the Microsoft DNS servers.
          Zone Transfer Settings for Infoblox Members: Specify the settings as described in *Configuring Zone Transfers*.
          Zone Transfer Settings for Microsoft Servers: Note that you cannot use a named ACL for access control though you can use individual ACEs. For information about named ACLs and access control, see *Configuring Access Control*. You can set access control for zone transfers for Microsoft servers to one of the following:
            - **None:** Does not allow zone transfers to any name server.
            - **Any:** Allows zone transfers to any IP address.
            - **Any Name Server:** Allows zone transfers to any name server in the Name Servers table.
            - **Address:** Allows zone transfers to the IP address that you specify.
        - If both the primary and secondary servers are Microsoft servers, the dialog box displays the **Zone Transfer Settings for Microsoft Servers** table only.
        - If no Microsoft servers are primary or secondary servers, then the dialog box displays the **Zone Transfer Settings for Infoblox Members** table only.
    - **Updates:** In this tab, you specify whether the zone can accept dynamic DNS updates. For information about dynamic DNS updates, see *Configuring DDNS Updates*. If the primary server is a Microsoft server, regardless of the secondary servers, the **Updates** tab displays the following:
        - **Dynamic Updates:** Select one of the following:
            - **None:** The zone does not accept dynamic updates.
            - **Secure Only:** This appears only if the zone is AD-integrated. The zone accepts GSS-TSIG-signed updates only.
            - **Nonsecure and Secure:** The zone accepts both nonsecure and GSS-TSIG-signed updates.
        - **Active Directory:**
            - **Automatically create underscore zones:** This option allows the appliance to create the following subzones that the DNS server must have to answer AD-related DNS queries:
              _msdcs.*zone*
              _sites.*zone*
              _tcp.*zone*
              _udp.*zone*
              domaindnszones.*zone*
              forestdnszones.*zone*

      Note that these zones are automatically generated. You cannot edit these zones or import data into them. They cannot be modified, thus providing protection against forged updates.

- **Extensible Attributes:** Extensible attributes apply to the zones only when they are managed from Grid Manager. For information, see *Using Extensible Attributes*.

- **Permissions:** These permissions apply to Infoblox Grid Manager administrators only. For information, see *About Administrative Permissions*.

Deleting and Restoring Synchronized Zones

When you delete a synchronized zone from the Grid, Grid Manager moves the zone and its resource records to the Recycle Bin. It deletes the zone and its resource records from the Microsoft server at the next synchronization.
Note that if you delete a zone on Grid Manager and plan to add it back to the database with different properties or resource records, ensure that you wait until after the deletion is synchronized to the Microsoft server to add the new zone. Otherwise, if you delete a zone and add a new zone with the same name within a synchronization interval, Grid Manager will synchronize the zone properties and resource records from the Microsoft server to the newly added zone on Grid Manager.
If a zone has subzones, you can choose to remove them and their resource records or "reparent" them to the parent zone of the one you are removing. For information, see *Removing Zones*.
If you restore deleted zones from the Recycle Bin, the Grid member restores it on the Microsoft server as well. For information, see *Restoring Zone Data*.

Managing Resource Records in Synchronized Zones

From Grid Manager, you can add and edit resource records in zones served by Microsoft servers. For information about adding and managing resource records, see *Managing Resource Records*. You can also use IP Map and the IP List to track A, AAAA and PTR records that are synchronized from Microsoft servers. For information, see *About IP Address Management*.
Microsoft DNS servers support all the resource records supported by Infoblox DNS servers, except for hosts, bulk hosts and shared record groups. You cannot add these records to zones served by Microsoft servers or assign zones with these records to Microsoft servers.
Following are guidelines for adding and managing resource records in synchronized zones:

- Infoblox DNS servers support defining a naming policy for the hostnames of A, AAAA, MX, and NS records based on user-defined or default patterns. For information, see *Specifying Hostname Policies*. The hostname policy applies only when records are created from Grid Manager. Resource records that originate from the Microsoft server are synchronized to the Grid member even if they do not comply with the hostname policy of the Grid member. The policy is enforced only if you edit the resource record from Grid manager.
- When you create an A or AAAA resource record on the NIOS appliance with the option to automatically create the corresponding PTR record, Grid Manager uses the deepest reverse zone that can hold the record. For example, a Grid has the following reverse zones: 10.in-addr.arpa, 0.10.in-addr.arpa, and 0.0.10.in-addr.arpa. When you create the A record www A with the IP address 10.0.0.1, Grid Manager creates a PTR record in the zone 0.0.10.in-addr.arpa. If the deepest zone does not allow the creation of the PTR record, Grid Manager creates the A record, but not the PTR record, and displays a warning.

  Note that if the **Enable PTR record removal for A/AAAA records** option is selected and if you try to delete the A or AAAA records in zones served by Microsoft servers, the appliance displays the *Delete Confirmation (A or AAAA Record)* dialog box to confirm whether you want to remove the corresponding PTR record that was automatically generated while creating the A or AAAA record. In the *Delete Confirmation* dialog box, select the **Remove associated PTR resource record(s)** checkbox and click **Yes** to delete the associated PTR record or click **No** to cancel. For information about enabling this option, see *Deleting PTR Records associated with A or AAAA Records*.
- You can add and edit DNAME records in a DNS zone assigned to a Microsoft server running Windows 2008 or Windows Server 2012. You cannot add or edit DNAME records in zones assigned to Microsoft servers running earlier Windows versions.
- You can disable synchronized resource records from Grid Manager. When you disable a resource record, it is removed from the Microsoft server at the next synchronization.
- If you add a resource record with invalid data from Grid Manager, such as a DNAME record with an alias name that has special characters, the invalid resource record is not synchronized to the Microsoft server and is eventually deleted from the Grid. The error is logged in the Microsoft log.
- If the zone of the resource record was created using Grid Manager, then it and all its resource records inherit their TTL values from the Grid. Note that these values might be different from those on the Microsoft server. You can

change these values to match those on the Microsoft server. For information on changing these values, see *Configuring DNS Service Properties*.

- Grid Manager and Microsoft DNS servers display TXT records differently.
  On Grid Manager, you enter the text string of TXT records as defined in RFC 1035. You can enter the following:
  - A contiguous set of characters without spaces. If you enclose the characters in double quotes, Grid Manager displays the character string without the double quotes. For example, if you enter **"abcdef"**, Grid Manager displays **abcdef**.
  - A string that contains any character, including spaces, enclosed in quotes.
    - If the string contains a quote ("), you must precede it with a backslash.
    - If you enter a text string with multiple spaces between each word and the string is not enclosed in double quotes, Grid Manager displays the text string with a single space between each word. For example, if you enter **text string**, the GUI displays **text string**. To preserve multiple spaces, enclose the string in double quotes.

Unlike on Microsoft DNS servers, you cannot enter a text string on multiple lines in Grid Manager. However, each contiguous set of characters or quoted string entered on Grid Manager is equivalent to a separate line entered on a Microsoft DNS server.
On a Microsoft DNS server, you can enter text without quotes and with each line on a separate line. Microsoft DNS servers then display the text in a brief format where the lines are separated by a comma and a space.
For example, if you enter the following in the **Text** field of the TXT Record wizard or editor on Grid Manager:

"this is a line""with another line""and a third one"

It is served by the Microsoft and Infoblox DNS servers as:

"this is a line""with another line""and a third one"

But it is displayed in the Microsoft DNS server as:

this is a line, with another line, and a third one

Synchronizing Updates

A Grid member synchronizes DNS data with each managed Microsoft server at regular intervals. Grid Manager admins with the applicable permissions can then update the synchronized DNS zones and resource records. During each synchronization, updates from Grid Manager are applied to the Microsoft server and updates from the Microsoft server are applied to the Grid as well. Note that the resource records are synchronized only if there is a change to the SOA record on either the Microsoft server or the Grid.
The following examples illustrate how Grid members synchronize DNS data:

- If a Microsoft server admin adds the finance.corpxyz.com zone, it is also added to the Grid after a synchronization.
- If a Grid Manager admin changes the A record of admin.corpxyz.com from 10.2.1.5 to 10.2.1.6, the IP address of its corresponding A record on the Microsoft server is updated to 10.2.1.6.
- If a Grid Manager admin deletes a DNS zone that is assigned to a Microsoft server, the corresponding zone on the Microsoft server is deleted as well in the next synchronization.

Because admins can update DNS data from the Microsoft server and from Grid Manager, conflicts can occur during synchronization. In addition, Microsoft servers and Infoblox DNS servers have some differences in the features they support and the way they handle certain zones and resource records.
The following guidelines describe how the Grid member resolves conflicts and handles any differences when DNS data is synchronized between a Microsoft server and the Grid.

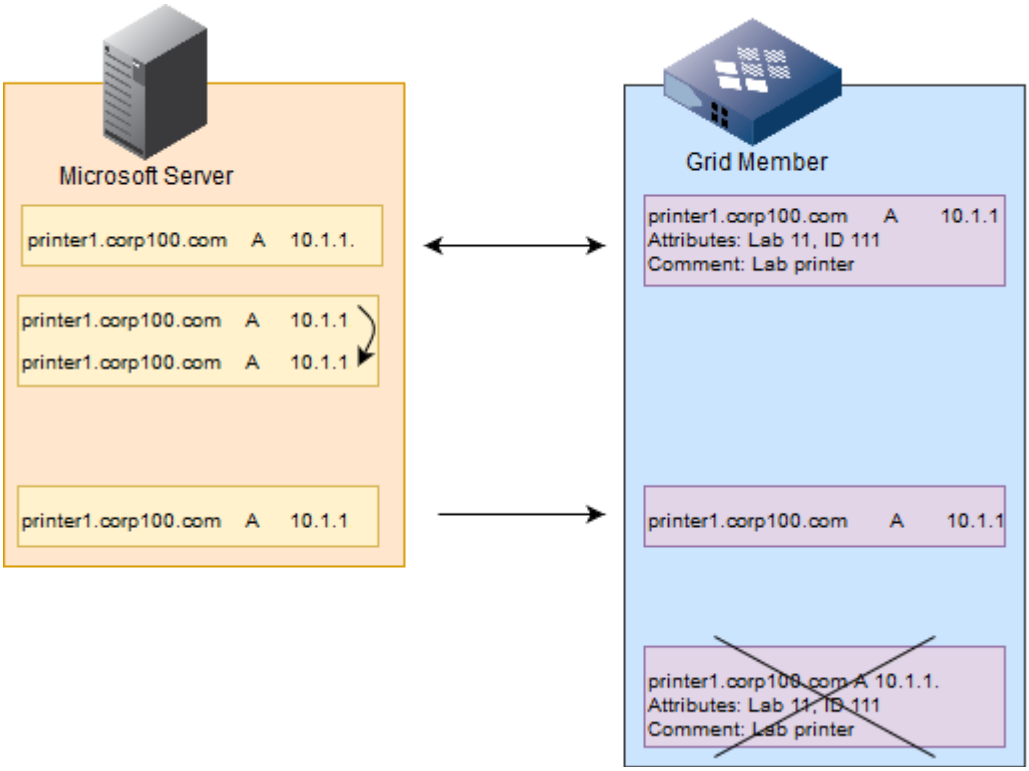
- On Microsoft servers, users can enter FQDNs and labels using a mix of upper and lower case characters. The servers preserve the original case when they store the data. When the Grid member synchronizes data with the Microsoft server, it displays the data in lower case in Grid Manager and the Infoblox API. The case of the data is preserved as long as no change is made to the DNS zone or resource record. If a Grid Manager admin modifies a DNS zone or resource record, the next synchronization converts the object name to lower case on the Microsoft server.
- If a Microsoft server admin modifies an object that has a pending scheduled task and synchronization occurs before the scheduled task, the object is modified in both the Microsoft server and the Grid member. When the scheduled task executes at its scheduled time, it fails and an error message is logged in the audit log.

- A situation could arise where two Microsoft servers in different domains are primary servers for zones with the same name. For example, two reverse-mapping zones could be named 1.1.10.in-addr-arpa in two Microsoft servers managed by the same member. If the two Microsoft servers are synchronized to different DNS views, the Grid member synchronizes each one separately. If the Microsoft servers are synchronized to the same DNS view, then the Grid member synchronizes the zone with the first Microsoft server. During the synchronization with the second Microsoft server, the Grid member logs an error and does not synchronize the zone.
- The Grid member does not synchronize the naming policy configured on Microsoft servers. Zones and resource records that fail the policy check on Microsoft servers are reported in the synchronization log file.
- When you remove a Microsoft server that is assigned to a zone, the succeeding synchronization removes the zone from the Microsoft server.
- When a Microsoft server admin and a Grid Manager admin change the same object, the Grid member retains the version that exists on the Microsoft server. Following are some examples:

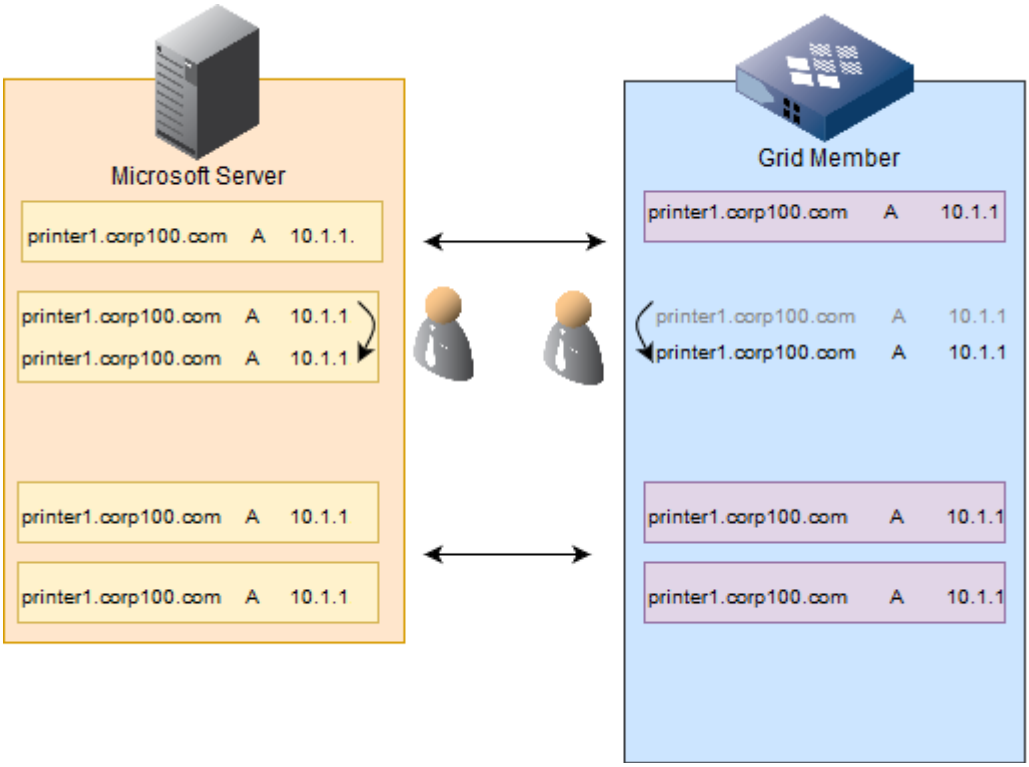
Grid Manager Admin...	Microsoft Server Admin...	After Synchronization
Deletes the corpxyz.com zone	Updates the corpxyz.com zone	The corpxyz.com zone is created on the Grid with the updates and is assigned to the Microsoft server .
Changes the zone transfer settings of the sales.corpxyz.com zone.	Deletes the sales.corpxyz.com zone.	The sales.corpxyz.com is deleted from the Grid as well.

- Changing the name or IP address of a resource record on the Microsoft server effectively deletes the original resource record and creates a new record with the current information. During the synchronization, the Grid member also deletes the original record, including its associated properties, such as its extensible attributes and administrative permissions, and creates a new record.

For example, as shown in the below figure, the A record for printer1.corpxyz.com is on both the Microsoft and Infoblox Grid member. On the Grid, the A record has extensible attributes and a comment. A Microsoft server admin changes the IP address of the A1 resource record from 10.1.1.2 to 10.1.1.3. On the Microsoft server, this is equivalent to deleting the A1 resource record with the IP address 10.1.1.2 and then adding a new A1 resource record with the IP address 10.1.1.3. When the data is synchronized, the Grid member deletes the original record with its extensible attributes and comments and creates a new A record with IP address 10.1.1.3.



- If a Microsoft server admin changes the IP address of a resource record and a Grid Manager admin changes the IP address of the same resource record, they are effectively deleting the record and each creating a new one. For example, as shown in the below figure, a Microsoft server admin changes the IP address of the A resource record for printer1.corpxyz.com from 10.1.1.2 to 10.1.1.3, and a Grid Manager admin changes the IP address of the same resource record to 10.1.1.4. When the data is synchronized, the Grid member deletes the A1 resource record with IP address 10.1.1.2 and creates an A resource record with IP address 10.1.1.3 and another A1 resource record with IP address 10.1.1.4.



- The Microsoft server does not allow the creation of arpa subzones as forward-mapping zones, similarly, the appliance restricts assigning arpa subzones (zone names ending with .arpa) to the Microsoft server.
- NIOS does not synchronize the top-level reverse-mapping zones (in-addr.arpa and ip6.arpa) created on the Microsoft server and the top-level reverse-mapping zones (in-addr.arpa and ip6.arpa) created on the NIOS appliance cannot be assigned to the Microsoft server.
- Grid members can synchronize classless IPv4 reverse-mapping zones from the Microsoft server to the Grid only if the zone prefix is in one of the following formats: *<subnet>/<subnet mask bit count>* or *<subnet>-<subnet mask bit count>* . For example, 128/26.2.0.192.in-addr.arpa. If the zone prefix is not in the specified format, the Grid member skips the zone and logs an error message. For information, see *http://technet.microsoft.com/en-us/library/cc961414.aspx*.
  Likewise, Grid Manager admins can add a classless IPv4 reverse-mapping authoritative or stub zone to a Microsoft server only if its prefix is in the specified format. For information about configuring classless IPv4 reverse-mapping zones in Grid Manager, see *Specifying an RFC 2317 Prefix*.
- Grid members synchronize DNS records that contain values that Infoblox does not support. Grid Manager admins can view these records, but they cannot edit or restore such records. For example, if a member synchronizes a NAPTR record that contains an unsupported value in the Service field, admins can view this record but they cannot edit or restore it, as long as it contains an unsupported value.
- When a Grid member synchronizes a zone from a Microsoft server to the appliance and that zone contains UTF-8 characters in the "Responsible Person" field, Grid Manager displays the "Responsible Person" value in the RNAME field of the SOA record of the zone. Note though that you cannot edit the SOA record if the RNAME field contains unsupported UTF-8 characters.
- Synchronizing a new zone from the Microsoft server to the Grid is a two-step process. First the zone name is synchronized, and then its properties and records are synchronized. The zone synchronization from the Microsoft server is not considered complete until both steps are done. NIOS drops any records that are created on the appliance for the synchronized zone before it is completely synchronized.
  For example, the corpxyz.com zone is created on a Microsoft server and then synchronized to the NIOS appliance. If a NIOS admin creates a record, such as an A record, in the corpxyz.com zone before it is fully synchronized, the record is removed from the corpxyz.com zone. Ensure that both the zone and its contents are completely synchronized before you add a record to a zone on the NIOS appliance.

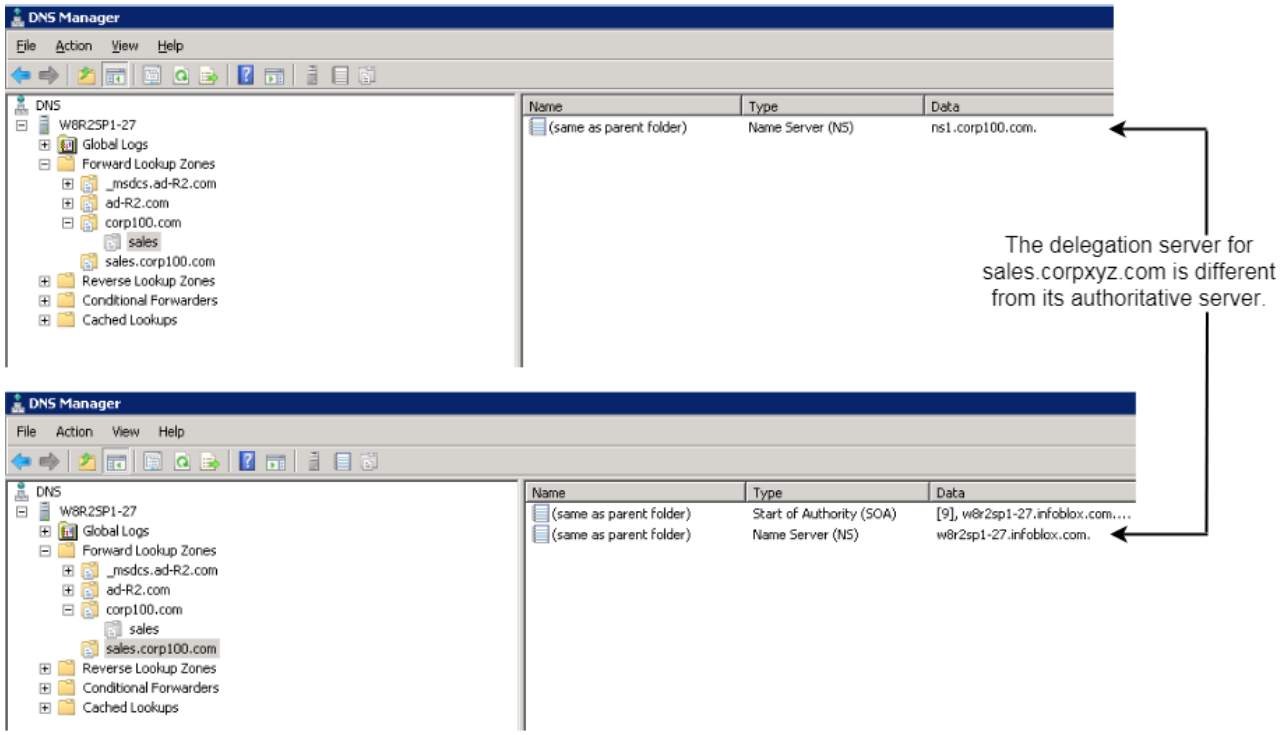
- When a Microsoft admin deletes a zone whose primary and secondary servers are Microsoft servers, the zone is deleted from the Grid after a synchronization. If the secondary Microsoft servers are managed by the member in Read-Write mode, the zone is removed from the secondary servers as well. But if some of the secondary Microsoft servers are managed by the member in Read-Only mode, then at the next synchronization the zone is recreated on the Grid with the Microsoft servers as the secondary servers and the masters defined for the zone as external primary servers.
- If you add Grid members or other Microsoft servers as secondary servers to a zone on the Microsoft server, NIOS does not automatically add them as Grid Secondary or Microsoft Secondary servers in the Name Servers tab of the zone after the synchronization. Instead, NIOS creates NS records for them in the zone.

Synchronizing Delegations

When a parent zone delegates a subdomain to one or more name servers, Infoblox DNS servers require the delegation name servers to also be authoritative for the subzone. Microsoft servers do not; they allow the delegation servers of a subzone to be different from its authoritative servers. Infoblox DNS servers support this configuration only if the primary server of the parent zone is a Microsoft server. This configuration is retained when delegations are synchronized from Microsoft servers to the Grid.

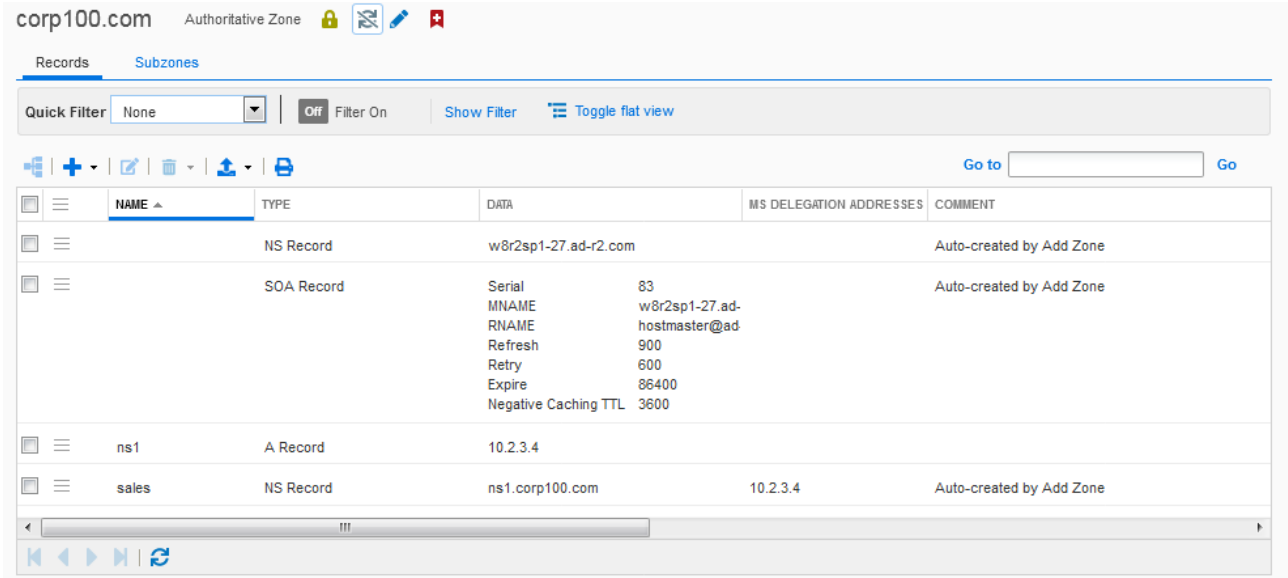
For example, as shown in the below figure, on a Microsoft server, corpxyz.com delegates sales.corpxyz.com to the name server ns1.corpxyz.com; but the authoritative server of sales.corpxyz.com is 2k3r264-2.infoblox.com.

Delegation Server and Authoritative Server for corpxyz.com



The following figure shows that after corpxyz.com and its subzone are synchronized to the Grid, corpxyz.com contains an NS record for sales.corpxyz.com and an A record for the delegation name server ns1.corpxyz.com. The *MS Delegation Addresses* column displays the IP address of the delegation server of the subzone sales.corpxyz.com.

corpxyz.com Synchronized to the Grid

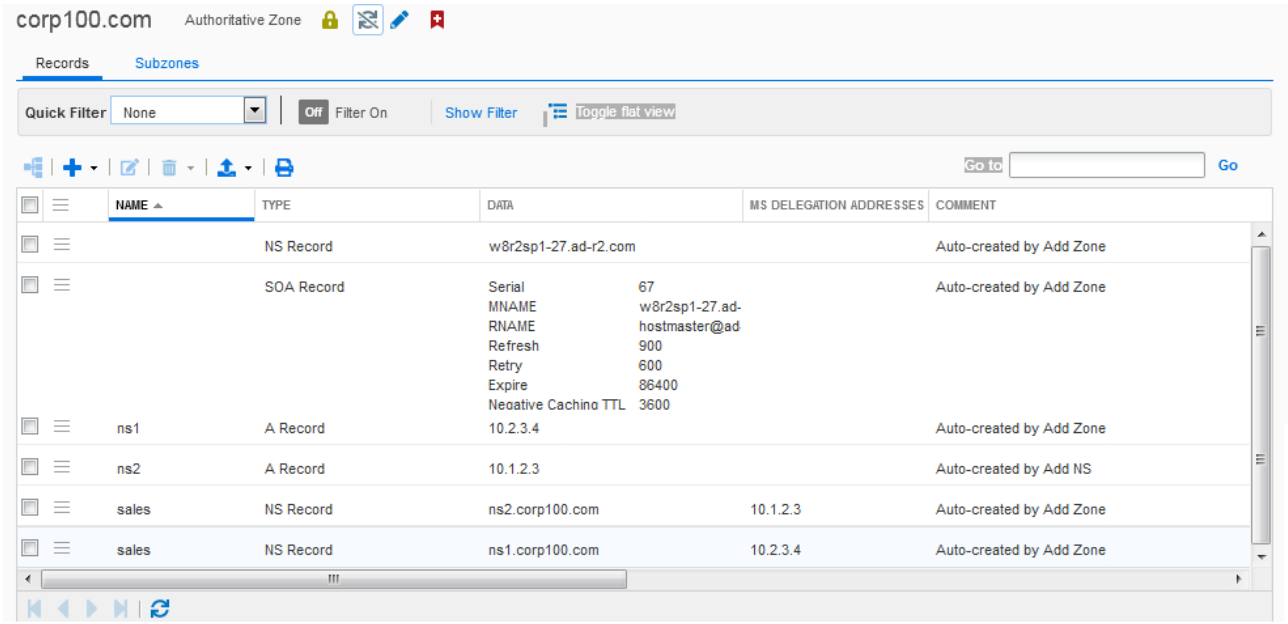


After the synchronization, you can add name servers for the delegation as follows:

1. Select the zone by navigating to the **Data Management** tab -> **DNS** -> **Zones** -> *parent_zone*.
2. Click the Add icon and select **Record** -> **NS Record**.
3. Complete the following and click **Next**:
    - **Name Server**: Enter the hostname you want to configure as the name server for the zone.
    - **Name**: Specify the name of the subzone. Note that you cannot change this name when you edit the record.
4. Enter the IP address of the name server.
5. Save the configuration.

NIOS adds an NS record for the new delegation server and synchronizes this update to the Microsoft server. In the following figure, a new delegation server, ns2.corpxyz.com, was added.

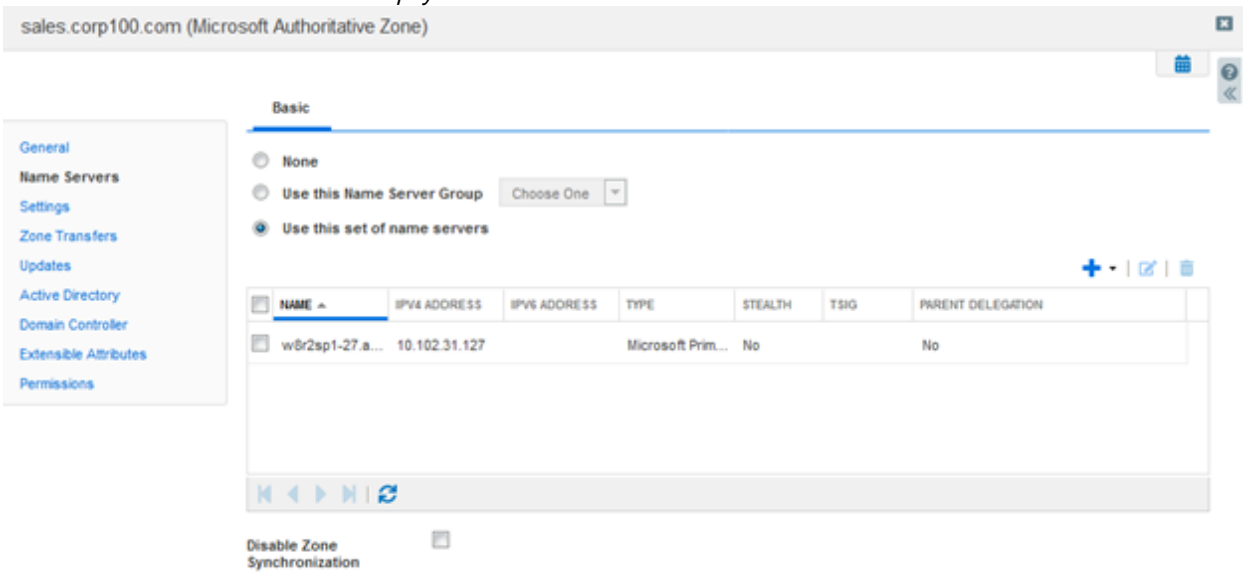
NS Record for ns2.corpxyz.com



When you navigate to the **Name Servers** tab of sales.corpxyz.com to view the authoritative name servers for the

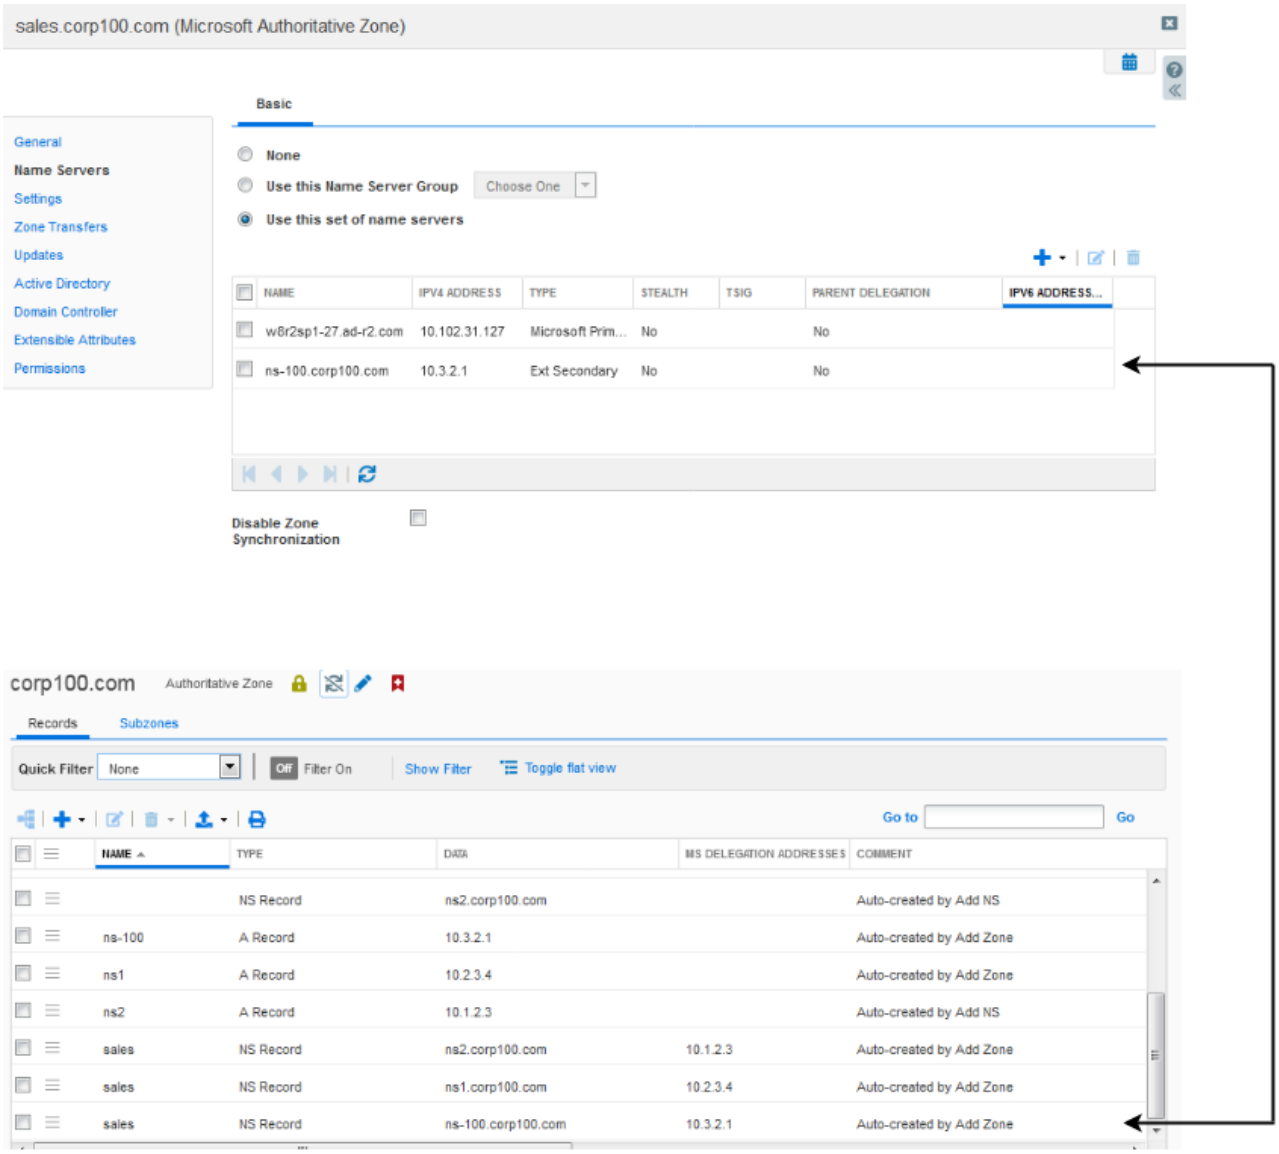
subzone, note that as shown in the following figure, the table displays 2k8r264-2.infoblox.com as the authoritative server for the subzone. The **Parent Delegation** column indicates if the FQDN and IP address of the authoritative name server for the zone matches the FQDN and IP address in the delegation zone's NS record. In the example, the authoritative name server 2k8r264-2.infoblox.com is different from the delegation name servers (ns1.corpxyz.com and ns2.corpxyz.com), so the column displays **No**.

Authoritative Name Server of sales.corpxyz.com



Note though that because Infoblox DNS servers require the delegation servers to also be authoritative for the subzone, if you add another authoritative name server to the subzone from Grid Manager, NIOS also adds it as a delegation server in the parent zone. For example, as shown in the below figure, when an admin adds the name server ns-100.corpxyz.com as an external secondary server for sales.corpxyz.com, NIOS automatically adds it as a delegation server by adding an NS record for it in the parent zone.

Adding Another Authoritative Server from Grid Manager



Synchronizing AD-Integrated Zones

An AD-integrated zone can be served by multiple domain controllers, and a Grid member can manage more than one of the domain controllers. If the domain controllers are configured to synchronize their DNS data to different DNS views, the Grid member synchronizes DNS data with each domain controller. If the domain controllers are configured to synchronize their DNS data to the same DNS view, the member selects a principal server for synchronization purposes and synchronizes data with that principal server only. The selection of the principal server is logged, as well as when it changes. The Grid member selects a principal server as follows:

- The first domain controller that is assigned as the primary server is designated principal server.
- If a domain controller fails three successive synchronizations, it loses its principal status. The Grid Master then checks the date that each domain controller last became a principal server and selects the one that has not been the designated principal the longest.
- If the domain controllers are managed in read-only and read/write modes, the Grid member always selects the domain controller that is managed in read/write mode.

When a zone is served by multiple Microsoft servers, the **MS Sync Server** column of the **Zones** tab shows which Microsoft server is actually performing the synchronization of that zone with the Grid.
The Grid member periodically checks if each zone has one principal server. If it does not find a principal server for a zone, the Grid member selects one among the name servers assigned to the zone. It gives priority to the server that was not the designated principal server the longest.
Following are additional guidelines when synchronizing AD-integrated zones:

- You can create an AD-integrated zone on Grid Manager and assign one domain controller as its primary server. If a domain controller admin adds more primary servers to the zone, they are added to the zone on Grid Manager when the zone is synchronized. If you want to delete the primary servers, you must delete all the primary servers at once. You cannot delete only a subset of the servers.
- A situation could arise where two domain controllers in different AD domains are primary servers for zones with the same name. For example, two reverse-mapping zones could be named 1.1.10.in-addr-arpa in two domain controllers managed by the same member. If the two domain controllers are synchronized to different DNS views, the Grid member synchronizes each one separately. If the domain controllers are synchronized to the same DNS view, then the Grid member synchronizes the zone with the first domain controller. During the synchronization with the second domain controller, the Grid member logs an error and does not synchronize the zone.
- If a Grid Manager admin deletes a CNAME record that has a blank canonical name from an AD-integrated zone, this CNAME record is not deleted from the Microsoft server after the synchronization if the AD-integrated zone is hosted on a Microsoft server running Windows 2008 R2 or Windows Server 2012.
- When a Microsoft server is the primary server of a zone that contains an _msdcs zone, it appends the parent zone name to the server name in the NS record of the _msdcs zone. But when an Infoblox Grid member is the primary server of a zone that contains an _msdcs zone, it specifies the server name only in the NS record. For example, the _msdcs zone is in the corpxyz.com zone and the name server is nameserver100.com. When a Microsoft server is the primary server of corpxyz.com, the server name on the NS record of the _msdcs zone is nameserver100.com.corpxyz.com. When a Grid member is the primary server, the server name on the NS record of the _msdcs zone is nameserver100.com.

Resolving Conflicts

Some conflicts require intervention from an admin. For example, a Grid member cannot synchronize a zone when its primary server on the Microsoft server is different from its primary server on the Grid. When a Grid member is unable to synchronize data due to such conflicts, it logs an error, skips the object with the error and continues synchronizing the rest of the data. You can then view the Microsoft logs to check which objects were not synchronized. If you resolve the problem, the Grid member synchronizes the object on its next attempt. For information about the logs, see *Viewing Synchronization Logs*.

Viewing Members and Managed Servers

You can view Infoblox and Microsoft DNS servers by navigating to the **Data Management** tab -> **DNS** tab, and then selecting the **Members/Servers** tab. The panel displays the following information about each DNS server:

- **Name**: The hostname of the Grid member or Microsoft server.
- **Status**: The status of the DNS service on the Grid member or Microsoft server.
- **Comment**: Comments that were entered for the Grid member or Microsoft server.
- **Site**: Values that were entered for this pre-defined attribute.
- **Address**: The IP address of the Grid member or Microsoft server. You can do the following:
- List the DNS views or zones served by the member or Microsoft server.
    - Click a Grid member or Microsoft server name.
- Edit the properties of a Grid member or Microsoft server.
    - Click the checkbox beside a Grid member or Microsoft server, and then click the Edit icon. To edit the DNS properties of a Grid member, see *Configuring DNS Service Properties*.
      To edit the DNS properties of a Microsoft server, see *Specifying Forwarders for Microsoft Servers*.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Export the list of Grid members and Microsoft servers to a .csv file.
    - Click the Export icon.

- Print the list of Grid members and Microsoft servers.
    - Click the Print icon.

Specifying Forwarders for Microsoft Servers

A forwarder is a name server to which all other name servers first send queries that they cannot resolve locally. The forwarder then sends these queries to DNS servers that are external to the network, avoiding the need for the other name servers in your network to send queries off-site. You can define a list of forwarders for each managed Microsoft server as follows:

1. From the **Data Management** tab, select the **DNS** tab -> **Members/Servers** tab -> *ms_server* checkbox -> Edit icon.
2. Click the Add icon and enter the IP address of the forwarder in the text field.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Disabling and Removing Microsoft DNS Servers

When you disable synchronization with a Microsoft server, the managing Grid member completes any ongoing synchronization and does not start a new one. Synchronization resumes when the Microsoft server is re-enabled. The synchronized DNS data stays in the same state until synchronization resumes. For information, see *Disabling Synchronization*.

When you remove a managed Microsoft server from the Grid, the managing Grid member terminates any ongoing synchronization and does not start a new one. Zones and their content on the Microsoft server remain in the state that existed the moment the Microsoft server was removed. The Grid retains the zones that were assigned to the Microsoft server that was removed, but deletes the Microsoft server from its assigned zones as follows:

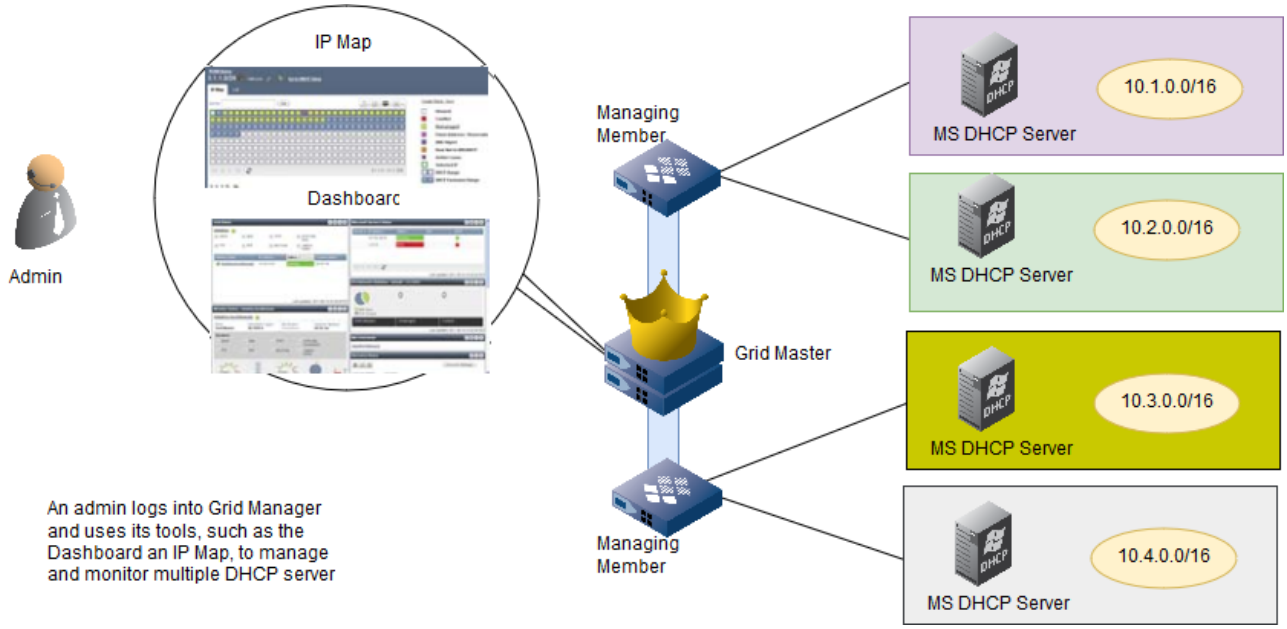
- If the Microsoft server is the only primary server and there are no other assigned servers or if the secondary server is an external secondary server, Grid Manager deletes all the server assignments.
- If the Microsoft server is the only primary server and there are Grid secondary servers, an external primary is created with the FQDN and IP address of the removed Microsoft server.
- If the Microsoft server is a secondary server and there is a Grid primary, an external secondary is created with the FQDN and IP address of the removed Microsoft server.
- If the Microsoft server is a server for a stub zone, the server is removed. To remove a Microsoft DNS server:

1. From the **Data Management** tab, select the **DNS** tab -> **Members/Servers** tab -> *ms_server* checkbox.
2. Expand the Toolbar and click **Delete**.
3. Click **Yes** when the confirmation dialog box appears.

Managing Microsoft DHCP Services

Grid Manager enables you to centrally manage the DHCP data of multiple Microsoft DHCP servers from a single interface. Once the DHCP data is synchronized, you can use the Dashboard on Grid Manager to monitor DHCP and server operations, or organize DHCP data into Smart Folders. Through IPAM tools, such as network maps and IP maps, you can track and manage IP address usage in your networks and monitor DHCP range utilization. You can also run a network discovery to retrieve IP allocation for both managed and unmanaged devices— including virtualized resources. For information about the IPAM features, see *About IP Address Management*.

Managing Microsoft DHCP Servers from Grid Manager



This section provides guidelines for using Grid Manager to manage Microsoft DHCP servers and for synchronizing DHCP data between Microsoft servers and the Grid. It discusses features of only Microsoft DHCP servers as they relate to the synchronization of data. Please review the Microsoft documentation for complete information about Microsoft DHCP servers and their features.

In addition, if you encounter technical issues with your Microsoft DHCP servers, contact Microsoft Technical Support or consult the Microsoft Support site at *http://support.microsoft.com/*. Some Windows versions require certain updates and hotfixes installed, so the Microsoft server can synchronize with the Grid member. For information about these requirements, see *Requirements*.

The topics in this section include:

- *Viewing Synchronized Leases*
- *Synchronizing DHCP Failover Relationships*
- *Synchronizing IP Addresses with Invalid MAC Addresses*
- *Managing Synchronized DHCP Data*
- *Synchronizing DHCP Data from Microsoft Servers*
- *Managing Microsoft DHCP Servers*

Viewing Synchronized Leases

A Grid member synchronizes all leases from its managed Microsoft server to the Grid. Microsoft servers automatically generate a static lease for each reservation. These static leases are synchronized to the Grid as well. You can view the synchronized leases by navigating to the **Data Management** -> **DHCP** -> **Leases** tab. For information about viewing current leases, see *Viewing Current Leases*. You can do the following:

- View lease details, by selecting a lease and clicking the Lease Details icon. For additional information, see *Viewing Detailed Lease Information*.
- Clear a lease, by selecting it and clicking the Clear Lease icon. Note that Grid Manager clears the lease immediately. It does not wait for the next synchronization.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information about using quick filters, see *Finding and Restoring Data.*

Additionally, you can enable a Grid member to log lease related operations, so you can view these events in the Lease History panel. For information about configuring the lease logging member, see *Configuring DHCP Logging* and see *Viewing Lease History*.

Synchronizing DHCP Failover Relationships

The synchronization of DHCP data with Microsoft DHCP servers running Microsoft Windows version 2012 or later includes the synchronization of DHCP failover relationships and the associated scopes. Note that this feature does not have any impact on the synchronized data with Microsoft servers running a Windows version earlier than 2012.
When you change the synchronization mode of a Microsoft server, it affects the way a failover relationship is synchronized and replicated, but you cannot change these settings directly. When a failover relationship synchronization mode changes from read-only to read/write, NIOS copies the DHCP configuration within the relationship between both partners, using the primary Microsoft server as the reference. When a failover relationship synchronization mode changes from read/write to read-only, NIOS does not change the DHCP configuration within the relationship on each Microsoft server.

About Microsoft DHCP Failover Relationships

A failover relationship represents the relationship between two Microsoft DHCP servers, where each of them is called a partner. A failover relationship that has at least one Grid member as a partner is called a NIOS failover relationship and if it has at least one Microsoft server as a partner, it is defined as a Microsoft failover relationship. A failover relationship can be configured with two Microsoft servers, a Microsoft server and an external server, two Grid members, a Grid member and an external server.
When you synchronize a failover relationship from a Microsoft server, the NIOS appliance copies the changes originating from the Microsoft server to the failover relationship of the partner, only if the two Microsoft servers match. Two failover relationships match if they have the same name, and if the address of the partner defined in one Microsoft server matches with the address of the other, and vice versa. Also, you must configure Microsoft servers to manage DHCP and enable synchronization on both the Microsoft servers.
The changes that originate from the Microsoft server are applied to the failover relationship on NIOS, and vice versa. The changes are effective on the partner server from its next scheduled synchronization.
The failover relationship synchronization mode for Microsoft is read/write if both partners are each Microsoft servers that are enabled for DHCP synchronization. For all other cases, the failover relationship synchronization is read only.
When NIOS fails to match a failover relationship, the partner of that relationship is considered to be unknown or external. In the case of multiple servers, you must define the Microsoft server on the appliance using the same IP and/or FQDN.
Infoblox recommends that you do the following for Microsoft servers in a failover relationship:

- The synchronization interval of two Microsoft servers in a failover relationship must be identical and small.
- Use the same managing member for Microsoft servers in a failover relationship.
- After a Microsoft server fails, you must turn off NIOS synchronization during restore to avoid transferring the old configuration to its partners.
- The primary and secondary Microsoft servers that you select in a failover relationship must be in the same network view. Note the following if the servers are on different network views:
    - You cannot modify or delete failover associations.
    - You cannot add, modify, or delete scopes that are associated with the failover association.
    - The appliance does not display the FQDN, but displays the IP address and status as 'unknown' for the secondary Microsoft server.
    - The appliance may not display the scopes that are assigned to the failover association.
    - The appliance does not allow you to perform any action on the objects in a failover association, as the objects will be in read-only mode.

Admin Permissions for Managing Microsoft DHCP Failover Relationship

To create, modify or delete a Microsoft failover relationship in NIOS, you must have the same permissions on both the Microsoft servers that are assigned to the failover relationship.
You can update the property of a failover relationship only if it has read/write permissions. You cannot update the properties of the Microsoft server or partner directly. You must first delete the relationship, create a new relationship and assign the DHCP scope to the new relationship. NIOS applies the changes to both Microsoft servers defined in the

failover relationship during its next synchronization schedule, only if they are in read/write mode during that time. You can delete a Microsoft failover relationship only if it is not associated with a DHCP range.

Microsoft Failover Relationships for DHCP Ranges

When you create or update a DHCP range on NIOS, administrators can assign or remove a DHCP range from a Microsoft failover relationship only if the failover relationship has two read/write Microsoft servers. Note that when you reassign a DHCP range that is assigned to a Microsoft failover relationship, NIOS removes the DHCP range from the failover relationship during the next synchronization of the respective server.
When you remove a DHCP range from a read/write Microsoft failover relationship, NIOS deletes a copy of the DHCP range from both the Microsoft servers defined in the failover relationship. When a DHCP range is associated with a Microsoft failover relationship, any change made to one copy of the range is automatically saved to the other copy.

Admin Permissions for Managing Failover Relationships for DHCP Ranges

You must have read/write permissions on the DHCP range and on each Microsoft server to assign or remove a DHCP range from a Microsoft failover relationship.
Note that the changes performed on a DHCP range, which is assigned to a read/write Microsoft failover relationship, are applied to both copies of the range and synchronized with each Microsoft server during each of their next scheduled synchronization.
You can delete a DHCP range that is assigned to a Microsoft failover relationship only if the failover relationship has two read/write Microsoft servers. When you delete a DHCP range that is assigned to a Microsoft failover relationship in read/write mode, NIOS deletes them on both Microsoft servers that is defined in the relationship during the next respective scheduled synchronization.

Limitations of Microsoft DHCP Failover Relationship on NIOS

Note the following limitations of Microsoft DHCP failover relationship on NIOS:

1. You cannot synchronize failover scope statistics on a Microsoft DHCP failover relationship.
2. The appliance does not support on demand replication for a Microsoft DHCP failover relationship.
3. You cannot set the functional peer in the PARTNER-DOWN state for a Microsoft DHCP failover on NIOS. For information about setting a peer in the partner-down state, see *Managing Failover Associations*.
4. The appliance does not support time synchronization of both partners and time synchronization monitoring. Infoblox recommends that the administrators of the Microsoft servers running the DHCP server must ensure that the time synchronization is appropriate.
5. You can only add up to 31 DHCP failovers to a Microsoft server in a failover relationship.

Synchronizing IP Addresses with Invalid MAC Addresses

An invalid MAC address is a MAC address whose length is not six bytes (48 bits). You can synchronize IP addresses with invalid MAC addresses only for Microsoft servers for which you have enabled DHCP synchronization. When you enable this setting for a Microsoft DHCP server, NIOS synchronizes any DHCP lease or reservation with an invalid MAC address and it is effective from the next scheduled DHCP lease or DHCP server synchronization. The synchronization does not affect a DHCP lease or reservation with a valid MAC address.
You can synchronize IP addresses with invalid MAC addresses at the Grid level and override them at the member level. This is valid for NIOS 6.11.0 and later releases. The appliance displays the invalid MAC address using a red cross mark in the list. You cannot save invalid MAC addresses, but you can view invalid MAC addresses in the list panels and editors.
When you disable synchronization for invalid MAC addresses, NIOS ignores any DHCP lease or reservation with an invalid MAC address and the object disappears from NIOS during the next synchronization of the Microsoft server to which it belongs. An invalid MAC address that you had synchronized earlier persists until NIOS updates the associated lease or reservation with a new MAC address, or the lease is cleared, or deleted, or expired.
To synchronize an invalid MAC address, complete the following:

1. **Grid**: From the **Grid** tab -> **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
   Member: From the **Grid** tab -> **Grid Manager** tab, click the **Members** tab, select the *member* checkbox, and click the Edit icon.

2. Select the **Microsoft Server Settings** tab in the *Grid Properties Editor* wizard and complete the following in the **Advanced** tab:
    - **Allow Invalid MAC Address to be synchronized**: This is enabled, by default. Select this to enable synchronization for invalid MAC addresses.
      You can click **Override** at the member level to specify a new value. The **Override** button changes to **Inherit**. Click **Inherit** to inherit the value from the Grid.
3. Save the configuration.

Managing Synchronized DHCP Data

When Grid members are configured to manage Microsoft DHCP servers in read/write mode, you can use Grid Manager to view, edit and delete the DHCP data of those servers. You can add and manage networks and DHCP ranges that are synchronized as scopes to the Microsoft server, and add and manage reservations and superscopes. All updates are synchronized to the Microsoft servers at regular intervals.
Grid Manager also allows you to set admin permissions, extensible attributes, and thresholds. These apply only when the DHCP data is managed on Grid Manager. These properties are not synchronized to Microsoft servers.
The following sections provide guidelines for managing Microsoft DHCP data from Grid Manager:

- *Adding and Managing Scopes*
- *Setting Network Properties*
- *Deleting and Restoring a Network*
- *Adding a DHCP Range/Scope*
- *Setting DHCP Range/Scope Properties*
- *Deleting and Restoring a DHCP Range/Scope*
- *Viewing Scopes*
- *Adding Fixed Addresses/Microsoft Reservations*
- *About Superscopes*
- *Synchronizing Updates*

Adding and Managing Scopes

To add a scope from Grid Manager, you must create an IPv4 network and a DHCP range, and then assign the Microsoft server to the network and range. To add a split-scope from Grid Manager, you must create an IPv4 network and a DHCP range, and then assign two Microsoft server to the network and range.
To edit a scope synchronized from a Microsoft server, you must edit the properties of its corresponding DHCP range. The following sections describe how to add, edit and remove scopes using Grid Manager.

> **Note**
>
> Microsoft servers do not support Infoblox hosts and reservations. You cannot add them to networks and DHCP ranges served by Microsoft servers.

Adding Networks for Scopes

Following are guidelines for adding a network for Microsoft scopes:

- The network must be served by Microsoft servers. It cannot be served by a mix of Microsoft and Infoblox DHCP servers.
- If you are adding a split-scope, you must assign the network to two Microsoft servers that serve the split-scope. A split-scope cannot be served by a mix of Microsoft and Infoblox DHCP servers.
- The network can contain only one DHCP range per Microsoft server. It can contain multiple DHCP ranges as long as they do not overlap and are each served by a different Microsoft server.
- You can set DHCP properties at the DHCP range level only, not the network level.

You can run discoveries on networks served by Microsoft servers. For information about network discoveries, see IP Discovery and vDiscovery below.

> **Note**
>
> Networks served by Microsoft DHCP servers do not support the split, join, and expand functions.

You can create a network from scratch or use a network template. For information about creating network templates, see *Adding IPv4 Network Templates*. To add an IPv4 network for a scope:

1. From the **Data Management** tab, select the **DHCP** tab.
2. If you have more than one network view in the system, select the network view in which you want to add the network. It must be the same network view to which the Microsoft server is assigned.
3. Expand the Toolbar and click **Add** -> **Network**.
4. In the *Add Network* wizard, select one of the following and click **Next**:
   - **Add Network**
     or
   - **Add Network using Template:** Click **Select Template** and select a network template. For more information, see *Adding IPv4 Network Templates*. In the *DHCP Network Template Selector* dialog box, select the template you want to use and click the Select icon. Note that when you use a template to create a network, the configurations of the template apply to the new network. The appliance populates the template properties in the wizard when you click **Next**. You can then edit the pre-populated properties, except for **Netmask**.
5. Complete the following and click **Next**:
   - **Address**: Enter the IP address of the network. You can enter the IP address with a CIDR block. For example, enter 10.0.0.0/24, and the netmask slider adjusts the netmask to /24. You can also enter partial IP address with a CIDR block. When you are done, Grid Manager displays the complete IP address with the CIDR block. For example, when you enter 15/24, Grid Manager displays 15.0.0.0/24 and the netmask slider adjusts the netmask to /24. Note that Microsoft DHCP servers do not support /32 subnets.
   - **Netmask**: Use the netmask slider to select the appropriate number of subnet mask bits for the network. Microsoft servers support /1 to /31 netmasks. Note that when you use a template that contains a fixed netmask, you cannot adjust the netmask for this network.
   - **Comment**: Enter additional information about the network, such as the name of the organization it serves.
   - **Automatically create reverse-mapping zone in view**: This function is enabled if the netmask of the network equals /8, /16, or /24. Select this to have the appliance automatically create reverse-mapping zones for the network. A reverse-mapping zone is an area of network space for which one or more name servers have the responsibility for responding to address-to-name queries. These zones are created in the DNS view assigned to receive dynamic DNS updates at the network view level.
   - **Disabled:** This option does not apply to networks assigned to Microsoft servers. The member ignores this field when the network is assigned to Microsoft servers. You can disable DHCP ranges assigned to Microsoft servers, but not networks.
6. Click **Next** to add Microsoft servers as DHCP servers for the network. Click the Add icon and select the following:
   - Add Microsoft Server: Select the Microsoft server from the *Microsoft Server Selector* dialog box. You can add multiple Microsoft servers, if you are adding multiple DHCP ranges served by different Microsoft servers. For a split-scope, you must assign two Microsoft servers to the network.
7. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *About Extensible Attributes*.
8. Save the configuration and click **Restart** if it appears at the top of the screen.
   or
   Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Setting Network Properties

You can change the Microsoft servers assigned to the network, and define extensible attributes and admin permissions to the network. You can also set thresholds for the network, to enable the appliance to make a syslog entry when address usage goes above or below the thresholds.
To set network properties:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon.

2. The *Network* editor contains the following basic tabs from which you can modify data:
    - **General Basic**: You can enter or modify comments.
    - **Member Assignment**: Add or delete Microsoft servers. For information, see as described inas described in *Adding IPv4 Networks*. If the network contains multiple DHCP ranges each managed by a different Microsoft server, then you can add those Microsoft servers here.
    - **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific network. You can also modify the values of the extensible attributes. For information, see *About Extensible Attributes*.
    - **Permissions**: This tab appears only if you belong to a superuser admin group. For information managing permissions, see *About Administrative Permissions*.
3. Optionally, you can click **Toggle Expert Mode** to display the following tabs from which you can modify advanced data.
    - **General Advanced***:* You can associate zones with a network. For information, see *Associating Networks with Zones*.
    - **Thresholds**: These watermarks represent thresholds above or below which address usage is unexpected and might warrant your attention. Thresholds are inherited from the Grid.
        - **High-water Mark:** Enter a number between 0 and 100. If the percentage of allocated addresses in a DHCP range exceeds this number, the appliance makes a syslog entry. The default is 95.
        - **Low-water Mark:** Enter a number between 0 and 100. If the percentage of allocated addresses in a DHCP range drops below this number, the appliance makes a syslog entry. The default is 0. Address usage must initially exceed the low-water mark threshold and then dip below it before the appliance considers low address usage an event requiring an alert.
4. Save the configuration and click **Restart** if it appears at the top of the screen.
   or
    - Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Deleting and Restoring a Network

When you delete a network, Grid Manager moves it and its DHCP ranges and fixed addresses to the Recycle Bin, and permanently deletes its leases. The corresponding scopes and reservations are deleted from the Microsoft server at the next synchronization. If you restore the network on Grid Manager, its DHCP ranges and fixed addresses are restored as well. The Grid member then adds the corresponding scopes and reservations to the Microsoft server on the next synchronization. For information about deleting networks, see *Configuring IPv4 Networks*. For information about restoring data, see *Using the Recycle Bin*.

Adding a DHCP Range/Scope

After you add a network for a scope, you must then define its DHCP range. You can create the DHCP range from scratch or use a DHCP Range template. For information about DHCP templates, see *About IPv4 Range Templates*.
You can add multiple ranges to the same network, as long as each range is served by a different Microsoft server and the ranges do not overlap.
When you add a split-scope, you must specify the Microsoft servers that serve the scopes and their exclusion ranges. Each scope inherits its options from its respective Microsoft server. Note that the enabled/disabled setting of the first range automatically applies to the second range. Therefore, if the first range is initially disabled, then the second range is initially disabled as well.
To add a DHCP range for a scope:

1. From the **Data Management** tab, select the **DHCP** tab.
2. Navigate to the network to which you want to add a DHCP range, and then click **Add** -> **DHCP Range** from the Toolbar. You can also add a DHCP range from any panel in the DHCP tab.
3. In the *Add Range* wizard, select one of the following and click **Next**:
    - **Add DHCP Range**
      or
    - **Add DHCP Range using Template**
      Click **Select Template** and select the template that you want to use. Note that when you use a template to create a DHCP range, the configurations of the template apply to the new range. The appliance automatically populates the DHCP range properties in the wizard. You can then edit the pre-populated

properties.

4. Complete the following:
    - **Network**: Click **Select Network** to select the network to which you want to add the DHCP range. The network must be served by a Microsoft server. If you are adding a DHCP range while viewing the contents of a specific network, the appliance displays the network address here. You can still select a different network by clicking **Select Network**.
    - **Start:** Enter the first IP address in the range.
    - **End:** Enter the last IP address in the range.
    - **Name**: You can enter a name for the DHCP range.
    - **Comment:** You can enter additional information. After the range is synchronized to the Microsoft server as a scope, this text appears in the Description field of the scope on the Microsoft server.
    - **Disable for DHCP:** Select this if you do not want the DHCP server to allocate IP addresses from this DHCP range at this time. If you select this, the Grid member synchronizes the range to the Microsoft server as an inactive scope.
5. Click **Next** and select one of the following to provide DHCP services for the DHCP range:

    None: Select this if you do not want to synchronize this range to the Microsoft DHCP server.
    Microsoft Server: This field displays the Microsoft server that you selected for the network. If several servers were assigned to the network, you can select one from the list.
    - **Microsoft Split-Scope:** Select this to create a split-scope, and then complete the following:
        - **Microsoft Server #1:** Read-only field that displays the Microsoft server that you specified in the preceding step.
        - **Microsoft Server #2:** Select the Microsoft server that will serve the split-scope.
        - **Split Percentage:** Specify the percentage of IP addresses in the scope that is allocated to the exclusion range of each Microsoft server. The default is 50%. You can either move the slider or enter the percentages in the text fields. When you use the slider, you are specifying the percentage of addresses in the exclusion range of the first server. A tooltip window displays the percentage as you adjust the slider. When you set the slider, the **Split Percentage**, **Exclusion Starting Address**, and **Exclusion Ending Address** fields are updated accordingly.
    - **Exclusion Starting Address:** When you set the split percentages, these fields automatically displays the starting address of the exclusion range of each Microsoft server. Alternatively, you can enter the starting address of the exclusion range of the first Microsoft server, and the **Split Percentage** and **Exclusion Ending Address** values adjust accordingly.
    - **Exclusion Ending Range:** When you set the split percentage, these fields automatically display the ending address of the exclusion range of each Microsoft server. Alternatively, you can enter the ending address of the exclusion range of the second Microsoft server, and the **Split Percentage** and **Exclusion Starting Address** values adjust accordingly.
6. Click **Next**, and optionally set operational parameters for the scope. Otherwise, the scope inherits its parameters from the first Microsoft DHCP server.
    - **Lease Time**: Specify the lease time. The default is 8 days. When the range is served by a Microsoft server and you enter a lease time of 1000 days or more, Grid Manager automatically grays out this field and checks the **Unlimited Lease Time** option after you save your entries.
        - **Unlimited Lease Time**: Select this option to set an infinite lease time for the IP addresses leased from this range.
        - **Routers**: In the table, enter the IP address of the router that is connected to the same network as the DHCP clients. Click the Add icon to add more routers.
        - **Domain Name**: Enter the name of the domain for which the Microsoft server serves DHCP data. The DHCP server includes this domain name in Option 15 when it responds with a DHCPOFFER packet to a DHCPDISCOVER packet from a client.
        - **DNS Servers**: In the table, enter the IP address of the DNS server to which the DHCP clients send name resolution requests. The DHCP server includes this information in the DHCPOFFER and DHCPACK messages.
        - **Broadcast Address**: Enter the broadcast IP address of the network to which the DHCP server is attached.
7. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes.*
8. Save the configuration and click **Restart** if it appears at the top of the screen.
   or

Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Setting DHCP Range/Scope Properties

A Microsoft scope inherits its properties from its Microsoft server. In Grid Manager, you can override the inherited values or set other properties by editing the DHCP range. You can also configure an exclusion range within the scope and set thresholds, to enable the appliance to make a syslog entry when address usage goes above or below the thresholds. You can modify a scope's properties, including its start and end addresses, servers, and exclusion ranges. If you edit the properties of a split-scope and it results in gaps or overlapping exclusion ranges so that the ranges are no longer identical, Grid Manager displays a warning indicating that continuing with the operation automatically removes the split-scope flag. Grid Manager also removes the flag when the start or end address of a scope changes, so its range is no longer the same.
To set DHCP range properties:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *addr_range* checkbox, and then click the Edit icon.
2. The *DHCP Range* editor contains the following basic tabs from which you can modify data:
    - **General**: Modify the fields, including the start and end addresses, as described in Adding a DHCP Range/Scope above.
    - **Server Assignment**: Switch to **None** or select a different Microsoft server for the DHCP range.
    - **IPv4 DHCP Options**: Keep the DHCP properties or override them and enter unique settings for the DHCP range.
      This tab displays DHCP and Microsoft vendor options that were synchronized from the Microsoft server. You can edit any of the options. When you select a different User Class or Vendor Class from the drop-down menus, Grid Manager automatically updates the option definitions in the drop-down list.
      To configure additional DHCP options, click **+** and select a User Class and Vendor Class from the drop-down menus. Select an option from the drop-down list, and enter a value in the field beside it. You can click - to remove an option.
    - **Extensible Attributes**: You can add and delete extensible attributes that are associated with a specific DHCP range. You can also modify the values of extensible attributes. For information, see *Managing Extensible Attributes*.
    - **Permissions**: This tab appears only if you belong to a superuser admin group. For information about managing permissions, see *About Administrative Permissions*.
3. Optionally, you can click **Toggle Expert Mode** to display the following tabs from which you can modify advanced data.
    - **DDNS**: Complete the following to set DDNS parameters for the range:
        - **Enable DDNS Updates:** Click the checkbox to enable the Microsoft DHCP server to send dynamic DNS updates or clear the checkbox to disable this function.
        - **Option 81 Support**
        - **DHCP Server Updates DNS If Requested by Client:** The DHCP server updates DNS only if it is requested by the client. Otherwise, the client updates DNS.
          DHCP Server Always Updates DNS: The DHCP server always updates DNS, regardless of any client request.
    - **Exclusion Ranges**: Configure a range of IP addresses that the server does not use to assign to clients. You can use these exclusion addresses as static IP addresses. For information, see *Configuring IPv4 Fixed Addresses.* In a split-scope, the exclusion range identifies the range of IP addresses that the other Microsoft server serves. If you edit the exclusion range of either of the scopes in a split-scope and the exclusion ranges no longer complement each other, NIOS removes the split-scope flag from both scopes.
    - **Thresholds**: Thresholds are inherited from the Grid. These watermarks represent thresholds above or below which address usage is unexpected and might warrant your attention.
        - **High-wate rMark:** Enter a number between 0 and 100. If the percentage of allocated addresses in a DHCP range exceeds this number, the appliance makes a syslog entry. The default is 95.
        - **Low-water Mark:** Enter a number between 0 and 100. If the percentage of allocated addresses in a DHCP range drops below this number, the appliance makes a syslog entry. The default is 0. Address usage must initially exceed the low-water mark threshold and then dip below it before the appliance considers low address usage an event requiring an alert.

4. Save the configuration and click **Restart** if it appears at the top of the screen.
   or
   - Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Deleting and Restoring a DHCP Range/Scope

When you delete a DHCP range, Grid Manager moves it and its exclusion range and fixed addresses to the Recycle Bin, and permanently deletes its leases. At the next synchronization, the member deletes the scope, its exclusion range and reservations from the Microsoft server. If you restore a DHCP range on Grid Manager, then the Grid member adds its corresponding scope, exclusion range and reservations to the Microsoft server at the next synchronization. For information about deleting DHCP ranges, see *Deleting IPv4 Address Ranges*. For information about restoring data, see *Using the Recycle Bin*.
If you delete a scope that is part of a split-scope, Grid Manager automatically removes the split-scope flag from the remaining scope.

Viewing Scopes

To view the scopes in a network, navigate to **DHCP** -> **Networks** -> *network*. The panel displays the objects in the network, including the scopes and split-scopes. For split-scopes, the panel displays both scopes with the same start and end address. It displays the following information about each object:

- **IP Address**: The IP address of the DHCP object. For a scope, this field displays the start and end addresses of the scope. Note that the appliance highlights all disabled DHCP objects in gray.
- **Split-Scope:** Displays **Yes** if the scope is a split-scope.
- **MS Server:** Displays the Microsoft server that is serving the scope.
- **Type**: The DHCP object type, such as **DHCP Range** or **Fixed Address**.
- **Name**: The object name. For example, if the IP address belongs to a host record, this field displays the hostname.
- **Comment**: The information you entered for the object.
- **IPv4 DHCP Utilization**: The percentage of the total DHCP usage of a DHCP range. This is the percentage of the total number of fixed addresses, reservations, hosts, and active leases in the DHCP range divided by the total IP addresses in the range, excluding the number of addresses in the exclusion ranges. Note that only enabled objects are included in the calculation.
- **Site**: The site to which the DHCP object belongs. This is one of the predefined extensible attributes.

You can select the following additional columns for display:

- **Static Addresses**: Indicates whether the IP address is a static address.
- **Dynamic Addresses**: Indicates whether the IP address is a dynamically assigned address.
- **Disabled**: Indicates whether the object is disabled.
- **Priority:** Displays the priority of a DHCP range when NAC filters are applied.
- Available extensible attributes.

You can also do the following in this panel:

- Sort the displayed data in ascending or descending order by column.
- Click **Go to IPAM View** to view information about the object in the **IPAM** tab.
- Add new objects, such as DHCP ranges, to the network.
- Delete or schedule the deletion of a selected object or multiple objects.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see as described in *Using Quick Filters*.as described in *Using Quick Filters*.
- Print or export the data.

You can also view the scopes in the IP Map.

Adding Fixed Addresses/Microsoft Reservations

To add a reservation from Grid Manager, add a fixed address and Grid Manager synchronizes it to the Microsoft server as a reservation. You can create fixed addresses from scratch or use fixed address templates. For information about fixed address templates, see *Adding IPv4 Fixed Address/Reservation Templates*.
To add a fixed address:

1. From the **Data Management** tab, select the **DHCP** tab.
2. Expand the Toolbar and click **Add** -> **Fixed Address**.
3. In the *Add Fixed Address* wizard, select one of the following and click **Next**:
   - **Add Fixed Address**
     or
   - **Add Fixed Address using Template**
     Click **Select Template** and select the template that you want to use.
4. Complete the following:
   - **Network:** Click **Select Network** to select the network to which you want to add the fixed address. If you are adding the fixed address from a specific network, the appliance displays the network address here. You can still select a different network by clicking **Select Network**.
   - **IP Address:** Enter the IPv4 address for the fixed address, or click **Next Available IP** to obtain the next available IP address.
   - **MAC Address:** Enter the MAC address of the host.
   - **Name**: Enter a name for the fixed address. This is required for reservations on Microsoft servers.
   - **Configure On:**
     None: Select this if you do not want this synchronized to the Microsoft server.
     Microsoft Server: Select the Microsoft server that serves this fixed address.
   - **Comment:** Optionally, enter additional information. The text in this field appears in the Description field of the Microsoft reservation after the fixed address is synchronized. Note that due to a length limit set by the Microsoft DHCP server, after you synchronize DHCP data, the Description field can display only up to 128 characters even though NIOS allows up to 256 characters for this field.
5. Click **Next**, and optionally set operational parameters for the fixed address. Otherwise, the fixed address inherits its parameters from its scope.
   - **Routers**: In the table, enter the IP address of the router that is connected to the same network as the DHCP client. Click the Add icon to add more routers.
   - **Domain Name**: Enter the name of the domain for which the Microsoft DHCP serves DHCP data. The DHCP server includes this domain name in Option 15 when it responds with a DHCPOFFER packet to a DHCPDISCOVER packet from a client.
   - **DNS Servers**: In the table, enter the IP address of the DNS server to which the DHCP client sends name resolution requests. The DHCP server includes this information in the DHCPOFFER and DHCPACK messages.
   - **Broadcast Address**: Enter the broadcast IP address of the network to which the DHCP server is attached.
6. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Using Extensible Attributes*.
7. Save the configuration and click **Restart** if it appears at the top of the screen.
   or
   - Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Setting Fixed Address/Reservation Properties

Microsoft reservations inherit their properties from their scopes. In Grid Manager, you can override the inherited values or set other properties of a Microsoft reservation, by editing its fixed address.
To modify a fixed address:

1. From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *fixed_address* checkbox, and then click the Edit icon.
2. The *Fixed Address* editor contains the following basic tabs from which you can enter data:
   - **General**: You can modify the fields described in Adding Fixed Addresses/Microsoft Reservations above.

- **IPv4 DHCP Options**: Keep the inherited properties, or override them and enter unique settings. This section displays DHCP and Microsoft vendor options that were synchronized from the Microsoft server. You can edit any of the options. When you select a different User Class or Vendor Class from the drop-down menus, Grid Manager automatically updates the option definitions in the drop-down list. To configure additional DHCP options, click **+** and select a User Class and Vendor Class from the drop-down menus. Select an option from the drop-down list, and enter a value in the field beside it. You can click - to remove an option.
- **Discovered Data**: If you ran a discovery on the network, Grid Manager displays the discovered data of the fixed address. For information, see *Viewing Discovered Data*. Note that conflicts can occur when discovered data does not match the existing IP address data. For information about resolving these conflicts, see *Resolving Conflicting Addresses*.
- **Extensible Attributes**: Add and delete extensible attributes that are associated with a specific network. You can also modify the values of extensible attributes. For information, see *Managing Extensible Attributes*.
- **Permissions**: This tab appears only if you belong to a superuser admin group. For information, see *About Administrative Permissions*.

3. Optionally, you can click **Toggle Expert Mode** to display the **DDNS** tab. To set DDNS parameters for the fixed address, complete the following:

- **Enable DDNS Updates:** Click the checkbox to enable the Microsoft DHCP server to send dynamic DNS updates or clear the checkbox to disable this function.
- **Option 81 Support**
- **DHCP Server Updates DNS If Requested by Client:** The DHCP server updates DNS only if it is requested by the client. Otherwise, the client updates DNS.
- **DHCP Server Always Updates DNS:** The DHCP server always updates DNS, regardless of any client request.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

or

- Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Deleting and Restoring a Fixed Address/Reservation

When you delete a fixed address, Grid Manager moves it to the Recycle Bin. At the next synchronization, the Grid member deletes its corresponding reservation from the Microsoft server. If you restore fixed address, then the Grid member adds its corresponding reservation to the Microsoft server at the next synchronization. For information about deleting fixed addresses, see *Deleting Fixed Addresses*. For information about restoring data, see *Using the Recycle Bin*.

About Superscopes

In Grid Manager, you can group DHCP ranges served by Microsoft servers into a superscope. You can add multiple DHCP ranges to a superscope, as long as the ranges are all served by the same Microsoft DHCP server. The Grid member then synchronizes the superscope and its associated DHCP ranges as superscopes and scopes to the Microsoft DHCP server.
You can also associate extensible attributes with superscopes in Grid Manager. Extensible attributes are not synchronized to the Microsoft DHCP server.
Only admins with read/write permission to superscopes can add and manage superscopes.

Adding Superscopes

Before you add a superscope, you must first create at least one DHCP range to include in the superscope. To add a superscope:

1. From the **Data Management** tab, select the **DHCP** tab.

2. If you have more than one network view in the system, select the network view in which you want to add the superscope. The network view must be the same one that is assigned to the Microsoft server.
3. Expand the Toolbar and click **Add** -> **Superscope**.
4. In the *Add Superscope* wizard, complete the following and click **Next:**
    - **Name**: Enter a name for the superscope.
    - **Comment**: Optionally, enter additional information about the superscope.
    - **Disabled:** Select this to disable the DHCP ranges in the superscope. They are then synchronized as inactive scopes on the Microsoft server.
5. Click the Add icon and select a range from the *Select Range* dialog box. This dialog box lists only the address ranges that are served by a Microsoft server.
6. Click **Next** to enter values for required extensible attributes or add optional extensible attributes. For information, see *Managing Extensible Attributes*.
7. Save the configuration and click **Restart** if it appears at the top of the screen.
   or

- Click the Schedule icon at the top of the wizard to schedule this task. In the *Schedule Change* panel, enter a date, time, and time zone. For information, see *Scheduling Tasks*.

Viewing Superscopes

To view superscopes, navigate to the **Data Management** tab -> **DHCP** tab -> **Networks** tab -> **Microsoft Superscopes**. Grid Manager displays the following information about each superscope that is displayed:

- **Name**: The name of the superscope. Grid Manager appends the FQDN of its associated Microsoft server so you can identify which superscope belongs to which server.
- **Comment**: The comment that was entered for the superscope.
- **DHCP Utilization**: The percentage of the total DHCP usage of the ranges in the superscope. Fixed addresses and reservations that are outside of a range are excluded from the calculation.
- **Site**: The site of the superscope. This is one of the predefined extensible attributes.

You can add the following columns for viewing:

- **Static Addresses**: The number of static addresses.
- **Dynamic Addresses**: The number of dynamic addresses.
- **Disabled**: Indicates whether the superscope is enabled.

You can do the following in this section:

- Click the link of a superscope to list its address ranges.
- Add a superscope.
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information about using quick filters, see *Finding and Restoring Data*.
- Print or export the information in this section.
- Delete a superscope.

Modifying Superscopes

To modify a superscope:

1. From the **Data Management** tab, select the **DHCP** tab -> **Network** tab -> **Microsoft Superscopes** -> *ms_superscope* checkbox, and then click the Edit icon.
2. The *Superscopes* editor contains the following tabs from which you can modify data:
    - **General:** You can modify the name and comment, and enable or disable the superscope. You can also add and delete address ranges from the superscope. Note that when you delete the last DHCP range in a superscope, Grid Manager automatically deletes the superscope as well.

- **Extensible Attributes**: Define extensible attributes for the superscope. These apply only when the superscope is managed in Grid Manager. For information, see *Managing Extensible Attributes.*
- **Permissions:** Define administrative permissions that apply to the superscope when it is managed in Grid Manager. For information see *About Administrative Permissions*.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Deleting Superscopes

When you delete a superscope in Grid Manager, it is permanently deleted from the database. The superscope is deleted from the Microsoft server at the next synchronization. Note that deleting a superscope does not delete the DHCP ranges in the superscope. These are retained in the database.
To delete a superscope:

1. From the **Data Management** tab, select the **DHCP** tab -> **Network** tab -> **Microsoft Superscopes** -> *ms_superscope* checkbox, and then click the Delete icon.
2. Click **Yes** when the confirmation dialog appears.

Synchronizing Updates

A Grid member synchronizes DHCP data with each of its managed Microsoft server at regular intervals. During each synchronization, updates from Grid Manager are applied to the Microsoft server and updates from the Microsoft server are applied to the Grid as well.
Because admins can update DHCP data from both the Microsoft server and from Grid Manager, conflicts can occur during synchronization. The following guidelines describe how the Grid member resolves conflicts and handles any differences when DHCP data is synchronized between a Microsoft server and the Grid.

- If a Microsoft server admin modifies an object that has a pending scheduled task in Grid Manager and synchronization occurs before the scheduled task, the object is modified in both the Microsoft server and the Grid member. When the scheduled task executes at its scheduled time, it fails and an error message is logged in the audit log.
- When a Microsoft server admin and a Grid Manager admin change the same object, the Grid member retains the version that exists on the Microsoft server. Following are some examples:

Grid Manager Admin...	Microsoft Server Admin...	After Synchronization
Deletes the 10.1.1.0/24 network which has two DHCP ranges	Adds a scope that is within the 10.1.1.0/24 network	The 10.1.1.0/24 network is created on the Grid with the updates and is assigned to the Microsoft server.
Changes the DHCP options of a scope	Deletes the scope.	The scope is deleted from the Grid as well.

- If a Grid member manages multiple Microsoft servers, it can synchronize scopes to the same network as long as they are served by different Microsoft servers and they do not overlap. If the Microsoft servers have scopes that overlap, the Grid member synchronizes only one of the scopes, including its reservations. It does not synchronize the other scopes and logs an error message for each scope that is not synchronized. For information about the Microsoft logs, see *Viewing Synchronization Logs*.
  Note that a Grid member can synchronize scopes with overlapping reservations because they are served by different Microsoft servers.
- When a Grid member synchronizes a split-scope to its respective Microsoft servers, the scopes use the default value for the DHCP Offer Delay value, since this property is not supported by NIOS.
- If you create a split-scope on a NIOS appliance, synchronization fails if there is an existing scope in the same network on one of the Microsoft servers. Only one scope is allowed in a network, per Microsoft server.
- If a Microsoft admin adds a DHCP range and a NIOS admin is in the process of adding the same range when a synchronization occurs, the NIOS admin will not be able to save the range after the synchronization. Grid Manager will display an error message indicating that the range already exists.
- If both a NIOS admin and a Microsoft admin create a scope or split-scope and conflicts occur, the Microsoft server always takes precedence. All conflicts are logged to the Microsoft log. Following are some examples:

- If the NIOS admin creates a scope and a Microsoft server admin creates a split-scope for the same DHCP range, the split-scope is synchronized to Grid Manager.
- If the NIOS admin creates a split-scope on Microsoft servers 1 and 2, and a Microsoft admin creates the same split-scope on Microsoft servers 1 and 3 but with different exclusion ranges, the scope created by the NIOS admin on Microsoft server 1 is dropped upon synchronization.
- If the NIOS admin creates a split-scope on Microsoft servers 1 and 2, and a Microsoft admin creates the same split-scope on the same Microsoft servers but with different exclusion ranges, the split-scope created by the Microsoft admin is synchronized to NIOS and retained. The split-scope created by the NIOS admin is dropped.

Synchronizing DHCP Data from Microsoft Servers

After you configure a member to manage the DHCP service of a Microsoft server, the Grid member connects to the server and starts synchronizing IPv4 DHCP data from the Microsoft server to the Grid database. It synchronizes the Microsoft server properties, leases, scopes and reservations.
The synchronization time varies, depending on different factors, such as the number of managed Microsoft servers and the amount of data being synchronized.

> **Note**
>
> Synchronizing IPv6 data is not supported.

As shown in the table below, Microsoft servers and Infoblox DHCP servers represent DHCP data differently. Scopes on Microsoft servers are DHCP ranges on Infoblox DHCP servers. Additionally, Microsoft servers support split-scopes, which is a scope assigned to two Microsoft servers. Each scope has an exclusion range on opposite ends to specify the pool of IP addresses that the other Microsoft server allocates. On an Infoblox DHCP server, each scope in the split-scope is represented as a DHCP range with an exclusion range. Note that NIOS also synchronizes scopes assigned to more than two Microsoft servers, but they are not synchronized as split-scopes.
Fixed addresses on Infoblox DHCP servers are the same as reservations on Microsoft servers. Infoblox reservations, which are IP addresses that are excluded from DHCP, are not supported on Microsoft servers. Microsoft superscopes, which are used to group scopes, are represented as superscopes and can be managed from Infoblox DHCP servers.

DHCP Data in Microsoft and Infoblox DHCP Servers

DHCP Data	Microsoft DHCP Servers	Infoblox DHCP Servers
Address pool from which the server allocates addresses	Scope	DHCP Address Range in a Network
An IP address that is always assigned to the same device	Reservation	Fixed Address
An IP address that is excluded from DHCP because a user intends to configure it manually on a network device	Not supported	Reservation
Administrative group of scopes	Superscope	Microsoft superscope

> **Note**
>
> In this chapter, reservations always refer to Microsoft reservations (Infoblox fixed addresses), unless otherwise specified.

When the member synchronizes a scope to the Grid, it converts the scope to a DHCP range and network. For example, it converts the Microsoft scope 10.1.1.1- 10.1.1.200 with a netmask of /24 to the network 10.1.1.0/24 and DHCP range 10.1.1.1- 10.1.1.200 on Grid Manager. The member associates the DHCP properties of the scope, including its DHCP and Microsoft vendor options, with the DHCP range. It synchronizes the leases within the range and if configured, the

exclusion range as well.
NIOS synchronizes two scopes as split-scopes if the following conditions are met:

- Two scopes have the same address range.
- The scopes are assigned to two different Microsoft servers.
- Each scope has an exclusion range and the exclusion ranges are at opposite ends of the scope, so they complement each other. For example, the scope 10.1.1.1-10.1.1.200 on Microsoft server A has an exclusion range of 10.1.1.100-10.1.1.200 and the same scope on Microsoft server B has en exclusion range of 10.1.1.1-10.1.1.99.

When the appliance synchronizes a split-scope, it sets a split-scope flag on each scope to indicate that it is part of a split-scope. For more information, see *Viewing Scopes*. It synchronizes any reservations that are configured in each scope as well.
When the member synchronizes a Microsoft reservation to the Grid, it converts the reservation to a fixed address and static lease on Grid Manager. It associates the DHCP properties and DHCP and Microsoft vendor options of the reservation with the fixed address record.
The Grid member synchronizes superscopes to the Grid as well. The Grid supports Microsoft superscopes, when an MS management license is installed. For information about adding and managing superscopes in Infoblox DHCP servers, see *About Superscopes*.
Following are some guidelines on how a Grid member synchronizes DHCP data from Microsoft servers to the Grid:

- If two superscopes have the same name, but are served by different servers, the member creates two different superscopes on the Grid, each appended with the Microsoft server FQDN.
- The member synchronizes all active and inactive scopes from a managed Microsoft server as long as the scopes do not conflict or include any networks currently served by a Grid member. The member does not synchronize a scope if its network already exists in the Grid and is served by a Grid member. It can synchronize a scope if its network is included in an existing network, only if the network is not served by DHCP.
- Synchronizing scopes that are larger than /12 is not supported.
- NIOS synchronizes all scopes except for those with serving ranges that overlap the serving ranges of existing DHCP ranges.
- If the appliance manages multiple Microsoft servers and synchronizes identical scopes from more than two Microsoft servers, it does not flag the scopes as split-scopes.
- If the appliance synchronizes one or more scopes from Microsoft servers that are identical to an existing split-scope, it removes the split-scope flag from the existing split-scope.
- NIOS does not synchronize partially overlapping scopes inside a single network from different Microsoft servers. It synchronizes only ranges that completely overlap.
- More than two scopes are not synchronized as split-scopes, even if they are identical and have exclusion ranges that complement each other.
- Scopes that have more than one exclusion range are not synchronized as split-scopes, even if the exclusion ranges complement each other. In addition, if a split-scope is synchronized from a Microsoft server and one of the scopes is split again on the Microsoft server, NIOS synchronizes the third scope, but does not set a split-scope flag. In addition, it removes the split-scope flag from the original split-scopes.

You can view the synchronized data as follows:

- To view the networks of the scopes, select the **Data Management** tab -> **DHCP** tab -> **Networks** tab -> **Networks** panel. This panel displays all IPv4 networks.
- To view the corresponding DHCP ranges and reservations, select the **Data Management** tab -> **DHCP** tab -> **Networks** tab, and click a network link. For information about this panel, see *Viewing Scopes*.

You can also use the features in the **IPAM** tab, such as the Net Map and IP Map, to view and manage the Microsoft DHCP data. For information, see *About IP Address Management*.

Managing Microsoft DHCP Servers

You can control the DHCP services of managed Microsoft servers and set certain properties as well. This section includes the following topics:

- *Setting Microsoft DHCP Server Properties*
- *Controlling the DHCP Service of a Microsoft Server*

- *Disabling and Removing Microsoft DHCP Servers*
- *Modifying DHCP Server Assignments*

Viewing Members and Managed DHCP Servers

You can view Infoblox and Microsoft DHCP servers by navigating to the **Data Management** tab -> **DHCP** tab, and then selecting the **Members/Servers** tab. The panel displays the following information about each DHCP server:

- **Name**: The hostname of the Grid member or Microsoft server.
- **Status**: The status of the DHCP service on the Grid member or Microsoft server.
- **Comment**: Comments that were entered for the Grid member or Microsoft server.
- **DHCP Utilization:** The percentage of the total DHCP utilization of the member or Microsoft server. This is the percentage of the total number of DHCP hosts, fixed addresses, reservations, and leases assigned to the member or Microsoft server versus the total number of IP addresses (excluding IP addresses in the exclusion range) and all DHCP objects assigned to the member or DHCP server. Note that only enabled objects are included in the calculation. The appliance updates the utilization data every 15 minutes. The appliance displays the utilization data in one of the following colors:
    - Red: The DHCP resources are 100% utilized.
    - Yellow: The utilization percentage is over the effective high watermark threshold.
    - Blue: The utilization percentage is below the effective low watermark threshold.
    - Black: The utilization percentage is at any number other than 100%, or within the effective thresholds.
- **Site**: Values that were entered for this pre-defined attribute.

You can select the following additional columns for display:

- **Address**: The IP address of the member or Microsoft server.
- **Static Addresses**: The number of static IP addresses.
- **Dynamic Addresses**: The number of dynamically assigned IP addresses.

You can do the following:

- Use filters and the **Goto** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Goto** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Edit the properties of a Grid member or Microsoft server.
    - Click the checkbox beside a Grid member or Microsoft server, and then click the Edit icon.
- Export the list of Grid members and Microsoft servers to a .csv file.
    - Click the Export icon.
- Print the list of Grid members and Microsoft servers.
    - Click the Print icon.

Setting Microsoft DHCP Server Properties

From Grid Manager, you can set DHCP properties supported by a Microsoft server. These are applied to the server at the next synchronization. You can also set other properties that apply to Grid Manager only, such as thresholds and the logging.
To set properties for a Microsoft DHCP server:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members/Servers** tab -> **Members/Servers** -> *ms_server* checkbox, and then click the Edit icon.
2. In the *Microsoft Server DHCP Properties* editor, you can configure DHCP properties in each tab as follows: **IPv4 DHCP Options** tab: Complete the following to configure basic DHCP options for the server:
    - **Routers**: Click the Add icon and enter the IP address of the router that is connected to the same network as the DHCP clients.
    - **Domain Name**: Enter the name of the domain for which the server serves DHCP data. The DHCP server includes this domain name in Option 15 when it responds with a DHCPOFFER packet to a DHCPDISCOVER packet from a client. If DDNS is enabled on the DHCP server, it combines the host name from the client and this domain name to create the FQDN (fully-qualified domain name) that it uses to update DNS.

- **DNS Servers**: Click the Add icon and enter the IP address of the DNS server to which the DHCP client sends name resolution requests. The DHCP server includes this information in the DHCPOFFER and DHCPACK messages.
- **Broadcast Address**: Enter the broadcast IP address of the network to which the DHCP server is attached.
- **Custom DHCP Options**: This section displays DHCP and Microsoft vendor options that were synchronized from the Microsoft server. You can edit any of the options. When you select a different User Class or Vendor Class from the drop-down menus, Grid Manager automatically updates the option definitions in the drop-down list.
  To configure additional DHCP options, click **+** and select a User Class and Vendor Class from the drop-down menus. Select an option from the drop-down list, and enter a value in the field beside it. You can click - to remove an option.

  DDNS tab**:** You can enable or disable dynamic DNS updates and set certain properties.
  - **Enable DDNS Updates:** Click the checkbox to enable the Microsoft DHCP server to send dynamic DNS updates or clear the checkbox to disable this function.
  - **Option 81 Support**
    DHCP Server Updates DNS If Requested by Client: The DHCP server updates DNS only if it is requested by the client. Otherwise, the client updates DNS.
    DHCP Server Always Updates DNS: The DHCP server always updates DNS, regardless of any client request.

    Thresholds tab: Thresholds are inherited from the Grid. These watermarks represent thresholds above or below which address usage is unexpected and might warrant your attention.
- **Enable DHCP Thresholds:** Select this checkbox to enable the feature.
  - **High-water Mark:** Enter a number between 0 and 100. If the percentage of allocated addresses in a DHCP range exceeds this number, the DHCP server makes a syslog entry. The default is 95.
  - **Low-water Mark:** Enter a number between 0 and 100. If the percentage of allocated addresses in a DHCP range drops below this number, the DHCP server makes a syslog entry. The default is 0. Address usage must initially exceed the low-water mark threshold and then dip below it before the appliance considers low address usage an event requiring an alert.

3. Optionally, you can click **Toggle Expert Mode** to display the **Logging** tab, where you can enable the managing member to log the lease events of the Microsoft server. This setting is inherited from the Grid. You can override that setting by clicking **Override**, and then selecting or clearing the **Log Lease Events from DHCP server** checkbox.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Controlling the DHCP Service of a Microsoft Server

You can start and stop the DHCP service of a managed Microsoft server from Grid Manager as follows:

1. From the **Data Management** tab, select the **DHCP** tab -> **Members/Servers** tab -> **Members/Servers** -> *ms_server* checkbox.
2. Expand the Toolbar and click **Start** or **Stop**.
3. Click **Yes** when the confirmation dialog appears.

Disabling and Removing Microsoft DHCP Servers

If you remove a Microsoft server as a managed server, Grid Manager deletes all the DHCP ranges, leases, and fixed addresses associated with the server. It also deletes networks that were assigned only to the Microsoft server. It does not delete a network if it was assigned to other Microsoft servers as well.
When you disable a Microsoft server, the managing Grid member terminates any on-going synchronization and restarts synchronization only when the server is re-enabled. The DHCP data associated with that server is preserved in the same state until synchronization resumes.
For information on removing and disabling Microsoft servers, see *Managing Microsoft Servers*.

Modifying DHCP Server Assignments

If you disable a Microsoft DHCP server or take it offline for maintenance purposes, for example, you can assign its scopes to a member DHCP server.
Following are the tasks to reassign scopes from a Microsoft server to a member DHCP server:

1. Set the server assignments of all fixed addresses in the scope to "None".
   From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *fixed_address* checkbox, and then click the Edit icon. You can change the server assignment in the **General** tab of the *Fixed Address* editor.
2. Set the server assignments of all address ranges served by the Microsoft server to "None".
   From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *addr_range* checkbox, and then click the Edit icon. You can change the server assignment in the **General** tab of the *DHCP Range* editor.
3. Change the sever assignments of the networks by deleting the Microsoft server and replacing it with a member DHCP server.
   From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon. You can change the server assignment in the **Member Assignment** tab of the *Network* editor. contains the following basic tabs from which you can modify data:
4. Modify the server assignments of all address ranges and specify the member DHCP server.
   From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *addr_range* checkbox, and then click the Edit icon. You can change the server assignment in the **General** tab of the *DHCP Range* editor.
5. Restart services.

The member DHCP server starts granting lease requests after the restart. Note that you do not need to clear the leases that were active on the Microsoft server, because the member automatically clears them when you change the DHCP server assignment.

Monitoring

This section explains how to use the different monitoring and reporting tools, including DHCP fingerprint detection and SNMP. It includes the following topics:

- *Monitoring the Appliance*
- *Configuring DHCP Fingerprints and Fingerprint Detection*
- *Monitoring with SNMP*

Monitoring the Appliance

Grid Manager provides tools for monitoring the status of the Grid, members, and services. You can monitor overall Grid and member status from the Dashboard, which provides a high-level view of your Grid, members and IP address data, and easy access to tasks. For information, see *Dashboards*.

Grid Manager also displays status icons to indicate the state of appliances, services, database capacity, Ethernet ports, HA, and Grid replication. Depending on your appliance, Grid Manager can display status icons for the power supplies as well as icons to indicate the state of the RAID array and disk controller backup battery.
You can monitor detailed status of the Grid, members, and services, and then decide how to manage them. Note that when any member or service encounters issues, the appliance sends SNMP traps. For information, see *Monitoring with SNMP*.

This section describes the status icons that indicate the state of appliances, services, database capacity, Ethernet ports, HA, and Grid replication. It also explains how to use the various logs and the traffic capture tool to monitor a NIOS appliance. It contains the following topics:

- *Viewing the Grid Node Tree*

Viewing the Grid Node Tree

You can view graphical representation of the Grid, with its members represented as nodes in the tree. The **Visualization** tab is disabled for new installations and this tab is displayed by default when you upgrade to NIOS 7.2.x and later. For information about enabling this option, see *Enabling Grid Visualization*. Each member is labeled with its hostname. You can click **Display Node Labels** on the left panel to display or hide the labels.
By default, the Grid Master is the root node at the center of the tree. It is represented by a color-coded icon connected to its members. You can then click a member to re-center the tree on that node. The left panel displays information about the member that is at the center of the node tree.
In the node tree, the shape of the icons indicate the role of the member in the Grid:

- Circle: Grid Master
- Ellipse: Grid Members

The colors of the icons indicate the status of the member:

- Green: The member is online and functioning properly.
- Grey: The member has not joined the Grid.
- Red: The member has operational problems.

The connectors indicate the connection status between the Grid Master and the member.

- Blue Line: Connects the Grid Master with online Grid members
- Thick White Line: Connects the Grid Master with Grid Master Candidates
- Dashed Line Connector: Connects the Grid Master with offline Grid members

The node tree includes zooming and panning capabilities to enable quick navigation and selection among multiple nodes. You can also hover your mouse over a node to view node information. It displays the same information as that displayed on the left panel, when a node is at the center of the tree.
For the Grid Master:

- Grid name
- Standalone or HA
- Number of members in the Grid
- Status of each protocol running on the Grid
- Grid status For a Member:
- Member name
- Standalone or HA
- HA Status if HA pair
- Status of each protocol running on that member

Member Status

You can monitor the overall status, such as the memory usage and system temperature, of a Grid member or an independent appliance using the *Member Status (System Status)* widget on the Dashboard.

To monitor the detailed status of a member, from the **Grid** tab, select the **Grid Manager** tab -> **Members** tab.

In the **Members** tab, Grid Manager displays the Grid Master first and then all other members in alphabetical order. If a member is an HA pair, you can click the arrow next to the member row to view information about the active and passive nodes. Grid Manager can display the following information:

- **Name**: The name of the member.
- **HA**: Indicates whether the member is an HA pair.
- **Status**: The service status of the member. For a vNIOS appliance whose license is revoked and is still operating in the Grid, Grid Manager displays a license violation warning here. You should immediately remove this member from the Grid.
- **IPv4 Address**: The IPv4 address of the appliance, or the VIP of an HA pair.
- **IPv6 Address**: The IPv6 address of the appliance, or the VIP of an HA pair.
- **Identify**: This field appears only if your appliance has the unit identification button. This can be On or Off. When you identify the appliance by pressing the UID button on the appliance or through the GUI or CLI command, this field displays On. Otherwise, this is Off.
- **DHCP**, **DNS**, **TFTP**, **HTTP**, **FTP**, **NTP**, **bloxTools**, **Captive Portal**, **DNS Accelerator usage**, **Reporting, Discovery, Threat Protection, Cloud-API, Threat Analytics, TAXII**: The status icons indicate whether these services are running properly. For information about service status, see *Monitoring Services*.
- **Hardware Type**: The hardware type of the appliance.
- **Hardware Model**: The hardware model of the appliance.
- **Serial Number**: The serial number of the appliance.
- **DB Utilization**: The current percentage of the database in use.
- **Host Platform**: The platform on which the appliance is running. For a vNIOS appliance, this field displays the name of the cloud management platform, such as **AWS**, **Azure**, **GCP**, or **VMware**, and for the vNIOS for GCP appliance, if the NIOS instance is running on a single network interface, the field displays **GCP (Single Interface)**. For physical NIOS appliances, this displays **Physical**. For appliances running on the CentOS operating system, the **Host Platform** column displays **Red Hat**.
- **Hypervisor**: The hypervisor of the appliance
- **Comment**: Information about the member.

> **Note**
>
> The placement of the **Host Platform** and **Hypervisor** columns may vary after a NIOS upgrade.

To turn the identification button on or off on the member, click the Hardware Identify icon from the horizontal navigation bar. Grid Manager displays a panel with the appliance name, status, and IP address. Hover your mouse over the row and click **Turn On** to turn the identification button on, or click **Turn Off** to turn it off.

To view detailed status, select a member checkbox, and then click the Detailed Status icon. Grid Manager displays the *Detailed Status* panel. If the selected member is an HA pair, Grid Manager displays the information in two columns, one for the active node and the other for the passive. The *Detailed Status* panel provides detailed information described in the following sections.

You can modify some of the data in the table. Double click a row, and either modify the data in the field or select an item from a drop-down list. Click **Save** to save the changes. Note that some fields are read only.

Appliance Status

The status icon indicates the operational status of a Grid member and a general description of its current operation. The status icon can be one of the following:

Icon	Color	Meaning
	Green	The appliance is operating normally in a "Running" state.

	Yellow	The appliance is connecting or synchronizing with its Grid Master.
	Red	The Grid member is offline, is not licensed (that is, it does not have a DNSone license with the Grid upgrade that permits Grid membership), is upgrading or downgrading, or is shutting down.

The following are descriptions that may appear: Running, Offline, Error, and Warning.

Disk Usage

Grid Manager displays the percentage of the data partition of the hard disk drive that is currently in use on the selected Grid member. It also displays whether the percentage of usage has exceeded the trigger or reset value. Note that the trigger and reset values are user configurable. The default trigger value is 85% and reset value is 70%. The status icon can be one of the following:

Icon	Color	Meaning
	Green	The disk usage is either below the reset value or has not yet reached the trigger value.
	Yellow	The disk usage is decreasing from the trigger value, but has not yet reached the reset value.
	Red	The disk usage has exceeded the trigger value.

DB Capacity Usage

Grid Manager displays the current percentage of the database in use on the selected Grid member. It also describes whether the usage has exceeded the trigger or reset value. Note that the trigger and reset values are user configurable. The default trigger value is 80% and the reset value is 70%. For information about using the capacity report, see *Monitoring Tools*. The status icon can be one of the following:

Icon	Color	Meaning
	Green	The database capacity is either below the reset value or has not yet reached the trigger value.
	Yellow	The database capacity is decreasing from the trigger value, but has not yet reached the reset value. When the capacity exceeds the trigger value, the icon changes from green to yellow.

LAN1/LAN2 Ports, HA Port, and MGMT Port

Grid Manager displays the IP address of the port. The status icons for these ports indicate the state of their network connectivity.

Icon	Color	Meaning
	Green	The port is properly connected to a network. Grid Manager displays the IP address of the network.
	Red	The port is not able to make a network connection.
	Gray	The port is disabled.

LCD

The LCD status icon indicates its operational status.

Icon	Color	Meaning
	Green	The LCD is functioning properly.
	Yellow	The LCD process is not running.

Memory Usage

Grid Manager displays the current percentage of system memory in use on the selected Grid member. It also describes whether the usage has exceeded the trigger or reset value. Note that the trigger and reset values are user configurable. The default trigger value is 90% and the reset value is 80%. You can see more details about memory usage through the CLI command: show memory. The status icon can be one of the following.

Icon	Color	Meaning
	Red	The memory usage has exceeded the trigger value.
	Yellow	The memory usage is decreasing from the trigger value, but has not yet reached the reset value.
	Green	The memory usage is either below the reset value or has not yet reached the trigger value.

Swap Usage

Grid Manager displays the current percentage of swap area in use on the selected Grid member. It also describes whether the usage has exceeded the trigger or reset value. Note that the trigger and reset values are user configurable. The default trigger value is 20% and the reset value is 10%. The status icon can be one of the following:

Icon	Color	Meaning
	Red	The memory usage has exceeded the trigger value.
	Yellow	The memory usage is decreasing from the trigger value, but has not yet reached the reset value.
	Green	The memory usage is either below the reset value or has not yet reached the trigger value.

FAN

The status icon indicates whether the fan is functioning properly. The corresponding description displays the fan speed. The status icon and fan speed are displayed for Fan1, Fan2, and Fan3.

> **Note**
>
> vNIOS appliances on VMware do not monitor or report the fan speed.

Icon	Color	Meaning
	Green	The fan is functioning properly.
	Red	The fan is not running.

NTP Synchronization

The status icon indicates the operational status of the current NTP synchronization status.

Icon	Color	Meaning
	Green	The NTP service is enabled and running properly.
	Yellow	The NTP service is enabled, and the appliance is synchronizing its time.

	Red	The NTP service is enabled, but it is not running properly or is out of synchronization.
	Gray	The NTP service is disabled.

Passive HA Connectivity Status

The status icon indicates the ARP connectivity status of the passive node of an HA pair. The status icon can be one of the following:

Icon	Color	Meaning
	Green	The passive HA node is connected to the local router.
	Yellow	The passive HA node fails to connect to the local router.
	Gray	ARP is disabled on the passive node of an HA pair.

CPU Temperature

This icon is always green. The description reports the CPU temperature.

> **Note**
> vNIOS appliances on VMware do not monitor or report the CPU temperature.

System Temperature

This icon is always green. The description reports the system temperature.

> **Note**
> vNIOS appliances on VMware do not monitor or report the system temperature.

CPU Usage

Grid Manager displays the current percentage of the CPU usage on the selected Grid member. The maximum is 100%. It also describes whether the CPU usage has exceeded the trigger or reset value. Note that the trigger and reset values are user configurable. The default trigger value is 81% and the reset value is 70%. You can see more details about CPU usage through the CLI command: show CPU.

The status icon can be one of the following:

Icon	Color	Meaning

	Green	The CPU usage is either below the reset value or has not yet reached the trigger value.
	Red	The CPU usage has exceeded the trigger value.

Enabling Grid Visualization

To enable Grid visualization:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, and then click **Grid Properties** -> **Edit** from the Toolbar.
2. In the *GridProperties* editor, click the **Advanced** tab.
3. Select the **Show Grid Visualization** checkbox.
4. Click **Save** to save the changes. The **Visualization** tab appears and displays a graphical representation of the Grid. This may take a long time depending on the number of members you have in the Grid. When you deselect this checkbox, you disable Grid visualization for all users.

Grid Status

You can monitor the overall status of the Grid using the *Grid Status* widget on the Dashboard.

You can also view the Grid status from the **Grid Manager** tab. To view Grid status, from the **Grid** tab, select the **Grid Manager** tab. Grid Manger displays the overall Grid status and status of all Grid services. The Grid status represents the status of the most critical members or services in the Grid. When all Grid members are running properly, the overall Grid status is green. When one of the members has operational problems, the overall Grid status is red. Grid Manager lists all Grid members in the **Members** tab so you can identify which member has issues. For information, see *Member Status*.

In addition, the service bar below the Grid status lists the status of all licensed services on your Grid. This can include DHCP, DNS, Cloud-API, TFTP, HTTP (File Distribution), FTP, NTP, bloxTools, Captive Portal, DNS Accelerator, Reporting, Discovery and others, depending on the active licenses you have installed. When you click a service link, Grid Manager displays detailed information about the selected service running on all members. For information, see *Monitoring Services*.

Grid Manager also provides icons you can use to edit Grid properties and bookmark the page.

Monitoring Services

The Grid or device status icon and the service icon indicates whether a service running on a member or an independent appliance is functioning properly or not.

Service Status

After you enable any of the services — DHCP, DNS, TFTP, HTTP (for file distribution), FTP, NTP, bloxTools, Captive Portal, Reporting, Discovery, Threat Protection and Cloud API — the appliance indicates their status as follows:

Icon	Color	Meaning
	Green	The service is enabled and running properly.

	Yellow	The service is enabled, but there may be some issues that require attention. For Threat Protection, this could mean that one of the members is in monitor mode.
	Red	The service is enabled, but it is not running properly. (A red status icon can also appear temporarily when a service is enabled and begins running, but the monitoring mechanism has not yet notified Grid Manager.)
	Gray	The service is not configured or it is disabled.

Note

When you enable reporting service on the Grid and configure multi-site cluster, you can monitor the status of all reporting members that you have configured. For information about reporting clusters, see *Configuring Reporting Clustering*.

Monitoring Grid Services

The status icon of a Grid service represents the status of the most critical service in the Grid. For example, if the Grid DHCP status icon is red, the DHCP service on one of the members in the Grid is not running properly. You can click the DHCP service link to view the service status of all Grid members and identify which member has a service problem. You can then decide to start or stop the service, or modify the service configuration on that member.
To monitor a Grid service:

1. From the **Grid** tab, select the **Grid Manager** tab, and then click a service link.
2. Grid Manager displays the following information in the **Services** tab:
   - **Name**: The name of the member.
   - **Service Status**: The current status of the service.
   - **IPv4 Address**: The IPv4 address of the appliance or the VIP of an HA pair.
   - **IPv6 Address**: The IPv6 address of the appliance or the VIP of an HA pair.
   - **Comments**: Information about the member or service.
   - **Site**: The site to which the member belongs. This is one of the predefined extensible attributes. You can select available extensible attributes for display.
   - **Reporting Site**: This field appears only when you enable the reporting service and configure the multi-site cluster. For information about how to configure the multi-site clustering mode, see *Configuring Reporting Clustering*.

Note

The **Reporting Site** column is hidden by default. To display this column, click the down arrow next to any column header and select **Columns** -> **Edit Columns** -> **Reporting Site** checkbox and click **Apply**. If the **Reporting Site** column is visible, then the extensible attribute value is automatically updated.

3. Optionally, click the Edit icon next to the service name to edit the Grid properties for the service.

or

Select a member checkbox, and do one of the following:

- Click the Edit icon to edit the member service configuration. Grid Manager displays the editor for the corresponding service. For example, when you edit the DHCP service, Grid Manager displays the *Member DHCP Configuration* editor.
- Click the Start icon to start the service.
- Click the Stop icon to stop the service.
- Grid Manager updates the service status based on your action.

Monitoring Member Services

You can view detailed service status on a selected member. Optionally, you can start and stop a service, and edit the service configuration.
To monitor a member service:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox, and then click the Manage Member Services icon.
   In the *Manage Services* panel, Grid Manager displays the following information:
   - **Service**: The name of the service.
   - **Status**: The current status of the service running on the member.
   - **Description**: The description of the status. Grid Manager displays the percentage of usage for the TFTP, HTTP (File Distribution), FTP, and bloxTools services.
2. Optionally, mouse over a service and do one of the following:
   - **Start/Stop Service**: Click this icon to start or stop the selected service. For example, when the DNS service is currently stopped, the appliance starts the service when you click this icon.
   - **Edit Service**: Click this icon to edit the selected service. Grid Manager displays the corresponding editor. For example, when you click the Edit Service icon for DNS, Grid Manager displays the *Member DNS Configuration* editor.
3. Click the Refresh icon to update the service status.

Capturing DNS Queries and Responses

You can capture DNS queries and responses for later analysis. When configuring this feature, you can choose to save the capture file locally on your appliance, as well as on the FTP (File Transfer Protocol) or SCP (Secure Copy) server. When you save it locally, you can use show query_capture to view the contents of the capture file. You can also use filter commands to exclude certain queries and view only the desired ones. Note that using multiple CLI commands to filter data for the appliances with large number of captured DNS queries and responses can significantly affect the system performance, protocol performance, and CLI command performance.

A capture file for logging DNS queries and responses is rolled over based on the configured time limit or when the file reaches 100 MB in size, whichever is sooner. The default time limit is 10 minutes. The capture file is automatically saved and exported to an FTP or SCP server based on your configuration. When you configure the appliance to save the capture file locally and later enable FTP or SCP, the appliance copies all the data starting with the oldest data. Infoblox recommends that you constantly monitor the FTP or SCP server to ensure that it has sufficient disk space. DNS queries and responses are stored on the appliance if the FTP or SCP server becomes unreachable. The maximum storage capacity varies based on the appliance model. After reaching the maximum limit, the appliance overwrites the old data with the new one. For information about the maximum hard drive space, see the table below. The amount of data captured depends on the DNS query rate and the domains that are included in or excluded from the capture. For information about how to exclude domains, see Excluding Domains From Query and Response Capture below.

You can also use the dnstap log format to achieve performance query logging. For information about dnstap implementation and configuring dnstap, see *Configuring dnstap*.

Capturing DNS Queries

You can capture queries to all domains or limit the capture to specific domains. You can also apply the Bulk Add Domains feature to tailor query capture to a desired subset of domains or zones. When capturing DNS queries, NIOS matches the specified domain name(s) and everything that belongs to the domain. For example, when you specify 'foo.com' as the domain, NIOS captures queries sent to 'foo.com,' 'mail.foo.com,' and 'ftp.foo.com.' NIOS captures queries to domains for which a name server is authoritative; it also captures recursive queries. Note that this feature does not support wildcard characters or regular expressions.

DNS Query Message Format

The DNS query generates a query message in the following format:

```
<dd-mmm-YYYY HH:MM:SS.uuu> <client IP>#<port> query: <query_Domain name>
@0x7fbad80bda00 <class name> <type name> <- or +>[SETDC] <(name server ip)>
```

where

```
+ = recursion
- = no recursion
S = TSIG
E = EDNS option set
T = TCP query
D = EDNS ‘DO’ flag set
C = ‘CD’ message flag set
```

Following is a sample DNS query message:

```
30-Apr-2013 13:35:02.187 client 10.120.20.32#42386: query: foo.com
@0x7fbad80bda00 IN A + (100.90.80.102)
```

Capturing DNS Responses

You can capture DNS responses for the DNS queries sent to the server. The amount of data captured depends on the domains that are included in or excluded from the capture. A DNS response is based on a query generated for a domain. In the response message, NIOS captures the TTL value of a resource record, the resource record type, and resource data.
Following are characteristics of the response messages:

- They log only the answer section and do not include the authority and additional sections.
- Responses to all queries are logged, including queries with the type "ANY."
- The RR (resource record) list is not available at the end of a response message if rcode has a value other than NOERROR or if the response is NOERROR (nodata).
- Responses to all RR types, including those records not managed by NIOS such as HINFO records, are logged. However, there are few exceptions for some of the scenarios with DNSSEC records.
- Responses containing DNSSEC RRs (DNSKEY, DS, NSEC, NSEC3, NSEC3PARAM, RRSIG) when queried for non-DNSSEC RRs are not logged. However, responses are logged if a DNSSEC RR is explicitly queried.
- DNS updates are not logged in responses.

DNS Response Message Format and Examples

The DNS query generates a response message in the following format:

```
<dd-mmm-YYYY HH:MM:SS.uuu> <client IP>#<port> query: <query_Domain name> <class name>
<type name> <- or +>[SETDC] <(name server ip)>
```

```
Flags = <- or +>[ATEDVL]
```

where

```
- = recursion not available
```

```
+ = recursion available (from DNS message header)
```

```
A = authoritative answer (from DNS message header)
```

```
t = truncated response (from DNS message header)
```

```
E = EDNS OPT record present (from DNS message header)
```

```
D = DNSSEC OK (from EDNS OPT RR)
```

```
V = responding server has validated DNSSEC records
```

```
L = response contains DTC synthetic record
```

The following is a sample DNS query message:

```
30-Apr-2020 13:35:02.187 client 10.120.20.32#42386: query: foo.com IN A +
(100.90.80.102)
```

Following are some DNS response samples:

Example 1: When querying an A record

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#57398 UDP: query: a2.foo.com IN A
response: NOERROR +AED a2.foo.com. 28800 IN A 1.1.1.2;
```

Example 2: When querying an AAAA record

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#57398 UDP: query: a4.foo.com IN
AAAA response: NOERROR +AED a4.foo.com. 28800 IN AAAA ab::a;
```

Example 3: When querying an A record over IPv6

```
07-Apr-2013 20:16:49.083 client 2001::2#57398 UDP: query: a2.foo.com IN A
response: NOERROR +AED a2.foo.com. 28800 IN A 1.1.1.2;
```

Example 4: When querying an A record over TCP

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#57398 TCP: query: a2.foo.com IN A
response: NOERROR +ED a2.foo.com. 28800 IN A 1.1.1.2;
```

Example 5: When querying ANY record

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#57398 UDP: query: a2.foo.com IN
ANY response: NOERROR +ED a2.foo.com. 28800 IN A 1.1.1.2;
```

Example 6: When querying an A record with multiple addresses

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#57398 UDP: query: a1.foo.com IN A
response: NOERROR +ED a1.foo.com. 28800 IN A 1.1.1.1; a1.foo.com. 28800 IN A
11.1.1.1;
```

Example 7: When querying an aliased A record

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#57398 UDP: query: c2.foo.com IN A
response: NOERROR +ED c2.foo.com. 28800 IN CNAME a2.foo.com.; a2.foo.com. 28800
IN A 1.1.1.2;
```

Example 8: When querying an NXDOMAIN

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#57398 UDP: query: non-
exist.foo.com IN A response: NXDOMAIN +ED
```

Example 9: Response message for NOERROR/nodata

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#57398 UDP: query: a1.foo.com IN
SRV response: NOERROR +ED
```

Example 10: Response message for refused query

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#57398 UDP: query: refused.com IN
A response: REFUSED +ED
```

Example 11: Response message when server fails

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#12345 UDP: query: servfail.com IN
A response: SERVFAIL +E
```

Example 12: Response message when query A record in a signed zone

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#57398 UDP: query: a1.signed.com
IN A response: NOERROR +ED a1.signed.com. 28800 IN A 1.1.1.1;
```

Example 13: Response message for explicit query to DNSSEC RRs

```
07-Apr-2013 20:16:49.083 client 10.120.20.198#57398 UDP: query: a1.signed.com
IN RRSIG response: NOERROR +ED a1.signed.com. 28800 IN RRSIG A 5 3 28800
20130616004903 20130611234903

```

Configuring DNS Query and Response Captures

To configure DNS query and response captures:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the **Toolbar** and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click **Toggle Advanced Mode** and select the **Logging** tab.
3. Under **Data Collection for all DNS Queries/Responses to a Domain**, complete the following:
   - Select the **Capture DNS Queries** checkbox to start capturing DNS queries. This enables the feature set for configuration. When you enable this option at the member level, the appliance captures DNS queries for the selected members only.

- Select the **Capture DNS Responses** checkbox to start capturing DNS responses. This enables the feature set for configuration. When you enable this option at the member level, the appliance captures DNS responses for the selected members only.

> ⚠ Note
>
> Enabling the logging of queries and responses at the same time can increase disk space usage and adversely affect DNS services and performance. Infoblox recommends that you do not configure both logging of queries and logging of responses at the same time.

- Select **Capture queries/responses for all domains** to capture queries and responses to all domains and zones.
- Select **Limit capture to these domains** to capture DNS queries and responses to domains and zones one at a time.
- Specify domains for DNS capture operations in the Domain table by clicking the Add icon, and choosing **Add Domain** or **Bulk Add Domains** from the menu.
- To define the destination for capture files, do the following:
  - **Retain captured queries on the local disk**: Select this checkbox to save the DNS queries on the appliance. In addition to the local disk, you can select to export the DNS queries to the remote server by selecting **SCP** in the **Export to** drop-down list.
  - **Export to:** From the drop-down list, select **SCP** to back up the DNS queries on the remote server and **None** to save queries only on the appliance. To save the captured DNS queries on both the appliance and the remote server, select the **Retain captured queries on the local disk** checkbox and **SCP** from the **Export to** drop-down list. When you configure an SCP server and enable the MGMT port, the NIOS appliance uses SSH for data transfer. It uses the same authentication and provides the same security as SSH. SCP uses the LAN1 port to communicate with the external servers.
- When you select **FTP** or **SCP** from the **Export to** drop-down list, complete the following:
  - In the **Directory Path** field, enter the directory to which the capture file will be saved on the server. Infoblox recommends that you use the ~ symbol for the remote server.
  - In the **Server Address** field, enter the IP address of the remote server to which the capture files will be saved.
  - Enter the file server account **Username** and **Password** values.
- **Limit query data collected per file to minutes or 100MB (whichever comes first)**: This option limits the collection of query data per capture file. A capture file for logging DNS queries and responses is rolled over based on the configured time limit or when the file reaches 100 MB in size, whichever is sooner. The default time limit is 10 minutes. You can enter a value from 1 to 10.

4. Save the configuration.

The following table lists the maximum hard drive space required for capturing DNS queries and responses for supported Infoblox appliance models.

Maximum Hard Drive Space used for DNS queries and Responses

Supported NIOS Appliances	Maximum Hard Drive Space for DNS Query/Response Capture (MB)
Trinzic 815 and IB-V815	900
Trinzic 825 and IB-V825	3100
Trinzic 1415 and IB-V1415	6000
Trinzic 1425 and IB-V1425	10000
Trinzic 2215 and IB-V2215	12000

Supported NIOS Appliances	Maximum Hard Drive Space for DNS Query/Response Capture (MB)
Trinzic 2225 and IB-V2225	28000
PT-1405	10000
PT-2205	28000

Excluding Domains From Query and Response Capture

You can exclude individual domains and their subdomains from DNS query and response capturing. You can also use the Bulk Add Domains feature for a subset of domains to exclude them from query and response capturing. Subdomains can also be specified for exclusion. NIOS matches the specified domain names and their subdomains while filtering them in the Exclusion list. For example, when you specify 'foo.com' as the domain to be excluded, NIOS filters queries for 'foo.com,' 'mail.foo.com,' and 'ftp.foo.com.'

> **Note**
>
> IDNs are not supported for the domains that are added to the Inclusion list and Exclusion list. You can use the punycode representation of an IDN in these lists.

To exclude a domain from query and response capturing, do the following:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the **Toolbar** and click **Grid DNS Properties**. **Member**: From the **Data Management** tab, select the **DNS** tab and click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click **Toggle Advanced Mode** and select the **Logging** tab.
3. Under **Data Collection for all DNS Queries/Responses to a Domain**, select the **Exclude the following domains** checkbox.
4. Click the Add icon and select **Add Domain** or **Bulk Add Domains** and specify domains in the Domain table.

> **Note**
>
> NIOS first matches the domains in the Exclusion list and then matches the domains in the Inclusion list. NIOS does not capture queries and responses for the subdomains in the **Capture DNS Queries/Responses** list (Inclusion list) if their domains are added to the **Exclude the following domains list** (Exclusion list).

The following table provides examples of domains and subdomains added to the inclusion and exclusion lists and the corresponding effects on the query and response capture operations:

Capture DNS Queries/ Responses (Inclusion List)	Exclude the Following Domains (Exclusion List)	Queried Domain	Captured Queries/ Responses	Results
foo.com	it.foo.com	• foo.com • finance.foo.com	Yes	Does not match the exclusion list and therefore NIOS captures queries/responses made to foo.com and finance.foo.com.

Capture DNS Queries/ Responses (Inclusion List)	Exclude the Following Domains (Exclusion List)	Queried Domain	Captured Queries/ Responses	Results
		• it.foo.com • ms.it.foo.com	No	Matches the exclusion list and excludes their subdomains. NIOS does not capture queries/responses made to it.foo.com and ms.it.foo.com.
it.foo.com	foo.com			Domain is added to the exclusion list and its subdomain is added to the inclusion list. Therefore, this is not a valid configuration as queries/responses are not captured. The appliance displays a warning message for such invalid configuration.
it.foo.com	it.foo.com			Domain is added to both the exclusion and the inclusion lists. This is not a valid configuration as queries/responses are not captured. The appliance displays a warning message for such invalid configuration.
foo.com	corp1.com			Domain added to the inclusion list is not the subdomain of the domain added to the exclusion list. This is a redundant configuration as the outcome is the same even if the domain is removed from the Exclusion list. The appliance displays a warning message for such invalid configuration.
foo.com		• foo.com • finance.foo.com	Yes	Exclusion list is empty and therefore matches the Inclusion list. NIOS captures queries/responses made to foo.com and finance.foo.com
		• corp1.com	No	NIOS does not capture queries/responses made to corp1.com as this domain is not mentioned in the inclusion list.
Capture All	foo.com	• foo.com	No	Matches the exclusion list and NIOS does not capture queries made to foo.com.
		• finance.foo.com	No	Subdomain matches the exclusion list and NIOS does not capture queries/responses made to finance.foo.com.
		• corp1.com	Yes	Does not match the exclusion list. Matches the inclusion list and therefore NIOS captures queries/responses made to corp1.com.

Monitoring Tools

You can use the audit log, the replication status, the traffic capture tool, and the capacity report in a Grid or HA pair to monitor administrative activities and capture traffic for diagnostic purposes. You can also use CLI commands to monitor certain DNS transactions.
This section includes the following topics:

- *Using the Traffic Capture Tool*
- *Using the Capacity Report*
- *Monitoring DNS Transactions*
- *Viewing DNS Alert Indicator Status*
- *Configuring DNS Alert Thresholds*

In addition, if Grid members manage Microsoft servers, Grid Manager creates a synchronization log file for each managed Microsoft server. For information about viewing synchronization logs, see *Monitoring Managed Microsoft Servers*.

Using the Audit Log

The audit log contains a record of all Infoblox administrative activities. It provides the following detailed information:

- Timestamp of the change. If you have different admin accounts with different time zone settings, the appliance uses the time zone of the admin account that you use to log in to the appliance to display the date and timestamp.
- Administrator name.
- Changed object name.
- New value of the object. If you change multiple properties of an object, the audit log lists all changes in a comma-separated log entry. You can also search the audit log to find the new value of an object.

The appliance logs the following successful operations:

- Logins to Grid Manager and the API.
- Logout events that include: When users log out by clicking the **Logout** button, when the Grid Manager GUI times out, and when users are logged out due to an error.
- Write operations such as the addition, modification, and deletion of objects.
- System management operations such as service restarts and appliance reboots.
- Scheduled tasks such as adding an A record or modifying a fixed address.
- WAPI (RESTful API) session log information for each WAPI call, such as PUT, POST, and DELETE.

Enabling Audit Log Rolling

When the audit log reaches its maximum size, which is 100 MB, the appliance automatically writes the file into a new file by adding a .0 extension to the first file and incrementing subsequent file extensions by 1. Files are compressed during the rotation process, adding a `.gz` extension following the numerical increment (`file.#.gz`). The sequential incrementation goes from zero through nine. When the eleventh file is started, the tenth log file (`file.9.gz`) is deleted, and subsequent files are renumbered accordingly. For example, the current log file moves to `file.0.gz` , the previous `file.0.gz` moves to `file.1.gz` , and so on through `file.9.gz` . A maximum of 10 log files (0-9) are kept. To list the audit log files and their sizes, log in to the Infoblox CLI and run the `show logfiles` command.
To enable audit log rolling:

1. On the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, and then click **Grid Properties** -> **Edit** in the Toolbar.
2. In the *Grid Properties* editor, on the **Security** tab, select **Enable Audit Log Rolling**.

Specifying the Audit Log Type

Select **Detailed** (default), or **Brief**, or **WAPI Detailed** audit log type as follows:

1. On the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, and then click **Grid Properties** -> **Edit** in the Toolbar.
   On the **System** tab, select the **System Manager** tab, and then click **System Properties** -> **Edit** in the Toolbar.
2. In the *Grid Properties Editor,* on the **General** tab, or in the *System Properties Editor*, on the **System** tab, select one of the following:

- **Detailed**: This is the default type. When you select this, Grid Manager displays detailed information on all administrative changes such as the timestamp of the change, administrator name, changed object name, and the new values of all properties in the logged message.
- **Brief**: Provides information on administrative changes such as the changed object name and action in the log message. The logged message does not show timestamp or admin name.
- **WAPI Detailed:** Select this option to view detailed RESTful API session information logs for successful WAPI calls such as PUT, POST, and DELETE. You can view the following session log information for each successful WAPI call:
    - **URI**: URI contains certain part of the incoming WAPI request. Example: version of WAPI and the associated object.
    - **InData**: InData contains input data fields of the incoming WAPI request. Example: Data field of the incoming WAPI request.
    - **Response Time**: Response time is calculated as the time difference between a WAPI request received and the response sent.

      This option helps you to troubleshoot and monitor performance issues that impact specific WAPI calls and track WAPI usage. When you select this option, you can view additional columns such as **URI, InData** and **Response Time** in the Audit log.

      The following example shows an audit log entry for a POST WAPI call:

      ```
      [2018-05-29 09:20:12.026Z] [admin]: Created(POST) v2.9/zone_auth {"fqdn":"foo.com"} 2.233 AuthZone foo.com DnsView=default: Set fqdn="foo.com"
      ```

      In the example above:
    - `POST` indicates the WAPI call
    - `v2.9/zone_auth` is the URI
    - `{"fqdn":"foo.com"}` represents InData
    - 2.233 is the response time.

> **Note**
>
> There might be a slight impact on the device performance as the session log information, such as URI, InData, and response time, are captured for all the successful WAPI calls. The audit log file size increases as the log entries increase, which may impact the storage capacity. Infoblox recommends that you select the **Copy Audit Log Messages to Syslog** checkbox in the *Grid Properties Editor* to move audit log information to the syslog and to an external server for longer retention. For more information about specifying syslog servers, see *Using a Syslog Server*. All Cloud WAPI, via Cloud Network Automation (CNA) or Cloud Platform (CP) appliances, related events are logged to syslog instead of the audit log. For more information, see *Cloud Network Automation*.

Viewing the Audit Log

To view an audit log:

1. On the **Administration** tab, select the **Logs** tab -> **Audit Log** tab.
2. Optionally, use the filters to narrow down the audit log messages you want to view. Click **Show Filters** to enable the filters. Configure the filter criteria, and then click **Apply**.
   Based on your filter criteria (if any), Grid Manager displays the following in the *Audit Log* viewer:
    - **Timestamp**: The date, time, and time zone the task was performed. The time zone is the time zone configured on the member.

- **Admin**: The admin user who performed the task.
  Note that the admin user displayed as $admin group name$ represents an internal user. You can create an **admin** filter with "**matches expression**" equals ^[^$] to filter out internal users.
- **Action**: The action performed. This can be CALLED, CREATED, DELETED, LOGIN_ALLOWED, LOGIN_DENIED, MESSAGE, MODIFIED, POST, PUT, and DELETE.
- **Object Type**: The object type of the object involved in this task. This field is not displayed by default. You can select this for display.
- **Object Name**: The name of the object involved in this task.
- **Execution Status**: The execution status of the task. Possible values are **Executed**, **Normal**, **Pending Approval** and **Scheduled**.
- **URI**: A certain part of the incoming WAPI request.
- **InData**: Input data fields of the incoming WAPI request.
- **Response Time:** The processing time of the incoming WAPI request.
- **Message**: Detailed information about the performed task.

You can also perform the following in the log viewer:

- Toggle between the single line view and the multi-line view for display.
- Navigate to the next or last page of the file using the paging buttons.
- Refresh the audit log view.
- Click the Follow icon to have the appliance automatically refresh the log every five seconds.
- Download the log.
- Clear the contents of the audit log.
- Use filters and the **Go To** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria.
- Export or print the content of the log.

Searching in the Audit Log

Instead of paging through the audit log file to locate messages, you can have the appliance search for messages with certain text strings.
To search for specific messages, enter a search value in the search field below the filters, and then click the **Search** icon.

The appliance searches through the audit log file and highlights the search value in the viewer. You can use the arrow keys next to the Search icon to locate the previous or next message that contains the search value.

Downloading the Audit Log

You can download the audit log file to a specified directory if you want to analyze it later. To download an audit log file:

1. On the **Administration** tab, select the **Logs** tab -> **Audit Log** tab, and then click the Download icon.
2. Navigate to a directory where you want to save the file, optionally change the file name (the default name is *auditLog.tar.gz*), and then click **OK**. If you want to download multiple audit log files to the same location, rename each downloaded file before downloading the next.

> ⚠ Note
>
> If your browser has a pop-up blocker enabled, you must turn off the pop-up blocker or configure your browser to allow pop-ups for downloading files.

Viewing the Replication Status

The *Replication Status* panel reports the status of the database replication between Grid members and Grid Master, and between the two nodes in an independent HA pair. You can use this information to check the health of the Grid and HA pair activity.
To view the current replication status, from the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, and then click

Toggle Replication Status View.
Grid Manager can display the following replication information for each member:

- **Name**: The FQDN (fully qualified domain name) of the appliance.
- **Send Queue**: The size of the queue from the Grid Master to the Grid member.
- **Last Send**: The timestamp of the last replication information sent by the Grid Master.
- **Receive Queue**: The size of the queue from the Grid member to the Grid Master.
- **Last Receive**: The timestamp of the last replication information received by the Grid Master.
- **Member Replication Status**: The replication status between the member and the Grid Master. Grid Manager displays the status in green when the status is fine or red when the member is offline.
- **HA Replication Status**: The HA replication status between the active and passive nodes. The status is at the member level, not at the node level. Grid Manager displays the status in red when one of the nodes is offline.
- **Status**: The current operational status of the appliance. The status can be one of the following:
    - **Green**: The appliance is operating normally in a "Running" state.
    - **Yellow**: The appliance is connecting or synchronizing with its Grid Master.
    - **Red**: The Grid member is offline, is not licensed (that is, it does not have a DNSone license with the Grid upgrade that permits Grid membership), is upgrading or downgrading, or is shutting down.
- **IPv4 Address**: The IPv4 address of the appliance or the VIP of an HA pair.
- **IPv6 Address**: The IPv6 address of the appliance or the VIP of an HA pair.
- **Identify**: This field appears only if your appliance has the unit identification button. This can be **On** or **Off**. When you identify the appliance by pressing the UID button on the appliance or through the GUI or the CLI command, this field displays **On**. Otherwise, this is **Off**.
- **DHCP**, **DNS**, **TFTP**, **HTTP**,**FTP**, **NTP**, **bloxTools**, **Captive Portal, DNS Accelerator Usage, Discovery, Reporting**: The current status of the service. The status can be one of the following:
    - **Green**: The service is enabled and running properly.
    - **Yellow**: The service is enabled, but there may be some issues that require attention.
    - **Red**: The service is enabled, but it is not running properly. A red status icon can also appear temporarily when a service is enabled and begins running, but the monitoring mechanism has not yet notified the Infoblox GUI.
    - **Gray**: The service is not configured or it is disabled.
- **Hardware Type**: The hardware type of the appliance, such as IB-1400.
- **Serial Number**: The serial number of the appliance.
- **DB Utilization**: The percentage of the database that is currently in use.
- **Comment**: Information about the appliance.
- **Site**: The location to which the member belongs. This is one of the predefined extensible attributes.
- **HA**: Indicates whether the member is an HA pair. If the member is an HA pair, Grid Manager displays the status of the HA pair.
- **Hardware Model**: The hardware model of the appliance.

You can do the following:

- Use filters and the **Go To** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria.
- Modify some of the data in the table. Double-click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- Edit the properties of a member.
    - Click the checkbox beside a member, and then click the Edit icon.
- Delete a member.
    - Click the checkbox beside a member, and then click the Delete icon.
- Export or print the list.

Using the Traffic Capture Tool

You can capture the traffic on one or all of the ports on a NIOS appliance, and then view it using a third-party network protocol analyzer application, such as the Wireshark – Network Protocol Analyzer™. Using this tool, you can capture traffic for a single member or multiple Grid members simultaneously. The NIOS appliance must have a minimum of 500 MB of free disk space to start the traffic capture; otherwise, the traffic capture might fail.
The NIOS appliance saves all the traffic it captures in a .cap file and compresses it into a .tar.gz file. Your management

system must have a utility that can extract the .tar file from the .gzip file, and an application that can read the .cap (capture) file format. The size of the .cap file is limited to 2 GB for Infoblox-4030-10GE, and the size is limited to 1 GB for all other NIOS appliances. You can also transfer the traffic capture file to your local management system, a TFTP server, an FTP server, or a SCP server.

NIOS saves failed traffic capture file transfer attempts in the syslog. Traffic capture file transfers can fail due to remote server issues, such as an invalid server IP address, or an incorrect username, or a password, or an invalid path. Note that the traffic capture fails when the disk space on the member is insufficient, but the file transfer will be successful. The NIOS appliance logs a warning message in the syslog when the traffic capture fails. You can find the following information about traffic capture and file transfers in the audit log:

- Start and stop actions performed on the members for traffic capture.
- Whether the traffic capture file was transferred to a server or downloaded to a local directory. For more information about the audit log, see Using the Audit Log above.

This section explains the process of capturing traffic, and how to download the traffic capture file to your management system. After that, you can extract the traffic capture file and view it with a third-party traffic analyzer application. The traffic capture file is shared between admin users.

You can also configure Grid Manager to trigger a traffic capture at set intervals and parameters. If Grid Manager detects that a parameter has breached a configured threshold or crossed the configured duration of time, it triggers a traffic capture. For more information about automated traffic capture, see *Enabling Automated Traffic Capture*.

> ⚠ Note
>
> The NIOS appliance always saves a traffic capture file as *<member name>_<timestamp>_tcpdumpLog.tar.gz*. Example: *infoblox.localdo_0_2018-10-15-03-47-53_tcpdumpLog.tar.gz*. For FTP and TFTP transfers, the name of the file is added as a prefix. Example: *filename.infoblox.localdo_0_2018-11-09-09-30-07_tcpdumpLog.tar.gz*

For a single member, you can also capture traffic on the NIOS appliance through the *Infoblox CLI* using the `set traffic_capture` command. However, you cannot use this command to capture traffic for multiple members. NIOS displays the traffic capture status and it allows you to download the captured traffic, irrespective of whether the traffic capture is initiated from the Infoblox CLI or from Grid Manager.
To capture traffic for a single member or multiple Grid members:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, and then click **Traffic Capture** from the Toolbar.
   OR
   From the **Administration** tab, select the **Logs** tab → **Syslog** tab, and then click **Traffic Capture** from the Toolbar.
2. In the *Traffic Capture* dialog box, complete the following:
   Members
   - **Name**: Click the Add icon to add either a single or multiple Grid members for which you want to capture traffic. When you click the Add icon, Grid Manager displays the *Member Selector* dialog box from which you can select one or multiple members. Use SHIFT+click to select multiple contiguous rows or use CTRL+click to select multiple non-contiguous rows. Click **OK**. The selected members are added to the list of members in the **Members** table. You cannot add offline members to the list or capture traffic on an offline member.
     Selecting members in the **Grid Manager** → **Members** tab does not capture traffic for the selected member. To capture traffic, you must select members from the *Member Selector* dialog box.
   - **Interface**: Select the port on which you want to capture traffic. You can view the selected interface while the traffic capture is in progress. Note that if you enabled the LAN2 failover feature, the LAN and LAN2 ports generate the same output and Grid Manager displays the interface as **BOND** while the traffic capture is in progress. By default, the interface is set to **ALL** after the traffic capture process stops. For information about the LAN2 failover feature, see as described in *About Port Redundancy*.

     For vNIOS appliances, some of the options in the drop-down list may vary depending on your vNIOS configuration. For example, if you are using a single network interface instance of a vNIOS for GCP appliance, you will see choices specific to the LAN1 interface only.
     - **LAN:** Select this to capture all the traffic the LAN port receives and transmits.

        - **MGMT:** Select this to capture all the traffic the MGMT port receives and transmits.
        - **LAN2**: Select to capture all the traffic the LAN2 port (if enabled) receives and transmits.
        - **ALL:** Select this to capture the traffic addressed to all ports. Note that the NIOS appliance only captures traffic that is addressed to it.
        - **LANxnnnn**: If you have configured VLANs on the LAN1 or LAN2 port, the appliance displays the VLANs in the format LANx nnnn, where x represents the port number and nnnn represents the associated VLAN ID.
    - **File Size:** Displays the size of the traffic capture log file, in kilobytes, for the respective member.
    - **Status**: Displays the status of the traffic capture session on the member. The status can be one of the following:
        - **STOPPED**: Indicates that the traffic capture session has stopped.
        - **RUNNING**: Indicates that the traffic capture session is in progress.
        - **NOT STARTED:** Indicates that the traffic capture session has not started.
    - **Transfer Status**: Displays the status of the traffic capture file transfer. The status can be one of the following:
        - **NOT STARTED**: Indicates that the file transfer has not started.
        - **STARTED**: Indicates that the file transfer has started.
        - **COMPLETED**: Indicates that the file transfer has been completed.
        - **FAILED**: Indicates that the file transfer has failed.
3. **Seconds to run:** Specify the number of seconds you want the traffic capture tool to run.
4. **Capture Control**: Click the Start icon to start the capture. Note that the start action will overwrite the existing traffic capture file. You can click the Stop icon to stop the capture after you start it.
5. **Transfer To**: Select the destination to transfer the traffic capture file. You can select **My Computer**, **TFTP**, **FTP**, or **SCP** from the drop-down list.
    - **My Computer**: Transfer the traffic capture file to a local directory on your computer. This is the default. Note to avoid consumption of the Grid Master disk space, NIOS restricts downloading the traffic capture files from multiple members to a local directory on your computer.
    - **TFTP**: Transfer the traffic capture file to a TFTP server.
        - **Filename**: Enter the directory path and the file name of the traffic capture file. For example, you can enter `/home/test/traffic_capture_filename` where `traffic_capture_filename` is the name of the file.
        - **IP Address of TFTP Server**: Enter the IP address of the TFTP server to which you want to transfer the traffic capture file.
    - **FTP**: Transfer the traffic capture file to an FTP server.
        - **Filename**: Enter the directory path and the file name of the traffic capture file. For example, you can enter `/home/test/traffic_capture_filename` where `traffic_capture_filename` is the name of the file.
        - **IP Address of FTP Server**: The IP address of the FTP server.
        - **Username**: Enter the username of your FTP account.
        - **Password**: Enter the password of your FTP account.
    - **SCP**: Transfer the traffic capture file to an SCP server.
        - **Filepath**: Enter the directory path of the traffic capture file. For example, you can enter `/home/test/`.
        - **IP Address of SCP Server**: The IP address of the SCP server.
        - **Username**: Enter the username of your SCP account.
        - **Password**: Enter the password of your SCP account.
6. **Uncompressed Capture File Size**: Select the members for which you want to download the traffic capture file and then click **Download** to download the captured traffic. You can download and save the file only after the capture stops, but not when the tool is running. You can rename the file if you want. NIOS updates the size of the report when the capture tool is running.
   Note the NIOS appliance must have free disk space of at least 500MB + size of the traffic capture file (2 GB/1 GB, depending on the appliance model) to download the traffic capture file.
7. **Last updated**: The timestamp of the last traffic capture process.
8. Use terminal window commands (Linux) or a software application (such as StuffIt™ or WinZip™) to extract the contents of the .tar.gz file.

9. When you see the traffic.cap file in the directory where you extract the .tar.gz file, open it with a third-party network protocol analyzer application.

Limitations of the Traffic Capture Tool

- You cannot add members to the list of members in the **Members** table on the *Traffic Capture* wizard when traffic capture is in progress.
- While the traffic capture file transfer is in progress on any member on the *Traffic Capture* wizard, Grid Manager does not allow you to start or stop traffic capture on members. However, you can start traffic capture using the CLI command even though the file transfer is in progress.
- If the traffic capture has already started on Grid Manager, you cannot initiate the capture again using the CLI command. You must wait until the process is complete.
- Traffic captures that are initiated using the CLI/WAPI commands do not appear in the **Members** table. To initiate traffic capture for a single member that was initiated and stopped using the CLI/WAPI command, add the respective member manually to the list of members in the **Members** table.
- Grid Manager does not allow you to initiate traffic capture on a list of selected members, if it has already been initiated for a member in the list using CLI/WAPI commands.

Using the Capacity Report

You can view the capacity usage and object type information of an appliance in a capacity report. The capacity report displays capacity and object type information of an independent appliance, a Grid Master, or a Grid member. For an HA pair, the report displays information on the active node.
The top half of the panel displays a capacity summary, and the bottom half displays the object types the appliance supports and the total counts for each object type.
To view a capacity report:

- From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox, and then click **Capacity Report** from the Toolbar.

The capacity summary contains the following information:

- **Name**: The name of the appliance.
- **Role**: The role of the appliance. The value can be **Grid Master**, **Grid Master Candidate**, **Grid Member**, or **Standalone**.
- **Hardware Type**: The type of hardware. For an HA pair, the report displays the hardware type for both the active and passive nodes.
- **Object Capacity**: The maximum number of objects the appliance can support.
- **Total Objects**: The total number of objects currently in the database.
- **% Capacity Used**: The percentage of the capacity in use.

The capacity report filters object types you can manage through the appliance. You can configure the object types you want to see in the following table by completing the following in the **Minimum Object Total** filter:

- **Minimum Object Total**: Enter the minimum number of objects within an object type of which Grid Manager displays. In the Object Type table, Grid Manager displays only the object types that contain at least the specified number of objects you enter in this field.

The capacity report displays the following information:

- **Object Type**: The type of objects. For example, DHCP Lease, Admin Group, or PTR Record. For objects that are only used for internal system operations, the report groups and shows them under **Other**.
- **Total**: The total number of objects for the specific object type. You can print the object type information or export it to a CSV file.

Monitoring DNS Transactions

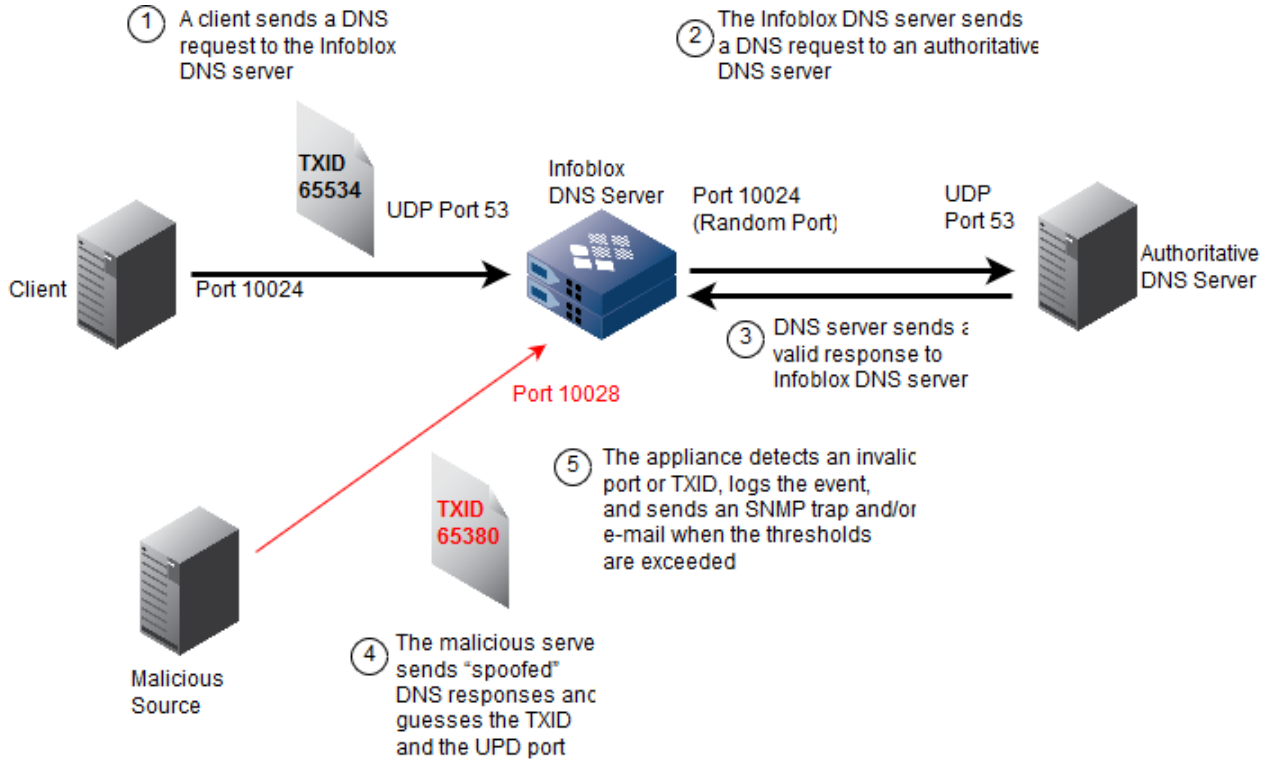
The NIOS appliance provides tools for monitoring DNS transactions and mitigating cache poisoning from UDP (User Datagram Protocol) traffic on source port 53. Cache poisoning can occur when a DNS server accepts maliciously created unauthentic data. The DNS server ends up locally caching the incorrect entries and serving them to users that make the same DNS requests. In a maliciously created situation, the attacker can redirect Internet traffic from the legitimate host to

another host that the attacker controls.
You can configure the appliance to track invalid DNS responses for recursive DNS queries. The appliance tracks DNS responses that arrive on invalid ports or have invalid TXIDs (DNS transaction IDs). Both invalid ports and invalid TXIDs could be indicators of cache poisoning. An invalid port is a DNS response that arrives from UDP (User Datagram Protocol) port 53 with either one of the following conditions:

- There are no outstanding DNS requests from the port on which the response arrives.
- The TXID of the DNS response matches the TXID of an outstanding request. However, the request was sent from a port other than the port on which the response arrives.

An invalid TXID is a DNS response that arrives from UDP port 53, and the TXID does not match the TXID of an outstanding DNS request. The below figure illustrates how the appliance detects an invalid port and an invalid TXID.

Invalid Port and Invalid TXID



Both invalid ports and invalid TXIDs could be indicators of DNS cache poisoning, although a small number of them is considered normal in situations where valid DNS responses arrive after the DNS queries have timed out. You can configure the appliance to track these indicators, and you can view their status. You can also configure thresholds for them. When the number of invalid ports or invalid TXIDs exceeds the thresholds, the appliance logs an event in the syslog file and sends an SNMP trap and e-mail notification, if you enable them. You can then configure rate limiting rules to limit incoming traffic or completely block connections from primary sources that send the invalid DNS responses.

Rate limiting is a token bucket system that accepts packets from a source based on the rate limit. You can configure the number of packets per minute that the Infoblox DNS server accepts from a specified source. You can also configure the number of packets for burst traffic, which is the maximum number of packets that the token bucket can accept. Once the bucket reaches the limit for burst traffic, it discards the packets and starts receiving new packets according to the rate limit.
The appliance monitors only UDP traffic from remote port 53 for the following reasons:

- The attacks that the appliance monitors do not happen over TCP.
- DNS responses are sent only from port 53. The appliance discards DNS responses that are sent from other ports.

To monitor invalid ports and invalid TXIDs on the Infoblox DNS server, follow these procedures:

- Enable DNS network monitoring and DNS alert monitoring. For information, see Enabling and Disabling DNS Alert Monitoring below.
- Configure the thresholds for DNS alert indicators. For information, see Configuring DNS Alert Thresholds below.
- Enable SNMP traps and e-mail notifications. For information, see *Configuring SNMP*.
- Review the DNS alert status. For information, see Viewing DNS Alert Indicator Status below.
- Identify the source of the attack by reviewing the DNS alert status, syslog file, and SNMP traps. For information on SNMP traps for DNS alerts and threshold crossing traps, see *SNMP MIB Hierarchy*.

To mitigate cache poisoning, you can limit incoming traffic or completely block connections from specific sources, as follows:

- Enable rate limiting on the DNS server. For information, see Enabling and Disabling Rate Limiting from External Sources below.
- Configure rate limit traffic rules from specific sources. For information, see Configuring Rate Limiting Rules below.

You can verify the rate limiting rules after you configure them. For information, see Viewing Rate Limiting Rules below.

Enabling and Disabling DNS Alert Monitoring

The appliance monitors only UDP traffic on port 53 for recursive queries, and then reports invalid DNS responses. DNS alert monitoring is disabled by default. For an HA pair, you must enable DNS alert monitoring on both the active and passive nodes.
To enable DNS network monitoring and DNS alert monitoring:

1. Log in to the Infoblox CLI as a superuser account.
2. Enter the following CLI command:

```
set monitor dns on
```

The appliance displays the following:

```
Turning on DNS Network Monitoring...
```

3. Enter the following command:

```
set monitor dns alert on
```

When you enable DNS alert monitoring, if DNS network monitoring is disabled, the appliance automatically enables DNS network monitoring and displays the following:

```
DNS Network Monitoring is disabled. It must be enabled for alerting to
function.

Enable DNS Monitoring now? (y or n):
```

You can also disable DNS network monitoring and DNS alert monitoring using the following commands:

```
set monitor dns off
 set monitor dns alert off
```

> **Note**
> When you restart DNS network monitoring, you also reset the SNMP counters for DNS alerts.

You can then view the alert status to identify the primary source of invalid DNS responses.

Viewing DNS Alert Indicator Status

To view DNS alert indicator status:

1. Log in to the Infoblox CLI as a superuser account.
2. Enter the following CLI command:

```
show monitor dns alert status
```

The appliance displays historical alert counts and up to five primary sources that generate invalid DNS responses, as shown in the following example:

```
Data last updated: Mon Oct 6 14:47:12 2008

DNS Alert1m5m15m60m24hEver
 ==========================================

port8 12  1212  12  12

txid8 12  1212  12  12

There were 80 DNS responses seen in the last minute.

10% were to an invalid port.

10% had an invalid TXID.

Primary sources of invalid responses:

4.4.4.4 (unknown) sent 4

2.2.2.2 (unknown) sent 3

7.7.7.7 (unknown) sent 1
```

The appliance attempts to resolve the hostnames of the sources that sent invalid responses, if the DNS resolver is enabled. If the appliance cannot resolve a hostname, it displays "unknown" as the hostname of the invalid response.

Configuring DNS Alert Thresholds

You can configure thresholds for DNS alerts to control when the appliance tracks DNS attacks on UDP port 53 and issues SNMP traps and e-mail notifications.

> ⚠ Note
>
> Ensure that you enable SNMP traps and e-mail notifications. For information, see *Configuring SNMP*.

You can configure thresholds for both invalid ports and invalid TXIDs. The default thresholds for both invalid ports and TXIDs are 50%. When the number of invalid ports or invalid TXIDs exceeds the thresholds, the appliance logs the event and sends SNMP traps and notifications. You can configure the thresholds either as absolute packet counts or as percentages of the total traffic during a one-minute time interval.
To configure DNS alert thresholds:

1. Log in to the Infoblox CLI as a superuser account.
2. Enter the following CLI command:

```
set monitor dns alert modify port | txid over threshold_value packets |
percent
```

where

`port | txid` = Enter `port` to set the threshold for invalid ports, or enter `txid` to set the threshold for invalid TXIDs.

`threshold_value =` Enter the number of packets or percentage for the threshold.

`packets | percent =` Enter `packets` if you want to track the total packet count, or enter `percentage` if you want to track a percentage of the total traffic. For a percentage-based threshold, the appliance does not generate a threshold crossing event if the traffic level is less than 100 packets per minute.

For example, if you want the appliance to send a DNS alert when the percentage of DNS responses arriving on invalid ports from UDP port 53 exceeds 70% per minute, you can enter the following command:

```
set monitor dns alert modify port over 70 percent
```

If you want the appliance to send a DNS alert when the total number of packets with invalid TXIDs from UDP port 53 is over 100 packets per minute, you can enter the following command:

```
set monitor dns alert modify txid over 100 packets
```

When there is a DNS alert, the appliance logs an event in the syslog file and sends an SNMP trap and e-mail notification if enabled.

Viewing DNS Alert Thresholds

You can view the DNS alert thresholds. The appliance displays the current thresholds. If you have not configured new thresholds, the appliance displays the default thresholds, which are 50% for both invalid port and TXID.
To view the DNS alert thresholds:

1. Log in to the Infoblox CLI as a superuser account.
2. Enter the following CLI command:

   ```
   show monitor dns alert
   ```

   The appliance displays the threshold information as shown in the following example:

   ```
   DNS Network Monitoring is enabled. Alerting is enabled.

   DNS Alert Threshold (per minute)
    ========================================
    portover 70% of packets

   txidover 100 packets
   ```

Enabling and Disabling Rate Limiting from External Sources

You can mitigate cache poisoning on your DNS server by limiting the traffic or blocking connections from UDP port 53. To enable rate limiting from sources:

1. Log in to the Infoblox CLI as a superuser account.
2. Enter the following CLI command:

   ```
   set ip_rate_limit on
   ```

   The appliance displays the following:

   ```
   Enabling rate limiting will discard packets and may degrade performance.
   ```

```
Are you sure? (y or n):
```

When you enable rate limiting, the appliance discards packets based on the configured rate limiting rules. This might affect the DNS performance when the appliance discards valid DNS responses.

3. Enter **y** to enable rate limiting.

When you enable rate limiting, the appliance applies the rate limiting rules that you configured. You might want to configure the rate limiting rules before enabling rate limiting. For information on how to configure rate limiting rules, see Configuring Rate Limiting Rules below.
You can also disable rate limiting by entering the following command:

```
set ip_rate_limit off
```

When you disable rate limiting, the appliance stops applying the rate limiting rules.

Configuring Rate Limiting Rules

You configure rate limiting rules to limit access or block connections from UDP port 53. The rules take effect when you enable rate limiting.
When adding rules, ensure that you do not include an IP address that matches the IP address of either the Grid Master or Grid member. Doing this could affect VPN connectivity. To configure rate limiting rules:

1. Log in to the Infoblox CLI as a superuser account.
2. Enter the following CLI command:

```
set ip_rate_limit add source all | ip_address [/mask] limit packets/m [burst burst_packets]
```

where

`all | ip_address` = Enter `all` or `0.0.0.0` if you want to limit all traffic from all sources, or enter the IP address from which you want to limit the traffic.

`[/mask]` = Optionally, enter the netmask of the host from which you want to limit the traffic.

`packets` = Enter the number of packets per minute that you want to receive from the source.

`[burst burst_packets]` = Optionally, enter `burst` and the number of packets for burst traffic. This is the maximum number of packets accepted.

The following are sample commands and descriptions for rate limiting rules:

- To block all traffic from host 10.10.1.1, enter the following command:

```
set ip_rate_limit add source 10.10.1.1 limit 0
```

- To limit traffic to five packets per minute from host 10.10.1.2, enter the following command:

```
set ip_rate_limit add source 10.10.1.2 limit 5/m
```

- To limit the traffic to five packets per minute from host 10.10.2.1/24 with an allowance for burst traffic of 10 packets, enter the following command:

```
set ip_rate_limit add source 10.10.2.1/24 limit 5/m burst 10
```

- To limit the traffic to 5000 packets per minute from all sources, enter the following command:

```
set ip_rate_limit add source all limit 5000/m
```

Removing Rate Limiting Rules

You can remove the existing rate limiting rules that limit access or block connections from UDP port 53. To remove all the existing rules:

1. Log in to the Infoblox CLI as a superuser account.
2. Enter the following CLI command:
   - To remove the rate limiting rule that limits traffic from all sources, enter:
     ```
     set ip_rate_limit remove source all
     ```
     or
   - To remove all of the rate limiting rules from all sources, enter:

   ```
   set ip_rate_limit remove all
   ```

To remove one of the existing rules for an existing host:

1. Log in to the Infoblox CLI as a superuser account.
2. Enter the following CLI command:

```
set ip_rate_limit remove source ip-address[/mask]
```

Viewing Rate Limiting Rules

You can view the existing rate limiting rules that limit access or block connections from UDP port 53. To view rate limiting rules:

1. Log in to the Infoblox CLI as a superuser account.
2. Enter the following CLI command:

   ```
   show ip_rate_limit
   ```

   The appliance displays the rules, as shown in the following example:

```
IP rate limiting is enabled.

Source           Limit            Burst
 ==========================================

10.10.1.1    0 packets/minute    0 packets

10.10.1.2    5 packets/minute    5 packets

10.10.2.1/24 5 packets/minute    10 packets

all          5000packets/minute  5000 packets
```

* Note: Copy audit to syslog feature should not alter. But increases the syslog file size.

Using a Syslog Server

Syslog is a widely used mechanism for logging system events. NIOS appliances generate syslog messages that you can view through the Syslog viewer and download to a directory on your management station. In addition, you can configure a NIOS appliance to send the messages to one or more external syslog servers for later analysis. Syslog messages provide information about appliance operations and processes. NIOS appliances include syslog messages generated by the BloxTools service. You can choose logging categories to send specific syslog messages. The prefixes in the syslog messages are based on the logging categories you configure in the syslog. Note that syslog messages are prefixed only when you select logging categories. For information about how to configure logging categories, see Specifying Syslog

Servers below. You can also include audit log messages and specific BIND messages among the messages the appliance sends to the syslog server.

In addition to saving system messages to a remote syslog server, a NIOS appliance also stores the system messages locally. When the syslog file reaches its maximum size, which is 300 MB for Infoblox appliances and VMware virtual appliances, the appliance automatically writes the file into a new file by adding a `.0` extension to the first file and incrementing subsequent file extensions by 1.

Files are compressed during the rotation process, adding `a.gz` extension following the numerical increment (`file.#.gz`). The sequential incrementation goes from zero through nine. When the eleventh file is started, the tenth log file (`file.9.gz`) is deleted, and subsequent files are renumbered accordingly. For example, the current log file moves to `file.0.gz` , the previous `file.0.gz` moves to `file.1.gz` , and so on through `file.9.gz` . A maximum of 10 log files (0-9) are kept.

You can set syslog parameters for RPZ at the Grid, member, and zone levels. At the member level, you can override Grid-level syslog settings and enable syslog proxy, also you can override Grid-level settings to zone level. For more information see about Modifying RPZs, see *Managing RPZs*.

You can configure the appliance to back up rotated syslog files to external servers through FTP or SCP. When you do so, the appliance forwards the rotated syslog files to the external servers that you configure. You can configure up to 10 external syslog backup servers each at the Grid, member, and zone levels. You can also override the Grid-level server configuration at the member level. For information about configuring syslog backup servers, see Configuring Syslog Backup Servers below.

This section includes the following topics:

Specifying Syslog Servers

To configure a NIOS appliance to send messages to a syslog server, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, and then click **Grid Properties** -> **Edit** from the Toolbar.
2. In the *Grid Properties* editor, select the **Monitoring** tab, and then complete the following:
   - **Syslog:** In addition to storing the syslog on a Grid member, you can configure the Grid to send the log to an external syslog server.
   - **Syslog size (MB)**: Specify the maximum size for a syslog file. Enter a value between 10 and 300. The default is 300.
     When the syslog file reaches the size you enter here, the appliance automatically writes the file into a new file by adding a .0 extension to the first file and incrementing subsequent file extensions by 1.
   - **Log to External Syslog Servers:** Select this to enable the appliance to send messages to a specified syslog server. Grid Manager displays the current syslog servers in the table. To define a new syslog server, click the Add icon and complete the following:
     - **Address:** Enter the IP address of the syslog server. Entries may be an IPv4 or IPv6 address.

- **Transport:** From the drop-down list, select whether the appliance uses **Secure TCP**, **TCP,** or **UDP** to connect to the external syslog server.
- **Server Certificate**: Click **Select** to upload a self-signed or a CA-signed server certificate. In the *Upload* dialog, click **Select** and navigate to the certificate file, and then click **Upload**. Note that this is valid only for **Secure TCP** transport.
- **Interface:** From the drop-down list, select the interface through which the appliance sends syslog messages to the syslog server.
    - **Any**: The appliance chooses any port that is available for sending syslog messages.
    - **LAN**: The appliance uses the LAN1 port to send syslog messages.
    - **MGMT**: The appliance uses the MGMT port if it has been configured. Otherwise, it uses the LAN1 port.
- **Source:** From the drop-down list, select which syslog messages the appliance sends to the external syslog server:
    - **Any:** The appliance sends both internal and external syslog messages.
    - **Internal:** The appliance sends syslog messages that it generates.
    - **External:** The appliance sends syslog messages that it receives from other devices, such as syslog servers and routers.
- **Node ID**: Specify the host or node identification string that identifies the appliance from which syslog messages are originated. This string appears in the header message of the syslog packet. Select one of the following:
    - **LAN**: Use the LAN1 IP address of the appliance. For an HA pair, this is the LAN1 address of the active or passive node. This is the default.
    - **Host Name**: Use the host name of the appliance in FQDN format.
    - **IP and Host Name**: Use both the FQDN and the IP address of the appliance. The IP address can be the LAN1 or MGMT IP address depending on whether the MGMT port has been configured. Note that if the MGMT port is not configured, the LAN1 IP address is used.
    - **MGMT**: Use the MGMT IP address, if the port has been configured. If the MGMT port is not configured, the LAN1 IP address is used. This can be an IPv4 or IPv6 address.
- **Port:** Enter the destination port number. The default is 514 for TCP and UDP. For Secure TCP, the default port is 6514.
- **Severity:** Choose a severity filter from the drop-down list. When you choose a severity level, the appliance sends log messages with the selected level and the levels above it. The severity levels range from the lowest, **debug**, to the highest, **emerg**. For example, if you choose **debug**, the appliance sends all syslog messages to the server. If you choose **err**, the appliance sends messages with severity levels **err**, **crit**, **alert**, and **emerg**.
    - **emerg**: Panic or emergency conditions. The system may be unusable.
    - **alert**: Alerts, such as NTP service failures, that require immediate actions.
    - **crit**: Critical conditions, such as hardware failures.
    - **err**: Error messages, such as client update failures and duplicate leases.
    - **warning**: Warning messages, such as missing keepalive options in a server configuration.
    - **notice**: Informational messages regarding routine system events, such as "starting BIND".
    - **info**: Informational messages, such as DHCPACK messages and discovery status.
    - **debug**: Messages that contain information for debugging purposes, such as changes in the latency timer settings and AD authentication failures for specific users.
- **Logging Category**: Select one of the following logging categories:
    - **Send all**: Select this to log all syslog messages, irrespective of categories to which it belongs. When you select this option, the appliance logs syslog messages for all the events, including all DNS and Infoblox related events. However, the syslog messages are not prefixed when you select this option.
    - **Send selected categories**: Select this to configure logging categories from the list of available logging categories. Use the arrows to move logging categories from the **Available** table to the **Selected** table and vice versa. The appliance sends syslog messages for the categories that are in the **Selected** table. When you select this option, you must add at least one logging category. The syslog messages are prefixed with a category name to which it belongs. Also, the RPZ events logged in the syslog messages uses specific prefixes for the selected categories. Note that the syslog messages are prefixed when you set logging categories for at least one external syslog server, even if you set other external

syslog servers as **Send All**. For more information about syslog prefixes, see Syslog Message Prefixes below.

- Click **Add** to add the external syslog server information.
- Optionally, click the **Test** button to test the connection to the syslog server that you configured.

- **Copy Audit Log Messages to Syslog:** Select this for the appliance to include audit log messages it sends to the syslog server. This function can be helpful for monitoring administrative activities on multiple appliances from a central location.
  - **Syslog Facility:** This is enabled when you select **Copy audit log messages to syslog**. Select the facility that determines the processes and daemons from which the log messages are generated.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

> ⚠ Note
> The syslog categories you specify here are different from the logging categories specified in the **Logging** tab in the *Grid DNS Properties* or *Member DNS Properties* editor. The external server preserves contents of the selected categories even when selection is changed from **Send all** to **Send selected categories** and vice versa.

Syslog Message Prefixes

You can configure the syslog external backup servers to send (archive) syslog files to different destinations by their logging categories. This allows you to split syslog files based on the service and efficiently perform troubleshooting. For example, you can archive all DNS related logs on Server 1, and all DHCP related logs on Server 2. For information about how to configure an external syslog backup server, see Specifying Syslog Servers above.

When you select the **Send selected categories** option, the syslog messages are prefixed with a category name to which it belongs.

For syslog message prefixes to be enabled, you must check the **Log to External Syslog Servers** checkbox in **Grid Properties** > **Monitoring**. Also, the external syslog server (which can be a virtual or a physical server) must have at least one of the syslog categories selected instead of the **Send all** option selected in the **Logging Category** field.

> ⚠ Note
> When you set **Send all** in the **Logging Category**, the appliance logs syslog messages for all the events and they are not prefixed. The syslog messages are prefixed even if one external syslog server is set with the **Send selected categories** option.

The following are the prefixes used for different logging categories:

- **DNS Logging Categories**: All DNS related messages use the following prefixes: `client, config, database, dnssec, general, lame_servers, network, notify, queries, query_rewrite, resolver, responses, rpz, security, update, update_security, xfer_in`, and `xfer_out.`

`Sample syslog message for queries:`

```
2022-01-18T09:35:35+00:00 daemon member1.com named[19355]: info client
@0x7fea340ccc90 10.111.45.104#34670 (a.solo.com): query: a.solo.com IN A
+E(0)K (10.34.122.22)
```

`Sample syslog message for xfer-out:`

```
2014-10-10T06:44:09+00:00 daemon infoblox.localdomain named[17630]: info
xfer-out:
```

`client 10.120.20.157#58275 (zone.com): transfer of 'zone.com/IN': AXFR started`

- **ADP**: All Infoblox related messages use prefix `adp`.

Note there is no prefix for RPZ syslog messages that do not belong to the DNS or ADP category.

- **DHCP**: All DHCP related messages use the following prefixes: `dhcpd, omshell, dhcrelay`, and `dhclient`.

`Sample syslog message for dhcp:`

`Sep 4 09:23:44 10.34.6.28 dhcpd[20310]: DHCPACK on 70.1.20.250 to fc:5c:fc:5f:10:85 via`

`eth1 relay 10.120.20.66 lease-duration 600`

- **DTC**: All DTC related messages use the following prefixes: `idns_healthd` and `idnsd`.

`Sample syslog message for idns_healthd:`

`Sep 3 12:12:35 10.34.6.30 idns_healthd[1220]: resource health status [Monitor 'icmp'`

`(ICMP, port 0) checked server 's1' (IP 10.34.6.23), status: IPv4=ONLINE]`

- **Cloud**: All cloud related messages use prefix `cloud_api`.

`Sample syslog message for cloud_api:`

`Sep 4 10:53:30 10.34.6.32 cloud_api[5354]: [admin]: Login_Allowed - -`

`to=Serial\040Console apparently_via=Remote ip=10.120.20.66 auth=Local`

`group=.admin-group`

- **NTP**: All NTP related messages use prefix `ntpd`.

`Sample syslog message for NTP:`

`Sep 28 06:57:21 10.35.116.7 ntpd[12186]: precision = 0.053 usec`

`Sep 28 06:57:21 10.35.116.7 ntpd[12186]: Listening on interface #0 wildcard, 0.0.0.0#123`

`Disabled`

- **File Distribution**: All File Distribution related messages use the following prefixes: `ftpd` and `tftp`.

`Sample syslog message for TFTP:`

`Sep 3 13:03:09 10.34.6.30 monitor[23623]: Type: TFTP, State: Red, Event: A TFTPD daemon`

`failure has occurred`

- **Authentication**: All Authentication related messages use the following prefixes: `auth, authpriv, AD`, and `radiusd.`

`Sample syslog message for RADIUS authentication:`

`Sep 28 10:09:55 10.35.116.4 httpd: 2015-09-28 10:09:55.912Z [user1]: Login_Allowed - -`

`to=AdminConnector ip=10.120.253.227 auth=RADIUS group=admin-group apparently_via=GUI`

- **Microsoft Integration**: All Microsoft Integration related messages use the following prefixes: `dns_server, connect_status, dns_zone, dhcp_server, dhcp_leases, clear_lease, ad_site`, and `ad_users`.

`Sample syslog message for microsoft integration:`

`dns_server:`

`Sep 7 09:46:17 10.34.22.20 mssyncd[22315]: dns_server address 10.102.30.157 : Conflict`

`in property Forwarders: NIOS value (property=<NULL IP array>) and Microsoft value`

`(property={10.0.2.35, 10.0.2.60}). Resolved by using the Microsoft value`

`dhcp_server:`

`Sep 7 10:08:48 10.34.22.20 mssyncd[22316]: dhcp_server address 10.102.30.157 : Couldn't`

`open RPC interface <MS-WKST>: an instance of a named pipe cannot be found in the listening`

`state`

`Sep 7 10:08:48 10.34.22.20 mssyncd[22317]: dns_server address 10.102.30.157 : Opened`

`RPC interface <MS-WKST> as user 'ad-15\frtest'`

IP Address Used in the Syslog Configuration File

The following table describes which IP address the appliance uses as the node ID in the syslog configuration file, provided that the MGMT port has been configured. If the MGMT port is not configured, the LAN1 IP address is always used regardless of the configuration.

IP address Used in Syslog Config File when MGMT Port is Configured

Interface	Node ID	IP used in syslog configuration file
Any	MGMT	MGMT IP address
Any	IP and Host Name	MGMT IP address
MGMT	MGMT	MGMT IP address
MGMT	IP and Host Name	MGMT IP address
LAN	MGMT	LAN1 IP address
LAN	IP and Host Name	LAN1 IP address

Configuring Syslog Backup Servers

You can configure external syslog backup servers to forward rotated syslog files. You can configure up to 10 external syslog backup servers.

To configure external backup servers, complete the following:

1. **Grid**: From the **Grid** tab -> **Grid Manager** tab, expand the Toolbar and click **Grid Properties** -> **Edit**.
   Member: From the **Grid** tab -> **Grid Manager** tab, click the **Members** tab, select the *member* checkbox, and click the **Edit** icon.
2. **Grid**: In the *Grid Properties* editor, select the **Syslog Backup** tab.
   Member: In the *Grid Member Properties* editor, select the **Syslog Backup** tab and then click **Override** to override the Grid-level settings.
   To modify backup server settings, complete the following:
   - **Address**: Enter the IP address of the external backup server. You are not allowed to configure more than one server using the same IP address at the same level (Grid or member). However, you can use the same server IP address at different levels (Grid or member). Note that you cannot modify the IP address for the overridden server.
   - **Protocol**: Select **SCP** or **FTP** from the drop-down list.
   - **Port**: Enter the destination port number. The default port is 20 for FTP and 22 for SCP.
   - **Path**: Enter the directory path for the syslog file.
   - **Username**: Enter the username of your FTP or SCP account.
   - **Password**: Enter the password of your FTP or SCP account. If you do not change the password of the overridden server, then make sure that you use the same password specified at the Grid level.
   - **Enabled**: Select this checkbox to enable the FTP or SCP server. The appliance forwards the rotated syslog files to the external servers that you configure only after you select this checkbox. Clear the checkbox to disable the server.
3. Click **Save and Close**.

Configuring Syslog for Grid Members

You can override Grid-level syslog settings and enable syslog proxy for individual members. When you enable syslog proxy, the member receives syslog messages from specified devices, such as syslog servers and routers, and then forwards these messages to an external syslog server. You can also enable appliances to use TCP for sending syslog messages. Using TCP is more reliable than using UDP; this reliability is important for security, accounting, and auditing messages sent through the syslog. Note that you cannot enable syslog proxy for Grid members, if they are configured on a Grid Master.
To configure syslog parameters for a member, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *Grid Member Properties* editor, select the **Monitoring** tab -> **Basic** tab, click **Override** in the Syslog section, and then complete the fields as described in Specifying Syslog Servers above.
   In addition to storing the system log on a Grid member, you can configure a member to send the log to a syslog server.
3. Select the **Advanced** tab and complete the following:
   - **Enable syslog proxy:** Select this to enable the appliance to receive syslog messages from other devices, such as syslog servers and routers, and then forward these messages to an external syslog server.
     - **Enable listening on TCP:** Select this if the appliance uses TCP to receive messages from other devices. Enter the number of the port through which the appliance receives syslog messages from other devices.
     - **Enable listening on UDP:** Select this if the appliance uses UDP to receive messages from other devices. Enter the number of the port through which the appliance receives syslog messages from other devices.
   - **Proxy Access Control:** Select one of the following to configure access control when receiving syslog messages from specific syslog servers or routers:
     - **None**: Select this if you do not want to configure syslog proxy. When you select this option, none of the devices can send syslog messages to the appliance. This is selected by default.
     - **Named ACL:** Select this and click **Select Named ACL** to select a named ACL that contains only IPv4 addresses and networks. This does not support TSIG key based ACEs. When you select this, the appliance permits clients that have **Allow** permission in the named ACL to allow syslog messages from specific syslog servers or routers. You can click **Clear** to remove the selected named ACL.
     - **Set of ACLs**: Select this to configure individual access control entries (ACEs). Click the Add icon and select one of the following from the drop-down list. Grid Manager adds a row to the table.
       - **IPv4 Address or IPv6 Address:** Select this to add an IPv4 or IPv6 address entry. Click the **Value** field and enter the address. The default permission is **Allow**, which means that the appliance allows access to and from this device. You can change this to **Deny** to block access.
       - **IPv4 Network or IPv6 Network:** Select this to add an IPv4 or Ipv6 network entry. Click the **Value** field and enter the network. The default permission is **Allow**, which means that the appliance allows syslog messages sent by this network. You can change this to **Deny** to block access.
       - **Any Address/Network:** Select this to allow or deny access to all IPv4 and IPv6 addresses and networks. The default permission is **Allow**, which means that the appliance allows syslog messages sent by all addresses and networks. You can change this to **Deny** to block access.

       After you have added access control entries, you can perform the following:
       - Select the ACEs that you want to group and put into a named ACL. Click the Create new named ACL icon and enter a name in the *Convert to Named ACL* dialog box.
       - Reorder the list of ACEs using the up and down arrows next to the table.
       - Select an IPv4 network and click the Edit icon to modify the entry.
       - Select an ACE and click the Delete icon to delete the entry. You can select multiple ACEs for deletion.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Setting DNS Logging Categories

You can specify logging categories you want the syslog to capture. Furthermore, you can filter these messages by severity at the Grid and member levels. For information about severity types, see Specifying Syslog Servers.

To specify logging categories, complete the following:

1. From the **Data Management** tab, select the **DNS** tab, and then click **Grid DNS Properties** from the Toolbar.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click **Toggle Expert Mode** if the editor is in the basic mode, select the **Logging** tab, and then complete the following:
   - **Logging Facility:** Select a facility from the drop-down list. This is the location on the syslog server to which you want to sort the DNS logging messages.
   - **Logging Category**: Select one or more of these log categories:
     - **general:** Records the BIND messages that are not specifically classified.
     - **client:** Enables the logging of messages related to query processing, but not the queries themselves. Examples of messages include exceeding recursive client quota, and other errors related to recursive clients, blacklist and NXDOMAIN interception, query name rewrite, and others.
     - **config:** Records the configuration file parsing messages.
     - **database:** Records BIND's internal database processes.
     - **dnssec:** Records the DNSSEC-signed responses.
     - **lame servers:** Records bad delegation instances.
     - **network:** Records the network operation messages.
     - **notify:** Records the asynchronous zone change notification messages.
     - **queries:** Records the DNS queries. Note that enabling the logging of queries and responses will significantly affect system performance. Ensure that your system has sufficient CPU capacity before you enable DNS query logging.
     - **rate-limit**: Logs RRL (Response Rate Limiting) events. You must enable RRL in order for the appliance to log RRL events to this logging category.
     - **resolver:** Logs messages related to outgoing queries from the 'named' process, when it is acting as a resolver on behalf of clients.
     - **responses**: Records DNS responses. Note that enabling the logging of queries and responses will significantly affect system performance. Ensure that your system has sufficient CPU capacity before you enable DNS response logging.
     - **rpz**: Records log messages when responses are modified through RPZs or for which explicit passthrus were invoked in the RPZs. This checkbox is not selected by default.
     - **security:** Logs miscellaneous messages that are related to security, such as denial or approval (mostly denial) of certain operations.
     - **transfer-in:** Records zone transfer messages from the remote name servers to the appliance.
     - **transfer-out:** Records zone transfer messages from the NIOS appliance to remote name servers.
     - **update:** Records the dynamic update instances.
     - **update-security**: Records the security updates.
     - **DTC load balancing**: Records information about which client is directed to which server.
     - **DTC health monitors**: Records any changes to the health state of a monitored server.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Viewing the Syslog

1. From the **Administration** tab, select the **Logs** tab -> **Syslog** tab.
2. From the drop-down list at the upper right-hand corner, select the Grid member on which you want to view the syslog.
3. Optionally, use the filters to narrow down the system messages you want to view. Click **Show Filters** to enable the filters. Configure the filter criteria, and then click **Apply.**
   Based on your filter criteria (if any), Grid Manager displays the following in the *Syslog* viewer:

-

: The Action icon column is displayed only when you have installed the RPZ license. Click this to view threat details in the *RPZ Threat Details* dialog box. For more information, see Viewing the RPZ Threat Details below.

- **Timestamp**: The date, time, and time zone of the log message. The time zone is the time zone configured on the member.
- **Facility**: The location on the syslog server that determines the processes and daemons from which the log messages are generated.
- **Level**: The severity of the message. This can be ALERT, CRITICAL, DEBUG, EMERGENCY, ERROR, INFO, NOTICE, or WARNING.
- **Server**: The name of the server that logs this message, plus the process ID.
- **Message**: Detailed information about the task performed. For Cloud Network Automation, this contains comma separated values of the admin, source, action, object, object type, and message values. Note that source is defined only if the cloud API request was proxied by the Cloud Platform Appliance. The format for this field is `proxied from:host,IP` where `host` and `IP` are the host name and IP address of the proxy.

> **Note**
> If the selected member is an HA pair, the Grid Manager displays the syslog in two tabs — **Active** and **Passive**.
>
> Click the corresponding tab to view the syslog for each node.

Viewing the RPZ Threat Details

Make sure that DNS resolution is enabled and running properly on the member to view threat details. To view threat details for the RPZ zones being queried, complete the following:

1. From the **Administration** tab, select the **Logs** tab -> **Syslog** tab.
2. Click the Action icon and select **View Threat Context** to open the *RPZ Threat Details* dialog. The **View Threat Context** option is disabled if there is no RPZ rule.
    - **RPZ Rule**: Displays the name of the RPZ rule.
    - **First Identified**: The date and timestamp of the first occasion that the threat was detected.
    - **Short Description**: The brief description of the threat.
    - **Description**: The description of the RPZ rule.
      Note the *RPZ Threat Details* dialog box may display *Unknown* if the threat is unknown, or *Unavailable* if the threat is known and threat details are not available.
3. Click the Close icon to close the *RPZ Threat Details* dialog.

You can also perform the following in the *Syslog* viewer:

- Toggle between the single line view and the multi-line view for display.
- Navigate to the next or last page of the file using the paging buttons.
- Refresh the syslog output with newly logged messages.
- Click the Follow icon to have the appliance automatically refresh the log every five seconds.
- Clear the contents of the syslog.
- Use filters and the **Go To** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go To** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria.
- To filter Microsoft synchronization related events, click **Show Filter**, select **Server** from the first drop-down list, and select **MS_Server** from the drop-down list in the value field. This filter displays entries that begin with the prefix **ms**. To view values that belong to a specific Microsoft server, you must specify either the name or IP address of a given Microsoft server in the **Message** field. When you filter the syslog for a specific Grid member, it displays the log entries of Microsoft servers that are assigned to the respective Grid member when the entries are logged.
- Print the report or export it in CSV format.
- Bookmark the syslog page.

Searching in the Syslog

Instead of paging through the syslog to locate messages, you can have the appliance search for syslog messages with certain text strings. To search for specific messages, perform the following:

- Enter a search value in the search field below the filters, and then click the **Search** icon.
  The appliance searches through the syslog and highlights the search value in the viewer. You can use the arrow keys next to the Search icon to locate the previous or next message that contains the search value.

Downloading the Syslog File

To download the syslog file to a specified directory, if you want to analyze it later, complete the following:

1. From the **Administration** tab, select the **Logs** tab -> **Syslog** tab, and then click the Download icon.
2. Navigate to a directory where you want to save the file, optionally change the file name (the default names are *node_1_sysLog.tar.gz* and *node_2_sysLog.tar.gz*), and then click **OK**. If you want to download multiple syslog files to the same location, rename each downloaded file before downloading the next.

> ⚠ Note
> If your browser has a pop-up blocker enabled, you must turn off the pop-up blocker or configure your browser to allow pop-ups for downloading files.

Enabling Automated Traffic Capture

Sometimes, there may be a sudden and unexplained change in the KPIs (Key Performance Indicators) in your network that may degrade your network performance and traffic capture during these events may not be available. For example, the cache hit ratio may drop below the configured value, or there may be an increase in authoritative delay.

You can configure NIOS so that a traffic capture may be triggered based on thresholds configured for DNS Cache Hit Ratio and Queries Per Seconds. You can then analyse the traffic capture data and use it to gather production data thus bringing down the time taken for root cause analysis. You can also attach the traffic capture data to a support case so that Infoblox Support can take the investigation forward.

You can choose to receive an SNMP trap or an email notification every time traffic capture is enabled or disabled or a support bundle is downloaded. For more information see, *Configuring SNMP*.

> ⚠ **Note**
>
> If DNS Cache Acceleration is enabled on the IB-FLEX platform, the cache hit ratio is not updated for a minute thus triggering a false traffic capture.

To configure automated traffic capture:

1. From the **Grid** tab, select the **Grid Manager** tab -> click **Grid Properties** -> **Edit** from the Toolbar.
   Or to configure automated traffic capture for a member, from the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> select the member -> click the Action icon and click **Edit**.
2. In *Grid Properties Editor (for Grid)* or *Grid Member Properties Editor* (for members), click **Monitoring** -> **Advanced** tab.
3. Select the **Enable Automated Traffic Capture** checkbox.
4. In the **Capture Duration** field, enter the number of seconds for which traffic must be captured. For example, if you enter 30 in the **Capture Duration** field, traffic is captured for 30 seconds and stored in the traffic capture file. After 30 seconds, traffic is captured once again and the details are stored in a new traffic capture file. A new traffic capture is started only after the earlier traffic capture file is packaged. You can set a value from 1 to 600 seconds. **Capture Duration** is a mandatory field. If the capture file exceeds 2 GB (for IB-40*XX* and PT-40*XX* appliances) and 1 GB (for all other appliances), NIOS stops the traffic capture.
5. Select the **Save Local Copy** checkbox to save traffic capture data in your local disk.
6. Select the **Include Support Bundle** checkbox to download the support bundle after the traffic capture is complete and the system has remained in a stable state for 5 minutes.
7. From the **Export to** drop-down list, select your local management system (FTP server or SCP server) to which to transfer the traffic capture file. The default is **None**.
8. In the **Directory Path For Capture** field, enter the destination directory on the NIOS server for which to transfer the traffic capture files.

9. In the **Directory Path For Support Bundle** field, enter the destination directory on the NIOS server for which to transfer the support bundles.
   Note that if you enable the **Include Support Bundle** checkbox but do not specify the directory path for the support bundle, NIOS transfers the support bundles to the directory path that you specify in the **Directory Path For Capture** field.
10. In the **Server Address** field, enter the IP address of the FTP or the SCP server that you selected from the **Export to** drop-down list.
11. In the **Username** and **Password** fields, enter the user credentials to upload to the FTP or SCP server.
12. Select the **Enable Cache Hit Ratio Trigger** checkbox if you want NIOS to trigger a traffic capture based on the value of the cache hit ratio of recursive queries. If the cache utilization goes above the value you specify in the **Cache Utilization** field and the cache hit ratio goes below the value you specify in the **Hit Ratio Threshold Trigger** field, traffic capture is triggered. Once the cache hit ratio reaches the value you specify in the **Reset** field, NIOS stops the traffic capture.
13. Select the **Enable Queries Per Second Trigger** checkbox if you want NIOS to monitor the QPS (queries per second). NIOS triggers a traffic capture if the QPS value goes below the threshold value you specify in the **QPS Threshold Trigger** field. Once the QPS value reaches the value you specify in the **Reset** field, NIOS stops the traffic capture. For information about QPS, see *About Dashboards*.
14. Select the **Enable Outgoing Recursive Queries Trigger** checkbox if you want NIOS to monitor the count of concurrent outgoing recursive queries. NIOS triggers a traffic capture if the count goes above the value you specify in the **Recursive Queries Threshold Trigger** field. If the number of concurrent recursive queries goes below the value you specify in the **Reset** field, NIOS stops the traffic capture. For information about recursive queries, see *Enabling Recursive Queries*.
15. Select the **Enable Authoritative DNS Latency Trigger** checkbox if you want NIOS to monitor the authoritative DNS latency. NIOS performs the DNS latency on the IPS address you choose from the **Query IP Address** field and triggers a traffic capture if the DNS latency goes above the value you specify in the **Authoritative DNS Latency Threshold Trigger** field. The DNS latency is determined by querying a reverse zone against the IP address you selected using the `dig` command. If the authoritative DNS query latency goes below the value you specify in the **Reset** field, NIOS stops the traffic capture. For information about DNS latency, enabling and disabling DNS alert monitoring, see *Monitoring Tools*.
16. Select the **Enable Recursive DNS Latency Trigger** checkbox if you want NIOS to monitor the recursive DNS latency. NIOS performs the DNS latency on the IPS address you choose from the **Query IP Address** field and triggers a traffic capture if the DNS latency goes above the value you specify in the **Recursive DNS Latency Threshold Trigger** field. The DNS latency is determined by querying each domain against the IP address you selected using the `dig` command. If the recursive DNS query latency goes below the value you specify in the **Reset** field, NIOS stops the traffic capture. For information about DNS latency, enabling and disabling DNS alert monitoring, see *Monitoring Tools*.
17. Click **Save & Close**.

Tracking Object Changes in the Database

If you have external applications that use information in the NIOS database, you can use the Object Change Tracking feature to get informed about changes in the NIOS database. You can then periodically synchronize IPAM, DNS, and DHCP data through the Infoblox API or RESTful API, which returns updated object information. When you enable this feature, the appliance tracks the changes that are made to NIOS objects. It assigns sequence IDs to all the changed objects. These sequence IDs are incremented when there is a change in the high-level objects such as IPv4 and IPv6 fixed addresses, networks, network containers, and others. When you query using the db_objects through the Infoblox API for desired object types, the application returns all the objects of those object types that changed after the sequence ID given in the query.
When you enable the Object Change Tracking feature, you can also specify the lifetime of deleted objects in the database and the total number of objects that must be present in the database. The deleted objects that are saved in the database are purged periodically. Note that you cannot track the user who created or updated an existing object.
Infoblox supports full and incremental synchronization for these changes. Certain events such as Grid Master Candidate promotions and upgrades require a full synchronization.
Users with read-only permission can use this feature. For more information, see *Administrative Permissions for Object Change Tracking*.
To enable and use the Object Change Tracking feature to track and synchronize updates, complete the following:

1. Enable the feature, as described in Enabling Object Change Tracking below.
2. Select whether you want to use a full synchronization or an incremental synchronization. When you use one of these synchronization methods to synchronize data through Infoblox API or RESTful API, they return updated objects that can be used to update your relational database. For full synchronization, see Using Full Synchronization below. For incremental synchronization, see Using Incremental Synchronization below.

Best Practices for Object Change Tracking

- The Object Change Tracking feature is optimized to reduce impact on the DDI services and it runs only on the Grid Master. The synchronization process synchronizes 1000 objects at a time with a 2 second pause in between. There might be a slight impact on the Grid Master Candidate as they get updates from the Grid Master. When protocol services are running on the Grid Master Candidate you might encounter a 5% drop in the protocol performance. This feature does not impact the services that are running on the Grid members.
- NIOS does not update the sequence ID of the respective parent when you modify a child object. For example, inserting an A record under DNS zone does not increase the sequence number of the zone object.
- When you delete a parent object, NIOS saves the child objects in the deleted object table. But, if the associated child objects are either resource records or leases, NIOS will neither save them in the deleted object table nor update the sequence ID for these child objects.
- If you update a parent object, then the sequence ID of its child objects will not change.
- NIOS updates the sequence ID of the host record and IPv4 and IPv6 host addresses, if there are any changes to host addresses, both IPv4 and IPv6. The sequence ID is also updated when you update the host alias records that results in increase in the sequence ID of the host record and all its child objects.

For example, if you create a host record hhh.test.com with an IPv4 address and perform an incremental synchronization to get updates, the response contains an updated host record and host address:

```
curl -k1 -u admin:infoblox -H content-type:application/json -X GET
https://10.32.2.202/wapi/v2.5/db_objects?
start_sequence_id=2830689052:0\&object_types=
record:host,record:host_ipv4addr\;_return_fields=last_sequence_id,object,obj
ect_type\;
_return_type=json-pretty
```

The response is as follows:

```
[
    {
        "_ref": "db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDIw:38",

   },
   {
      "_ref": "db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDIz:3956302770%3A38",
      "last_sequence_id": "3956302770:38"
   }
]
```

- When you update DNS host, host address, and host alias, NIOS updates the sequence IDs of child objects associated with these parent objects even though the changes do not affect the child objects. For example, when you update an existing comment in the host record, NIOS updates the sequence IDs of child objects associated with the respective host record.
  Example:

```
curl -k1 -u admin:infoblox -H content-type:application/json -X GET
https://10.32.2.202/wapi/v2.5/db_objects?
start_sequence_id=2830689052:0\&object_types=
record:host,record:host_ipv4addr\;_return_fields=last_sequence_id,object,obj
ect_type,o
bject.comment\;_return_type=json-pretty
```

The response is as follows:

```
[
    {
          "_ref": "db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDI:27",
          "object": {
              "_ref":
"record:host/ZG5zLmhvc3QkLl9kZWZhdWx0LmNvbS50ZXN0LmhoaA:hhh.test.com/
```

```
default",
                "comment": "hi"
            },
            "object_type": "record:host"
            "unique_id": "1ab6c989d8fd454ca06ffac6ac600fe6"
        },
        {
            "_ref": "db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDM:27",
            "object": {
                "_ref":
"record:host_ipv4addr/
ZG5zLmhvc3RfYWRkcmVzcyQuX2RlZmF1bHQuY29tLnRlc3QuaGhoLjEuMC4wLjEu
:1.0.0.1/hhh.test.com/default",
                "configure_for_dhcp": false,
                "host": "hhh.test.com",
                "ipv4addr": "1.0.0.1"
            },
            "object_type": "record:host_ipv4addr"
            "unique_id": "1ab6c989d8fd454ca06ffac6ac600fe7"
        },
        {
            "_ref": "db_objects/
Li5hbGxfY2hhbmdlZF9vYmplY3RzJDQ:2830689052%3A27",
            "last_sequence_id": "2830689052:27"
        }
```

- When an IPv4 or an IPv6 host address changes, NIOS deletes the old record and creates a new record with the updated IP address. Note that new sequence IDs are generated for the associated objects. When you query a host record, NIOS displays the list of host addresses associated with it.

Example:

```
curl -k1 -u admin:infoblox -H content-type:application/json -X GET
https://10.32.2.202/wapi/v2.5/db_objects?
start_sequence_id=2830689052:0\&object_types=
record:host,record:host_ipv4addr\;_return_fields=last_sequence_id,object,obj
ect_type\;
_return_type=json-pretty
```

The response is as follows:

```
[
    {
          "_ref": "db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDA:28",
          "object": {
              "_ref":
"record:host/ZG5zLmhvc3QkLl9kZWZhdWx0LmNvbS50ZXN0LmhoaA:hhh.test.com/
default",
              "ipv4addrs": [
                  {
                    "_ref":
"record:host_ipv4addr/

    }
```

- NIOS returns the shared records per zone when you query for them. For example, consider two zones, z1 and z2, and a shared record group, srg1, which contains a shared record sr1. The shared record group srg1 is associated with the zones z1 and z2. Hence, the shared record sr1 is shared between two zones, z1 and z2, but NIOS saves only a single copy of the shared record sr1 in the database. When you query for shared record updates, NIOS returns two records for z1 and z2, as sr1 is associated with both the zones, z1 and z2, and saves these records with a UUID and a sequence ID in the table. The response also contains new records with zone pointing to the zone it belongs to, UUID and sequence ID of the new records and a `shared_record_grou` p , which indicates that it is a shared record and not a normal resource record. When you enable Object Change Tracking feature, NIOS clears this table and recreates a new table for the existing shared records.
- Note that NIOS generates two leases in the database when a client sends a DHCP request to the NIOS DHCP server, which is configured with failover association. You can perform either a full or an incremental synchronization in this scenario. Infoblox recommends that you ignore the lease that is generated by the failover DHCP server with `binding_state` as `BACKUP` and consider the lease with `binding_state` as `ACTIVE` .
- File distribution service automatically removes old files from `wapi_output` directory if there is no sufficient space for new files. NIOS allocates 50% each of the file distribution area to `wapi_output` directory and normal files. For example, if the file distribution area is allocated 500 MB, then 250 MB is used for `wapi_output` directory and the remaining 250 MB is used for normal files.
- NIOS does not support WAPI paging mechanism. As the synchronization results are displayed in the order of `sequence_id` , you must `specify _max_results` to achieve paging mechanism for synchronization.
- NIOS deletes all previous scheduled tasks after a restore or an upgrade operation.

Enabling Object Change Tracking

To enable object change tracking:

1. **Grid**: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, and then click **Grid Properties** -> **Edit** from the Toolbar.

Standalone appliance: From the **System** tab → **System Manager** tab, expand the Toolbar and click **System Properties** -> **Edit**.

2. In the *Grid Properties* editor, click **Object Change Tracking** and complete the following:
    - **Enable Object Change Tracking**: Select this checkbox to enable object change tracking for the objects.
    - **Status**: Indicates whether object change tracking is enabled or not. You can view what percentage of the operation is complete.

      Note his operation might take a longer time to complete when you have a large database. For example, 1 million objects on an IB-4015 appliance takes approximately 1 hour. Infoblox rectommends that you enable this feature during off-peak hours.

    - **Maximum number of deleted objects that will be tracked**: Specify the total number of deleted objects that must be present in the database. The minimum value is 2,000 and the maximum value is 20,000. The default value is 4,000.
3. Save the configuration.

Using Full Synchronization

Full synchronization synchronizes the entire set of objects irrespective of updates. You can perform a full synchronization only on the Grid Master and Grid Master Candidate. Note that the tasks created on the Grid Master and Grid Master Candidates will be executed on them respectively and you can download the synchronized data on to the member where the task was created. The Grid Master Candidate can execute only read-only tasks. To save the output of a full synchronization, you must specify the output location. The output of a full synchronization is in the following formats: JSON, XML, ROWJSON, or ROWXML.

You can specify one of the following output locations: `"FILE_DISTRIBUTION"` and `"LOCAL".`

- When `_output_location = "FILE_DISTRIBUTION"`

When you set the output location as mentioned above, you must specify a file name or a prefix for the file. NIOS saves the output file in the file distribution area and displays an error message if you do not specify a file name or a prefix. For more information about file distribution area, see *Managing Directories*.

When you select the above output location for a Grid Master Candidate, you must select **Allow Upload to Grid Members** to upload files to the file distribution area. Infoblox recommends that you use the Grid Master Candidate to offload the Grid Master. You must enable a full synchronization during off-peak hours if protocol services are running on the Grid Master Candidate. For more information, see *Enabling Upload to Grid Members*.

Example:

```
curl -k1 -u admin:infoblox -X POST 'https://..../wapi/v2.5/fileop?
_function=read' -H 'Content-Type: application/json; charset=UTF-8' -d
'{"_filename": "test.json",
"_output_location":"FILE_DISTRIBUTION","_object": "db_objects",
"all_object_types_supported_in_version": "2.5","_encoding": "ROWJSON"}'
```

You can specify either `_object = db_objects` or `all_object_types_supported_in_version=2.5` to retrieve all objects. When you specify `_object = db_objects,` NIOS returns only standard Restful API fields as response. To retrieve all fields of all objects, you can specify `all_object_types_supported_in_version=2.5.` To fetch the output file, start file distribution service and use the following URL:

```
curl -k1 -u admin:infoblox -X GET http://<ipaddress>/wapi_output/test.json -H
'Content-Type:application/json'
```

- When `_output_location = "LOCAL"`
  - If you schedule a full synchronization and set the output location as mentioned above, a file name is generated based on the task ID and the output file is saved at another location. You do not have to specify a file name or a prefix.
  - If you do not schedule a synchronization, then NIOS returns an URL and a token, which is used for the download complete function, in the response.
  - If you do not specify an output location, NIOS saves the file in the file distribution area.
  - Use the above output location for saving full synchronization files when file distribution area does not have enough space for storage.

Example:

```
curl -k1 -u admin:infoblox -X POST 'https://127.0.0.1/wapi/v2.5/fileop?
_function=read&_schedinfo.schedule_now=true' -H 'Content-Type: application/
json; charset=UTF-8' -d '{"_output_location": "LOCAL", "_object":
"db_objects", "all_object_types_supported_in_version": "2.5", "_encoding":
"JSON"}'
```

NIOS saves the output file in the file distribution area if you do not specify an output location as shown in the code below:

```
curl -k1 -u admin:infoblox -X POST 'https://..../wapi/v2.5/fileop?
_function=read' -H 'Content-Type: application/json; charset=UTF-8' -d
'{"_filename": "test.json",
"_output_location":"FILE_DISTRIBUTION","_object": "db_objects",
"all_object_types_supported_in_version": "2.5","_encoding": "ROWJSON"}'
```

Note the following about full synchronization:

- A full synchronization is required initially for a complete snapshot of the database.
- Depending on the size of requested data, a full synchronization may take a longer time to complete. For example, when 1 million objects are requested with all fields on an IB-4015 appliance, full synchronization takes a couple of hours. When 1 million objects are requested with standard RESTful API fields on an IB-4015 appliance, full synchronization takes less than an hour.
- Infoblox recommends that you request only object types with standard RESTful API fields and specify any additional required fields during a full synchronization.
- To dump full synchronization updates into a file using `fileop->read` operation when the updated objects are large in number, you can specify `_object=db_objects` and all the necessary parameters.
- Infoblox recommends a full synchronization in the following cases:
  - After an upgrade, restore or master promotion, which resets the sequence ID.
  - During off-peak hours for busy Grids with high rate of change that is greater than 500/sec.
  - When the maximum time or maximum number to track deleted objects is met, with the default being 4 hours and 4000 objects, then synchronization API returns an error if the last deleted sequence ID is newer than the current sequence ID.

Following are a few samples of API requests for full synchronization:

- If you specify `_output_location = "local"` and schedule the task, then you must use `fileop ->get_file_url` to retrieve the URL:

```
curl -k1 -u admin:infoblox -X POST 'https://127.0.0.1/wapi/v2.5/fileop?
_function=get_file_url' -H "Content-Type: application/json" -d
'{"task_id":1}'
```

The response is as follows:

```
"url":
 "https://10.32.2.202/http_direct_file_io/req_id-OBJECTS-1/nios-db-objects-1.json"
```

You can fetch this file using the following API request:

```
curl -k1 -u admin:infoblox -X GET https://10.32.2.202/http_direct_file_io/req_id-OBJECTS-1/nios-db-objects-1.JSON -H 'Content-Type: application/json; charset=UTF-8'
```

- If you specify `_output_location = "local"` and do not schedule the task, then NIOS returns an URL and a token:

```
curl -k1 -u admin:infoblox -X POST 'https://127.0.0.1/wapi/v2.5/fileop?_function=read'
 -H 'Content-Type: application/json; charset=UTF-8' -d
'{ "_output_location":"LOCAL","_object": "db_objects",
"all_object_types_supported_in_version": "2.5","_encoding": "JSON"}'
```

The response is as follows:

```
{
    "token":
"eJy1kU1vwyAMhu/8kfaSD/JB0t5aZZU2Ta3UTtrRSoB2nlJggUztv5+ZtJ123QFk/L7mMUZK6+4w\n6QujTVr
jwzTLYCfmOFtKNGc7jPaWWqPjCnenPev60MNRn5krmAQYZhwDGgCmUAbmSrZUrmKnhb45\nnO4Q8KoXzNVsxyt RtKVYFU0qqqpuBWf+tJinkWRBBW8hOL/OMp6nZZ2KtG2ymAKF1FuAM44a0GaT\n/gBUSXd43T8fNl3C85xnBq1 P1AB2eCevT5J8leR1UuRcQFGsy3pN1KfTYU+sJmJRUdQS9a/rSFpF\nk6KnUsxz8mWe5tJfdBau7n/64vyHCdp
Iq9BcYrYg+Pbx21D+Gq5WxanyOOhu87KB48Munmvmw9Fx\nET+BNyTi0DtA4+YAn3ryaE20tWzvh/QLT4Gbhw=
 =\n",
    "url":
 "https://10.35.6.87/http_direct_file_io/req_id-DOWNLOAD-1001/nios-db_objects--09-05-20
16_22:35:27.JSON"
 }
```

- To save the file in a local area instead of the file distribution area:

```
curl -k1 -u admin:infoblox -X POST 'https://127.0.0.1/wapi/v2.5/fileop?_function=read&_schedinfo.schedule_now=true' -H 'Content-Type: application/
```

```
json; charset=UTF-8' -d '{"_output_location": "LOCAL", "_object":
"db_objects", "all_object_types_supported_in_version": "2.5", "_encoding":
"JSON"}'
```

The response is as follows:

```
scheduledtask/b25lLnF1ZXVlZF90YXNrJDE:1/WAITING_EXECUTION
```

- You can also schedule a full synchronization task as follows:

```
curl -k1 -u admin:infoblox -X POST 'https://127.0.0.1/wapi/v2.5/fileop?
_function=read&_schedinfo.schedule_now=true' -H 'Content-Type: application/
json; charset=UTF-8' -d '{"_filename": "test2.txt", "_object": "db_objects",
"all_object_types_supported_in_version": "2.5", "_encoding": "JSON"}'
scheduledtask/b25lLnF1ZXVlZF90YXNrJDE:1/WAITING_EXECUTION
```

NIOS returns the scheduled task reference so that you can query and find out when will the scheduled task be complete:

```
curl -k1 -u admin:infoblox -X GET
https://127.0.0.1/wapi/v2.5/scheduledtask/b25lLnF1ZXVlZF90YXNrJDE:1/
WAITING_EXECUTION
```

The response is as follows:

```
{ "_ref": "scheduledtask/b25lLnF1ZXVlZF90YXNrJDE:1/COMPLETED",
"approval_status": "NONE", "execution_status": "COMPLETED", "task_id": 1 }
```

Note that the result is in either JSON or XML format. You can fetch the output file from the `wapi-output` directory of the file distribution area when the scheduled task is complete.

Using Incremental Synchronization

Incremental synchronization synchronizes only those objects that are updated since the previous synchronization. With incremental synchronization, you can query NIOS for any updates and when updates are found, NIOS returns the changed objects since the previous incremental synchronization. Incremental synchronization synchronizes the NIOS database for object changes such as addition, updates, or deletion, mostly via scripts. The incremental synchronization query consists of object types, a cookie of the form `<id of db:sequence_id>`, a sequence ID and an optional `exclude_deleted` object to indicate if the deleted objects must be excluded from the results. NIOS includes the deleted records in the results by default.

> **Note**
>
> Infoblox recommends that you use `fileop->read` for incremental synchronization when the updated objects are large in number.

Note the following about incremental synchronization:

- You cannot request an incremental synchronization to get updated (created, updated or deleted) objects after a full synchronization.

- For performance reasons, NIOS returns the objects that changed and not the object data that changed. Infoblox recommends that you figure out what changed by comparing the object with the previous version in the client database.
- Incremental synchronization may take a longer time to complete depending on the number of changes. For example, if 50K objects are requested with all fields on an IB-4015 appliance, an incremental synchronization approximately takes 2 minutes. When 50K objects are requested with standard RESTful API fields on an IB-4015, the synchronization process completes in approximately 1 minute.
- The size of the memory increases when the number of objects increases. Infoblox recommends that you use `_max_results` to limit the number of results or use the asynchronous `fileop->read` operation.
- Infoblox recommends that for a busy Grid with a high Rate of Change that is greater than 500/sec, you must run an incremental synchronization more frequently. Example: If the expected Rate of Change for objects in the Grid is 50/sec, you can schedule an incremental synchronization every 5-10 minutes. If the Rate of Change for objects is 200/sec, schedule an incremental synchronization every minute or every 2 minutes.
- Infoblox recommends that you include all object types when you query using an incremental synchronization, so that it returns the highest sequence ID for all objects that can be used for subsequent incremental updates. If you query only selected object types such as A record and zone, NIOS returns the highest sequence ID for those object types only.
  Consider an example where A record, Network, and A record are the object types with sequence ID 4, 5 and 6 respectively. When you query for an A record object type with a previous sequence ID using incremental synchronization, NIOS returns A record with the highest sequence ID, which is 6 and does not return the network object. Meanwhile, if you add or update a network object, then in the subsequent incremental synchronization it does not return the network object and you will lose updates made to the network object. Hence, Infoblox recommends that you include all object types in the query to ensure that you do not lose updates made to other object types.
- You cannot perform a full or an incremental synchronization during Grid Master Candidate promotions, restores, and upgrades.
- The output of an incremental synchronization is either in JSON or XML format.

The following are a few samples of API requests for incremental synchronization:

- To get updates with all_objects_supported_in_version=2.5:

```
curl -k1 -u admin:infoblox -H content-type:application/json -X GET
https://10.35.6.87/wapi/v2.5/db_objects?
start_sequence_id=992684967:0\&all_object_type
s_supported_in_version=2.5\;
return_fields=last_sequence_id,object,object_type,unique
_id\;_return_type=json
```

  The response for the above API request contains all fields of all object types.

- To get an A record and an auth zone object update:

```
curl -k1 -u admin:infoblox -H content-type:application/jason -X GET
https://10.32.2.202/wapi/v2.5/db_objects?
start_sequence_id=183566281:0\&object_types=r
ecord:a,zone_auth\;_return_fields=last_sequence_id,object,object_type,unique
_id\;_return_type=json
```

  The response is as follows:

```
[{"_ref": "db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDA:19", "object":
{"_ref":
```

```
"zone_auth/ZG5zLnpvbmUkLl9kZWZhdWx0LmNvbS5mb28:foo.com/default", "fqdn":
"foo.com",
"view": "default"}, "object_type": "zone_auth", "unique_id":
"087af628fa03418faa0577b953807efc"}, {"_ref":
"db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDE:21", "object": {"_ref":
"record:a/
ZG5zLmJpbmRfYSQuX2RlZmF1bHQuY29tLmZvbyxhcmVjMSwxLjIuMy4y:arec1.foo.com/
default", "ipv4addr": "1.2.3.2", "name": "arec1.foo.com", "view":
"default"}, "object_type":
"record:a", "unique_id": "89314c3fae2841f49600e1b686b0c7b7"},{"_ref":
"db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDI:183566281%3A21",
"last_sequence_id":
"183566281:21"},
```

- NIOS returns deleted objects as synthetic deleted objects. To get updates on deleted host objects:

```
curl -s -k1 -u admin:infoblox -H content-type:application/json -X GET
https://10.34.19.220/wapi/v2.5/db_objects?
start_sequence_id=1207501969:0\&object_types
=record:host,bulkhost,record:host_ipv6addr,record:host_ipv6addr\&exclude_del
eted=false
```

The response is as follows:

```
[{ "_ref": "db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDM2YQ:130",
        "object": {
            "_ref": "deleted_objects/Li5kZWxldGVkX29iamVjdHMkMA",
            "object_type": "record:host_ipv6addr"
        },
        "object_type": "deleted_objects",
        "unique_id": "f7d87ec4b9204e16a3d14bfb340c402d" },
{ "_ref": "db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDM2Yg:130",
        "object": {
           "_ref": "deleted_objects/Li5kZWxldGVkX29iamVjdHMkMQ",
           "object_type": "record:host_ipv4addr" },
        "object_type": "deleted_objects",
        "unique_id": "68316853600f41f083e2be134628ce62" },
{ "_ref": "db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDM2Yw:130",
        "object": {
           "_ref": "deleted_objects/Li5kZWxldGVkX29iamVjdHMkMg",
```

```
          "object_type": "record:host" },
        "object_type": "deleted_objects",
        "unique_id": "7a5e0622e9db441caa47c12ca30700d5" },
{ "_ref": "db_objects/Li5hbGxfY2hhbmdlZF9vYmplY3RzJDM2ZA:1207501969%3A130",
        "last_sequence_id": "1207501969:130" }]
```

- To dump incremental synchronization updates into a file using `fileop->read` operation when the updated objects are large in number, you can specify `_object=db_objects` and all the necessary parameters for incremental synchronization:

```
curl -k1 -u admin:infoblox -X POST 'https://10.34.19.100/wapi/v2.5/fileop?
_function=read' -H 'Content-Type: application/json; charset=UTF-8' -d
'{"_output_location": "LOCAL", "_object": "db_objects",
"start_sequence_id" :
"1973553522:0","all_object_types_supported_in_version": "2.5",
"_max_results": 1000000,"_encoding": "JSON"}'
```

For more information about supported objects in the Infoblox API and Restful API, refer to the Infoblox API Documentation and the Infoblox WAPI Documentation.

Configuring the PTop Instance to Collect CPU Utilization Data

The NIOS appliance allows you to configure the collection of CPU utilization data of top processes that are running on the Grid Master and all members of a Grid, or a standalone system. The PTop tool that runs in the background, collects the CPU utilization data and logs it in PTop logs.

To configure the PTop instance, complete the following steps:

1. **Grid**: From the **Grid** tab, select the **Grid Manager** tab. Expand the Toolbar, and then select **Grid Properties** -> **Edit**.
   Or,
   Standalone system: From the **System** tab, select the **System Manager** tab. Expand the Toolbar, and then select **System Properties** -> **Edit**.
2. In the *Grid Properties* editor or the *System Properties* editor, click the **Monitoring** tab, and then complete the following steps in the *PTop Log* section:
   - **Number of Top Processes**: Enter the number of top processes for which you want to check the CPU utilization. If you enter 11, NIOS displays the CPU utilization of the top 11 processes. The minimum number of processes for which you can check the utilization is 10 and the maximum is 25. By default, the widget displays the CPU utilization for 10 top processes.
   - **PTop Interval**: Enter the time interval in seconds to determine the frequency with which the Ptop tool must run and collect data. The Ptop tool is an internal tool that runs in the background and collects CPU utilization and other data. The minimum interval that you can enter is 2 seconds and the maximum is 30 seconds. By default, the PTop interval is set as 2 seconds.
3. Click **Save & Close**.

Collecting Database Performance Data

The NIOS appliance provides Ptop logs that consist of database metrics that you can use to determine the health of the NIOS database and baseline its performance. The metrics help you to ascertain the impact of changes such as adding a Grid member or enabling features such as Grid replication for DNS zones or multi-master DNS, on the database performance.

You can download the Ptop logs by using the WAPI calls and then use the logs for further analysis. These WAPI calls allow you to download only the Ptop logs instead of the whole support bundle.

To download the Ptop log files, perform the following steps. The steps are showing sample WAPI requests.

1. Run the following command to get the URL for downloading the Ptop logs:

   ```
   $curl -k1 -u admin:infoblox -H "Content-Type: application/json" -X POST ht
   tps://10.12.21.107/wapi/v2.9.7/fileop?_function\=get_log_files -d
   '{"include_rotated":false,"log_type":"PTOPLOG","node_type":"ACTIVE"}'
   ```

   The output includes the token for this transaction and the URL from where to download the Ptop logs as follows:

   ```
   {
   "token":
   "eJytUEFuwyAQvPOR5BLM2jEkvaVyI1WqEimp1OPKBuwi2YYCqZK+vhA2jZ2WFmR0rrbuj1\nQN
   Il7Ryiv8hoPXFAltLMve1Ge6V21vnEm9OBNG1s8aR74koiEbuLGaOZEYkyMhJXkaVya3Je6Ksz\
   n/
   obRTHpBXE32UIs156LiQDeMiRK2JJwXFz8mmCfCe4wuPBQFMAoloyVQYKLIXVQm2YvYmjm+HV6O
   u2YFUNaMV5yB4ExUdeGidaMdaGw9Hb7S/yJLGZWi5/G7t5UjXVwBKnCCmX\ndtBFnNw/
   mQL4EUEvOzw97fO7JiGeHPCcOogE9kKO3kWn9nbcgh79+1Ds3sLhE/tQ/
   GzhnbJqy6567j3wFfoFk=\n",
   "url": "https://10.12.21.107/http_direct_file_io/req_id-
   DOWNLOAD-1125063601760735/ptoplog.tar.gz"
   }
   ```

2. Download the Ptop log files using the obtained URL:

   ```
   $curl -k1 -u admin:infoblox -H "Content-type:application/force-download"
   -O https://10.12.21.107/http_direct_file_io/req_id-
   DOWNLOAD-1125063601760735/ptoplog.tar.gz
   ```

3. To ensure that the URL does not remain open for a long time, use the token obtained in step 1 and close the URL as follows:

   ```
   $curl -k -u admin:infoblox -H 'Content-Type:application/json' -X POST http
   s://10.12.21.107/wapi/v2.9.7/fileop?_function=downloadcomplete -d
   '{"token":
   "eJytUEFuwyAQvPOR5BLM2jEkvaVyI1WqEimp1OPKBuwi2YYCqZK+vhA2jZ2WFmR0rrbuj1\nQN

   GzhnbJqy6567j3wFfoFk=\n"}'
   {}
   ```

Configuring dnstap

You can use the dnstap log format to log DNS queries and responses at high rates to well-known destinations. NIOS logs all valid DNS queries and responses that are not dropped by Advanced DNS Protection. For information about dnstap, see *https://dnstap.info/*.

For information about capturing DNS queries and responses without using dnstap, see *Capturing DNS Queries and Responses*.

> **Note**
>
> dnstap for high-performance query logging is supported on Infoblox appliances on which Advanced DNS Protection or DNS Cache Acceleration is running.

This section includes the following topics:

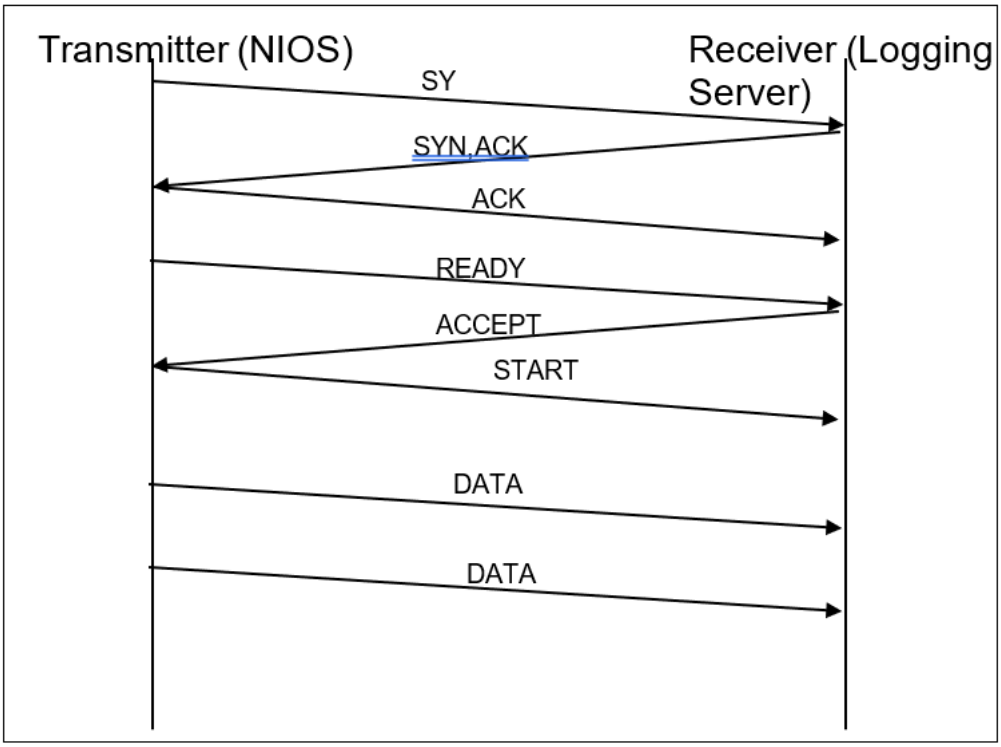
- *About dnstap Implementation*
- *Protobuf Template for Infoblox dnstap*
- *Configuring dnstap to Log DNS Queries and Responses*

About dnstap Implementation

dnstap is implemented using the Google protocol buffer (protobuf) for packaging logged data, and Frame Streams as a lightweight streaming protocol to transmit the data to a receiver.

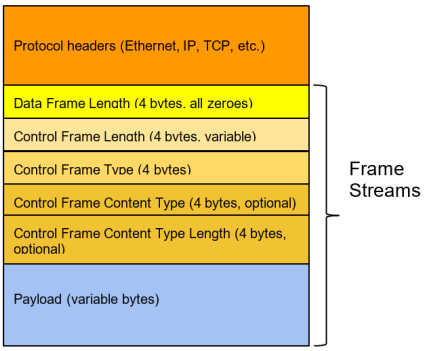
A bi-directional communication starts with a 3-way handshake sequence of Frame Streams control packets over a TCP (or other reliable byte-streaming). The following figure illustrates the connection between the transmitter and receiver pair.

Packet Flow for Frame Streams 3-way handshake initialization and data frames over a TCP connection



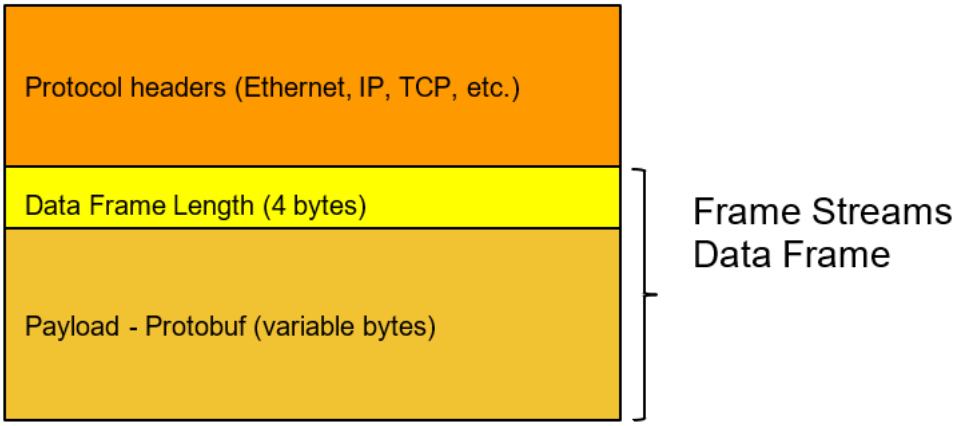
The transmitter initiates the communications to the receiver by first sending a READY control frame carrying the `protobuf:dnstap.Dnstap` string. The receiver responds with an ACCEPT control frame carrying the same `protobuf:dnstap.Dnstap` string. The handshake is completed when the transmitter sends a START control frame carrying the same `protobuf:dnstap.Dnstap` string.

Frame Streams Control Frame Format



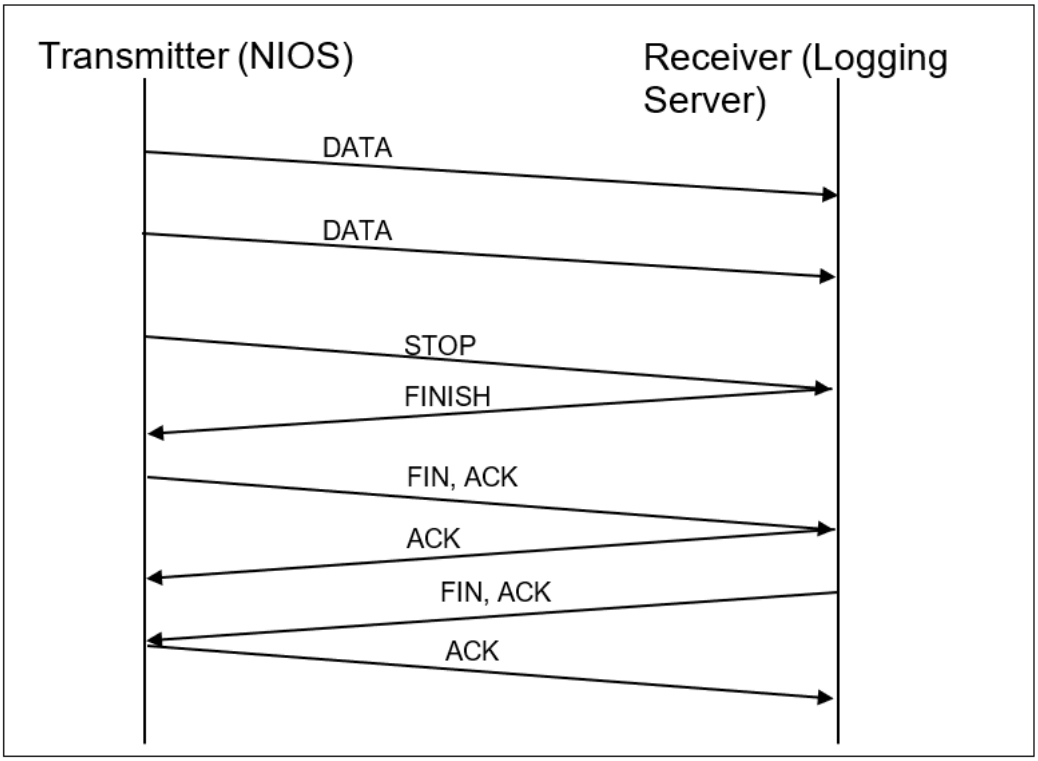
Data packets are carried over the connection with only a 4-byte framing overhead as illustrated in the following figure.

Frame Streams Data Frame Format



To end the bi-directional communication that is shown in the following figure, the sequence starts with a STOP control frame from one of the communicating pairs, followed by a FINISH acknowledgment control frame from the other half of the pair.

Packet flow for Frame Streams termination over a TCP connection



Protobuf Template for Infoblox dnstap

The following is a sample template that you can create for flexible and efficient use of your logged data. You can specify the way in which information must be logged by defining protobuf message types.

```
// dnstap: flexible, structured event replication format for DNS software,
// This file contains the protobuf schemas for the "dnstap" structured event
// replication format for DNS software.
// Written in 2013-2014 by Farsight Security, Inc.
// Updated in 2019-2020 by Infoblox, Inc.
// To the extent possible under law, the author(s) have dedicated all copyright
// and related and neighboring rights to this file to the public domain
worldwide.
// This file is distributed without any warranty.
// You should have received a copy of the CC0 Public Domain Dedication along
with this file.
// If not, see:
// <http://creativecommons.org/publicdomain/zero/1.0/>. package dnstap;
// "Dnstap": this is the top-level dnstap type, which is a "union" type that
// contains other kinds of dnstap payloads, although currently only one type
// of dnstap payload is defined.
```

```
// See: https://developers.google.com/protocol-buffers/docs/techniques#union
message Dnstap {
// DNS server identity.
optional bytes identity = 1;
// DNS server version.
optional bytes version = 2;
// Extra data for this payload.
optional bytes extra = 3;
// Identifies which field below is filled in.
enum Type {
MESSAGE = 1;
}
required Type type = 15;
// One of the following will be filled in.
optional Message message = 14;
}
// SocketFamily: the network protocol family of a socket. This specifies how
// to interpret "network address" fields.
enum SocketFamily {
INET = 1; // IPv4 (RFC 791)
INET6 = 2; // IPv6 (RFC 2460)
}
// SocketProtocol: the transport protocol of a socket. This specifies how to
// interpret "transport port" fields.
enum SocketProtocol {
UDP = 1; // User Datagram Protocol (RFC 768)
TCP = 2; // Transmission Control Protocol (RFC 793)
}
// Message: a wire-format (RFC 1035 section 4) DNS message and associated
// metadata. Applications generating "Message" payloads should follow
// certain requirements based on the MessageType, see below.
message Message {
// We are supporting the following types of messages
// CQ: CLIENT_QUERY
// CR: CLIENT_RESPONSE
enum Type {
// CLIENT_QUERY is a DNS query message sent from a client to a DNS
```

```
// server which is expected to perform further recursion, from the
// perspective of the DNS server. The client may be a stub resolver or
// forwarder or some other type of software which typically sets the RD
// (recursion desired) bit when querying the DNS server. The DNS server
// may be a simple forwarding proxy or it may be a full recursive
// resolver.
CLIENT_QUERY = 5;
// CLIENT_RESPONSE is a DNS response message sent from a DNS server to
// a client, from the perspective of the DNS server. The DNS server
// typically sets the RA (recursion available) bit when responding.
CLIENT_RESPONSE = 6;
}
// One of the Type values described above.
required Type type = 1;
// One of the SocketFamily values described above.
optional SocketFamily socket_family = 2;
// One of the SocketProtocol values described above.
optional SocketProtocol socket_protocol = 3;
// The network address of the message initiator.
// For SocketFamily INET, this field is 4 octets (IPv4 address).
// For SocketFamily INET6, this field is 16 octets (IPv6 address).
optional bytes query_address = 4;
// The network address of the message responder.
// For SocketFamily INET, this field is 4 octets (IPv4 address).
// For SocketFamily INET6, this field is 16 octets (IPv6 address).
optional bytes response_address = 5;
// The transport port of the message initiator.
// This is a 16-bit UDP or TCP port number, depending on SocketProtocol.
optional uint32 query_port = 6;
// The transport port of the message responder.
// This is a 16-bit UDP or TCP port number, depending on SocketProtocol.
optional uint32 response_port = 7;
// The time at which the DNS query message was sent or received, depending
// on whether this is an AUTH_QUERY, RESOLVER_QUERY, or CLIENT_QUERY.
// This is the number of seconds since the UNIX epoch.
optional uint64 query_time_sec = 8;
// The time at which the DNS query message was sent or received.
```

```
// This is the seconds fraction, expressed as a count of nanoseconds.
optional fixed32 query_time_nsec = 9;
// The initiator's original wire-format DNS query message, verbatim.
optional bytes query_message = 10;
// This is a wire-format DNS domain name.
// Currently, we are not supporting this.
optional bytes query_zone = 11;
// The time at which the DNS response message was sent or received,
// depending on whether this is an CLIENT_RESPONSE.
// This is the number of seconds since the UNIX epoch.
optional uint64 response_time_sec = 12;
// The time at which the DNS response message was sent or received.
// This is the seconds fraction, expressed as a count of nanoseconds.
optional fixed32 response_time_nsec = 13;
// The responder's original wire-format DNS response message, verbatim.
optional bytes response_message = 14;
// Start of Infoblox specific log messages
optional bytes subscriber_id = 15; // 32 bytes
optional uint64 local_id = 16; // 8 bytes
optional bytes pcp_ssp = 17; // 16 bytes
optional bytes proxy_all = 18; // Proxy all
optional bytes fqdn = 19; // MAX 255 bytes
required uint32 txid = 20; //16-bit transaction id
}
// All fields except for 'type' in the Message schema are optional.
// It is recommended that at least the following fields be filled in for
// particular types of Messages.
// CLIENT_QUERY:
// socket_family, socket_protocol
// query_message
// query_time_sec, query_time_nsec
// CLIENT_RESPONSE:
// socket_family, socket_protocol
// query_time_sec, query_time_nsec
// response_message
// response_time_sec, response_time_nsec
```

Configuring dnstap to Log DNS Queries and Responses

You can use the dnstap log format to log DNS queries and responses at high rates to well-known destinations and achieve high performance query and response logging. NIOS logs all valid DNS queries and responses that are not dropped by Advanced DNS Protection. For information about dnstap, see *https://dnstap.info/* .

To use the dnstap log format, you need to enable dnstap by running the *set enable_dnstap* command. To view whether the dnstap log format is enabled or disabled, run the *show dnstap-status* command. To view the number of queries and responses sent to the destination when the dnstap log format is enabled for high-performance logging of queries and responses, run the *show dnstap-stats* command.

If you choose to enable the dnstap log format, you will not be able to capture queries and responses using the **Data connector for all DNS Queries/Responses to a Domain** fields. And if you use the **Data connector for all DNS Queries/ Responses to a Domain** fields for query capture, the **DNSTAP settings for DNS Queries/Responses** fields will be disabled.

> ⚠ Note
>
> For Advanced DNS Protection software with acceleration, you must download the latest ruleset before enabling dnstap.

Limitations of Using dnstap to Log Queries and Responses

Ensure that you understand the following limitations before you use dnstap to log queries and responses:

- dnstap supports UDP, TCP, and EDNS protocols that require additional processing thus leading to a decrease in performance.
- NIOS does not support BIND9 dnstap.
- If the remote logging server is not accessible, then the logs are dropped and not buffered.
- The dnstap server cannot truncate EDNS0 queries.
- If you run a query that contains +edns=1, a dnstap server that uses the Golang DNS library to process the captured data displays it as a bad signature (TSIG signature failure).
- Capturing the queries and responses also depends on other factors such as the size of the flavor deployed and features enabled over it.
- dnstap does not support query and response logging on the MGMT interface.

Configuring dnstap to Log DNS Queries and Response Captures

To configure dnstap to log DNS queries and to capture responses, complete the following:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the **Toolbar,** and then click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab, and then click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click **Toggle Advanced Mode** and then select the **Logging** tab.
3. Select the **Queries** checkbox to start capturing DNS queries. When you enable this option at the member level, NIOS captures DNS queries for only the selected member.
4. Select the **Responses** checkbox to start capturing DNS responses. When you enable this option at the member level, NIOS captures DNS responses for only the selected member.
5. In the **DNSTAP Receiver Address** field, enter the IP address from which you want to capture queries or responses. It supports both IPv4 and IPv6 addresses.
6. In the **DNSTAP Receiver Port field,** enter the port number on which you want to configure the dnstap client system. The default port number is 6000.
7. Click **Save and Close**.

Infoblox recommends the configurations in the following table to meet high-performance query logging using the dnstap log format:

Feature	Total CPU	Total Virtual Memory (without Advanced DNS Protection software)	Total Virtual Memory (with Advanced DNS Protection software)	Database Object Count	Grid Master Capable
Small recursive DNS (with acceleration)	10	16	24	100,000	No
Medium recursive DNS (with acceleration)	16	24	32	100,000	No
Large recursive DNS (with acceleration)	26	34	42	100,000	No

Configuring DHCP Fingerprints and Fingerprint Detection

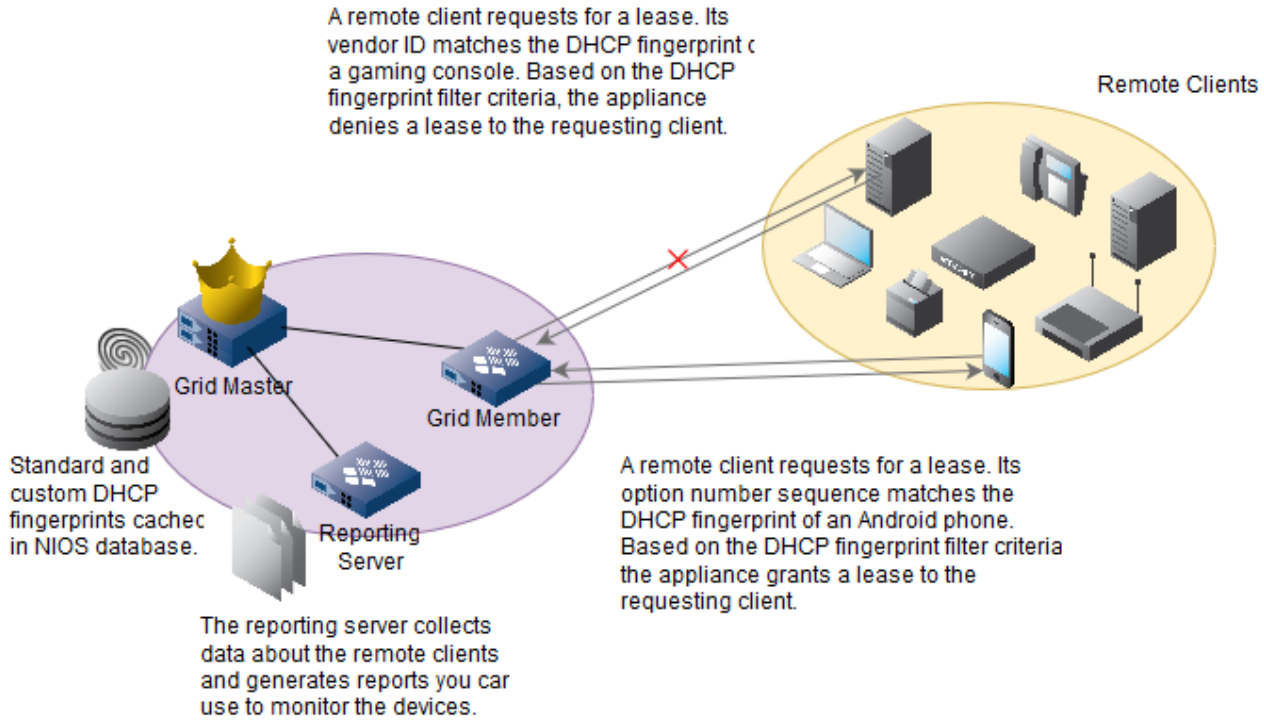
This section explains the Infoblox DHCP fingerprint detection feature and how to configure it on the appliance. It also explains how to configure DHCP fingerprints for IPv4 and IPv6. It contains the following sections:

DHCP Fingerprint Detection

The NIOS appliance utilizes DHCP fingerprint detection to identify IPv4 and IPv6 mobile devices such as laptop computers, tablets and smart phones, on your network. Due to the broadcast and pervasive nature of DHCP, using DHCP fingerprint detection is an efficient way to perform system identification and inventory. You can use DHCP fingerprint detection to track devices on your network, block those that are not allowed (such as gaming consoles and home routers), and plan for future growth by accessing trending information such as the number of Apple iPhones versus that of Android phones.

When a remote DHCP client sends a DHCP REQUEST message, it includes a set of DHCP options, such as option 55 and 60. Option 55 contains an option number sequence the appliance uses to interpret the list of DHCP options that the client requests. The appliance returns the values of these requested options if the information is available.
Option 60 contains a value that indicates the device type of the requesting client. Information in option 55 or 60 is incorporated to form a unique identifier known as the DHCP fingerprint, which the appliance uses to identify the requesting client.
On an Infoblox appliance, DHCP fingerprint detection is enabled by default for all new installations. You can disable this feature at the Grid and member levels. For information, see *Enabling and Disabling DHCP Fingerprint Detection*. As illustrated in the below figure, the appliance automatically matches option 55 and then option 60 in DHCP REQUEST messages against standard and custom DHCP fingerprints in the database. Once the appliance finds a match, it either grants or denies a lease to the requesting client based on the DHCP fingerprint filters that you apply to the DHCP range. For information about how to configure DHCP fingerprints, see *Configuring DHCP Fingerprint Filters*. For information about how to define and apply DHCP fingerprint filters, see *Configuring DHCP Fingerprint Filters*. To obtain trending information about the top OSs (operating systems) or vendor IDs for remote clients, Infoblox provides a few reports from which you can extract data. For information about reports, see *Infoblox Reporting and Analytics*.

DHCP Fingerprint Detection



About DHCP Fingerprints

When a DHCP client sends a REQUEST message and includes DHCP option 55 (the parameter request list) and option 60 (the vendor identifier), it provides information about its OS and the device type. The combination of the option sequence or vendor ID in option 55 or 60 is used to infer the OS and device type of the remote client. These parameters are then incorporated into a DHCP fingerprint that provides unique information about this client.
For example, the option number sequence for a Microsoft Windows Kernel 5.1 and 5.2 systems in option 55 can be one of the following:

```
1,15,3,6,44,46,4
1,15,3,6,44,46,47,31,33,121,249,43,200
1,15,3,6,44,46,47,31,33,249,43
1,15,3,6,44,46,47,31,33,249,43,252
1,15,3,6,44,46,47,31,33,249,43,252,12
15,3,6,44,46,47,31,33,249,43
15,3,6,44,46,47,31,33,249,43,252
15,3,6,44,46,47,31,33,249,43,252,12
28,2,3,15,6,12,44,47
```

The option number sequence for an Apple Mobile Device can be one of the following:

```
1,121,3,6,15,119,252,0,0,0,0,0,0,0,0,0
1,121,3,6,15,119,252,118
1,3,6,12,15,28,44,121
```

`1,3,6,15,19`

`1,3,6,21,1,25,2,82`

Additionally, DHCP option 60 tracks the vendor ID. The vendor ID can be generic or specific. For example, the vendor ID `MSFT 5.0` for a Microsoft Windows Kernel 5.1 or 5.2 system and a Microsoft Windows Kernel 6.0 system can be the same. For certain Microsoft Windows Kernel 5.0 systems, the vendor ID can be `MSFT`, which is generic, or it can be `MSFT 5.0`, which is specific. Depending on how specific the option number sequence and the vendor ID are, this information can form a unique identifier, the DHCP fingerprint for a remote client.

> **Note**
>
> If you have enabled a firewall and if the corresponding firewall rules or policies are set to modify options 55 and 60 of the remote DHCP client to mask the identity of the client, then fingerprinting clients cannot be achieved.

Enabling and Disabling DHCP Fingerprint Detection

Grid DHCP fingerprint detection is enabled by default for new installations, and no special licenses are required. You can disable this or override the Grid setting at a member level. Note that when you enable DHCP fingerprint detection, there will be a slight impact on DHCP performance.
When you enable DHCP fingerprint on an HA pair, both peers in a failover association maintain the same DHCP fingerprinting state (enabled or disabled) even when one of the peers fails or becomes operational again. Note that both peers must be in the same Grid for the fingerprinting state to stay the same. For information about DHCP failover, see *DHCP Failover*.
To enable and disable Grid DHCP fingerprinting:

1. **Grid**: From the **Data Management** tab, select the **DHCP** tab, and then click **Grid DHCP Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DHCP** tab -> **Members** tab -> **Members** -> *member* checkbox, and then click the Edit icon.
2. In the *Grid DHCP Properties* or *Member DHCP Properties* editor, select the **Fingerprinting** tab.
3. Complete the following
   - **Enable Fingerprint Detection:** Deselect this checkbox to disable the feature. You can enable DHCP fingerprint detection again by selecting the checkbox. Click **Override** to change the configuration for a member, or click **Inherit** to inherit the Grid setting.
4. Save the configuration and click **Restart** at the top of the screen.

Standard and Custom DHCP Fingerprints

Standard DHCP fingerprints are automatically installed on the appliance when you first set it up or after you have completed an upgrade from previous NIOS releases to NIOS 6.7 and later. Note that new DHCP fingerprints are added to the appliance during a major NIOS upgrade. For more information about upgrades, see *Upgrading NIOS*.

> **Note**
>
> When you upgrade to NIOS 6.7 and later, DHCP fingerprint detection is disabled during the upgrade. You must enable it if you want the appliance to use DHCP fingerprint detection. For information, see *Enabling and Disabling DHCP Fingerprint Detection*.

You can configure custom DHCP fingerprints for devices whose DHCP fingerprints are not captured in the standard DHCP fingerprints. For information about how to add custom DHCP fingerprints, see as described in *Adding New DHCP Fingerprints*.
Both standard and custom DHCP fingerprints are cached in memory for matching purposes. Depending on the information provided in a DHCP fingerprint, the appliance first matches the option number sequence sent in the DHCP REQUEST message. If option 55 is not included in the request or if there is no match from the cached DHCP

fingerprints, the appliance then tries to match the vendor ID in option 60. When there is an option number sequence match, the appliance displays the name of the DHCP fingerprint in Grid Manager. If there is no option number sequence match but there is a vendor ID match, the appliance displays the vendor ID. For information about how to view fingerprint information, see as described in *Viewing DHCP Fingerprint Information*.
You can also create IPv4 and IPv6 DHCP fingerprint filters and then apply them as class filters to specific IPv4 and IPv6 DHCP ranges and range templates. For information about how to configure and use DHCP fingerprint filters, see *Configuring DHCP Fingerprint Filters*.

Administrative Permissions

DHCP fingerprint detection is enabled by default for new installations. For upgrades, you must enable this feature after the upgrade is completed. For information, see *Enabling and Disabling DHCP Fingerprint Detection*. No special licenses are required for this feature.
Superusers can add, modify, and delete DHCP fingerprints and DHCP fingerprint filters. Limited-access users with Read/Write permission to DHCP fingerprints can add, modify, and delete DHCP fingerprints while those who have Read-only permission can only view information in the **Data Management** tab -> **DHCP** tab -> **Fingerprints** tab. For information about administrative permissions, see *About Administrative Permissions*.

Configuring DHCP Fingerprints

The appliance installs standard DHCP fingerprints when you first install or upgrade to NIOS 6.7 or later. You cannot modify standard DHCP fingerprints nor delete them, but you can disable them. When you disable a DHCP fingerprint, the appliance disables the associated option number sequence and vendor ID, and it cannot match a remote device against the disabled DHCP fingerprint.
When you add a new DHCP fingerprint, the appliance marks it as a custom DHCP fingerprint. For information about adding custom DHCP fingerprints, see Adding New DHCP Fingerprints below. You can modify information about custom DHCP fingerprints, and you can delete them. For information, see Modifying Custom DHCP Fingerprints and Deleting Custom DHCP Fingerprints below. When you delete a custom DHCP fingerprint, the appliance moves it to the Recycle Bin, if enabled. You can later restore it from the Recycle Bin if needed.
Activities such as additions, modifications, and deletions of DHCP fingerprints are recorded in the audit log. For information about how to use the audit log, see *Monitoring Tools*.

> **Note**
>
> The appliance periodically updates the cached DHCP fingerprints. When you add, modify, or delete a DHCP fingerprint, you do not need to restart the services, but it may take up to two minutes before the appliance updates the DHCP fingerprint.

Adding New DHCP Fingerprints

To add a custom DHCP fingerprint, complete the following steps:

1. From the **Data Management** tab, select the **DHCP** tab -> **Fingerprints** tab, and then click the Add icon.
2. In the *Add DHCP Fingerprint* wizard, complete the following:
   - **Name**: Enter the name of the custom DHCP fingerprint. The name must be unique, and it cannot contain any UTF-8 characters.
   - **Device Class**: From the drop-down list, select the device category to which this new fingerprint belongs. You can also enter a new device class here. When you enter a device class that already exists, the appliance matches the entry and uses the class from the current list. Device class is used for filtering purposes. For information about defining a DHCP fingerprint filter, see *Configuring DHCP Fingerprint Filters*.
   - **Protocol**: From the drop-down list, select the protocol used for custom DHCP fingerprint.
   - **Option Number Sequence**: Click the Add icon in the table. The appliance adds a row to the table. Click the row and enter the DHCP option number that you want the appliance to validate. Valid values are from 0 to 255. When you enter more than one option, you must use commas (without spaces) to separate the numbers. For example, you can enter `1,15,3,6,44,46,47,31,33,249,43` for a Microsoft

Windows Kernel 5.1,5.2 system.
You can also select an option sequence and click the Delete icon to delete it. Note that if you enter an option sequence that already exists in a standard DHCP fingerprint, you must disable that standard fingerprint before you can add the option sequence to the new DHCP fingerprint.

- **Vendor Identifier**: Click the Add icon in the table. The appliance adds a row to the table. Click the row and enter a vendor ID for this fingerprint. You can add more than one vendor ID. You can also select a vendor ID and click the Delete icon to delete it.
- **Comment**: Enter additional information about the custom DHCP fingerprint.
- **Disabled**: Select this if you want to save the configuration for the DHCP fingerprint but do not want to activate it yet. You can clear this checkbox when you are ready to use this DHCP fingerprint.

3. Save the configuration or click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.

To schedule this task, click the Schedule icon at the top of the wizard. In the *Schedule Change* panel, click **Later**, and then specify a date, time, and time zone.

Modifying Custom DHCP Fingerprints

You can modify custom DHCP fingerprints, but not the standard ones. Note that the appliance periodically updates the cached DHCP fingerprints. When you modify a DHCP fingerprint, you do not have to restart the services, but it may take up to two minutes before the appliance updates the DHCP fingerprint.
To modify a custom DHCP fingerprint, complete the following steps:

1. From the **Data Management** tab, select the **DHCP** tab -> **Fingerprints** tab -> *custom_fingerprint* checkbox, and then click the Edit icon.
2. The *DHCP Fingerprint* editor provides the following tabs from which you can modify information:
   - **General**: Modify the general information, such as the name and device class, as described in Adding New DHCP Fingerprints above. Note that when you change the name of a DHCP fingerprint, the old name no longer exists, and you cannot use it for searching or filtering purposes. You may not be able to modify all fields in a standard DHCP fingerprint.
   - **Extensible Attributes**: Add and delete extensible attributes that are associated with the DHCP fingerprint. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*. Note that you cannot modify extensible attributes for standard fingerprints.
3. Save the configuration.

To schedule this task, click the Schedule icon at the top of the wizard. In the *Schedule Change* panel, click **Later**, and then specify a date, time, and time zone.

Deleting Custom DHCP Fingerprints

When you delete a custom DHCP fingerprint, the appliance moves it to the Recycle Bin, if enabled. You can later restore the DHCP fingerprint if needed. Note that you cannot delete standard DHCP fingerprints.
To delete a custom DHCP fingerprint, complete the following steps:

1. From the **Data Management** tab, select the **DHCP** tab -> **Fingerprints** tab -> *custom_fingerprint* checkbox, and then click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes** to delete the DHCP fingerprint.

To schedule this task, click the Delete icon -> **Schedule Delete**. In the *Schedule Deletion* dialog box, click **Delete Later**, and then specify a date, time, and time zone.

Viewing DHCP Fingerprint Information

The following are a few ways that you can use to view the DHCP fingerprint information:

- In a Grid with a reporting server, you can view reports that contain information about the top OSs and device types of the leasing clients in your network. For more information about DHCP Dashboards, see *Predefined Dashboards*.

- The appliance provides a few predefined smart folders from which you can view lease information about specific device groups, such as gaming consoles and Microsoft Windows devices. For more information, see *Predefined Smart Folders*.
- When the appliance finds a DHCP fingerprint match for a client, Grid Manager displays either the fingerprint name or the vendor ID in the following panels of Grid Manager: *IP List*, *Current Lease*, *Lease History*, and *DHCP Range*. You can see this information in the **Fingerprints** column in these panels.
- The appliance records all DHCP fingerprint related activities in the audit log. For more information about using the audit log, see *Monitoring Tools*.

Monitoring with SNMP

This section describes how you can use SNMP (Simple Network Management Protocol) to monitor NIOS appliances in your network. It contains the following topics:

- *Understanding Simple Network Management Protocol*
- *Configuring SNMP*
- *SNMP MIB Hierarchy*

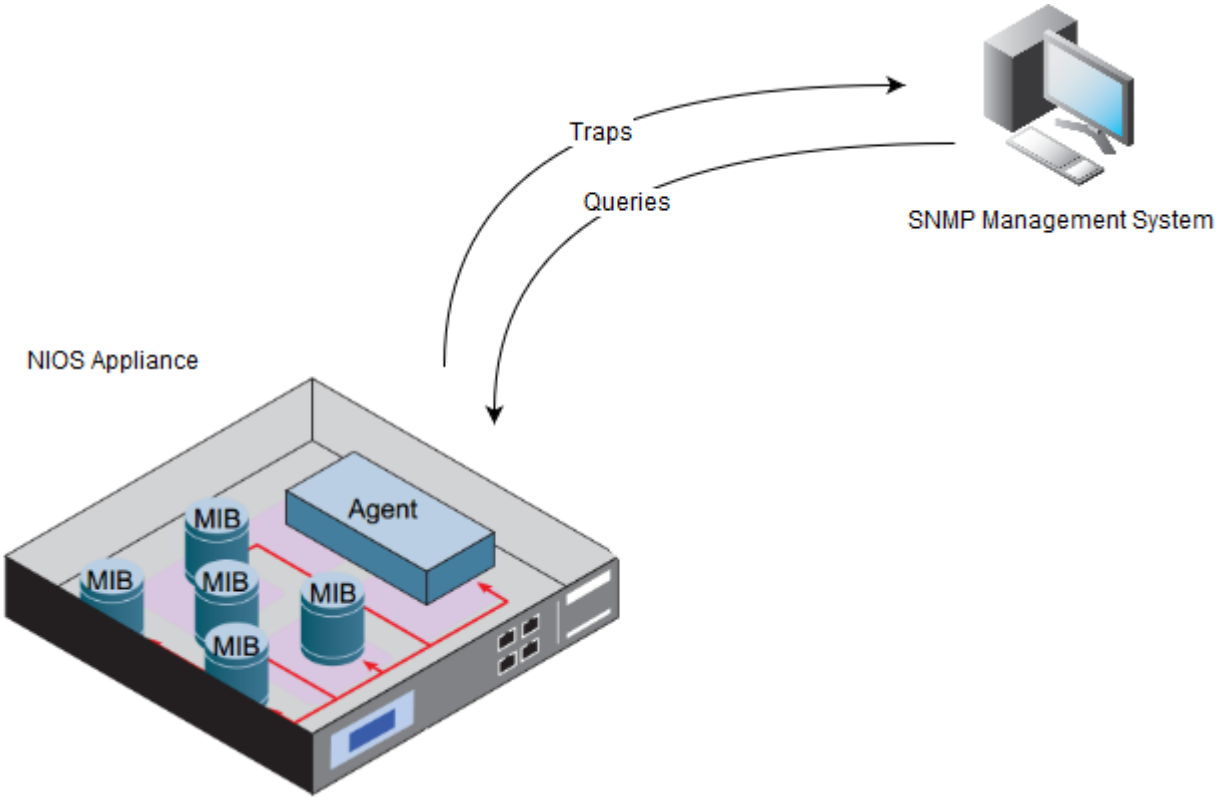
Related topic

Understanding Simple Network Management Protocol

Understanding Simple Network Management Protocol

You can use SNMP (Simple Network Management Protocol) to manage network devices and monitor their processes. An SNMP-managed device, such as a NIOS appliance, has an SNMP agent that collects data and stores them as objects in MIBs (Management Information Bases). The SNMP agent can also send traps (or notifications) to alert you when certain events occur within the appliance or on the network. You can view data in the SNMP MIBs and receive SNMP traps on a management system running an SNMP management application, such as HP OpenView, IBM Tivoli NetView, or any of the freely available or commercial SNMP management applications on the Internet.

SNMP Overview



The NIOS appliance supports SNMPv1, SNMPv2, and SNMPv3. It also adheres to the following RFCs:

- *RFC 3411, An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks*
- *RFC 3412, Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)*
- *RFC 3413, Simple Network Management Protocol (SNMP) Applications*
- *RFC 3414, User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMP)*
- *RFC 3416, Version 2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)*
- *RFC 3418, Management Information Base (MIB) for the Simple Network Management Protocol (SNMP)*
- *RFC 1155, Structure and identification of Management information for TCP/IP-based internets*
- *RFC 1213, Management Information Base for Network Management of TCP/IP-based internets:MIB-II*
- *RFC 2578, Structure of Management Information Version 2 (SMIv2)*

About SNMPv1 and SNMPv2

SNMPv1 is the initial implementation of SNMP. It operates over protocols such as UDP (User Datagram Protocol) and IP (Internet Protocol). SNMPv2 includes improvements in performance and security. It adds new protocol operations such as GetBulk and Inform, which allow the management system to request larger blocks of data from the agent. Both SNMPv1 and SNMPv2 use common strings that are sent in clear text to authenticate clients.

The NIOS appliance supports SNMPv1 and SNMPv2 in which the SNMPv2 agent acts as a proxy agent for the SNMPv1 management systems. When an SNMPv1 management system sends a query to the appliance, the SNMPv2 proxy agent forwards the request to the SNMPv1 agent. The proxy agent maps the SNMPv1 trap messages to the SNMPv2 trap messages, and then forward the messages to the management system.

You can enable the appliance to receive queries from SNMPv1 and SNMPv2 management systems. You can also add SNMPv1 and SNMPv2 management systems to receive traps from the appliance. For information about how to configure SNMPv1 and SNMPv2 on the appliance, see *Configuring SNMP*.

About User-Based Security Model in SNMPv3

SNMPv3 adds security and remote configuration enhancements to SNMPv1 and SNMPv2. The NIOS appliance supports the USM (User-based Security Model) in SNMPv3 for the authentication, encryption, and decryption of SNMP data. SNMPv3 uses the same MIB objects as those supported in SNMPv1 and SNMPv2.
SNMPv3 provides the following security measures:

- Data integrity: Ensure that SNMP data is not maliciously modified by unauthorized entities during its transmission through the network. This protects against unauthorized management operations, such as falsifying the value of a MIB object.
- Authentication: Verify the identities of the origin of the SNMP data to protect against masquerade threats that may temper the identity of users who have the appropriate authorization to send and receive SNMP data.
- Confidentiality: Ensure that unauthorized users cannot eavesdrop on any data exchanges between SNMP agents and management systems, depending on local policies of the systems.
- Timeliness: Ensure that the SNMP data is received in a timely manner to prevent malicious reordering of data by unauthorized entities.

To enable SNMPv3 on the NIOS appliance to provide user-based security, you must first configure SNMPv3 users on the appliance to enable access by SNMP management systems. The appliance supports HMAC-MD5-96 and HMAC-SHA-96 hash functions as the authentication protocols, and DES (Data Encryption Standard) and AES (Advanced Encryptions Standard) as the encryption methods for SNMPv3 users. For information, see *Configuring SNMP*.

Configuring SNMP

You can configure the appliance to receive SNMP queries from specific management systems and send SNMP traps to specific trap receivers. SNMP operation supports both IPv4 and IPv6 networks. The appliance supports SNMPv1, SNMPv2, and SNMPv3. You can set up either SNMPv1/SNMPv2 or SNMPv3, or all of them for a Grid. You can also override the Grid settings at a member level.

To configure SNMPv1 and SNMPv2 on the appliance, do the following:

- Enable the NIOS appliance to accept queries, as described in *Accepting Queries* in the following section.
- Specify the management systems to which the appliance sends traps, as described in *Adding Trap Receivers* in the following section.
- Specify system information using managed objects in MIB-II, the standard MIB defined in *RFC 1213*. For information, see *Setting SNMP System Information* in the following section.

To configure SNMPv3 on the appliance, do the following:

- Add an SNMPv3 user and set up authentication and privacy protocols. For information, see *Configuring SNMPv3 User*. in the following section. After you set up an SNMPv3 user, you can modify and delete it.
- Enable the NIOS appliance to accept queries, as described in *Accepting Queries* in the following section.
- Specify the management systems to which the appliance sends traps, as described in see *Adding Trap Receivers* in the following section.
- Specify system information using managed objects in MIB-II, the standard MIB defined in *RFC 1213*.

Configuring SNMPv3 Users

To enable SNMPv3, you must first configure SNMPv3 users on the appliance. For information about SNMPv3, see *Understanding Simple Network Management Protocol*.
To configure an SNMPv3 user:

1. From the **Administration** tab, select the **SNMPv3 Users** tab, and then click the Add icon.
2. In the *Add SNMPv3 User* wizard, complete the following:
    - **Name:** Enter a user name for the SNMPv3 management system.
    - **Authentication Protocol:** Select one of the following:
        - **MD5**: Select this to use the HMAC-MD5-96 authentication protocol to authenticate the SNMPv3 user.
          This protocol uses the MD5 (Message-Digest algorithm 5) hash function in HMAC (Hash-based

Message Authentication Code) and truncates the output to 96 bits. The output is included as part of the SNMP message sent to the receiver. For detailed information about the protocol, refer to *RFC1321, The MD5 Message-Digest Algorithm*.

- **SHA**: Select this to use the HMAC-SHA-96 authentication protocol to authenticate the SNMPv3 user.
  This protocol uses the SHA (Secure Hash Algorithm) hash function and truncates the output to 96 bits. The output is included as part of the SNMP message sent to the receiver.
- **None**: Select this to decline using any authentication protocol for this SNMPv3 user. When you select this option, you are not required to enter a password.
  - **Password:** Enter a password for the selected authentication protocol.
  - **Confirm Password:** Enter the same password.

- **Privacy Protocol:** Select one of the following:
  - **DES**: Select this to use DES for data encryption. DES is a block cipher that employs a 56-bit key size and 64-bit block size in the encryption.
  - **AES**: Select this to use AES for data encryption. AES is a symmetric-key encryption standard that comprises AES-128 block cipher. The cipher has a 128-bit block size and a key size of 128 bits.
  - **None**: Select this to decline using any privacy protocol for this SNMPv3 user. When you select this option, you are not required to enter a password.
    - **Password:** Enter a password for the privacy protocol.
    - **Confirm Password:** Enter the same password.
- **Comment:** Enter useful information about the SNMP user, such as location or department.
- **Disable:** Select this checkbox to retain an inactive profile for this SNMP user in the configuration. You can clear this checkbox to activate the profile.
  If an SNMPv3 user is configured to send SNMP queries, you cannot delete the user.

3. Click **Next** to define extensible attributes. For information, see *Using Extensible Attributes*.
4. Save the configuration.

Modifying SNMPv3 Users

1. From the **Administration** tab, select the **SNMPv3 Users** tab -> *snmpv3user*, and then click the Edit icon.
2. The *SNMPv3 User* editor provides the following tabs from which you can edit data:
   - **General**: Modify the data as described in *Configuring SNMPv3 Users* in this topic.
   - **Extensible Attributes**: Add and delete extensible attributes that are associated with the SNMPv3 user account. You can also modify the values of extensible attributes. For information, see *Using Extensible Attributes*.
3. Save the configuration.

Deleting SNMPv3 Users

When you delete an SNMPv3 user that is configured to send queries or receive traps, a warning message states that the SNMPv3 is associated with the corresponding function. You can then decide whether you want to delete the user or not. To delete an SNMPv3 user:

1. From the **Administration** tab, select the **SNMPv3 Users** tab -> *snmpv3user*, and then click the Delete icon.
2. In the *Delete confirmation* dialog box, click **Yes**. You cannot schedule the deletion of an SNMPv3 user.

Accepting Queries

You can allow specific management systems to send SNMP queries to a NIOS appliance. For SNMPv1 and SNMPv2, you must specify a community string. The appliance accepts queries only from management systems that provide the correct community string. You can also specify SNMPv3 users to send queries.
To configure an appliance to accept SNMP queries:

1. Grid: From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar.
   Member: From the **Grid** tab, select the **Grid Manager** -> **Members** tab -> *member*, and then click the **Edit** icon.
2. In the *Grid Properties* or *Grid Member Properties* editor, select the **SNMP** tab. To override Grid settings, click **Override** in the *Grid Member Properties* editor.
3. Complete the following in the **SNMP** section.

- **Enable SNMPv1/SNMPv2 Queries:** Select this to accept SNMPv1 and SNMPv2 queries from management systems.
    - **Community String:** Enter a text string that the management system must send together with its queries to the appliance. A community string is similar to a password in that the appliance accepts queries only from management systems that send the correct community string. Note that this community string must match exactly what you enter in the management system.
- **Engine ID**: Displays the engine ID of the appliance that manages the SNMP agent. The management system needs this ID to send traps to the appliance. If the appliance is an HA pair, this field displays the engine IDs for both the active and passive nodes.
- **Enable SNMPv3 Queries**: Select this to enable queries from SNMPv3 management systems. Click the Add icon to add SNMPv3 users that you have configured on the appliance. In the *SNMPv3 User Selector* dialog box, click the SNMPv3 user you want to add. The appliance displays the selected SNMPv3 users in the table. You can add comments in the table. You can also select an SNMPv3 user and click the Delete icon to remove it from the table. Note that a disabled SNMPv3 user cannot send queries to the appliance.

4. Save the configuration.

Adding Trap Receivers

You can enable the NIOS appliance to send traps to specific management systems using either SNMPv1/SNMPv2 or SNMPv3, or all versions of SNMP. You can then add management systems that are allowed to receive traps from the appliance. Note that you cannot enable both SNMPv1/SNMPv2 and SNMPv3 on the same trap receiver. The appliance sends traps when certain events occur. You can enable SNMP traps and add trap receivers to the Grid. You can also override the Grid settings at the member level.
To enable the appliance to send traps and to add trap receivers, do the following:

1. Grid: From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar. Member: From the **Grid** tab, select the **Grid Manager** -> **Members** tab -> *member*, and then click the **Edit** icon.
2. In the *Grid Properties* or *Grid Member Properties* editor, select the **SNMP** tab. To override Grid settings, click **Override** in the *Grid Member Properties* editor.
3. Complete the following in the **SNMP** tab:
    - **Enable SNMPv1/SNMPv2 Traps:** Select this to enable the appliance to send traps to specified management systems.
        - **Community String:** Enter a text string that the NIOS appliance sends to the management system together with its traps. Note that this community string must match exactly what you enter in the management system.
    - **Enable SNMPv3 Traps:** Select this to enable the appliance to send traps to specified SNMPv3 users.
4. Click the Add icon and select one of the following from the drop-down menu to add an SNMP trap receiver:
    - **SNMPv1/SNMPv2**: Select this to add an SNMPv1 or SNMPv2 management system as a trap receiver. Grid Manager adds a row to the table. In the **Address** field, enter the IP address of the SNMP management system to which you want the SNMP agent on the appliance to send traps. You can enter more than one trap receiver. To remove a trap receiver from the list, select the address, and then click the Delete icon.
    - **SNMPv3**: Select this to add an SNMPv3 management system as a trap receiver. Grid Manager displays the *SNMPv3 User Selector* dialog box. Click the name of the SNMPv3 user in the dialog box. Grid Manager adds the user to the table. In the **Address** field, enter the IP address of the SNMP management system to which you want the SNMP agent on the appliance to send traps. You can add more than one trap receiver. To remove a trap receiver from the list, select the address, and then click the Delete icon. Trap receiver IP addresses may be in IPv4 or IPv6 format.
    - In the Trap Receiver table, Grid Manager displays the following information about the trap receivers:
        - **Address**: The IPv4 or IPv6 address of the trap receiver. Note that when an SNMPv3 user is disabled, SNMPv1/SNMPv2 traps are disabled. You can modify the IP address of the trap receiver even when the following are disabled: SNMPv3 users, SNMPv1/SNMPv2 traps, and SNMPv3 traps.
            - **SNMPv3 User**: The user name of the SNMPv3 trap receiver. This is for SNMPv3 only.
            - **Comment**: Information you entered about the management system.
5. Save the configuration.

Setting SNMP System Information

You can enter values for certain managed objects in MIB-II, the standard MIB defined in *RFC 1213*. Management systems that are allowed to send queries to the appliance can query these values. You can enter these values for the Grid and specific members. You can also override the Grid values at a member level.
To enter system information:

1. Grid: From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar. Member: From the **Grid** tab, select the **Grid Manager** -> **Members** tab -> *member*, and then click the **Edit** icon.
2. In the *Grid Properties* or *Grid Member Properties* editor, select the **SNMP** tab. To override Grid settings, click **Override** in the *Grid Member Properties* editor.
3. Complete the following in the **SNMP** tab. For an HA member, click **Override Node 2 settings** to enter information for node 2 of the HA pair.
    - **sysContact:** Enter the name of the contact person for the appliance.
    - **sysLocation:** Enter the physical location of the appliance.
    - **sysName:** Enter the fully qualified domain name of the appliance.
    - **sysDescr:** Enter useful information about the appliance, such as the software version it is running.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Defining Thresholds for Traps

Threshold events for appliance performance are configurable. For each event, you can set a value that triggers the appliance to send a trap and another value at which the appliance sends a CLEAR trap. The appliance sends a CLEAR trap the first time the event value reaches the reset value after it reached the trigger value.

To define the threshold values:

1. Grid: From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar. Member: From the **Grid** tab, select the **Grid Manager** -> **Members** tab -> *member*, and then click the **Edit** icon.
2. In the *Grid Properties* or *Grid Member Properties* editor, click **Toggle Advanced Mode,** and then select the **SNMP Threshold** tab. To override Grid settings, click **Override** in the *Grid Member Properties* editor.
3. Complete the following in the **SNMP Threshold** tab. Each of the following event types have default Trigger and Reset values. You can change the values for any of them. You can set SNMP thresholds above or below which the appliance sends SNMP traps and email notifications, if configured to do so. When any allocated usage exceeds the Trigger value, the appliance sends an SNMP trap and email notification to the designated destination, and the status icon for that usage turns red. When usage drops to the Reset value, the status color goes back to normal and turns green.
    - **CPU Usage**: The percentage of the CPU that is currently in use. The default Trigger value is 81%, and the default Reset value is 70%. Note that these default values are set to disable the CPU usage trap. You can enable this trap and configure the trigger and reset values using the CLI command set thresholdtrap. Sometimes you may see high CPU usage on Network Insight discovery members. In most cases, this high CPU usage is the result of CPU-intensive tasks run by the MySQL database during the consolidation of customer data. Network Insight is not a real-time system, so high CPU usage itself does not lead to loss of functionality. Therefore this alert should not be treated as critical if no other negative symptoms are observed on discovery members.
    - **Database Objects:** The percentage of database capacity that is currently in use. The default Trigger value is 80%, and the default Reset value is 70%.
    - **Disk:** The percentage of the primary hard disk that is currently in use. The default Trigger value is 85%, and the default Reset value is 70%.
    - **File Distribution Usage**: The percentage of the file distribution storage capacity that is currently in use on the selected member. The default Trigger value is 90%, and the default Reset value is 70%.
    - **IPAM Utilization:** For a network, this is the percentage based on the IP addresses in use divided by the total addresses in the network and for a network container that contains subnets, this is the percentage of the total address space defined within the container regardless of whether any of the IP addresses in the subnets are in use. The default Trigger value is 95% and the default Reset value is 85%. The status icon turns red when utilization crosses the configured trigger value. When utilization is below the trigger value, the status color turns blue.
    - **Memory:** The percentage of the system memory that is currently in use. The default Trigger value is 90%, and the default Reset value is 80%.

- **Network Capacity**: When the Grid is part of a Master Grid, this is the percentage of the Master Grid's network capacity that is used by the Grid's networks. The default Trigger value is 85% and default Reset value is 75%.
- **Recursive Clients**: The percentage of the limit of concurrent recursive queries. The default Trigger value is 80%, and the default Reset value is 30%. You must also enable the recursive client limit in order for the appliance to send recursive client traps. For information about how to set this limit and restricting recursive client queries, see *Enabling Recursive Queries*. When you configure the Trigger and Reset values, ensure that you do not set them too low or too close together. If the Trigger and Reset values are too close together, the appliance may send excessive traps and email notifications because both trigger and reset traps are sent based on the calculated value of simultaneous recursive client queries. For example, when you set the recursive client limit at 50, Trigger value at 71%, and Reset value at 70%, the value for simultaneous recursive client queries is calculated at 50 x .71 = 35 (integer math truncation) and 50 x .70 = 35. This could result in the appliance sending trigger and reset traps for the same value of simultaneous recursive client queries.
- **Root File System:** The percentage of the root file system ("/") that is currently in use. The default Trigger value is 85%, and the default Reset value is 70%.
- **Swap Usage:** The percentage of the swap area that is currently in use. The factory default trigger value is 50% and the factory default reset value is 30%. Grid Manager displays zero for both the trigger and reset values indicating the optimized usage of platform specific default values. For information about available memory on each appliance model, see the table below.
- **Reporting**: The number of reports created on the system that can trigger an SNMP trap. The default Trigger value is 85, and the default Reset value is 70. Note that the maximum number of reports supported per Grid is 300. This field is displayed only when you have configured a reporting server.
- **Reporting Volume:** The percentage of data transmissions to the reporting server. The default Trigger value is 80%, and the default Reset value is 71%. This field is displayed only when you have configured a reporting server.
- **Threat Protection Dropped Traffic:** The percentage of packets dropped based on the threat protection rule configuration. The default Trigger value is 90%, and the default Reset value is 70%. This field is displayed only when Threat Protection licenses are installed on the appliance. When the percentage of Threat Protection dropped traffic exceeds the Trigger value or drops below the Reset value, the appliance sends an SNMP trap and an email notification — if configured to do so. For information about setting SNMP traps and email notifications, see *Setting SNMP and Email Notifications* in the following section.
- **Threat Protection Total Traffic:** The percentage of total traffic received (dropped and passed packets) on the external interfaces. The default Trigger value is 90%, and the default Reset value is 70%. This field is displayed only when Threat Protection licenses are installed on the appliance. When the percentage of total Threat Protection traffic exceeds the Trigger value or drops below the Reset value, the appliance sends an SNMP trap and an email notification — if configured to do so.

  If you have installed Threat Protection licenses on the appliance and are using the Infoblox feature, Grid Manager displays the following for **Trigger events per second** and **Reset events per second**:
  - **Alert Rate**: The number of SNMP traps sent per second when the appliance sends alerts while passing packets based on threat protection rule configuration. The default trigger value is based on the events per second configured for the rule.
  - **Drop Rate**: The number of SNMP traps sent per second when the appliance drops packets based on the threat protection rule configuration. The default trigger value resets based on the number of events that are reset.
    If you have installed an RPZ license on the NIOS appliance, you can configure the thresholds to monitor the RPZ hit rate in the **Response Policy Zones Hit Rate Configuration** section. For information, see *Configuring Thresholds for RPZ Hit Rate*.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

For information on available Infoblox appliance models and their available memory see the NIOS 8.6 Release Notes on the Infoblox Support Site. Note that TE appliances are IB appliances in Grid Manager.

Setting SNMP and Email Notifications

You can specify the event types that trigger trap and email notifications. To set SNMP trap and email notifications:

1. Grid: From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar.
   Member: From the **Grid** tab, select the **Grid Manager** -> **Members** tab -> *member*, and then click the **Edit** icon.
2. In the *Grid Properties* or *Grid Member Properties* editor, click **Toggle Advanced Mode,** and then select the **Notification** tab. To override Grid settings, click **Override** in the *Grid Member Properties* editor.
3. Complete the following:
   - **Enable All SNMP Notifications:** Select this checkbox if you want the appliance to send SNMP notifications (traps) for all events to the configured trap receivers. This is selected by default. To send SNMP notifications for specific events to the configured trap receiver, select the checkbox for respective event type.
     For information on configuring trap receivers, see *Adding Trap Receivers* in this topic.
   - **Enable All Email Notifications:** Select this checkbox if you want the appliance to send email notifications (traps) for all events to the configured email recipients. This is deselected by default. To send email notifications for specific events to the configured email recipients, select the checkbox for each respective event type. For information on enabling email notifications and specifying recipients, see *Notifying Administrators*.
   - Alternatively, you can select specific event types from the table, and specify whether you want the appliance to send SNMP Notifications and Email notifications for each type of event.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Selecting SNMP and Email Notification Types

Instead of enabling and receiving SNMP and email notifications for all hardware and software events, you can select specific alert types when a specific hardware or software encounters issues. To enable SNMP or email notifications for specific event types, select the corresponding checkboxes in the Notification tab of the Grid Properties or Member Properties editor. The following table lists the event types you can select:

Event Types

Event Type	Description	Sample SNMP Trap
Automated Traffic Capture	Sends notifications each time traffic capture is enabled or disabled or a support bundle is downloaded. For more information, see *Enabling Automated Traffic Capture*.	01:09:57.938095 IP (tos 0x0, ttl 60, id 37373, offset 0, flags [DF], proto UDP (17), length 356) 10.34.172.4.54004 > 10.120.20.61.162: [udp sum ok] { SNMPv2c { V2Trap(309) R=1114072091 .1.3.6.1.2.1.1.3.0=5985 .1.3.6.1.6.3.1.1.4.1.0=.1.3.6.1.4.1.7779.3.1.1.1.1.7 .1.3.6.1.4.1.7779.3.1.1.1.2.1.0="infoblox.localdomain" .1.3.6.1.4.1.7779.3.1.1.1.2.2.0=2 .1.3.6.1.4.1.7779.3.1.1.1.2.5.0="Automated Traffic Capture" .1.3.6.1.4.1.7779.3.1.1.1.2.4.0=4 .1.3.6.1.4.1.7779.3.1.1.1.2.11.0="Automated traffic capture triggered by hitting Queries per second threshold: threshold=100, current=0" } }
BGP	Sends notifications when the BGP software has failed. For more information about the table ibProbableCause Values (OID 3.1.1.1.2.4.0), see *SNMP MIB Hierarchy*.	2012-11-22 04:49:06 eng-lab-883.inca.infoblox.com [UDP: [10.35.3.115]:38185->[10.120.20.160]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (45366) 0:07:33.66 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibTrapOneModule.2 IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.3.115" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: critical(5) IB-TRAP-MIB::ibSubsystemName.0 = STRING: bgp IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibRevokedLicense(53) IB-TRAP-MIB::ibTrapDesc.0 = STRING: An BGP routing daemon failure has occurred.

Event Type	Description	Sample SNMP Trap
Backup	Sends notifications about the status of backup operation. For more information about the Processing and Software Failure traps, see *SNMP MIB Hierarchy*.	2011-09-22 09:14:17 ib-10-34-41-4.infoblox.com [UDP: [10.34.41.4]:41243->[10.34.41.4]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (48621) 0:08:06.21 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.34.41.4" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: minor(3) IB-TRAP-MIB::ibSubsystemName.0 = STRING: scheduled_tftp_backups IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibBackupSoftwareFailure(29) IB-TRAP-MIB::ibTrapDesc.0 = STRING: Backup failed.
BloxTools	Sends notifications about the status of bloxTools. For more information about the Object State Change traps, see *SNMP MIB Hierarchy*.	2011-09-13 20:38:46 10.34.42.4 [UDP: [10.34.42.4]:38187->[10.34.42.2]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (742156) 2:03:41.56 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.34.42.4" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: bloxTools IB-TRAP-MIB::ibPreviousState.0 = INTEGER: bloxtools-service-failed(41) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: bloxtools-service-working(39) IB-TRAP-MIB::ibTrapDesc.0 = STRING: BloxTools Service is working.
CPU	Sends notifications about the status of CPU usage. For more information about the Threshold Crossing Event traps, see *SNMP MIB Hierarchy*.	2012-04-12 01:54:59 eng-lab-631.inca.infoblox.com [UDP: [10.35.2.119]:42546->[10.120.20.160]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (786308) 2:11:03.08 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibTrapOneModule.3 IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.2.119" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: major(4) IB-TRAP-MIB::ibObjectName.0 = STRING: cpu_usage IB-TRAP-MIB::ibCurThresholdValue.0 = INTEGER: 51 IB-TRAP-MIB::ibThresholdHigh.0 = INTEGER: 5 IB-TRAP-MIB::ibThresholdLow.0 = INTEGER: 3 IB-TRAP-MIB::ibTrapDesc.0 = STRING: CPU usage above threshold value.

Event Type	Description	Sample SNMP Trap
CaptivePortal	Sends notifications about the Captive Portal service. For more information about the ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0) tables, see *SNMP MIB Hierarchy*.	2016-01-08 02:58:23 10.35.107.4 [UDP: [10.35.107.4]:45111->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (22280) 0:03:42.80 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.107.4" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: captive_portal IB-TRAP-MIB::ibPreviousState.0 = INTEGER: captive-portal-service-inactive(51) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: capative-portal-service-working(49) IB-TRAP-MIB::ibTrapDesc.0 = STRING: Captive Portal Service is working.
Cisco ISE	Sends notifications about the status of the Cisco ISE service. For more information about Object State Change Traps, see *SNMP MIB Hierarchy*.	2016-01-07 22:26:19 10.40.240.111 [UDP: [10.40.240.111]:47355->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (16384) 0:02:43.84 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.40.240.111" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: cisco_ise_server IB-TRAP-MIB::ibPreviousState.0 = INTEGER: 124 IB-TRAP-MIB::ibCurrentState.0 = INTEGER: 123 IB-TRAP-MIB::ibTrapDesc.0 = STRING: CiscoISE server 10.36.141.15 is OK.
Clear	Sends notifications when the SNMP trap is cleared. When you select the checkbox, the CLEAR trap is sent for the following software failures: LDAP servers, OCSP responders, LCD, Serial Console, OSPF, OSPF6, BGP, HSM, Controld, SSH, HTTP, Cluster, Login, and Duplicate IP. For file distribution, the trap is sent when the service is restored. If you deselect the checkbox, the CLEAR trap is not sent when any of the mentioned software fails. For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2015-11-12 22:46:21 10.35.124.1 [UDP: [10.35.124.1]:48446->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (12793) 0:02:07.93 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.124.1" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: minor(3) IB-TRAP-MIB::ibSubsystemName.0 = STRING: Login IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibClear(0) IB-TRAP-MIB::ibTrapDesc.0 = STRING: SNMP Trap is cleared. GUI Login

Event Type	Description	Sample SNMP Trap
Cloud API	Sends notifications about whether the Cloud API service is functioning or not. For information about Cloud Network Automation, see Introduction to *Cloud Network Automation*.	2014-11-13 00:52:37 10.35.114.10 [UDP: [10.35.114.10]:57772->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (480221) 1:20:02.21 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.114.10" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: cloud_api IB-TRAP-MIB::ibPreviousState.0 = INTEGER: 105 IB-TRAP-MIB::ibCurrentState.0 = INTEGER: 103 IB-TRAP-MIB::ibTrapDesc.0 = STRING: Cloud API service is working.

Event Type	Description	Sample SNMP Trap
Cloud DNS Sync	Sends notification about the status of the Cloud DNS Sync service.	DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (45114) 0:07:31.14 SNMPv2-MIB::snmpTrapOID.0 = OID: SNMPv2-SMI::enterprises.7779.3.1.1.1.1.4 SNMPv2-SMI::enterprises.7779.3.1.1.1.2.1.0 = STRING: "172.29.2.154" SNMPv2-SMI::enterprises.7779.3.1.1.1.2.2.0 = INTEGER: 2 SNMPv2-SMI::enterprises.7779.3.1.1.1.2.3.0 = STRING: "cloud_dns_sync" SNMPv2-SMI::enterprises.7779.3.1.1.1.2.9.0 = INTEGER: 166 SNMPv2-SMI::enterprises.7779.3.1.1.1.2.10.0 = INTEGER: 169 SNMPv2-SMI::enterprises.7779.3.1.1.1.2.11.0 = STRING: "Cloud DNS Sync Service is not running." Event Type	Description	Sample SNMP Trap
Cluster	Sends notifications about the status of NIOS clusterd process. For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2011-12-10 09:43:23 infoblox.localdomain [UDP: [10.35.2.70]:44193->[10.35.2.70]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (47140) 0:07:51.40 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "0" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: critical(5) IB-TRAP-MIB::ibSubsystemName.0 = STRING: Clusterd_Monitor IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibFDSoftwareFailure(32) IB-TRAP-MIB::ibTrapDesc.0 = STRING: WATCHDOG: A grid daemon failure has occurred on 10.35.2.70
Controld	Sends notifications about the NIOS controld process. For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2012-08-17 05:29:30 <UNKNOWN> [UDP: [10.32.2.80]:43475->[10.32.2.80]:162]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (24722) 0:04:07.22 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "192.168.1.2" IB-TRAP MIB::ibTrapSeverity.0 = INTEGER: critical(5) IB-TRAP-MIB::ibSubsystemName.0 = STRING: controld IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibControldSoftwareFailure(11) IB-TRAP-MIB::ibTrapDesc.0 = STRING: A controld failure has occurred.
DHCP	Sends notifications about the status of DHCP service. For more information about the ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0) tables, see *SNMP MIB Hierarchy*.	2016-04-18 02:42:36 10.35.139.15 [UDP: [10.35.139.15]:35531->[10.120.21.204]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (8809) 0:01:28.09 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.139.15" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: dhcpd IB-TRAP-MIB::ibPreviousState.0 = INTEGER: dhcp-service-inactive(48) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: dhcp-service-working(45) IB-TRAP-MIB::ibTrapDesc.0 = STRING: DHCP Service is working.

Event Type	Description	Sample SNMP Trap
DNS	Sends notifications about the status of DNS service. For more information about the ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0) tables, see *SNMP MIB Hierarchy*.	2016-01-08 01:10:53 10.35.3.154 [UDP: [10.35.3.154]:59876->[10.120.20.12]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (324160) 0:54:01.60 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.3.154" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING:DNS IB-TRAP-MIB::ibPreviousState.0 = INTEGER: dns-service-working(32) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: dns-service-inactive(34) IB-TRAP-MIB::ibTrapDesc.0 = STRING: DNS Service is inactive.
DNS Attack	Sends notifications about the status of the DNS attacks. For more information about the ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0) tables, see *SNMP MIB Hierarchy*.	2016-01-07 23:55:56 10.35.3.201 [UDP: [10.35.3.201]:33199->[10.120.21.204]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (25100) 0:04:11.00 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.3.201" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: minor(3) IB-TRAP-MIB::ibObjectName.0 = STRING: DNSAttack IB-TRAP-MIB::ibPreviousState.0 = INTEGER: dns-attack-active(115) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: dns-attack-inactive(116) IB-TRAP-MIB::ibTrapDesc.0 = STRING: DNS attack conditions have ended.
DNS Forwarding to BloxOne Threat Defense Cloud	Sends notifications about whether DNS forwarding to BloxOne Threat Defense Cloud is functioning or not. For information about DNS forwarding to BloxOne Threat Defense Cloud, see *Using Forwarders*.	2017-11-03 14:06:19 192.168.1.3 [UDP: [192.168.1.3]:33577->[192.168.1.2]:162]: Trap, DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (180166) 0:30:01.66, SNMPv2-MIB::snmpTrapOID.0 = OID: SNMPv2-SMI::enterprises.7779.3.1.1.1.1.4, SNMPv2-SMI::enterprises.7779.3.1.1.1.2.1.0=STRING: "192.168.1.3", SNMPv2-SMI::enterprises.7779.3.1.1.1.2.2.0 =INTEGER: 2, SNMPv2-SMI::enterprises.7779.3.1.1.1.2.3.0 =STRING: "DNS", SNMPv2-SMI::enterprises.7779.3.1.1.1.2.9.0 =INTEGER: 32, SNMPv2-SMI::enterprises.7779.3.1.1.1.2.10.0= INTEGER: 133, SNMPv2-SMI::enterprises.7779.3.1.1.1.2.11.0= STRING: "The appliance is still serving DNS even though forwarding DNS queries to BloxOne Threat Defense Cloud is not functioning properly.

Event Type	Description	Sample SNMP Trap
DNS Integrity Check	Sends notifications about whether DNS integrity check is functioning or not. For information about DNS integrity check, see *Configuring DNS Integrity Check for Authoritative Zones*.	2014-06-03 05:35:45 10.34.82.121 [UDP: [10.34.82.121]:42577->[10.120.20.232]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (427200) 1:11:12.00 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.34.154.3" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibSubsystemName.0 = STRING: DNS Integrity Check IB-TRAP-MIB::ibProbableCause.0 =INTEGER: ibDNSIntegrityCheckNameserversFailed(102) IB-TRAP-MIB::ibTrapDesc.0 = STRING: DNS Integrity Check is unable to connect to any name servers required to perform the check. There are list of nameservers failure: (['10.35.0.56'])
DNS Integrity Check Connection	Sends notifications about whether DNS integrity check connection is functioning or not. For more information about the ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0) tables, see *SNMP MIB Hierarchy*.	016-01-12 05:10:27 10.35.129.15 [UDP: [10.35.129.15]:35201->[10.120.20.12]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (213856) 0:35:38.56 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeN ame.0 = STRING: "10.35.129.15" IB-TRAP-MIB::ibTrapSeverity.0= INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: DNS Integrity Check IB-TRAP-MIB: :ibPreviousState.0 = INTEGER: dns-integrity-check-severity-indetermined(97) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: dns-integrity-check-severity-informational(99) IB-TRAP-MIB::ibTrapDesc.0 = STRING: DNS Integrity Check severity has changed. For DNS zone 'default-com.info', severity has changed from 'NONE' to 'INFORMATIONAL'. Reason: While checking server ib-10-35-133-2.infoblox.com.(ipv4=10.35.133.2) INFORMATIONAL discrepancy found because our servers have record(s): info.com. I N NS ib-10-35-12

Event Type	Description	Sample SNMP Trap
Database	Sends notifications about the database status. For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2013-04-05 02:27:01 10.35.116.2 [UDP: [10.35.116.2]:45332->[10.120.20.160]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (120021) 0:20:00.21 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibThresholdCrossingEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.116.2" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: minor(3) IB-TRAP-MIB::ibObjectName.0 = STRING: db_usage IB-TRAP-MIB::ibCurThresholdValue.0 = INTEGER: 1 IB-TRAP-MIB::ibThresholdHigh.0 = INTEGER: 85 IB-TRAP-MIB::ibThresholdLow.0 = INTEGER: 0 IB-TRAP-MIB::ibTrapDesc.0 = STRING: Database capacity used is OK.
Disconnected Grid	Sends notifications about whether a Grid has been disconnected from the Master Grid. For more information about object state change traps, see *SNMP MIB Hierarchy*.	2011-12-27 23:38:44 eng-lab-089.inca.infoblox.com [UDP: [10.35.0.89]:53010->[10.120.20.160]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (1049) 0:00:10.49 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.0.89" IB-TRAP-MIB::ibObjectName.0 = STRING: ID_Grid IB-TRAP-MIB::ibPreviousState.0 = INTEGER: grid-disconnected(5) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: grid-connected(4) IB-TRAP-MIB::ibTrapDesc.0 = STRING: The grid member is connected to the grid master.
Discovery	Sends notifications about the discovery status. For information about the Discovery feature, see *Infoblox Network Insight*.	2013-10-22 01:35:53 eng-lab-302.inca.infoblox.com [UDP: [10.35.1.46]:57126->[10.120.20.102]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (122717) 0:20:27.17 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.1.46" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: discovery_collector IB-TRAP-MIB::ibPreviousState.0 = INTEGER: 89 IB-TRAP-MIB::ibCurrentState.0 = INTEGER: 86 IB-TRAP-MIB::ibTrapDesc.0 = STRING: Discovery Collector Service is working.

Event Type	Description	Sample SNMP Trap
Discovery Conflict	Sends notifications about conflicts between the DHCP address and the existing IP address.For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2014-06-20 00:48:06 10.34.125.2 [UDP: [10.34.125.2]:36159->[10.120.20.232]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (2241) 0:00:22.41 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.34.125.2" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: major(4) IB-TRAP-MIB::ibSubsystemName.0 = STRING: DHCP IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibDHCPHostConflict(66) IB-TRAP-MIB::ibTrapDesc.0 = STRING: DHCP address conflicts with an existing host address. [*IP address*]
Discovery Unmanaged	Sends notifications related to the discovery of unmanaged devices and networks. You can configure the maximum number of unmanaged objects the appliance discovers and how often it notifies about these events. For more information about how to configure these parameters, see *Defining Seed Routers for Probe Members*.	2015-02-09 22:53:57 10.35.103.18 [UDP: [10.35.103.18]:45156->[10.120.20.46]]: DISMAN-EVENT-MIB::sysUpTimeInstance =Timeticks: (46090) 0:07:40.90 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibOperationTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.103.18" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: major(4) IB-TRAP-MIB::ibSubsystemName.0 = STRING: Discovery IB-TRAP-MIB::ibProbableCause.0 =INTEGER: 4012 IB-TRAP-MIB::ibTrapDesc.0 =STRING: New unmanaged devices/networks were found during network discovery process. New unmanaged devices in '10.40.16.0/20' network in 'default' network view.
Disk	Sends notifications about the status of the primary disk. For more information about threshold crossing traps, see *SNMP MIB Hierarchy*.	2012-11-22 03:34:32 eng-lab-883.inca.infoblox.com [UDP: [10.35.3.115]:37542->[10.120.20.160]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (87141) 0:14:31.41 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibTrapOneModule.3 IB-TRAP-MIB::ibNodeName.0 = STRING:"10.35.3.115" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: minor(3) IB-TRAP-MIB::ibObjectName.0 =STRING: disk_usage IB-TRAP-MIB::ibCurThresholdValue.0 = INTEGER: 15 IB-TRAP-MIB::ibThresholdHigh.0 =INTEGER: 10 IB-TRAP-MIB::ibThresholdLow.0 = INTEGER: 5 IB-TRAP-MIB::ibTrapDesc.0 = STRING: System primary hard disk usage is over threshold value.

Event Type	Description	Sample SNMP Trap
DuplicateIP	Sends notifications when there are duplicate IP addresses. For more information about ibProbableCause Values, see *SNMP MIB Hierarchy*.	2016-04-18 22:47:38 10.35.139.15 [UDP: [10.35.139.15]:35531->[10.120.21.204]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (7239201) 20:06:32.01 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.139.15" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: major(4) IB-TRAP-MIB::ibSubsystemName.0 = STRING: Equipment IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibDuplicateIPAddressFailure(52) IB-TRAP-MIB::ibTrapDesc.0 = STRING: A Duplicate IP Address has been detected.
ENAT	Sends notifications about the Ethernet port status.For more information about the ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0) tables, see *SNMP MIB Hierarchy*.	2012-08-27 03:05:25 10.36.3.132 [UDP: [10.36.3.132]:47962->[10.120.20.232]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (16624) 0:02:46.24 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.3.132" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: major(4) IB-TRAP-MIB::ibObjectName.0 = STRING: LAN IB-TRAP-MIB::ibPreviousState.0 = INTEGER: enet-link-up(6) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: enet-link-down(7) IB-TRAP-MIB::ibTrapDesc.0 = STRING: LAN1 port link is down. Please check the connection.
File Distribution Usage	Sends notifications about the HTTP file distribution process. For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2016-01-08 01:48:57 10.40.240.113 [UDP: [10.40.240.113]:41443->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (183757) 0:30:37.57 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.40.240.113" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: critical(5) IB-TRAP-MIB::ibSubsystemName.0 = STRING: fd_usage IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibFDSoftwareFailure(42) IB-TRAP-MIB::ibTrapDesc.0 = STRING: File Distribution services storage usage is OK.

Event Type	Description	Sample SNMP Trap
FTP	Sends notifications about the status of FTP service. For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2016-01-07 23:27:22 10.40.240.113 [UDP: [10.40.240.113]:36063->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (380473) 1:03:24.73 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.40.240.113" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: critical(5) IB-TRAP-MIB::ibSubsystemName.0 = STRING: ftp IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibFTPDSoftwareFailure(44) IB-TRAP-MIB::ibTrapDesc.0 = STRING: An FTPD daemon failure has occurred.
Fan	Sends notifications about the status of the system fan. For more information about IEquipment Failure Traps, see *SNMP MIB Hierarchy*.	2012-02-23 23:34:50 10.32.1.222 [UDP: [10.32.1.222]:42742->[10.35.109.24]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (89508) 0:14:55.08 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibEquipmentFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.32.1.222" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: minor(3) IB-TRAP-MIB::ibObjectName.0 = STRING: fan IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibFan1Failure(37) IB-TRAP-MIB::ibTrapDesc.0 = STRING: Fan 1 failure has occurred.
HA	Sends notifications about the status of the HA port link. For more information about the ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0) tables, see *SNMP MIB Hierarchy*.	2014-05-23 00:49:32 eng-lab-589.inca.infoblox.com [UDP: [10.35.2.77]:46426->[10.36.0.200]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (3912) 0:00:39.12 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.20.70" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: HA_Replication IB-TRAP-MIB::ibPreviousState.0 = INTEGER: ha-replication-offline(14) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: ha-replication-online(13) IB-TRAP-MIB::ibTrapDesc.0 = STRING: HA replication is online.

Event Type	Description	Sample SNMP Trap
HSM	Sends notifications about the status of the HSM operation. For more information about the ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0) tables, see *SNMP MIB Hierarchy*.	2016-01-12 20:52:12 10.39.13.77 [UDP: [10.39.13.77]:44962->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (131909) 0:21:59.09 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.39.13.77" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: DNS IB-TRAP-MIB::ibPreviousState.0 = INTEGER: dns-service-working(32) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: 55 IB-TRAP-MIB::ibTrapDesc.0 = STRING: DNS Service restarted not using HSM
HTTP	Sends notifications about the status of the HTTP service. For more information about the ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0) tables, see *SNMP MIB Hierarchy*.	2016-01-07 23:16:40 10.40.240.113 [UDP: [10.40.240.113]:36063->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (316247) 0:52:42.47 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.40.240.113" IB-TRAP-MIB::ibTrapSeverity.0= INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: http_file_dist IB-TRAP-MIB::ibPreviousState.0 = INTEGER: http-file-dist-service-inactive(40) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: http-file-dist-service-working(38) IB-TRAP-MIB::ibTrapDesc.0 = STRING: HTTP File Dist Service is working
IFMAP	Sends notifications about the status of the IF-MAP service. For more information about ibProbableCause Values, see *SNMP MIB Hierarchy*.	2016-04-20 23:40:00 10.34.41.60 [UDP: [10.34.41.60]:33231->[10.120.21.204]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (45256) 0:07:32.56 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.34.41.60" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: critical(5) IB-TRAP-MIB::ibSubsystemName.0 = STRING: ifmapd IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibIFMAPSoftwareFailure(50) IB-TRAP-MIB::ibTrapDesc.0 = STRING: An IF-MAP server failure has occurred.

Event Type	Description	Sample SNMP Trap
IPMI Device	Sends notifications about the status of the IPMI device. For more information about ibProbableCause Values, see *SNMP MIB Hierarchy*.	2015-03-24 04:10:21 eng-lab-598.inca.infoblox.com [UDP: [10.35.2.86]:56092->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (103490) 0:17:14.90 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibOperationTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.2.86" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibSubsystemName.0 = STRING: IPMI Status Check IB-TRAP-MIB::ibProbableCause.0 = INTEGER: 2105 IB-TRAP-MIB::ibTrapDesc.0 = STRING: IPMI is used by some hardware monitors to test hardware health. The IPMI Device is now available; subsequent hardware monitor failures are likely to be genuine.
IPAM Utilization	Sends notifications about the percentage of IPv4 addresses that are used in a network. For a network container that contains subnets, this indicates the percentage of the total address space defined within the container regardless of whether any of the IP addresses are used in the subnetwork. For more information about threshold crossing traps, see *SNMP MIB Hierarchy*.	2014-07-06 19:33:01 eng-lab-514.inca.infoblox.com [UDP: [10.35.2.2]:33413->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (1038846) 2:53:08.46 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibThresholdCrossingEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.2.2" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: Threshold IB-TRAP-MIB::ibCurThresholdValue.0 = INTEGER: 0 IB-TRAP-MIB::ibThresholdHigh.0 = INTEGER: 5 IB-TRAP-MIB::ibThresholdLow.0 = INTEGER: 3 IB-TRAP-MIB::ibTrapDesc.0 = STRING: Network IPAM Utilization capacity usage is OK. Network: 20.0.0.0/29/netview
Load Balancer Device	Sends notifications about whether the LB device is in sync or not. For more information about the ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0) tables, see *SNMP MIB Hierarchy*.	2013-07-08 02:36:39 10.35.113.2 [UDP: [10.35.113.2]:45568->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (996274) 2:46:02.74 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.113.2" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: device IB-TRAP-MIB::ibPreviousState.0 = INTEGER: lb-device-down(74) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: lb-device-up(73) IB-TRAP-MIB::ibTrapDesc.0 = STRING: Load Balancer device 10.36.128.1 sync is OK.

Event Type	Description	Sample SNMP Trap
LCD	Sends notifications about the status of the LCD process. For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2011-12-01 06:31:28 ib-10-35-3-125.infoblox.com [UDP: [10.35.3.125]:56609->[10.35.3.125]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (187334) 0:31:13.34 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.3.125" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: major(4) IB-TRAP-MIB::ibSubsystemName.0 = STRING: lcd IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibLCDSoftwareFailure(18) IB-TRAP-MIB::ibTrapDesc.0 = STRING: An LCD failure has occurred.
LDAP Servers	Sends notifications about whether LDAP servers are available or not. For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2011-09-21 21:33:17 10.34.42.6 [UDP: [10.34.42.6]:49776->[10.34.42.2]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (6508) 0:01:05.08 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.34.42.6" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: minor(3) IB-TRAP-MIB::ibSubsystemName.0 = STRING: ssh IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibClear(0) IB-TRAP-MIB::ibTrapDesc.0 = STRING: SNMP Trap is cleared. SSHD SW

Event Type	Description	Sample SNMP Trap
SerialConsole	Sends notifications when the serial console login has failed or the admin failed to login to the serial console. For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2014-12-15 02:47:59 UDP/IPv6: 2620:10a:6000:2400::8104]:55038 [UDP/IPv6: [2620:10a:6000:2400::8104]:55038]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (501585) 1:23:35.85 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "2620:10a:6000:2400::8104" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: minor(3) IB-TRAP-MIB::ibSubsystemName.0 = STRING: Login IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibSerialConsoleLoginFailure(59) IB-TRAP-MIB::ibTrapDesc.0 = STRING: A Serial Console login failure has occurred.
Swap Usage	Sends notifications about whether the swap usage has exceeded the trigger or reset value. For more information about defining thresholds for traps, see above.	2013-11-25 05:35:56 10.35.129.1 [UDP: [10.35.129.1]:49489->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (24009) 0:04:00.09 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibThresholdCrossingEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.129.1" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: major(4) IB-TRAP-MIB::ibObjectName.0 = STRING: swap_usage IB-TRAP-MIB::ibCurThresholdValue.0 = INTEGER: 100 IB-TRAP-MIB::ibThresholdHigh.0 = INTEGER: 5 IB-TRAP-MIB::ibThresholdLow.0 = INTEGER: 2 IB-TRAP-MIB::ibTrapDesc.0 = STRING: System swap space usage exceeds the critical threshold value.
Syslog	Sends notifications when the syslog process stops. For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2016-01-14 01:29:42 10.34.142.105 [UDP: [10.34.142.105]:37566->[10.120.21.204]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (296285) 0:49:22.85 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.34.142.105" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: critical(5) IB-TRAP-MIB::ibSubsystemName.0 = STRING: check_syslog_conf IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibSyslogFailure(67) IB-TRAP-MIB::ibTrapDesc.0 = STRING: Syslog daemon is not running.

Event Type	Description	Sample SNMP Trap
System	Sends notifications about the status of the NIOS system. For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2014-03-14 05:54:42 eng-lab-636.inca.infoblox.com [UDP: [10.35.2.124]:33232->[10.36.0.200]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (2654067) 7:22:20.67 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.120.17" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: minor(3) IB-TRAP-MIB::ibSubsystemName.0 = STRING: ID_Grid IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibSystemRestart(61) IB-TRAP-MIB::ibTrapDesc.0 = STRING: The system is being restarted.
TAXII	Sends notifications when you start and stop the TAXII service. For more information about object state change traps, see *SNMP MIB Hierarchy*.	2016-01-06 20:16:13 eng-lab-242.inca.infoblox.com [UDP: [10.35.0.242]:42213->[10.120.20.21]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (17553) 0:02:55.53 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.0.242" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: taxii IB-TRAP-MIB::ibPreviousState.0 = INTEGER: 122 IB-TRAP-MIB::ibCurrentState.0 = INTEGER: 119 IB-TRAP-MIB::ibTrapDesc.0 = STRING: TAXII Service is working.
TFTP	Sends notifications about the status of the TFTP service.For more information about processing and software failure traps, see *SNMP MIB Hierarchy*.	2011-09-16 06:54:08 eng-lab-443.inca.infoblox.com [UDP: [10.35.1.187]:35794->[10.120.20.160]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (50382) 0:08:23.82 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibProcessingFailureTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.1.187" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: critical(5) IB-TRAP-MIB::ibSubsystemName.0 = STRING: tftp IB-TRAP-MIB::ibProbableCause.0 = INTEGER: ibTFTPDSoftwareFailure(27) IB-TRAP-MIB::ibTrapDesc.0 = STRING: A TFTPD daemon failure has occurred.

Event Type	Description	Sample SNMP Trap
Threat Analytics	Sends notifications about the status of the Threat Analytics service. For more information about ibProbableCause Values (OID 3.1.1.1.2.4.0), see *SNMP MIB Hierarchy*.	2016-01-08 00:19:34 10.35.3.154 [UDP: [10.35.3.154]:59876->[10.120.20.12]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (16184) 0:02:41.84 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.3.154" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: Threat Analytics IB-TRAP-MIB::ibPreviousState.0 = INTEGER: 127 IB-TRAP-MIB::ibCurrentState.0 = INTEGER: 126 IB-TRAP-MIB::ibTrapDesc.0 = STRING: Threat Analytics Service is working.
Threat Analytics DNS Tunneling	Sends notifications about the DNS tunneling detection. For more information about ibProbableCause Values (OID 3.1.1.1.2.4.0), see *SNMP MIB Hierarchy*.	2016-01-08 00:22:07 10.35.3.154 [UDP: [10.35.3.154]:59876->[10.120.20.12]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (31567) 0:05:15.67 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibOperationTrap IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.3.154" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: major(4) IB-TRAP-MIB::ibSubsystemName.0 = STRING: Software IB-TRAP-MIB::ibProbableCause.0 = INTEGER: 4013 IB-TRAP-MIB::ibTrapDesc.0 = STRING: DNS Tunneling detected: The record '*.any.knjuqljsfyyc2t.com' is successfully added into BlackList RPZ zone with comment '[2016-08-01 08:22:06 UTC] [member: infoblox.localdomain] DNS Tunneling' and policy 'No Data'.
Threat Protection	Sends notifications about whether the threat protection service for Infoblox DNS Protection is functioning properly. For more information about the ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0) tables, see *SNMP MIB Hierarchy*.	2016-04-18 22:48:08 10.35.139.15 [UDP: [10.35.139.15]:54407->[10.120.21.204]]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (3926) 0:00:39.26 SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibStateChangeEvent IB-TRAP-MIB::ibNodeName.0 = STRING: "10.35.139.15" IB-TRAP-MIB::ibTrapSeverity.0 = INTEGER: info(2) IB-TRAP-MIB::ibObjectName.0 = STRING: threat_protection IB-TRAP-MIB::ibPreviousState.0 = INTEGER: threat-protection-service-inactive(93) IB-TRAP-MIB::ibCurrentState.0 = INTEGER: threat-protection-service-inactive(93) IB-TRAP-MIB::ibTrapDesc.0 = STRING: Threat Protection Service is inactive.

Testing the SNMP Configuration

After you configure SNMP on the appliance, you can do the following to test your SNMP configuration:

- From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox, and then select **Test SNMP** from the Toolbar.

The appliance sends a “test trap” string to the trap receiver and displays a confirmation message at the top of the screen if your SNMP configuration is properly set up. If your SNMP configuration is not complete or if it is invalid, the appliance displays an error message. You can check your configuration and try again.

The following is a sample test trap that the trap receiver can get:

```
2011-04-04 17:37:14 10.32.2.80 [UDP: [10.32.2.80]:49244->[10.32.2.80]]:

SNMPv2-MIB::snmpTrapOID.0 = OID: SNMPv2-MIB::snmpTrapOID

SNMPv2-MIB::sysName.0 = STRING: 'Test trap'
```

Defining Interface for SNMP Traps

By default, the NIOS appliance sends SNMP traps through the MGMT interface to specific trap receivers, or through the LAN1 interface when the MGMT interface is disabled. However, you can choose an interface, instead of the default interface, to send SNMP traps to the trap receivers. For example, if you select LAN2 interface from the drop-down list, the traps are sent from the LAN2 interface instead of the default MGMT interface.

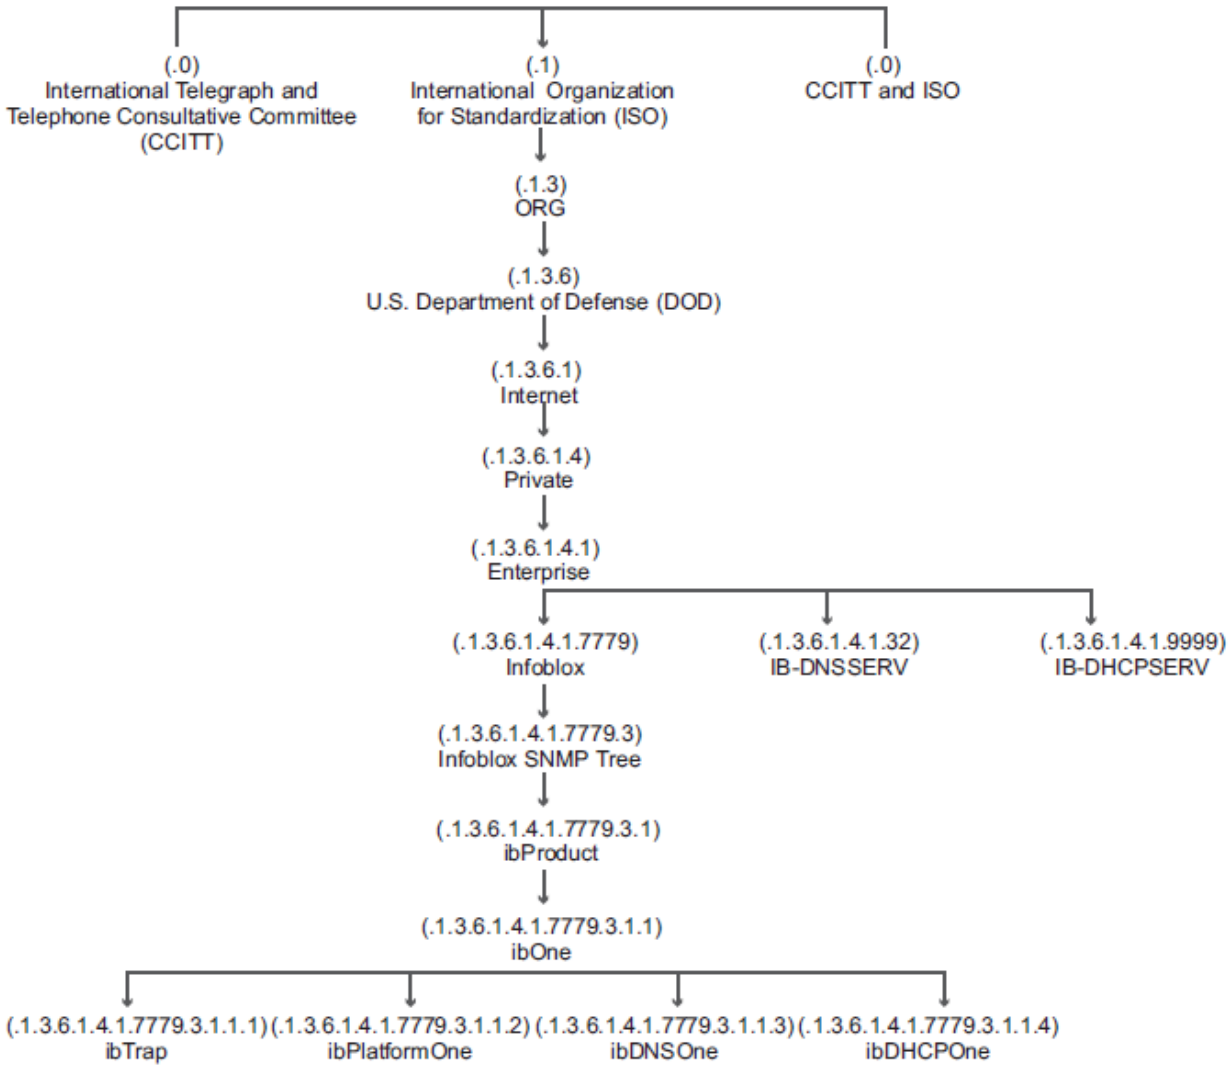
To choose an interface, other than MGMT or LAN1, for a Grid member and a standalone Grid:

1. **Grid**: From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *Grid_member* checkbox.
   Standalone: From the **System** tab, select the **System Manager** tab, expand the Toolbar and click **System Properties** -> **Edit.**
2. In the editor, click **Toggle Advanced Mode**.
3. When the additional tabs appear, click the **Advanced** subtab of the **SNMP** tab.
4. Complete the following:
   - **Interface**: Select an interface from the drop-down list:
     - **ANY**: The default value is **ANY**. SNMP traps are sent through the MGMT interface, if it is enabled, when you select this option. If the interface is disabled, the traps are sent through the LAN1 interface.
     - **LAN1**: Select this option to send SNMP traps through the LAN1 interface.
     - **LAN2**: Select this option to send SNMP traps through the LAN2 interface.
     - **MGMT**: Select this option to send SNMP traps through the MGMT interface.
5. Click **Save & Close** to save the changes or **Cancel** to exit.

SNMP MIB Hierarchy

In addition to implementing its own enterprise MIBs, Infoblox supports the standard MIBs defined in *RFC-1213, Management Information Base for Network Management of TCP/IP-based internets: MIB-II.*
The Infoblox MIBs are part of a universal hierarchical structure, usually referred to as the MIB tree. The MIB tree has an unlabeled root with three subtrees. The below figure illustrates the branch of the MIB tree that leads to the Infoblox enterprise MIBs. Each object in the MIB tree has a label that consists of a textual description and an OID (object identifier). An OID is a unique dotted-decimal number that identifies the location of the object in the MIB tree. Note that all OIDs begin with a dot (.) to indicate the root of the MIB tree.
As shown in the figure below, Infoblox is a branch of the Enterprise subtree. IANA (Internet Assigned Numbers Authority) administers the Enterprise subtree, which is designated specifically for vendors who define their own MIBs. The IANA-assigned enterprise number of Infoblox is 7779; therefore, the OIDs of all Infoblox MIB objects begin with the prefix .1.3.6.1.4.1.7779. In addition, IB-DNSSERV and IB-DHCPSERV are branches of the Enterprise subtree as well.
The Infoblox SNMP subtree branches down through two levels, ibProduct and ibOne, to the Infoblox MIBs: ibTrap, ibPlatformOne, ibDNSone, and ibDHCPOne. The ibTrap MIB defines the traps that NIOS appliances send, and the ibPlatformOne, ibDNSone, and ibDHCPOne MIBs provide information about the appliance. For detailed information about these MIBS, see the *Infoblox MIBs* section.

MIB Hierarchy



MIB Objects

The Infoblox MIB objects were implemented according to the guidelines in RFCs 1155 and 2578. They specify two types of macros for defining MIB objects: OBJECT-TYPE and NOTIFICATION-TYPE. These macros contain clauses that describe the characteristics of an object, such as its syntax and its status. OBJECT-TYPE macros describe MIB objects, and NOTIFICATION-TYPE macros describe objects used in SNMP traps.
Each object in the ibPlatformOne, ibDNSone, and ibDHCPOne MIBs contains the following clauses from the OBJECT-TYPE macro:

OBJECT-TYPE: Provides the administratively-assigned name of the object.

- SYNTAX: Identifies the data structure of the object, such as integers, counters, and octet strings.
- MAX-ACCESS: Identifies the type of access that a management station has to the object. All Infoblox MIB objects provide read-only access.
- STATUS: Identifies the status of the object. Values are current, obsolete, and deprecated.
- DESCRIPTION: Provides a textual description of the object.
- INDEX or AUGMENTS: An object that represents a conceptual row must have either an INDEX or AUGMENTS clause that defines a key for selecting a row in a table.

- OID: The dotted decimal object identifier that defines the location of the object in the universal MIB tree.

The ibTrap MIB defines the SNMP traps that a NIOS appliance can send. Each object in the ibTrap MIB contains the following clauses from the NOTIFICATION-TYPE macro:

NOTIFICATION-TYPE: Provides the administratively-assigned name of the object.

- OBJECTS: Provides an ordered list of MIB objects that are in the trap.
- STATUS: Identifies the status of the object. Values are current, obsolete, and deprecated.
- DESCRIPTION: Provides the notification information.

System Object IDs

Infoblox uses the SNMP system object identifier sysObjectID to identify Infoblox appliances. The following table is a definition of sysObjectID from the SNMPv2 MIB, *Management Information Base (MIB) for the Simple Network Management Protocol (SNMP)*:

OBJECT-TYPE	sysObjectID
SYNTAX	Object Identifier
MAX-ACCESS	read-only
STATUS	current
DESCRIPTION	"The vendor's authoritative identification of the network management subsystem contained in the entity. This value is allocated within the SMI enterprises subtree (1.3.6.1.4.1) and provides an easy and unambiguous means for determining `what kind of box' is being managed. For example, if vendor `Flintstones,Inc.' was assigned the subtree 1.3.6.1.4.1.424242, it could assign the identifier 1.3.6.1.4.1.424242.1.1 to its `Fred Router'."

The following table lists the enterprise IDs and their corresponding Infoblox hardware platforms that an SNMP query can return when you request the sysObjectID value. Note that the IDs shown in the table do not include 1.3.6.1.4.1.7779.1. (the infobloxProducts prefix).

sysObjectID for Infoblox Hardware

ID	**Description**	**Definition**
1000	ibDefault	Default environments, such as chroot
1002	ibCisco	Cisco servers
1003	ibvm	vNIOS appliances on VMware ESX or ESXi servers
1004	ibvnios	Virtual NIOS
1401	ib810	Trinzic 810 appliances
1402	ib820	Trinzic 820 appliances
1403	ib1410	Trinzic 1410 appliances

ID	Description	Definition
1404	ib1420	Trinzic 1420 appliances
1405	ib1400	Trinzic Reporting 1400 appliances
1406	ib800	Trinzic Reporting 800 appliances
1411	ib2200	Trinzic Reporting 2200 appliances
1412	ib2210	Trinzic 2210 appliances
1413	ib2220	Trinzic 2220 appliances
1423	ib4000	Infoblox-4000 appliances
1431	ib100	Trinzic 100 appliances
1444	nd4000	Network Insight 4000 appliances
1501	ib815	Trinzic 815 appliances
1502	ib825	Trinzic 825 appliances
1503	ib1415	Trinzic 1415 appliances
1504	ib1425	Trinzic 1425 appliances
1505	ib1405	Trinzic 1405 appliances
1506	ib805	Trinzic 805 appliances
1507	pt1405	Advanced 1405 appliances
1511	ib2205	Trinzic 2205 appliances
1512	ib2215	Trinzic 2215 appliances
1513	ib2225	Trinzic 2225 appliances
1514	pt2205	Advanced 2205 appliances
1521	ib4015	Trinzic 4015 appliances
1522	ib4035	Trinzic 4035 appliances

ID	Description	Definition
1523	ib4005	Trinzic 4005 appliances
1524	pt4005	Advanced 4005 appliances
1525	ib4025	Trinzic 4025 appliances
1541	nd805	Network Insight 805 appliances
1542	nd1405	Network Insight 1405 appliances
1543	nd2205	Network Insight 2205 appliances
1544	nd4005	Network Insight 4005 appliances

Infoblox MIBs

You can configure a NIOS appliance as an SNMP-managed device so that an SNMP management station can send queries to the appliance and retrieve information from its MIBs. Perform the following tasks to access the Infoblox MIBs:

1. Configure a NIOS appliance to accept queries, as described in Configuring SNMPv3 Users, see *Configuring SNMP*.
2. Load the MIB files onto the management system. To obtain the latest Infoblox MIB files:
    a. From the **Data Management** tab, select the **Grid** tab -> **Grid Manager** tab, and then select **Download** -> **SNMP MIBs** from the Toolbar.
    b. In the Save As dialog box, navigate to a directory to which you want to save the MIBs.
    c. Click Save.

1. Use a MIB browser or SNMP management application to query the objects in each MIB.

The NIOS appliance allows read-only access to the MIBs. This is equivalent to the Get and Get Next operations in SNMP.

Loading the Infoblox MIBs

If you are using an SNMP manager toolkit with strict dependency checking, you must download the following Infoblox MIBs in the order they are listed:

1. IB-SMI-MIB.txt
2. IB-TRAP-MIB.txt
3. IB-PLATFORMONE-MIB.txt
4. IB-DNSONE-MIB.txt
5. IB-DHCPONE-MIB.txt
6. IB-DNSSERV-MIB.txt
7. IB-DHCPSERV-MIB.txt
8. IB-DHCPV6ONE-MIB.txt

In addition, if the SNMP manager toolkit you use requires a different MIB file naming convention, you can rename the MIB files accordingly.

NET-SNMP MIBs

NIOS appliances support NET-SNMP (formerly UCD-SNMP), a collection of applications used to implement the SNMP protocol. The NET-SNMP MIBs provide the top-level infrastructure for the SNMP MIB tree. They define, among other

things, the objects in the SNMP traps that the agent sends when the SNMP engine starts and stops. For information about NET-SNMP and the MIB files distributed with NET-SNMP, refer to *http://net-snmp.sourceforge.net/* .
For SNMP traps to function properly, you must download the following NET-SNMP MIBs directly from *http://net-snmp.sourceforge.net/docs/mibs*

- NET-SNMP-MIB
- UCD-SNMP-MIB

> **Note**
> Ensure that you save the MIBs as text files in the directory to which you save all the other MIB files.

BGP4 MIB

Infoblox supports BGP4 (Border Gateway Protocol) for DNS anycast addressing. BGP is configured to send SNMP traps to neighboring routers, as defined in *RFC4273DefinitionsofManagedObjectsforBGP-4*. You must enable and configure the SNMP trap receiver on the Grid member for the member to send SNMP traps.
The BGP protocol service is configured to send SNMP queries about BGP runtime data. The information is returned using the following OIDs and definitions:

OID	Definition
1.3.6.1.2.1.15.900.1.1	Number of peers
1.3.6.1.2.1.15.900.1.2	Number of active peers
1.3.6.1.2.1.15.900.1.3	Number of AS path entries
1.3.6.1.2.1.15.900.1.4	Number of BGP community entries
1.3.6.1.2.1.15.900.1.5	Total number of prefixes

For each configured BGP peer (a, b, c, d), the information is returned using the following OIDs and definitions:

OID	Definition
1.3.6.1.2.1.15.900.1.9.a.b.c.d.1	IP address: same as a.b.c.d
1.3.6.1.2.1.15.900.1.9.a.b.c.d.2	State: 0=down, 1=up
1.3.6.1.2.1.15.900.1.9.a.b.c.d.3	ASN
1.3.6.1.2.1.15.900.1.9.a.b.c.d.4	Prefixes
1.3.6.1.2.1.15.900.1.9.a.b.c.d.5	Up/Down time

ibTrap MIB

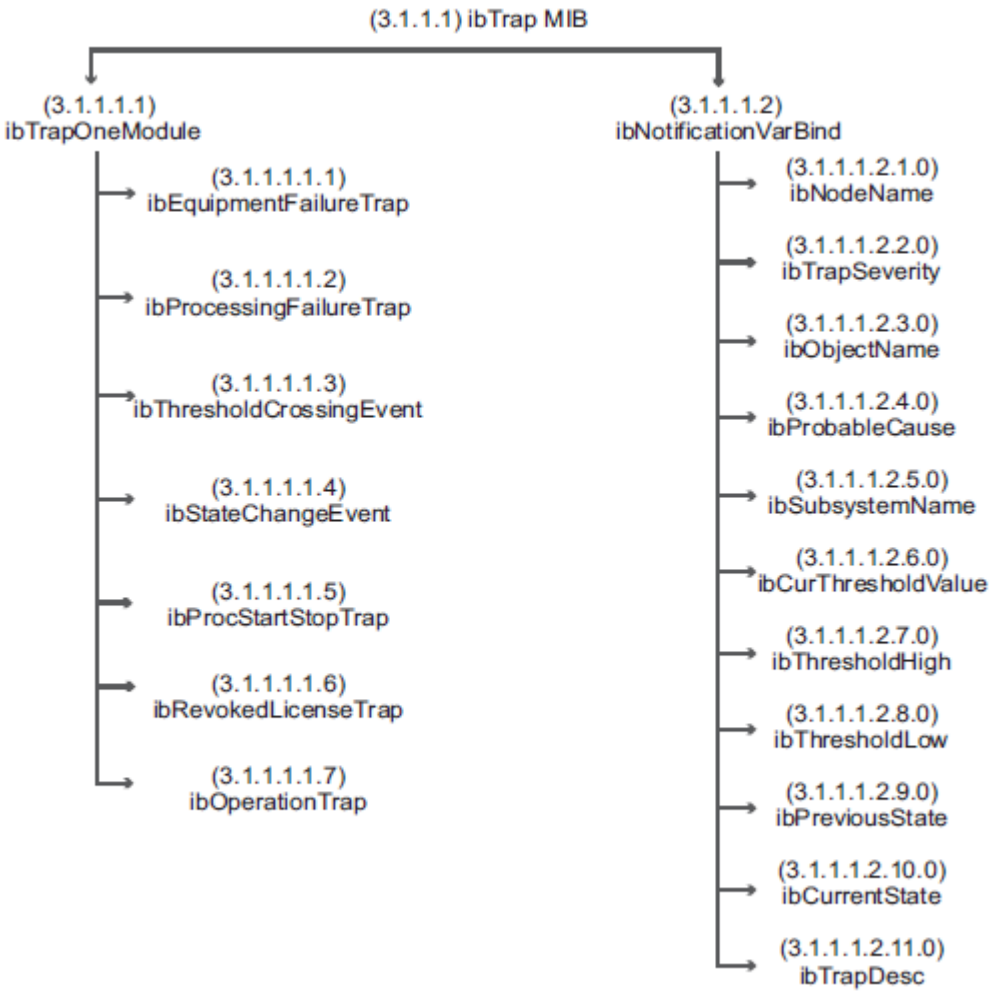
NIOS appliances send SNMP traps when events, internal process failures, or critical service failures occur. The ibTrap MIB defines the types of traps that a NIOS appliance sends and the value that each MIB object represents. The Infoblox

SNMP traps report objects which the ibTrap MIB defines. The below figure illustrates the ibTrap MIB structure. It provides the OID and textual description for each object.

> **Note**
>
> OIDs shown in the illustrations and tables in this section do not include the prefix .1.3.6.1.4.1.7779.

The ibTrap MIB comprises two trees, ibTrapOneModule and ibNotificationVarBind. The ibTraponeModule tree contains objects for the types of traps that a NIOS appliance sends. The ibNotificationVarBind tree contains objects that the Infoblox SNMP traps report. You cannot send queries for the objects in this MIB module. The objects are used only in the SNMP traps.

ibTrapOne MIB Structure



Interpreting Infoblox SNMP Traps

Depending on the SNMP management application your management system uses, the SNMP traps you receive may list the OIDs for all relevant MIB objects from both the ibTrapOneModule and ibNotificationVarBind trees. For OIDs that have string values, the trap lists the text. For OIDs that contain integers, you can use the tables in this section to find out the values. Some SNMP management applications list only the object names and their corresponding values in the SNMP

traps. Whether or not your SNMP management application lists OIDs, you can use the tables in this section to find out the corresponding value and definition for each MIB object.

The following is a sample trap a NIOS appliance sends:

```
418:Jan 31 18:52:26 (none) snmptrapd[6087]: 2008-01-31 18:52:26 10.35.1.156
[UDP:

[10.35.1.156]:32772]: DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks:
(1080)

0:00:10.80 SNMPv2-MIB::snmpTrapOID.0 = OID: SNMPv2-
SMI::enterprises.7779.3.1.1.1.1.4.0

SNMPv2-SMI::enterprises.7779.3.1.1.1.2.1.0 = STRING: "10.35.1.156"

SNMPv2-SMI::enterprises.

7779.3.1.1.1.2.3.0 = STRING: "ntp_sync" SNMPv2-
SMI::enterprises.7779.3.1.1.1.2.9.0 =

INTEGER: 15 SNMPv2-SMI::enterprises.7779.3.1.1.1.2.10.0 = INTEGER: 16

SNMPv2-SMI::enterprises.7779.3.1.1.1.2.11.0 = STRING: "The NTP service is
out of

synchronization."
```

The sample trap lists the OIDs and their corresponding values that can help you identify the cause of an event or problem. To identify the possible cause and recommended actions for the trap, use the ibTrapDesc tables.

You can interpret the sample trap as follows:

Using the *ibTrapOneModule* table, you find out OID 7779.3.1.1.1.1.4.0 represents an Object State Change trap. This trap includes the following objects: ibNodeName, ibOjectName, ibPreviousState, ibCurrentState, and ibtrapDesc. For each object, the trap displays the OID and its corresponding value. The following is how you can interpret the rest of the trap:

- ibNodeName (OID 7779.3.1.1.1.2.1.0)
  - Using the *ibNotificationVarBind (OID 3.1.1.1.2)* table, you find out OID 7779.3.1.1.1.2.1.0 represents the MIB object ibNodeName, which is the IP address of the appliance on which the trap occurred. Therefore, the statement `"7779.3.1.1.1.2.1.0 = STRING: "10.35.1.156" SNMPv2-SMI::enterprises."` tells you the IP address of the appliance on which the trap occurred.
- ibObjectName (OID 7779.3.1.1.1.2.3.0)
  - The statement `"7779.3.1.1.1.2.3.0 = STRING: "ntp_sync" SNMPv2-SMI::enterprises."` tells you the MIB object ibOjectName, which is the name of the object for which the trap was generated, has a value of "ntp_sync" that indicates NTP synchronization issues.
- ibPreviousState (OID 7779.3.1.1.1.2.9.0)
  - The statement `"7779.3.1.1.1.2.9.0 = INTEGER: 15 SNMPv2-SMI::enterprises."` tells you the MIB object ibPreviousState, which indicates the previous state of the appliance, has a value of 15. Using the *ibPreviousState and ibCurrentState Values* table, you know that 15 represents "ntp-sync-up", which means the NTP server was up and running.
- ibCurrentState (OID 7779.3.1.1.1.2.10.0)

    - The statement `"7779.3.1.1.1.2.10.0 = INTEGER: 16 SNMPv2-SMI::enterprises."` tells you the MIB object ibCurrentState, which indicates the current state of the appliance, has a value of 16. Using the *ibPreviousState and ibCurrentState Values* table, you know that 16 represents "ntp-sync-down", which means the NTP server is now out of sync.
- ibTrapDesc (OID 7779.3.1.1.1.2.11.0)
    - The last statement `"7779.3.1.1.1.2.11.0 = STRING: "The NTP service is out of synchronization."` states the description of the trap. Using the *Object State Change Traps* table for ibTrapDesc, you can find out the trap description and recommended actions for this problem.

Types of Traps (OID 3.1.1.1.1)

ibTrapOneModule defines the types of traps that the NIOS appliance can send. There are five types of SNMP traps. The table below describe the types of traps and their objects in the ibTrapOneModule tree.

> **Note**
>
> Some SNMP traps for ibThresholdCrossingEvent, ibStateChangeEvent, ibProcStartStopTrap, and ibRevokedLicenseTrap do not have an associated ibProbableCause. The following table lists traps that provide ibProbableCause and those that do not have an ibProbableCause value.

ibTrapOneModule
Trap Binding Variables (OID 3.1.1.1.2)

OID	Trap Type	MIB Object	Description
3.1.1.1.1.1	Equipment Failure	ibEquipmentFailureTrap	The NIOS appliance generates this trap when a hardware failure occurs. This trap includes the following objects: • ibNodeName • ibTrapSevertiy • ibObjectName (equipment name) • ibProbableCause • ibTrapDesc
3.1.1.1.1.2	Processing and Software Failure	ibProcessingFailureTrap	The NIOS appliance generates this trap when a failure occurs in one of the software processes. This trap includes the following objects: • ibNodeName • ibTrapSeverity • ibSubsystemName • ibProbableCause • ibTrapDesc

3.1.1.1.1.3	Threshold Crossing	ibThresholdCrossingEvent	The NIOS appliance generates this trap when any of the following events occur: • System memory or disk usage exceeds 90%. • CPU usage exceeds the trigger value for 15 seconds. • A problem occurs when the Grid Master replicates its database to its Grid members. • DHCP address usage crosses a watermark threshold. • The number or percentage of the DNS security alerts exceeds the thresholds of the DNS security alert triggers. This trap includes the following objects: • ibNodeName • ibTrapSeverity • ibObjectName (threshold name) • ibCurThresholdvalue • ibThresholdHigh • ibThresholdLow • ibTrapDesc
3.1.1.1.1.4	Object State Change	ibStateChangeEvent	The NIOS appliance generates this trap when there is a change in its state, such as: • The link to one of the configured ports goes down, and then goes back up again. • A failover occurs in an HA (high availability) pair configuration. • A member connects to the Grid Master. • An appliance in a Grid goes offline. This trap includes the following objects: • ibNodeName • ibTrapSeverity • ibObjectName • ibPreviousState • ibCurrentState • ibTrapDesc

3.1.1.1.1.5	Process Started and Stopped	ibProcStartStopTrap	The NIOS appliance generates this type of trap when any of the following events occur: • When you enable HTTP redirection. • When you change the HTTP access setting. • When you change the HTTP session time out setting. • When a failover occurs in an HA pair configuration. This trap includes the following objects: • ibNodeName • ibSubsystemName • ibTrapDesc
3.1.1.1.1.6		ibRevokedLicenseTrap	The NIOS appliance generates this trap when a license is revoked. This trap includes the following objects: • ibNodeName • ibTrapSeverity • ibSubsystemName • ibTrapDesc
3.1.1.1.1.7		ibOperationTrap	The NIOS appliance generates this trap when a software operation is noteworthy. This trap includes the following objects: • ibNodeName • ibTrapSeverity • ibSubsystemName • ibProbableCause • ibTrapDesc

Each SNMP trap contains information about the event or the problem. The Infoblox SNMP traps include MIB objects and their corresponding values from the ibNotificationVarBind module. The following table describes the objects in the ibNotificationVarBind module.

The OIDs shown in the following table do not include the prefix ".1.3.6.1.4.1.7779.":

ibNotificationVarBind (OID 3.1.1.1.2)

OID	MIB Object (Type)	Description
3.1.1.1.2.1.0	ibNodeName (DisplayString)	The IP address of the appliance on which the trap occurs. This may or may not be the same as the appliance that sends the trap. This object is used in all types of traps.

3.1.1.1.2.2.0	ibTrapSeverity (Integer)	The severity of the trap. There are five levels of severity. See the Trap Severity table (OID 3.1.1.1.2.2.0) for details below.
3.1.1.1.2.3.0	ibObjectName (DisplayString)	The name of the object for which the trap was generated. This is used in the Equipment Failure traps, Threshold Crossing Event traps, and the Object State Change traps. The following shows what this object represents depending on the type of traps: • Equipment Failure traps: The equipment name. • Threshold Crossing Event traps: The object name of the trap. • State Change traps: The object that changes state.
3.1.1.1.2.4.0	ibProbableCause (Integer)	The probable cause of the trap.
3.1.1.1.2.5.0	ibSubsystemName (DisplayString)	The subsystem for which the trap was generated, such as NTP or SNMP. This object is used in the Processing and Software Failure traps and the Process Start and Stop traps.
3.1.1.1.2.6.0	ibCurThresholdValue (Integer)	The current value of the threshold counter. This object is used in the Threshold Crossing traps.
3.1.1.1.2.7.0	ibThresholdHigh (Integer)	This object is used in Threshold Crossing traps. For CPU usage, this is the trigger value of the SNMP trap. For DHCP address usage, this is the value of the high watermark. This only applies when the appliance sends a trap to indicate that DHCP address usage is above the configured high watermark value for a DHCP address range.
3.1.1.1.2.8.0	ibThresholdLow (Integer)	This object is used in Threshold Crossing traps. For CPU usage, this is the reset value of the SNMP trap. For DHCP address usage, this is the value for the low watermark. This only applies when the appliance sends a trap to indicate that DHCP address usage went below the configured low watermark value for a DHCP address range.
3.1.1.1.2.9.0	ibPreviousState (Integer)	The previous state of the appliance. This object is used in the Object State Change traps. See the *ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0)* section for definitions of each value.
3.1.1.1.2.10.0	ibCurrentState (Integer)	The current state of the appliance. This object is used in the Object State Change traps. See the *ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0)* section for definitions of each value.
3.1.1.1.2.11.0	ibTrapDesc (DisplayString)	The description of the trap. This object is used in all types of traps. See the *ibTrapDesc (OID 3.1.1.1.2.11.0)* section for the description, possible cause, and recommended actions for each Infoblox SNMP trap.

Trap Severity (OID 3.1.1.1.2.2.0)

The object ibTrapSeverity defines the severity level for each Infoblox SNMP trap. There are five levels of severity:

Value	Description
1	Indetermined [sic]
2	Informational: Event that requires no further action.
3	Minor: Event that does not require user intervention.
4	Major: Event that requires user intervention and assistance from Infoblox Technical Support.
5	Critical: Problem that affects services and system operations, and requires assistance from Infoblox Technical Support.

ibProbableCause Values (OID 3.1.1.1.2.4.0)

The following table lists the values that are associated with the object ibProbableCause (OID 3.1.1.1.2.4.0). These values provide information about the events such as hardware, software for process failures, that trigger SNMP traps.

ibProbableCause Values

Value	OID 3.1.1.1.2.4.0 ibProbableCause	Equipment, Software, or Process Failure Traps
0	ibClear	SNMP Trap is cleared.
1	ibUnknown	An unknown failure has occurred.
2	ibPrimaryDiskFailure	A primary drive failure has occurred.
3	ibFanFailure-old	Unused.
4	ibPowerSupplyFailure	A power supply failure has occurred.
5	ibDBFailure	A database daemon monitoring failure has occurred.
6	ibApacheSoftwareFailure	An apache software failure has occurred.
7	ibSerialConsoleFailure	An Infoblox serial console software failure has occurred.
11	ibControldSoftwareFailure	A controld failure has occurred.
12	ibUpgradeFailure	A system upgrade failure has occurred.
13	ibSNMPDFailure	SNMP Server failure has occurred.

15	ibSSHDSoftwareFailure	An SSH daemon failure has occurred.
16	ibNTPDSoftwareFailure	An NTP daemon failure has occurred.
17	ibClusterdSoftwareFailure	A cluster daemon failure has occurred.
18	ibLCDSoftwareFailure	An LCD daemon failure has occurred.
19	ibDHCPdSoftwareFailure	A DHCP daemon monitoring failure has occurred.
20	ibNamedSoftwareFailure	A named daemon monitoring failure has occurred.
21	ibAuthServerGroupDown	NAC Authentication server group is down.
22	ibAuthServerGroupUp	NAC Authentication server group is up.
24	ibNTLMSoftwareFailure	An NTLM monitoring failure has occurred.
25	ibNetBIOSDaemonFailure	A NetBIOS daemon monitoring failure has occurred.
26	ibWindowBindDaemonFailure	An NT domain service monitoring failure has occurred.
27	ibTFTPDSoftwareFailure	A TFTPD daemon failure has occurred.
28	ibUNUSED28	Unused.
29	ibBackupSoftwareFailure	Backup failed.
30	ibBackupDatabaseSoftwareFailure	Database backup failed.
31	ibBackupModuleSoftwareFailure	Module backup failed.
32	ibBackupSizeSoftwareFailure	File size exceeded the quota. Backup failed.
33	ibBackupLockSoftwareFailure	Another backup is in progress. Backup will not be performed.
34	ibHTTPFileDistSoftwareFailure	An HTTP file distribution daemon failure has occurred.
35	ibOSPFSoftwareFailure	An OSPF routing daemon failure has occurred.
36	ibAuthDHCPNamedSoftwareFailure	An auth named server failure has occurred.
37	ibFan1Failure	Fan 1 failure has occurred.
38	ibFan2Failure	Fan 2 failure has occurred.

39	ibFan3Failure	Fan 3 failure has occurred.
40	ibFan1OK	Fan 1 is OK.
41	ibFan2OK	Fan 2 is OK.
42	ibFan3OK	Fan 3 is OK.
44	ibFTPDSoftwareFailure	An FTPD daemon failure has occurred.
45	ibBloxtoolsSoftwareFailure	A Bloxtools service failure has occurred.
46	ibPowerSupplyOK	The power supply is OK.
47	ibWebUISoftwareFailure	A WebUI software failure has occurred.
48	ibUNUSED48	Unused.
49	ibADAgentSyncFailure	An AD agent client synchronizing domain data failure has occurred.
50	ibIFMAPSoftwareFailure	An IF-MAP server failure has occurred.
51	ibCaptivePortalSoftwareFailure	A Captive Portal service failure has occurred.
52	ibDuplicateIPAddressFailure	A Duplicate IP Address has been detected.
53	ibBGPSoftwareFailure	An BGP routing daemon failure has occurred.
54	ibRevokedLicense	A license has been revoked.
58	ibGUILoginFailure	An admin failed to log in to the GUI.
59	ibSerialConsoleLoginFailure	An admin failed to log in to the serial console.
60	ibSystemReboot	A system reboot was initiated.
61	ibSystemRestart	A system restart was initiated.
62	ibZoneTransferFailure	A zone transfer failure occurred.
63	ibDHCPLeaseConflict	DHCP address conflicts with an existing lease.
64	ibDHCPAddressConflict	DHCP address conflicts with an existing fixed address.
65	ibDHCPRangeConflict	DHCP address conflicts with an existing range.

66	ibDHCPHostConflict	DHCP address conflicts with an existing host.
67	ibSyslogFailure	A syslog daemon failure occurred.
68	ibPowerSupply1Failure	Power supply 1 failure has occurred.
69	ibPowerSupply2Failure	Power supply 2 failure has occurred.
70	ibPowerSupply1OK	Power supply 1 is OK.
71	ibPowerSupply2OK	Power supply 2 is OK.
72	ibReportingTaskSwFailure	A reporting task monitoring failure has occurred.
73	ibReportingDbBackupFailure	A reporting db backup/restore operation failure has occurred.
74	ibFan4Failure	Fan 4 failure has occurred.
75	ibFan5Failure	Fan 5 failure has occurred.
76	ibFan6Failure	Fan 6 failure has occurred.
77	ibFan7Failure	Fan 7 failure has occurred.
78	ibFan8Failure	Fan 8 failure has occurred.
79	ibFan4OK	Fan 4 is OK.
80	ibFan5OK	Fan 5 is OK.
81	ibFan6OK	Fan 6 is OK.
82	ibFan7OK	Fan 7 is OK.
83	ibFan8OK	Fan 8 is OK.
84	ibOSPF6SoftwareFailure	An OSPF6 routing daemon failure has occurred.
85	ibOCSPResponderFailure	OCSP responder failed.
86	ibReportingAlertTriggered	A reporting alert is triggered.
87	ibCapturedQueriesUploadFailure	Upload for captured DNS queries failed.
88	ibLDAPServerFailure	The LDAP server failed.

89	ibRIRWIPRegistrationFailure	RIR SWIP registration failed.
90	ibPowerSupply1Removed	Power supply 1 has been removed.
91	ibPowerSupply2Removed	Power supply 2 has been removed.
92	ibIPMISensorErrorDetected	Error detected on the sensor for the IPMI port (used for LOM)
93	ibDiscoveryConsolidatorTaskSwFailure	Discovery service on the Consolidator failed.
94	ibDiscoveryCollectorTaskSwFailure	Discovery service on probes failed.
95	ibDiscoveryBackupSwFailure	Discovery backup service failed.
96	ibThreatProtectionAutoDownloadFailure	Automatic download of threat protection rule failed.
97	ibThreatProtectionPublishFailure	Threat protection rule publish failed.
98	ibPassiveHANodeARPConnectivityFailure	HA node failed to connect to local router.
99	ibPassiveHANodeARPConnectivitySuccess	HA node successfully connects to local router.
100	ibDNSIntegrityCheckConnectionFailed	Connection between Grid member and Grid Master failed.
101	ibDNSIntegrityCheckPrimaryServersFailed	DNS data (NS RRset) check for Grid primaries failed.
102	ibDNSIntegrityCheckNameserversFailed	DNS data (NS RRset) check for name servers failed.
103	ibCloudAPIFailure	Cloud API service failed.
104	ibRpzRefreshFailure	An RPZ refresh failure has occurred.
105	ibUnboundSoftwareFailure	Unbound software failure has occurred.
106	ibAnalyticsAutoDownloadFailure	Automatic download of analytic module set failed.
107	ibDnsHealthCheckFailed	The DNS health check has failed.
108	ibDnsHealthCheckSucceed	The DNS health check is successful.
109	ibBFDSoftwareFailure	BFD has failed to detect failure in the bidirectional path between two interfaces.
110	ibOutboundWorkerFailed	An Outbound worker has failed.
3001	ibRAIDIsOptimal	The system’s RAID array is now running in an optimal state.

3002	ibRAIDIsDegraded	The system’s RAID array is in a degraded state.
3003	ibRAIDIsRebuilding	The system’s RAID array is rebuilding.
3004	ibRAIDStatusUnknown	Unable to retrieve RAID array state!
3005	ibRAIDBatteryIsOK	The system’s RAID battery is OK.
3006	ibRAIDBatteryFailed	A RAID battery failure has occurred.
3007	ibRAIDOptimalMismatch	The system's RAID array is now running in an optimal state (Mismatched disk(s) found).
3008	ibRAIDDegradedMismatch	The system's RAID array is in a degraded state (Mismatched disk(s) found).
3009	ibRAIDRebuildingMismatch	The system's RAID array is rebuilding (Mismatched disk(s) found).
3010	ibRAIDBatteryWeak	Please replace the system's RAID battery soon.
3011	ibRAIDIsDegradedDisk1	The system's RAID array is in a degraded state. RAID Disk1 is EMPTY.
3012	ibRAIDIsDegradedDisk2	The system's RAID array is in a degraded state. RAID Disk2 is EMPTY.
3013	ibRAIDIsDegradedDisk3	The system's RAID array is in a degraded state. RAID Disk3 is EMPTY.
3014	ibRAIDIsDegradedDisk4	The system's RAID array is in a degraded state. RAID Disk4 is EMPTY.
3015	ibRAIDIsDegradedDisk5	The system's RAID array is in a degraded state. RAID Disk5 is EMPTY.
3016	ibRAIDIsDegradedDisk6	The system's RAID array is in a degraded state. RAID Disk6 is EMPTY.
3017	ibRAIDIsDegradedDisk7	The system's RAID array is in a degraded state. RAID Disk7 is EMPTY.
3018	ibRAIDIsDegradedDisk8	The system's RAID array is in a degraded state. RAID Disk8 is EMPTY.
3019	ibRAIDIsRebuildingDisk1	The system's RAID array is rebuilding. RAID Disk1 is OFFLINE.
3020	ibRAIDIsRebuildingDisk2	The system's RAID array is rebuilding. RAID Disk2 is OFFLINE.
3021	ibRAIDIsRebuildingDisk3	The system's RAID array is rebuilding. RAID Disk3 is OFFLINE.
3022	ibRAIDIsRebuildingDisk4	The system's RAID array is rebuilding. RAID Disk4 is OFFLINE.
3023	ibRAIDIsRebuildingDisk5	The system's RAID array is rebuilding. RAID Disk5 is OFFLINE.
3024	ibRAIDIsRebuildingDisk6	The system's RAID array is rebuilding. RAID Disk6 is OFFLINE.

3025	ibRAIDIsRebuildingDisk7	The system's RAID array is rebuilding. RAID Disk7 is OFFLINE.
3026	ibRAIDIsRebuildingDisk8	The system's RAID array is rebuilding. RAID Disk8 is OFFLINE.
3027	ibRAIDDegradedMismatchDisk1	The system's RAID array is in a degraded state (Mismatched disk(s) found). RAID Disk1 is EMPTY.
3028	ibRAIDDegradedMismatchDisk2	The system's RAID array is in a degraded state (Mismatched disk(s) found). RAID Disk2 is EMPTY.
3029	ibRAIDDegradedMismatchDisk3	The system's RAID array is in a degraded state (Mismatched disk(s) found). RAID Disk3 is EMPTY.
3030	ibRAIDDegradedMismatchDisk4	The system's RAID array is in a degraded state (Mismatched disk(s) found). RAID Disk4 is EMPTY.
3031	ibRAIDDegradedMismatchDisk5	The system's RAID array is in a degraded state (Mismatched disk(s) found). RAID Disk5 is EMPTY.
3032	ibRAIDDegradedMismatchDisk6	The system's RAID array is in a degraded state (Mismatched disk(s) found). RAID Disk6 is EMPTY.
3033	ibRAIDDegradedMismatchDisk7	The system's RAID array is in a degraded state (Mismatched disk(s) found). RAID Disk7 is EMPTY.
3034	ibRAIDDegradedMismatchDisk8	The system's RAID array is in a degraded state (Mismatched disk(s) found). RAID Disk8 is EMPTY.
3035	ibRAIDRebuildingMismatchDisk1	The system's RAID array is rebuilding (Mismatched disk(s) found). RAID Disk1 is OFFLINE.
3036	ibRAIDRebuildingMismatchDisk2	The system's RAID array is rebuilding (Mismatched disk(s) found). RAID Disk2 is OFFLINE.
3037	ibRAIDRebuildingMismatchDisk3	The system's RAID array is rebuilding (Mismatched disk(s) found). RAID Disk3 is OFFLINE.
3038	ibRAIDRebuildingMismatchDisk4	The system's RAID array is rebuilding (Mismatched disk(s) found). RAID Disk4 is OFFLINE.
3039	ibRAIDRebuildingMismatchDisk5	The system's RAID array is rebuilding (Mismatched disk(s) found). RAID Disk5 is OFFLINE.
3040	ibRAIDRebuildingMismatchDisk6	The system's RAID array is rebuilding (Mismatched disk(s) found). RAID Disk6 is OFFLINE.
3041	ibRAIDRebuildingMismatchDisk7	The system's RAID array is rebuilding (Mismatched disk(s) found). RAID Disk7 is OFFLINE.
3042	ibRAIDRebuildingMismatchDisk8	The system's RAID array is rebuilding (Mismatched disk(s) found). RAID Disk8 is OFFLINE.

3043	ibRAIDIsInoperable	The system’s RAID array is inoperable.
3044	ibRAIDPredictedDegraded	The system's RAID array is in a predicted degraded state.
3045	ibRAIDPredictedDegradedDisk1	The system's RAID array is in a predicted degraded state. RAID Disk1 is in such predicted degraded state.
3046	ibRAIDPredictedDegradedDisk2	The system's RAID array is in a predicted degraded state. RAID Disk2 is in such predicted degraded state.
3047	ibRAIDPredictedDegradedDisk3	The system's RAID array is in a predicted degraded state. RAID Disk3 is in such predicted degraded state.
3048	ibRAIDPredictedDegradedDisk4	The system's RAID array is in a predicted degraded state. RAID Disk4 is in such predicted degraded state.
3049	ibRAIDPredictedDegradedDisk5	The system's RAID array is in a predicted degraded state. RAID Disk5 is in such predicted degraded state.
3050	ibRAIDPredictedDegradedDisk6	The system's RAID array is in a predicted degraded state. RAID Disk6 is in such predicted degraded state.
3051	ibRAIDPredictedDegradedDisk7	The system's RAID array is in a predicted degraded state. RAID Disk7 is in such predicted degraded state.
3052	ibRAIDPredictedDegradedDisk8	The system's RAID array is in a predicted degraded state. RAID Disk8 is in such predicted degraded state.
4001	ibDisconnectGridAttachFailed	A disconnected Grid failed to attach to the Master Grid.
4002	ibDisconnectedGridDetachFailed	A disconnected Grid failed to detach from the Master Grid.
4003	ibDisconnectedGridDetachFailedSubgrid Offline	An offline Grid failed to detach from the Master Grid.
4004	ibDisconnectedGridSnapshotFailed	The snapshot operation failed on a disconnected Grid.
4005	ibDnssecAutomaticKSKRolloverApproching	An automatic rollover of the KSK will be performed in seven days.
4006	ibDnssecManualKSKRolloverDueApproching	A manual KSK rollover is due within the next seven days.
4007	ibDnssecAutomaticKSKRolloverDone	The KSK has been automatically rolled over.
4008	ibDnssecManualKSKRolloverDone	The KSK has been manually rolled over.
4009	ibDnssecKSKRolloverOverdue	The KSK rollover is overdue.
4010	ibPortDiscoveryConflict	A port detection conflict has been detected.

4011	ibDeviceDiscoveryConflict	A device detection conflict has been detected.
4012	ibDeviceUnmanaged	New unmanaged devices/networks were found during network discovery process.
4013	ibAnalyticsDnstUpdate	The DNS tunneling detection has occurred.
4014	ibSyslogBackupDone	The syslog backup process is successful.
4015	ibSyslogBackupFailed	The syslog backup process failed.

ibSubsystemName Values (OID 3.1.1.1.2.5.0)

The below table lists the values that are associated with the object ibSubsystemName (OID 3.1.1.1.2.5.0). These values provide information about the subsystems that trigger the traps.

ibSubsystemName Values

Value	OID 3.1.1.1.2.5.0 ibSubsystemName
0	Uses the original ibObjectName and ibSubsystemName when the trap is cleared. The process failure trap is appended to the CLEAR trap descriptions.

ibPreviousState (OID 3.1.1.1.2.9.0) and ibCurrentState (OID 3.1.1.1.2.10.0)

The ibPreviousState object indicates the state of the appliance before the event triggered the trap. The ibCurrentState object indicates the current state of the appliance. The following table shows the message and description for each state:

ibPreviousState and ibCurrentState Values

Value	Description	Definition
1	ha-active	The HA pair is in ACTIVE state.
2	ha-passive	The HA pair is in PASSIVE state.
3	ha-initial	The HA pair is in INITIAL state.
4	Grid-connected	The Grid member is connected to the Grid Master.
5	Grid-disconnected	The Grid member is not connected to the Grid Master.
12	service-down	The service is down.
13	ha-replication-online	The HA pair replication is online.
14	ha-replication-offline	The HA pair replication is offline.

15	ntp-syn-up	The NTP server is synchronizing.
16	ntp-syn-down	The NTP server is out of synchronization.
17	ms-server-up	Microsoft server is up.
18	ms-server-down	Microsoft server is down.
19	ms-service-up	Microsoft service connection is active.
20	ms-service-down	Microsoft service connection is inactive.
21	nac-server-group-down	NAC Authentication server group is down.
22	nac-server-group-up	NAC Authentication server group is up.
23	mgm-service-up	MGM service is active.
24	mgm-service-down	MGM service is inactive.
25	ha-active-active	HA Pair is in Dual Active state.
26	ftp-service-working	FTP service is working.
27	ftp-service-failed	FTP service failed.
28	ftp-service-inactive	FTP service is inactive.
29	tftp-service-working	TFTP service is working.
30	tftp-service-failed	TFTP service failed.
31	tftp-service-inactive	TFTP service is inactive.
32	dns-service-working	DNS service is working.
33	dns-service-failed	DNS service failed. Review the syslog file.
34	dns-service-inactive	DNS service is inactive. Check if an administrator disabled the service.
35	ntp-service-working	NTP service is working.
36	ntp-service-failed	NTP service failed.
37	ntp-service-inactive	NTP service is inactive.

38	http-file-dist-service-working	HTTP File Dist service is working.
39	http-file-dist-service-failed	HTTP File Dist service failed.
40	http-file-dist-service-inactive	HTTP File Dist service is inactive.
41	bloxtools-service-working	bloxTools service is working.
42	bloxtools-service-warning	bloxTools service is in warning state.
43	bloxtools-service-failed	bloxTools service failed.
44	bloxtools-service-inactive	bloxTools service is inactive.
45	dhcp-service-working	DHCP service is working. No action required.
46	dhcp-service-warning	DHCP service is in warning state. Review the syslog file.
47	dhcp-service-failed	DHCP service failed. Review the syslog file.
48	dhcp-service-inactive	DHCP service is inactive. Check if an administrator disabled the service.
49	captive-portal-service-working	Captive portal service is working.
50	captive-portal-service-failed	Captive portal service failed.
51	captive-portal-service-inactive	Captive portal service inactive.
52	ifmap-service-working	IF-MAP service is working.
53	ifmap-service-failed	IF-MAP service failed.
54	ifmap-service-inactive	IF-MAP service inactive.
56	hsm-group-down	HSM operation failed.
57	hsm-group-up	HSM operation succeeded.
59	reporting-service-working	Reporting service is working.
60	reporting-service-failed	Reporting service failed.
61	reporting-service-inactive	Reporting service inactive.
62	dns-cache-acceleration-working	DNS cache acceleration is working.

63	dns-cache-acceleration-failed	DNS cache acceleration failed.
64	dns-cache-acceleration-inactive	DNS cache acceleration is inactive.
65	ocsp-responders-ok	All OCSP responders are available.
66	ocsp-responder-failed	At least one OCSP responder has become unavailable.
67	ocsp-responders-unavailable	All OCSP responders are out of service.
68	cas-inactive	Certificate authentication service is inactive.
69	subgrid-attached	In a Multi-Grid configuration, sub Grid is attached to the Master Grid.
70	subgrid-detached	In a Multi-Grid configuration, sub Grid is detached from the Master Grid.
71	snapshot-disabled	In a Multi-Grid configuration, the snapshot of the Grid's current state is disabled.
72	snapshot-enabled	In a Multi-Grid configuration, the snapshot of the Grid's current state is enabled.
73	lb-device-up	Load balancer device is working.
74	lb-device-down	Load balancer device is down.
76	ldap-servers-ok	All LDAP servers are available.
77	ldap-server-failure	At least one LDAP server is unavailable.
78	ldap-servers-unavailable	All LDAP servers are unavailable.
79	ldap-service-inactive	LDAP service is inactive.
80	sgm-state-online	SGM is online.
81	sgm-state-offline	SGM is offline.
82	discovery-consolidator-service-working	Service on discovery the consolidator for Network Insight is working.
83	discovery-consolidator-service-warning	Service on discovery the consolidator for Network Insight is in warning state.
84	discovery-consolidator-service-failed	Service on discovery the consolidator for Network Insight failed.
85	discovery-consolidator-service-inactive	Service on discovery the consolidator for Network Insight is inactive.

86	discovery-collector-service-working	Service on discovery probes for Network Insight is working.
87	discovery-collector-service-warning	Service on discovery probes for Network Insight is in warning state.
88	discovery-collector-service-failed	Service on discovery probes for Network Insight failed.
89	discovery-collector-service-inactive	Service on discovery probes for Network Insight is inactive.
90	threat-protection-service-working	Threat protection service for Infoblox DNS Protection is working.
91	threat-protection-service-warning	Threat protection service for Infoblox DNS Protection is in warning state
92	threat-protection-service-failed	Threat protection service for Infoblox DNS Protection failed.
93	threat-protection-service inactive	Threat protection service for Infoblox DNS Protection is inactive.
94	mgm-external-storage-disabled	MGM external storage is disabled.
95	dns-integrity-check-failed	DNS Integrity check for authoritative zones failed.
96	dns-integrity-check-working	DNS Integrity check for authoritative zones is working.
97	dns-integrity-check-severity-indetermined	DNS Integrity check severity is None.
98	dns-integrity-check-severity-normal	DNS Integrity check severity is NORMAL.
99	dns-integrity-check-severity-informational	DNS Integrity check severity is INFORMATIONAL.
100	dns-integrity-check-severity-warning	DNS Integrity check severity is WARNING.
101	dns-integrity-check-severity-severe	DNS Integrity check severity is SEVERE.
102	dns-integrity-check-severity-critical	DNS Integrity check severity is CRITICAL.
103	cloud-api-service-working	Cloud API service is working.
104	cloud-api-service-failed	Cloud API service failed.

105	cloud-api-service-inactive	Could API service is inactive.
106	dns-service-dtc-failed	DNS sub-feature DNS Traffic Control failed.
107	raid-status-is-unavailable	RAID hardware status is unavailable.
108	raid-status-is-available	RAID hardware status is available again.
109	ipmi-device-warning	IPMI device is not available.
110	ipmi-device-unavailable	IPMI device repeatedly is not available.
111	ipmi-device-available	IPMI device is available again.
112	rpz-refresh-working	RPZ refresh is working.
113	rpz-refresh-failed	RPZ refresh failed.
114	rpz-refresh-unknown	RPZ refresh unknown.
115	dns-attack-active	DNS attack is active.
116	dns-attack-inactive	DNS attack is inactive.
117	high-rpz-hit-rate	RPZ hit rate exceeds the normal value.
118	normal-rpz-hit-rate	RPZ hit rate has returned to normal value.
119	taxii-working	TAXII server is working.
120	taxii-warning	TAXII server is warning.
121	taxii-failed	TAXII server is failed.
122	taxii-inactive	TAXII server is inactive.
123	cisco-ise-server-up	Cisco ISE server is connected.
124	cisco-ise-server-down	Cisco ISE server is not connected.
125	threat-analytics-service-inactive	Threat Analytics service is inactive.
126	threat-analytics-service-working	Threat Analytics service is working.
127	threat-analytics-service-warning	Threat Analytics service is in warning state.

128	threat-analytics-service-failed	Threat Analytics Service is failed.
129	outbound-service-manager-started	OUTBOUND Service Manager is working
130	outbound-service-manager-failed	OUTBOUND Service Manager is failed
131	outbound-service-manager-stopped	OUTBOUND Service Manager is inactive
133	imc-servers-ok	Subscriber Collection Service is working.
134	imc-server-failure	Subscriber Collection Service failed.
135	imc-servers-unavailable	All NAS gateways are unavailable.
136	imc-service-inactive	Subscriber Collection Service is inactive.
137	imc-zvelo-service-unavailable	Initial category information data is downloading.
138	imc-server-initializing	Initial Subscriber Collection service interim interval.

The Grid member running Subscriber Collection Service has a default state of 136 (imc-service-inactive). When Subscriber Collection Service is enabled, it goes to the 138 (imc-server-initializing) state. That is, the service will be enabled but not fully populated until the interim interval expires. Once the interim interval expires, it transitions to the 133 (imc-servers-ok) state unless parental control is enabled. If parental control is enabled, the state changes to 137 (imc-zvelo-service-unavailable) until the category data is downloaded. After this it goes to state 133 (imc-servers-ok). If the collector service is not running, it transitions to state 134 (imc-server-failure).

Trap 136 implies that subscriber collection is not active. Trap 134 implies that the collector is not running. If the monitor is disabled , then trap 136 (imc-service-inactive) is triggered.

⚠ Note

- When downloading the category data, it is around 2.8 GB when compressed and around 6 GB when uncompressed. This data size remains unchanged even for incremental downloads. Ensure that the proxy settings are modified accordingly, before the download.
- The data from the earlier service provider is deleted after the upgrade and the categorization will not work until the categorization DB is downloaded.

ibTrapDesc (OID 3.1.1.1.2.11.0)

The ibTrapDesc object lists the trap messages of all Infoblox SNMP traps. This section lists all the SNMP traps by their trap types. Each trap table describes the trap message, severity, cause, and recommended actions.

⚠ Note
Contact Infoblox Technical Support for assistance when the recommended actions do not resolve the problems.

lEquipment Failure Traps

ibTrapDesc OID 3.1.1.1.2.11.0	ibTrapSeverity OID 3.1.1.1.2.2	Description/Cause	Recommended Actions
Primary Drive Full			
Primary drive is full.	Major	The primary disk drive reached 100% of usage.	Review the syslog file to identify the possible cause of this problem.
Fan Monitoring			
Fan <n> failure has occurred.	Minor	The specified fan <n> failed, where <n> indicates the fan number.	Inspect the specified fan for mechanical or electrical problems.
Fan <n> is OK.	Informational	The specified fan <n> is functioning properly, where <n> indicates the fan number.	No action is required.
Power Supply Failure: monitored at 1 minute			
A power supply failure has occurred.	Major	The power supply failed.	Inspect the power supply for the possible cause of the failure.
Power supply <n> failure has occurred.	Major	The specified power supply <n> failed, where <n> indicates the power supply number.	Inspect the specified power supply for the possible cause of the failure.
The power supply is OK.	Informational	The power supply is functioning properly.	No action is required.
Power supply <n> is OK.	Informational	The specified power supply <n> is functioning properly, where <n> indicates the power supply number.	No action is required.
RAID monitoring, at 1 minute interval			
A RAID battery failure has occurred.	Major	The system RAID battery failed. The alert light is red.	Inspect the battery for the possible cause of the failure.
The system's RAID battery is OK.	Informational	The system RAID battery is charging and functioning properly. The alert light changed from red to green.	No action is required.
Unable to retrieve RAID array state!	Undetermined	The appliance failed to retrieve the RAID array state. The alert light is red.	Review the syslog file to identify the possible cause of this problem.
The system's RAID array is now running in an optimal state.	Informational	The RAID system is functioning at an optimal state.	No action is required.

The system's RAID array is in a degraded state. RAID Disk <n> is EMPTY.	Major	The RAID system is degrading. The specified RAID Disk <n> is empty, where <n> indicates the RAID disk number.	Review the syslog file to identify the possible cause of this problem.
The system's RAID array is rebuilding. RAID Disk <n> is OFFLINE.	Minor	The RAID system is rebuilding. The specified RAID Disk <n> is offline, where <n> indicates the RAID disk number.	No action is required.
Syslog Backup Processes			
The syslog backup process is successful.	Informational	Rotated syslog files are uploaded successfully to the external backup server.	No action is required.
The syslog backup process failed.	Major	Failed to forward the rotated syslog files to the external backup server.	Review the syslog messages to identify the possible cause of this problem.

Processing and Software Failure Traps

The ibSubsystemName object is associated with certain traps of the Processing and Software Failure traps. Therefore, you cannot map all the traps of the Processing and Software Failure traps with the ibSubsystemName. If there is no value in the ibSubsystemName, then it belongs to the N/A category. For more information on the values for the ibSubsystemName, see the *ibSubsystemName Values* table.

Named Daemon Failure			
A named daemon monitoring failure has occurred.	Critical	The named process failed.	Review the syslog file to identify the possible cause of this problem.
DHCP Daemon Failure			
A DHCP daemon monitoring failure has occurred.	Critical	The dhcpd process failed.	Review the syslog file to identify the possible cause of this problem.
SSH Daemon Failure			
An SSH daemon failure has occurred.	Major	The sshd process failed.	Review the syslog file to identify the possible cause of this problem.
NTP Daemon Failure, monitored every 10 minutes			
An NTP daemon failure has occurred.	Major	The ntpd process failed.	Review the syslog file to identify the possible cause of this problem.
Cluster Daemon Failure			

A grid daemon failure has occurred.	Critical	The clusterd process failed.	Review the syslog file to identify the possible cause of this problem.
LCD Daemon Failure			
An LCD failure has occurred.	Major	The LCD process failed. The alert light is yellow.	1. Inspect the LCD panel for the possible cause of this problem. 2. Review the syslog file to identify the possible cause of this problem.
Apache Software httpd failure, monitored every 2 minutes			
An Apache software failure has occurred.	Critical	The request to monitor the Apache server failed.	Review the syslog file to identify the possible cause of this problem.
Serial Console Failure			
An Infoblox serial console software failure has occurred.	Major	The Infoblox serial console failed.	Review the syslog file to identify the possible cause of this problem.
Controld Software Failure			
A controld failure has occurred.	Critical	The controld process failed.	Review the syslog file to identify the possible cause of this problem.
SNMP Sub-agent Failure			
An SNMP server failure has occurred.	Major	The one-subagent process failed.	Review the syslog file to identify the possible cause of this problem.
TFTPD and FTPD Failure			
A TFTPD daemon failure has occurred.	Critical	The tftpd process failed.	Review the syslog file to identify the possible cause of this problem.
An FTPD daemon failure has occurred.	Critical	The ftpd process failed.	Review the syslog file to identify the possible cause of this problem.
HTTP File Distribution, monitored at 10 second intervals			
An HTTP file distribution daemon failure has occurred.	Critical	The HTTP file distribution process failed.	Review the syslog file to identify the possible cause of this problem.

DNS ONE quagga Processes (zebra & ospfd)			
An OSPF routing daemon failure has occurred.	Critical	Either the zebra process or the ospfd process failed. Both the zebra and ospfd process belongs to ospf subsystem.	Review the syslog file to identify the possible cause of this problem.
Backup Failure			
Backup failed.	Minor	The backup failed. One of the following could be the cause of the failure: • The appliance could not access a backup directory. • The backup was interrupted by one of the following signals: SIGINT, SIGHUP, or SIGTERM. • Incorrect login or connection failure in an FTP backup. • The backup failed to create temporary files.	Review the syslog file to identify the possible cause of this problem.
Database Backup Failure			
Database backup failed.	Not implemented	The db_dump process failed.	Review the syslog file to identify the possible cause of this problem.
Backup Module Failure			
Module backup failed.	Not implemented	The backup of product- specific files failed.	Review the syslog file to identify the possible cause of this problem.
Backup File Size Exceeded			
File size exceeded the quota. Backup failed.	Not implemented	The backup failed because the file size exceeded the limit of 5GB.	Limit the size of the backup file to less than 5GB.
Another backup is in progress. Backup will not be performed.	Not implemented	The backup failed because of an attempt to back up or merge files while another backup or restore was in progress.	Wait until the backup or restore is complete before starting another backup.
Watchdog Process Monitoring			

WATCHDOG: *<registered client name>* failed on *<server IP address>*	Critical	The watchdog process detected a registered client failure on a specific server. The *<registered client name>* could be one of the following: • Clusterd _timeout • DB_Sentinel • Process_Manager • Clusterd_monitor • Disk_monitor	Review the syslog file to identify the possible cause of this problem.
Microsoft Server			
Microsoft server *<hostname>/<IP address>* has failed.	Major	The Microsoft server could not be reached.	Check that the Microsoft server is connected to the network and configured properly.
Microsoft server *<hostname>/<IP address>* is OK.	Informational	The Microsoft server can be reached and is functioning properly.	No action is required.
Microsoft DNS/DHCP Service			
Service connection to Microsoft DNS server *<hostname>/<IP address>* has failed.	Major	The Microsoft DNS service is not responding.	Check that the DNS service is configured and running on the Microsoft server.
Service connection to Microsoft DHCP server *<hostname>/<IP address>* has failed.	Major	The Microsoft DHCP service is not responding.	Check that the DHCP service is configured and running on the Microsoft server.
Service connection to Microsoft DNS server *<hostname>/<IP address>* is OK.	Informational	The Microsoft DNS service is responding.	No action is required.
Service connection to Microsoft DHCP server *<hostname>/<IP address>* is OK.	Informational	The Microsoft DHCP service is responding.	No action is required.
NAC Authentication Server Group			
NAC Authentication server group is down	Major	None of the servers in the NAC authentication server group can be reached.	Review the syslog.
NAC Authentication server group is up	Informational	The NAC authentication server group is responding.	No action is required.
GUI Login			
A GUI login failure has occurred	Major	An admin failed to log in to the GUI.	Check the credentials of the admin.

Serial Console Login			
A Serial Console login failure has occurred	Major	An admin failed to log in through the serial console.	Check the credentials and permissions, and check that the serial console is enabled.
Reboot			
The system is rebooting.	Informational	A system reboot command was sent.	No action is required.
DHCP Lease Conflict			
DHCP address conflicts with an existing lease.	Major	The discovery process found a DHCP lease conflict.	In the IP Map or List panel, select a conflicting address, and then click **Resolve Conflict**. For more information about resolving DHCP lease conflicts, see *Managing Discovered Data*.
DHCP Fixed Address Conflict			
DHCP address conflicts with an existing fixed address.	Major	The discovery process found a fixed address conflict.	In the IP Map or List panel, select a conflicting address, and then click **Resolve Conflict**. For more information about resolving fixed address conflicts, see *Managing Discovered Data*.
DHCP Range Conflict			
DHCP address conflicts with an existing range.	Major	The discovery process found a conflict with an existing range.	In the IP Map or List panel, select a conflicting address, and then click **Resolve Conflict**. For more information about resolving DHCP range conflicts, see *Managing Discovered Data*.
DHCP Host Conflict			
DHCP address conflicts with an existing host address.	Major	The discovery process found a conflict with an existing host address.	In the IP Map or List panel, select a conflicting address, and then click **Resolve Conflict**. For more information about resolving host conflicts, see *Managing Discovered Data*.
DNS Health Check Monitor			
DNS Health Check query failed.	Major	DNS Health Check query has failed.	Review the syslog file to identify the possible cause of this problem.
DNS Health Check query has succeeded	Informational	DNS Health Check query has succeeded.	No action required.

Syslog Daemon Failure			
Syslog daemon is not running.	Critical	Syslog process stopped.	Review the syslog file to identify the possible cause of this problem.
BFD Daemon Failure			
An BFD daemon failure has occurred.	Major	BFD has failed to detect failure in the bidirectional path between two interfaces.	Review the syslog file to identify the possible cause of this problem.
Process Stop/Start			
The system stopped and started a process.	Major	The system restarted a process.	Review the syslog file to identify the possible cause of this problem.
Zone Transfer Failed			
A zone transfer failure has occurred.	Major	A zone transfer failed.	Review the syslog file to identify the possible cause of this problem.
RPZ Refresh Failed			
RPZ refresh failure has occurred.	Critical	An RPZ refresh has failed. The appliance sends this trap only when RPZ refresh from all the configured primary servers fail.	Review the syslog file to identify the possible cause of this problem.
Unbound Software Failed			
A unbound daemon monitoring failure has occurred.	Major	Unbound software failure has occurred.	Review the syslog file to identify the possible cause of this problem.
Threat Analytics Service Failed			
Threat Analytics Auto Download has failed.	Major	Auto download for Threat Analytics has failed.	Review the syslog file to identify the possible cause of this problem.
Outbound Service Failed			
The Outbound worker failed.	Major	The Outbound service failure has occurred.	Review the syslog file to identify the possible cause of this problem.
Clear			
SNMP Trap is cleared. LCD failure	N/A	The SNMP Trap for LCD failure is cleared.	No action is required.

SNMP Trap is cleared. Serial Console	N/A	The SNMP Trap for Serial Console is cleared.	No action is required.
SNMP Trap is cleared. ControlD failure	N/A	The SNMP Trap for ControlD failure is cleared.	No action is required.
SNMP Trap is cleared. GUI Login	N/A	The SNMP Trap for GUI Login is cleared.	No action is required.
SNMP Trap is cleared. Serial Console Login	N/A	The SNMP Trap for Serial Console Login is cleared.	No action is required.
SNMP Trap is cleared. SSHD failure	N/A	The SNMP Trap for SSHD failure is cleared.	No action is required.
SNMP Trap is cleared. LDAP servers	N/A	The SNMP Trap for LDAP server is cleared.	No action is required.
SNMP Trap is cleared. OCSP Responders	N/A	The SNMP Trap for OCSP Responders is cleared.	No action is required.
SNMP Trap is cleared. OSPF	N/A	The SNMP Trap for OSPF is cleared.	No action is required.
SNMP Trap is cleared. OSPF6	N/A	The SNMP Trap for OSPF6 is cleared.	No action is required.
SNMP Trap is cleared. BGP	N/A	The SNMP Trap for BGP is cleared.	No action is required.
SNMP Trap is cleared. HSM	N/A	The SNMP Trap for HSM is cleared.	No action is required.
SNMP Trap is cleared. HTTP	N/A	The SNMP Trap for HTTP is cleared.	No action is required.
SNMP Trap is cleared. Cluster	N/A	The SNMP Trap for Cluster is cleared.	No action is required.
SNMP Trap is cleared. DuplicateIP	N/A	The SNMP Trap for Duplicate IP is cleared.	No action is required.
Restart			
The system is being restarted.	Informational	A system restart command was sent.	No action is required.
DNS Integrity Check			

Cannot perform DNS Integrity Check because the appliance is unable to connect to the external DNS server. There are list of nameservers failure: *<IP addresses>*	N/A	The DNS integrity check cannot be performed because the appliance is unable to connect to the external DNS server.	No action is required.

Threshold Crossing Traps

ibTrapDesc **OID 3.1.1.1.2.11.0**	**ibTrapSeverity**	**ibObjectName** **OID 3.1.1.1.2.3.0**	**Description/Cause**	**Recommended Actions**	
System Memory Usage					

System has run out of memory.	Major	memory	The appliance ran out of memory. The appliance encountered this problem when one of the following occurred: • The total free memory on the appliance was less than or equal to 0%. • The total physical memory was less than the total free memory. • The percentage of free memory compared to the total physical memory was less than 5%, and the free swap percentage was less than 80%. • The percentage of free memory compared to the total physical memory was less than 5%, plus the numbers of both swap INs and swap OUTs were greater than or equal to 3,200.		

			• The percentage of free memory compared to the total physical memory was between 5% and 10%, the free swap percentage was greater than or equal to 80%, plus the numbers of both swap INs and swap OUTs were greater than or equal to 3,200. • The percentage of free memory compared to the total physical memory was greater than 10%, the free swap percentage was less than 80%, plus the numbers of both swap INs and swap OUTs were greater than or equal to 3,200. **Note:** Free memory = free physical RAM + free cache buffers. The high threshold for swap pages is 3,200.		

System memory usage exceeds the critical threshold value.	Minor	memory	The memory usage on the appliance exceeded the configured Trigger value. For more information about defining thresholds for traps, see *Configuring SNMP*. The appliance encountered this problem when one of the following occurred: • The percentage of free memory compared to the total physical memory was less than 5%, and the free swap percentage was less than 90%. • The percentage of free memory compared to the total physical memory was less than 5%, plus the number of swap INs was less than 3,200 and the number of swap OUTs was greater than or equal to 3,200.		

			• The percentage of free memory compared to the total physical memory was between 5% and 10%, and the free swap percentage was less than 80%. • The percentage of free memory compared to the total physical memory was greater than 5%, plus the number of swap INs was less than 3,200 and the number of swap OUTs was greater than or equal to 3,200. **Note:** Free memory = free physical RAM + free cache buffers. The high threshold for swap pages is 3,200.		
System memory usage is OK.	Minor	memory	The memory usage on the system is at or below the Reset value after it went above the Trigger value.		
Primary Hard Drive Usage (monitored every 30 seconds)					

System primary hard disk usage is over threshold value.	Minor	disk_usage	The appliance sends this trap when primary hard disk usage first exceeds the configured Trigger value. The default value is 85. The alert light is yellow. For more information about defining thresholds for traps, see *Configuring SNMP*.	Review the syslog file to identify the possible cause of this problem.
Primary drive is full.	Major	disk_usage	The primary hard disk usage exceeded 95%. The alert light is red.	Review the syslog file to identify the possible cause of this problem.
Primary drive usage is OK.	Minor	disk_usage	The appliance sends this trap when the primary hard disk usage first moves at or below the configured Reset value after it exceeded the Trigger value. The default is 70. The alert light is green.	No action is required.
CPU Usage				
CPU usage above threshold value.	Major	cpu_usage	CPU usage exceeded the Trigger value for 15 seconds. For more information about defining thresholds for traps, see *Configuring SNMP*.	Monitor CPU usage.
CPU usage OK.	Minor	cpu_usage	CPU usage dipped below the reset value after the "CPU usage above threshold value" trap was sent.	No action is required.
Note: Use the CLI command set thresholdtrap to enable the CPU usage trap and configure the trigger and reset values. For information, refer to the *Infoblox CLI Guide*.				
Swap Usage				
System swap space usage exceeds the critical threshold value.	Major	swap_usage	System swap space usage exceeded the Trigger value. For more information about defining thresholds for traps, see *Configuring SNMP*.	Monitor System swap usage.

System swap space usage is OK.	Minor	swap_usage	System swap space usage dipped below the reset value after it exceeded the Trigger value.	No action is required.	
Replication Statistics Monitoring					
Grid queue replication problem.	N/A	For send trap: Cluster_Send_ Queue For receive trap: Cluster_Recv_ Queue	The system encountered this problem when all of the following conditions occurred: • The node was online. • The number of the replication queue being sent from the master column was greater than 0, or the number of the queue received was greater than 0. • It was more than 10 minutes since the last replication queue was sent and monitored.	Review the syslog file to identify the possible cause of this problem.	
DHCP Range Threshold Crossing					

DHCP high threshold crossed: Member: *<DHCP server node VIP>* Network: *<network>/ <network view>* Range: *<DHCP range>/ <network view>* High Trigger Mark: *<high percentage>* (95% by default) High Reset Mark: *<reset percentage>* (80% by default) Current Usage: *<current usage percentage>* Active Leases: *<number of active leases>* Available Leases: *<number of available leases>* Total Addresses: *<total addresses>*	N/A	Threshold	The system encountered this problem when the address usage in the DHCP range is greater than the configured High Trigger value.	Review the syslog file to identify the possible cause of this problem.	
DHCP high threshold reset: Member: *<DHCP server node VIP>* Network: *<network>/ <network view>* Range: *<DHCP range>/<network view>* High Trigger Mark: *<high percentage>* (95% by default) High Reset Mark: *<reset percentage>* (80% by default) Current Usage: *<current usage percentage>* Active Leases: *<number of active leases>* Available Leases: *<number of available leases>* Total Addresses: *<total addresses>*	N/A	Threshold	The system encountered this problem when the address usage in the DHCP range goes below the Reset value after it hit the Trigger value.		
IPAM Utilization Threshold Crossing					
Network IPAM Utilization capacity usage is over the threshold value. Network: *<network>/ <network view>*	N/A	Threshold	The appliance sends this trap when the IPAM utilization for a network is above the configured Trigger value.	Review the syslog file to identify the possible cause of this problem.	

Network Container IPAM Utilization capacity usage is over the threshold value. Network container: *<network>/ <network view>*	N/A	Threshold	The appliance sends this trap when the IPAM utilization for a network container is above the configured Trigger value.	Review the syslog file to identify the possible cause of this problem.
Network IPAM Utilization capacity usage is OK. Network: *<network>/ <network view>*	N/A	Threshold	The appliance sends this trap when the IPAM utilization for a network is below the configured Reset value.	Review the syslog file to identify the possible cause of this problem.
Network Container IPAM Utilization capacity usage is OK. Network container: *<network>/ <network view>*	N/A	Threshold	The appliance sends this trap when the IPAM utilization for a network container is below the configured Reset value.	Review the syslog file to identify the possible cause of this problem.
DHCP DDNS Updates Deferred				
DHCP DNS updates deferred: Retried at least once: *<number of retries>* Maximum number of deferred updates since start of problem episode (or restart): *<max number>*	N/A	Threshold	The DNS updates were deferred because of DDNS update errors.	Review the syslog file to identify the possible cause of this problem.
RPZ Hit Rate				
RPZ hit rate exceed normal value.	N/A	Threshold	The appliance sends this trap when the RPZ hit rate exceeds the configured Trigger value.	Review the syslog file to identify the possible cause of this problem.
RPZ hit rate has returned to normal value.	N/A	Threshold	The appliance sends this trap when the RPZ hit rate equals the configured Reset value.	Review the syslog file to identify the possible cause of this problem.
Threat Protection Total Traffic				
Threat Protection Service total traffic is above threshold.	N/A	Threshold	The appliance sends this trap when the Treat Protection total traffic exceeds the configured Trigger value.	Review the syslog file to identify the possible cause of this problem.

Threat Protection Service total traffic is OK.	N/A	Threshold	The appliance sends this trap when the Threat Protection total traffic is less than the configured Reset value.	Review the syslog file to identify the possible cause of this problem.
Threat Protection Dropped Traffic				
Threat Protection Service dropped traffic is above threshold.	N/A	Threshold	The appliance sends this trap when the Treat Protection dropped traffic exceeds the configured Trigger value.	Review the syslog file to identify the possible cause of this problem.
Threat Protection Service dropped traffic is OK.	N/A	Threshold	The appliance sends this trap when the Threat Protection dropped traffic is less than the configured Reset value.	Review the syslog file to identify the possible cause of this problem.
Database Capacity Usage				
Database capacity used is over the threshold value.	Minor	db_usage	The appliance database usage exceeded the configured threshold value.	Increase the database capacity.
Database capacity used is OK.	Minor	db_usage	The appliance database usage is less than the configured threshold value.	No action is required.
DNS Monitor				

DNS security alert. There were *actual* DNS responses to invalid ports in the last minute, comprising *percent%* of all responses. Primary sources: *ip_address* sent *count*, *ip_address* sent *count*.	Major	dns_security_ port	DNS security alert. There were *actual* DNS responses to invalid ports in the last minute, comprising *percent%* of all responses. Primary sources: *ip_address* sent *count*, *ip_address* sent *count*. where • *actual* is the total number of DNS responses arrive on invalid ports. • *percent%* is the percentage of invalid DNS responses over the total number of DNS responses. • *ip_address* is the IP address of the primary source that generated the invalid DNS responses. • *count* is the number of invalid responses generated by the specified IP address.	1. Review the following: • DNS alert status • syslog file 2. Limit access or block connections from the primary sources. For information about configuring rate limiting rules, see *Monitoring Tools*.

			Example: DNS security alert. There were 1072 DNS responses to invalid ports in the last minute, comprising 92% of all responses. Primary sources: 10.0.0.0 sent 1058, 2.2.2.2 sent 14.	

DNS security alert. There were *actual* DNS responses with invalid TXID in the last minute, comprising *percent%* of all responses. Primary sources: *ip_address* sent *count*, *ip_address* sent *count*.	N/A	dns_security_t xid	DNS security alert. There were *actual* DNS responses with invalid TXID in the last minute, comprising *percent%* of all responses. Primary sources: *ip_address* sent *count*, *ip_address* sent *count*. where • *actual* is the total number of DNS responses that have invalid TXIDs. • *percent%* is the percentage of invalid DNS responses over the total number of DNS responses. • *ip_address* is the IP address of the primary source that generated the invalid DNS responses. • *count* is the number of invalid responses generated by the specified IP address.	1. Review the following: • DNS alert status • syslog file 2. Limit access or block connections from the primary sources. For information about configuring rate limiting rules, see *Monitoring Tools*.

			Example: DNS security alert. There were 1072 DNS responses with invalid TXID in the last minute, comprising 92% of all responses. Primary sources: 10.0.0.0 sent 1058, 2.2.2.2 sent 14.		
RootFS Partition Monitor					
Root file system is full.	Major	Root filesystem	The Root filesystem usage exceeded the maximum.	Review the syslog file to identify the possible cause of this problem.	
Root file system disk usage is over threshold value.	Minor	Root filesystem	The appliance sends this trap when the Root filesystem usage first exceeds the configured Trigger value.	Review the syslog file to identify the possible cause of this problem.	
Root file system disk usage is OK.	Minor	Root filesystem	The appliance sends this trap when the Root filesystem disk usage first moves at or below the configured Reset value after it exceeded the Trigger value. For more information about defining thresholds for traps, see *Configuring SNMP*.	No action	
Reporting					
Reporting drive is full.	Major	reporting_service	Reporting drive reached the maximum capacity.	Review the syslog file to identify the possible cause of this problem.	

Reporting drive usage is over threshold value.	Minor	reporting_service	The appliance sends this trap when the Reporting volume first exceeds the configured Trigger value. The default Trigger value is 80.	Review the syslog file to identify the possible cause of this problem.	
Reporting drive usage is OK.	Minor	reporting_service	The appliance sends this trap when the Reporting volume first moves at or below the configured Reset value after it exceeded the Trigger value. The default Reset value is 71. For information on setting the Trigger and Reset values, see *Configuring SNMP*.	No action	
File Distribution					
File Distribution services storage usage reached the threshold value.	N/A	File Distribution	File distribution service storage reached the configured threshold value.	Review the syslog file to identify the possible cause of this problem.	

Object State Change Traps

ibTrapDesc OID 3.1.1.1.2.11.0	ibTrapSeverity	Description/Cause	Recommended Actions
Service Shutdown			
Shutting down services due to database snapshot.	Major	The appliance is shutting down its services while synchronizing the database with the Grid Master.	No action is required.
Network Interfaces Monitoring			
LAN1 port link is down. Please check the connection.	Major	The LAN1 port is up, but the link is down.	Check the LAN1 link connection.
LAN2 port link is down. Please check the connection.	Major	The LAN2 port is up, but the link is down.	Check the LAN2 link connection.
HA port link is down. Please check the connection.	Major	The HA port is up, but the link is down.	Check the HA link connection.
MGMT port link is down. Please check the connection.	Major	The MGMT port is enabled, but the link is down.	Check the MGMT link connection.
LAN1 port link is up.	Major	The LAN1 port link is up and running.	No action is required.

LAN2 port link is up.	Major	The LAN2 port link is up and running.	No action is required.
HA port link is up.	Major	The HA port link is up and running.	No action is required.
MGMT port link is up.	Major	The MGMT port link is up and running.	No action is required.
HA State Change from Initial to Active			
The node has become ACTIVE.	Informational	A node in an HA pair becomes active. The HA pair starts up.	No action is required.
HA State Change from Passive to Active			
The node has become ACTIVE.	Informational	The node changed from a passive to an active node.	No action is required.
HA State Change to Active-Active			
The node is in an ACTIVE-ACTIVE state.	Informational	The node is in the active state.	No action is required.
HA State Change from Initial to Passive			
The node has become PASSIVE.	Informational	A node in an HA pair becomes passive. The HA pair starts up, and the node is not a Grid Master candidate.	No action is required.
Node Connected to Grid			
The Grid member is connected to the Grid master.	Informational	The Grid member joined the Grid, and it is not a Grid Master candidate.	No action is required.
Node Disconnected from Grid			
The Grid member is not connected to the Grid master.	Informational	The Grid member lost its connection to the Grid Master.	No action is required.
Replication State Monitoring			
HA replication is online.	Informational	The HA replication is online.	No action is required.
HA replication is offline.	Informational	The HA replication is offline.	No action is required.
NTP is out of sync, monitored every 30 seconds			
The NTP service is out of synchronization.	Major	The Infoblox NTP server and the external NTP server are not synchronized.	Review the syslog file to identify the possible cause of this problem.

NTP Service is working.	Informational	The NTP service started working again.	No action is required.
NTP service is synchronizing to local clock			
The NTP service is synchronizing to local clock.	Major	The Infoblox NTP server synchronizes its clients with its local clock.	No action is required.
DHCP service state change			
DHCP Service is working.	Informational	The DHCP service started working again.	No action is required.
DHCP Service is in a warning state.	Informational	The DHCP service is in a warning state.	Review the syslog file
DHCP Service Failed	Informational	The DHCP service is in failed state.	Review the syslog file.
DHCP Service is inactive.	Informational	The DHCP service became inactive.	Check if an admin disabled the service.
DNS service state change			
DNS Service is working.	Informational	The DNS service started working again.	No action is required.
DNS Service failed	Informational	The DNS service is in a failed state.	Review the syslog file.
DNS Service is inactive.	Informational	The DNS service became inactive.	Check if an admin disabled the service.
NTP service state change			
The NTP service resumed synchronization.	Informational	The NTP service started working again.	No action is required.
NTP Service is inactive.	Informational	The NTP service became inactive.	Check if an admin disabled the service.
TFTP service state change			
TFTP Service is working.	Informational	The TFTP service started working again.	No action is required.
TFTP Service is inactive.	Informational	The TFTP service became inactive.	Check if an admin disabled the service.
FTP service state change			
FTP Service is working.	Informational	The FTP service started working again.	No action is required.
FTP Service is inactive.	Informational	The FTP service became inactive.	Check if an admin disabled the service.

HTTP service state change			
HTTP File Dist Service is working.	Informational	The HTTP file distribution service started working again.	No action is required.
HTTP File Dist Service is inactive.	Informational	The HTTP file distribution service became inactive.	Check if an admin disabled the service.
bloxTools service state change			
BloxTools Service is working.	Informational	The bloxTools service started working again.	No action is required.
BloxTools Service is in warning state.	Informational	The bloxTools service is in a warning state.	Review the syslog file
BloxTools Service is inactive.	Informational	The bloxTools service became inactive.	Check if an admin disabled the service.
BloxTools Service failed.	Critical	The bloxTools daemon failed.	Review the syslog file.
Captive Portal service state change			
Captive Portal Service is working.	Informational	The captive portal service started working again.	No action is required.
Captive Portal Service is inactive.	Informational	The captive portal service became inactive.	Check if an admin disabled the service.
Discovery Collector service state change			
Discovery Collector Service is working.	Informational	The discovery collector service started working again.	No action is required.
Discovery Collector Service is inactive.	Informational	The discovery collector service became inactive.	Check if an admin disabled the service.
Discovery Collector Service is in warning state.	Informational	The discovery collector service is in a warning state.	Review the syslog file.
Discovery Collector Service has failed.	Informational	The discovery collector service has failed.	Review the syslog file.
Discovery Collector service state change			
Discovery Consolidator Service is working.	Informational	The discovery consolidator service started working again.	No action is required.
Discovery Consolidator Service is inactive.	Informational	The discovery consolidator service became inactive.	Check if an admin disabled the service.
Discovery Consolidator Service is in warning state.	Informational	The discovery consolidator service is in a warning state.	Review the syslog file

Discovery Consolidator Service has failed.	Critical	The discovery consolidator service has failed.	Review the syslog file
IF-MAP service state change			
IFMAP Service is inactive.	Informational	The IF-MAP service became inactive.	Check if an admin disabled the service.
IFMAP Service is working.	Informational	The IF-MAP service started working again.	No action is required.
LDAP service state change			
LDAP service is inactive.	Informational	The LDAP service became inactive.	Check if an admin disabled the LDAP service.
All LDAP servers are available.	Informational	All LDAP servers are available.	No action is required.
At least one LDAP server is unavailable.	Major	At least one LDAP server is out of service.	• Check if an admin disabled the LDAP server. • Review the syslog file.
All LDAP servers are unavailable.	Informational	All LDAP servers are not available.	• Check if an admin disabled the LDAP server. • Review the syslog file.
Certificate Authentication Service state change			
CAS service is working.	Informational	The certificate authentication service started working again.	No action is required.
CAS service is inactive.	Informational	The certificate authentication service became inactive.	Check if an admin disabled the service.
OCSP responders state change			
All OCSP responders available.	Informational	The OCSP responders are available.	No action is required.
All OCSP responders are out of service.	Informational	The OCSP responders are out of service.	• Check if an admin disabled the service. • Review the syslog file.

OCSP service inactive.	Informational	The OCSP responders service became inactive.	• Check if an admin disabled the service. • Review the syslog file.
Reporting service state change			
Reporting Service is working.	Informational	The Reporting service started working again.	No action is required.
Reporting Service failed.	Informational	The Reporting Service is in Failed state.	Review the syslog file.
Reporting Service is inactive.	Informational	The Reporting service became inactive.	Check if an admin disabled the service.
Reporting Service is in warning state.	Informational	The Reporting service is in warning state.	Review the audit log file.
Threat Analytics state change			
Threat Analytics Service is working.	Informational	The Threat Analytics service started working again.	No action is required.
Threat Analytics Service is inactive.	Informational	The Threat Analytics service became inactive.	Check if an admin disabled the service.
Threat Analytics Service is failed.	Informational	The Threat Analytics service has failed.	Review the audit log file.
Threat Analytics Service is in warning state.	Informational	The Threat Analytics service is in warning state.	Review the audit log file.
RPZ refresh state change			
RPZ refresh is OK.	Informational	An RPZ refresh succeeded. The appliance sends this trap every time an RPZ zone transfer is successful.	No action is required.
Cisco ISE service state change			
Cisco ISE server is OK.	Informational	The Cisco ISE service started working again.	No action is required.
Connection Error has occurred In Cisco ISE server.	Informational	There is a loss of connection between the NIOS appliance and Cisco ISE server.	• Check if an admin disabled the service. • Review the audit log file.
Cloud API service state change			
Cloud API service is working.	Informational	The Cloud API service started working again.	No action is required.

Cloud API service is inactive.	Informational	The Cloud API service became inactive	• Check if an admin disabled the Cloud API service. • Review the audit log file.
Cloud API service has failed.	Critical	The Cloud API service has failed.	• Check if an admin disabled the Cloud API service. • Review the audit log file.
DNS Integrity Check state change			
DNS Integrity Check is working.	Informational	The DNS Integrity Check started working again.	No action is required.
DNS Integrity Check failed.	Informational	The DNS Integrity Check has failed.	• Check if an admin disabled the service. • Review the audit log file.
DNS Integrity Check severity has changed.	Informational	The DNS Integrity Check has changed.	Review the syslog file.
TAXII service state change			
TAXII service is working.	Informational	The TAXII service started working again.	No action is required.
TAXII Service is failed.	Informational	The TAXII service has failed.	• Check if an admin disabled the service. • Review the audit log file.
TAXII service is inactive.	Informational	The TAXII service became inactive.	• Check if an admin disabled the service. • Review the audit log file.
TAXII Service is in warning state.	Informational	The TAXII service is in warning state.	Review the audit log file.
Outbound service state change			

The Outbound Service Manager stopped.	Informational	The Outbound service manager has stopped working.	• Check if an admin disabled the service. • Review the audit log file.
The Outbound Service Manager failed.	Major	The Outbound service manager has failed.	• Check if an admin disabled the service. • Review the audit log file.
The Outbound Service Manager started.	Informational	The Outbound service manager has started.	No action is required.
The Outbound worker failed.	Major	The Outbound worker has failed.	Review the audit log file.
IPMI Device state change			
IPMI is used by some hardware monitors to test hardware health. The IPMI Device has not responded. Hardware monitors may show spurious failures.	Informational	The IPMI Device has not responded.	• Check if an admin disabled the IPMI interface. • Review the audit log file.
IPMI is used by some hardware monitors to test hardware health. Because the IPMI Device has not responded for a while, hardware monitor failures are likely to be spurious.	Informational	The IPMI Device has not responded.	• Check if an admin disabled the IPMI interface. • Review the audit log file.
IPMI is used by some hardware monitors to test hardware health. The IPMI Device is now available; subsequent hardware monitor failures are likely to be genuine.	Informational	The IPMI Device is now available	No action required.

Process Started and Stopped Traps

ibTrapDesc **OID 3.1.1.1.2.11.0**	**ibTrapSeverity**	**Description/Cause**	**Recommended Actions**
Httpd Start			
The process started normally.	Informational	The httpd process started.	No action is required.
Httpd Stop			
The process stopped normally.	Informational	The httpd process stopped.	No action is required.

Process Stop/Start			
The system stopped and started a process.	Major	The system restarted a process.	No action is required.
Zone Transfer Failed			
A zone transfer failure has occurred.	Critical	A zone transfer failed.	Review the syslog file

Revoked License Trap

ibTrapDesc OID 3.1.1.1.2.11.0	ibTrapSeverity	Description/Cause	Recommended Actions
Revoked License			
This trap is generated when a license is revoked	Critical	A license was revoked.	Obtain and install new license

ibPlatformOne MIB

The ibPlatformOne MIB provides information about the CPU temperature of the appliance, the replication status, the average latency of DNS requests, DNS security alerts, CPU and memory utilization of the appliance, and the Infoblox service status. The figure below illustrates the structure of the PlatformOne MIB. (Note that the OIDs in the illustration do not include the prefix .1.3.6.1.4.1.7779.)
The ibPlatformOne MIB contains the following objects:

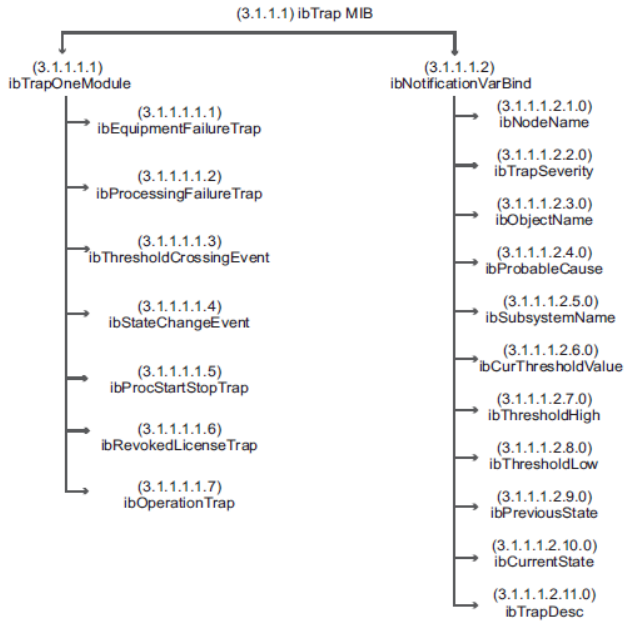
- ibCPUTemperature (IbString) tracks the CPU temperature of the appliance.
- ibClusterReplicationStatusTable provides information in tabular format about the replication status of the appliance.
- ibNetworkMonitor provides information about the average latency of authoritative and nonauthoritative replies to DNS queries for different time intervals. It also provides information about invalid DNS responses that arrive on invalid ports or have invalid DNS transaction IDs.
- ibHardwareType (IbString) provides information about the hardware platform. For an Infoblox appliance, it provides the model number of the Infoblox hardware platform. For vNIOS appliances, it identifies if the hardware platform is VMware.
- ibHardwareId (IbString) provides the hardware ID of the NIOS appliance.
- ibSerialNumber (IbString) provides the serial number of the Infoblox hardware platform.
- ibNiosVersion (IbString) provides the version of the NIOS software.
- ibSystemMonitor provides information about the CPU and memory utilization of the appliance.
- ibGridStatus provides information about an appliance. It indicates whether the appliance is a Grid Master, member, or an independent appliance.
- ibHAStatus provides information about the HA status of a member. It indicates if the member is part of an HA configuration, and if it is the active or passive node.
- ibGridMasterCandStatus indicates if a member is a Grid Master candidate.
- ibGridMasterVIP provides the Grid Master virtual IP address.
- ibGridReplicationState provides information about the replication status.

The ibPlatformOne MIB also contains the following tables that provide status of the Infoblox services as well as system and hardware services on the appliance you query:

- ibMemberServiceStatusTable provides status of the Infoblox services, such as the DNS and DHCP services, on a queried appliance.
- ibMemberNodeServiceStatusTable provides status of the system and hardware services on a queried appliance.

- ibMemberPassiveNodeServiceStatusTable provides status of the system and hardware services on the passive node of an HA pair if the queried appliance is the VIP or the active node of an HA pair. For independent appliances and the passive nodes of HA pairs, this table does not display any status.

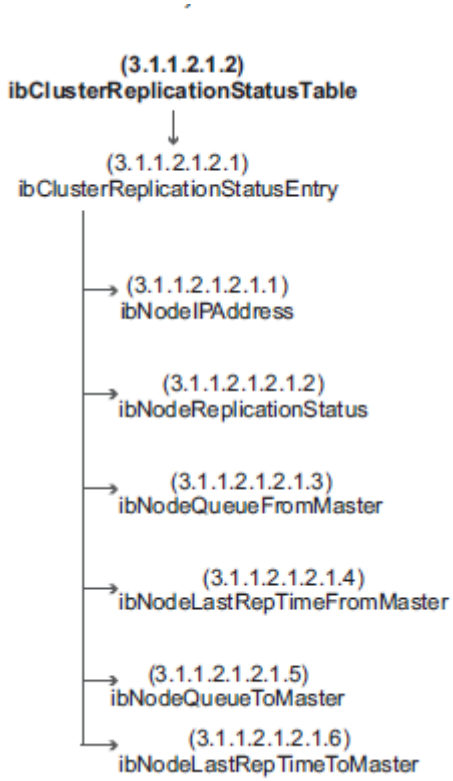
ibPlatformOne MIB Structure



ibClusterReplicationStatusTable

ibClusterRepliactionStatusTable (object ID 3.1.1.2.1.2.1) provides information about the Grid replication status. The following figure shows the sub branches of ibClusterReplicationStatusTable:

ibClusterReplicationStatusTable Objects



The following table provides information about the ibClusterReplicationStatusTable objects:

ibClusterReplicationStatusTableObjects

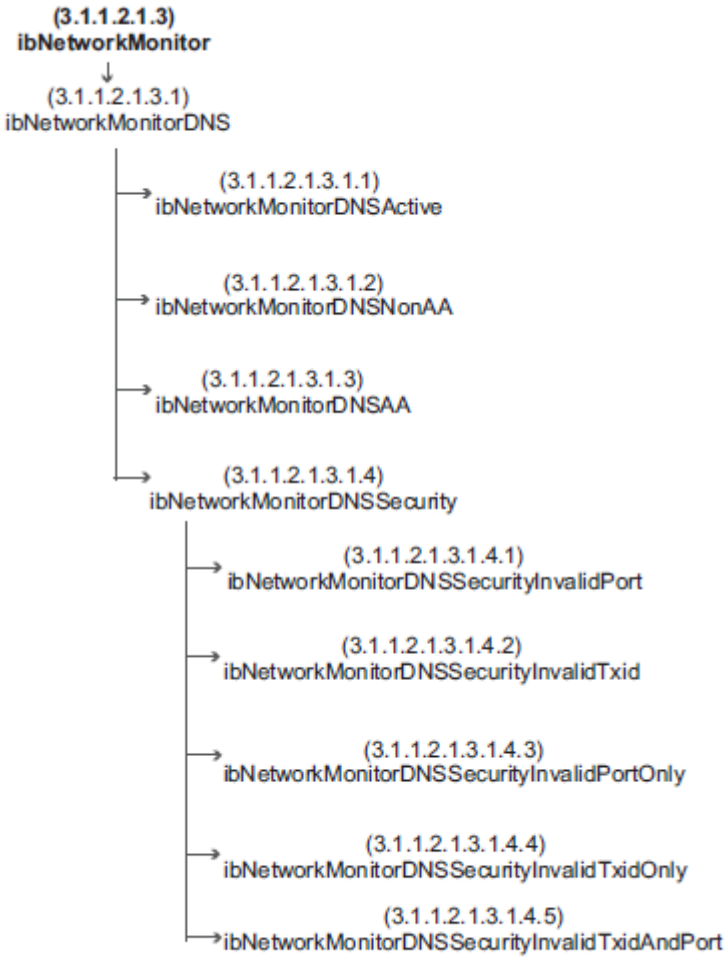
Object (Type)	Description
ibClusterReplicationStatusEntry	A conceptual row that provides information about the Grid replication status. The status indicates whether the appliance is sending replication queues, receiving queues, or having problems with the replication.
ibNodeIPAddress (IbIpAddr)	IP address of a Grid member.
ibNodeReplicationStatus (IbString)	Replication status of the Grid member. The replication status can be one of the following: online, offline, or snapshotting.
ibNodeQueueFromMaster (Integer)	“Sent” queue size from master.
ibNodeLastRepTimeFromMaster (IbString)	Last sent time from master.
ibNodeQueueToMaster (Integer)	“Receive” queue size from master.
ibNodeLastRepTimeToMaster (IbString)	Last receive time from master.

ibNetwork Monitor

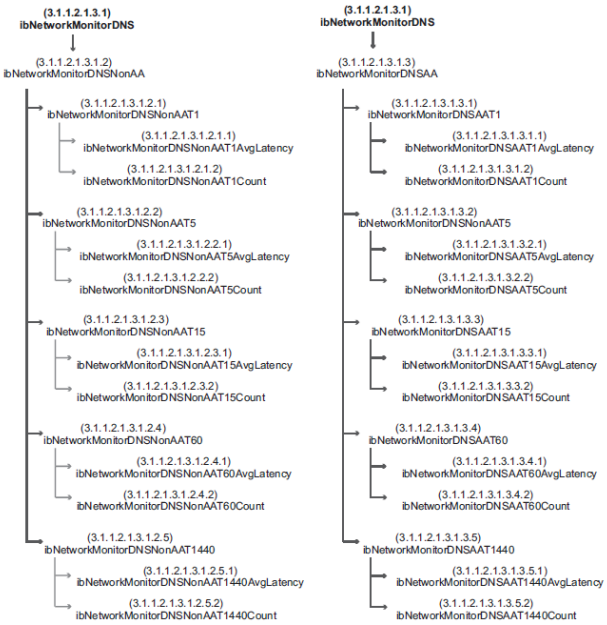
As shown in the following ibNetWorkMonitorObjects figure, the ibNetwork Monitor has one subtree, ibNetworkMonitorDNS, that branches out into the following:

- ibNetworkMonitorDNSActive (Integer) reports on whether DNS latency monitoring is enabled. You can enable DNS latency monitoring using the CLI command set monitor dns. For more information about enabling and disabling DNS alert monitoring, see *Monitoring Tools*. This is the only object in this branch. When you send a query for this object, the appliance responds with either "active" (1) or "nonactive" (0).
- ibNetworkMonitorDNSNonAA provides information about the average latency of nonauthoritative replies to DNS queries for 1-, 5-, 15-, and 60-minute intervals.
- ibNetworkMonitorDNSAA provides information about the average latency of authoritative replies to DNS queries for 1-, 5-, 15-, and 60-minute intervals.
- ibNetworkMonitorDNSSecurity provides information about the invalid DNS responses that arrive on invalid ports or have invalid DNS transaction IDs. ibNetworkMonitorDNSSecurity branches out into the following:
    - ibNetworkMonitorDNSSecurityInvalidPort
    - ibNetworkMonitorDNSSecurityInvalidTxid
    - ibNetworkMonitorDNSSecurityInvalidPortOnly (Counter)
    - ibNetworkMonitorDNSSecurityInvalidPortCount (Counter)
    - ibNetworkMonitorDNSSecurityInvalidTxidOnly (Counter)
    - ibNetworkMonitorDNSSecurityInvalidTxidCount (Counter)
    - ibNetworkMonitorDNSSecurityInvalidTxidAndPort (Counter)

ibNetWorkMonitorObjects



ibNetworkMonitorDNSNonAAandibNetworkMonitorDNSAASubtrees



The table below describes the objects in ibNetworkMonitorDNSNonAA. You can send queries to retrieve values for these objects.

ibNetworkMonitorDNSNonAA Objects

Object (Type)	Description
ibNetworkMonitorDNSNonAAT1	File that contains the objects for monitoring the average latency of nonauthoritative replies to queries in the last minute.
ibNetworkMonitorDNSNonAAT1AvgLatency (Integer)	Indicates the average latency in microseconds of nonauthoritative replies to queries in the last minute.
ibNetworkMonitorDNSNonAAT1Count (Integer)	Indicates the number of queries used to calculate the average latency of nonauthoritative replies in the last minute.
ibNetworkMonitorDNSNonAAT5	File that contains the objects for monitoring the average latency of nonauthoritative replies to queries in the last five minutes.
ibNetworkMonitorDNSNonAAT5AvgLatency (Integer)	Indicates the average latency in microseconds of nonauthoritative replies to queries in the last five minutes.
ibNetworkMonitorDNSNonAAT5Count (Integer)	Indicates the number of queries used to calculate the average latency of nonauthoritative replies in the last five minutes.
ibNetworkMonitorDNSNonAAT15	File that contains the objects for monitoring the average latency of nonauthoritative replies to queries in the last 15 minutes.
ibNetworkMonitorDNSNonAAT15AvgLatency (Integer)	Indicates the average latency in microseconds of nonauthoritative replies to queries in the last 15 minutes.

ibNetworkMonitorDNSNonAAT15Count (Integer)	Indicates the number of queries used to calculate the average latency of nonauthoritative replies in the last 15 minutes.
ibNetworkMonitorDNSNonAAT60	File that contains the objects for monitoring the average latency of nonauthoritative replies to queries in the last 60 minutes.
ibNetworkMonitorDNSNonAAT60AvgLatency (Integer)	Indicates the average latency in microseconds of nonauthoritative replies to queries in the last 60 minutes.
ibNetworkMonitorDNSNonAAT60Count (Integer)	Indicates the number of queries used to calculate the average latency of nonauthoritative replies in the last 60 minutes.
ibNetworkMonitorDNSNonAAT1440	File that contains the objects for monitoring the average latency of nonauthoritative replies to queries in the last 24 hours.
ibNetworkMonitorDNSNonAAT1440AvgLatency (Integer)	Indicates the average latency in microseconds of nonauthoritative replies to queries in the last 24 hours.
ibNetworkMonitorDNSNonAAT1440Count (Integer)	Indicates the number of queries used to calculate the average latency of nonauthoritative replies in the last 24 hours.

The table below describes the objects in ibNetworkMonitorDNSAA. You can send queries to retrieve values for these objects.

ibNetworkMonitorDNSAA Objects

Object (Type)	**Description**
ibNetworkMonitorDNSAAT1	File that contains the objects for monitoring the average latency of authoritative replies to queries in the last minute.
ibNetworkMonitorDNSAAT1AvgLatency (Integer)	Indicates the average latency in microseconds of authoritative replies to queries in the last minute.
ibNetworkMonitorDNSAAT1Count (Integer)	Indicates the number of queries used to calculate the average latency of authoritative replies in the last minute.
ibNetworkMonitorDNSAAT5	File that contains the objects for monitoring the average latency of authoritative replies to queries in the last five minutes.
ibNetworkMonitorDNSAAT5AvgLatency (Integer)	Indicates the average latency in microseconds of authoritative replies to queries in the last five minutes.
ibNetworkMonitorDNSAAT5Count (Integer)	Indicates the number of queries used to calculate the average latency of authoritative replies in the last five minutes.
ibNetworkMonitorDNSAAT15	File that contains the objects for monitoring the average latency of authoritative replies to queries in the last 15 minutes.
ibNetworkMonitorDNSAAT15AvgLatency (Integer)	Indicates the average latency in microseconds of authoritative replies to queries in the last 15 minutes.

ibNetworkMonitorDNSAAT15Count (Integer)	Indicates the number of queries used to calculate the average latency of authoritative replies in the last 15 minutes.
ibNetworkMonitorDNSAAT60	File that contains the objects for monitoring the average latency of authoritative replies to queries in the last 60 minutes.
ibNetworkMonitorDNSAAT60AvgLatency (Integer)	Indicates the average latency in microseconds of authoritative replies to queries in the last 60 minutes.
ibNetworkMonitorDNSAAT60Count (Integer)	Indicates the number of queries used to calculate the average latency of authoritative replies in the last 60 minutes.
ibNetworkMonitorDNSAAT1440	File that contains the objects for monitoring the average latency of authoritative replies to queries in the last 24 hours.
ibNetworkMonitorDNSAAT1440AvgLatency (Integer)	Indicates the average latency in microseconds of authoritative replies to queries in the last 24 hours.
ibNetworkMonitorDNSAAT1440Count (Integer)	Indicates the number of queries used to calculate the average latency of authoritative replies in the last 24 hours.

The below table describes the objects in ibNetworkMonitorDNSSecurity. When you enable the following, the SNMP traps with these objects are received:

- SNMP traps
- DNS network monitoring
- DNS alert monitoring

ibNetworkMonitorDNSSecurityObjects

Object (Type)	Description
ibNetworkMonitorDNSSecurityInvalidPort	Tracks the number of invalid DNS responses that arrive on invalid ports. For information about invalid ports, monitoring DNS transactions, see *Monitoring Tools*. This object contains a subtree with six objects that track invalid ports within a certain time interval.
ibNetworkMonitorDNSSecurityInvalidTxid	Tracks the number of invalid TXIDs (DNS transaction IDs). For information about invalid TXIDs, monitoring DNS transactions, see *Monitoring Tools*. This object contains a subtree with six objects that track invalid TXIDs within a certain time interval.
ibNetworkMonitorDNSSecurityInvalidPortOnly (Counter)	Tracks the number of DNS responses with both of the following conditions: • Arrive on invalid ports • Have valid TXIDs
ibNetworkMonitorDNSSecurityInvalidTxidOnly (Counter)	Tracks the number of DNS responses with both of the following conditions: • Arrive on valid ports • Have Invalid TXIDs
ibNetworkMonitorDNSSecurityInvalidPortCount (Counter)	Tracks the total number of invalid DNS responses that arrive on invalid ports.

ibNetworkMonitorDNSSecurityInvalidTxidCount (Counter)	Tracks the total number of DNS responses that have invalid DNS transaction IDs.
ibNetworkMonitorDNSSecurityInvalidTxidAndPort (Counter)	Tracks the number of DNS responses with both of the following conditions: • Arrive on invalid ports • Have invalid TXIDs

The following table describes the objects in ibNetworkMonitorDNSSecurityInvalidPort:

ibNetworkMonitorDNSSecurityInvalidPort Objects

Object (Type)	Description
ibNetworkMonitorDNSSecurityInvalidPort1 (Integer)	Tracks the number of invalid DNS responses that arrive on invalid ports in the last one minute.
ibNetworkMonitorDNSSecurityInvalidPort5 (Integer)	Tracks the number of invalid DNS responses that arrive on invalid ports in the last five minutes.
ibNetworkMonitorDNSSecurityInvalidPort15 (Integer)	Tracks the number of invalid DNS responses that arrive on invalid ports in the last 15 minutes.
ibNetworkMonitorDNSSecurityInvalidPort60 (Integer)	Tracks the number of invalid DNS responses that arrive on invalid ports in the last 60 minutes.
ibNetworkMonitorDNSSecurityInvalidPort1440 (Integer)	Tracks the number of invalid DNS responses that arrive on invalid ports in the last 24 hours.
ibNetworkMonitorDNSSecurityInvalidPortCount (Counter)	Tracks the total number of invalid DNS responses that arrive on invalid ports.

The following table below describes the objects in ibNetworkMonitorDNSSecurityInvalidTxid:

ibNetworkMonitorDNSSecurityInvalidTxid Objects

Object (Type)	Description
ibNetworkMonitorDNSSecurityInvalidTxid1 (Integer)	Tracks the number of DNS responses that have invalid DNS transaction IDs in the last one minute.
ibNetworkMonitorDNSSecurityInvalidTxid5 (Integer)	Tracks the number of DNS responses that have invalid DNS transaction IDs in the last five minutes.
ibNetworkMonitorDNSSecurityInvalidTxid15 (Integer)	Tracks the number of DNS responses that have invalid DNS transaction IDs in the last 15 minutes.

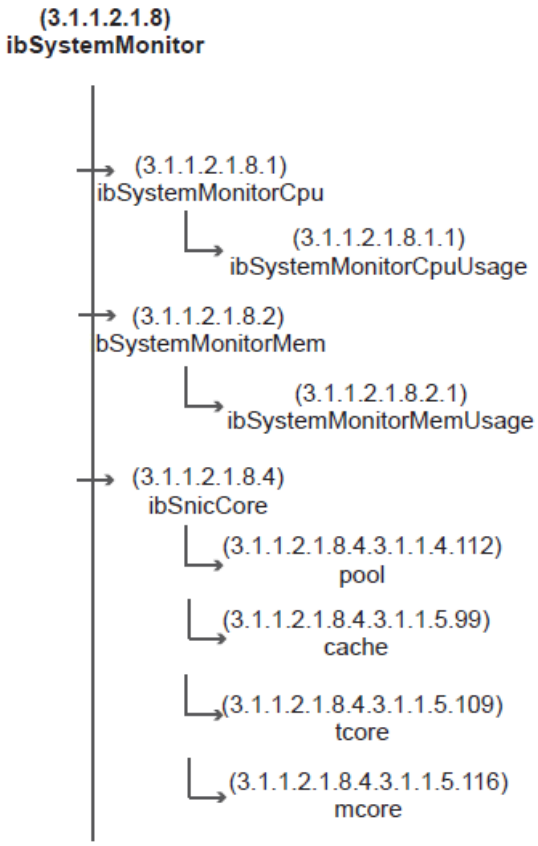
ibNetworkMonitorDNSSecurityInvalidTxid60 (Integer)	Tracks the number of DNS responses that have invalid DNS transaction IDs in the last 60 minutes.
ibNetworkMonitorDNSSecurityInvalidTxid1440 (Integer)	Tracks the number of DNS responses that have invalid DNS transaction IDs in the last 24 hours.
ibNetworkMonitorDNSSecurityInvalidTxidCount (Counter)	Tracks the total number of DNS responses that have invalid DNS transaction IDs.

ibSystemMonitor

As shown in the figure below, ibSystemMonitor (object ID 3.1.1.2.1.2.8) has the following subtrees:

- ibSystemMonitorCpu: Contains ibSystemMonitorCpuUsage (Integer) that reports the CPU usage of the appliance.
- ibSystemMonitorMem: Contains ibSystemMonitorMemUsage (Integer) that reports the memory usage of the appliance.
- ibSystemMonitorSwap: Contains ibSystemMonitorSwapUsage (integer) that reports the swap usage of the appliance.
- ibSystemMonitorSnic: Contains ibSystemMonitorSnicStatsTable1 (integer) and ibSystemMonitorSnicStatsTable5 (integer) that contains the smart NIC (SNIC) details. The OID 3.1.1.2.1.8.4.3.1.1.4.112.111.111.108 indicates that the member is a pool, 3.1.1.2.1.8.4.3.1.1.5.99.97.99.104.101 indicates that the member is a cache, 3.1.1.2.1.8.4.3.1.1.5.116.99.111.114.101 indicates that the cache is tcore, and 3.1.1.2.1.8.4.3.1.1.5.109.99.111.114.101 indicates that the cache is mcore.

ibSystemMonitor Objects3



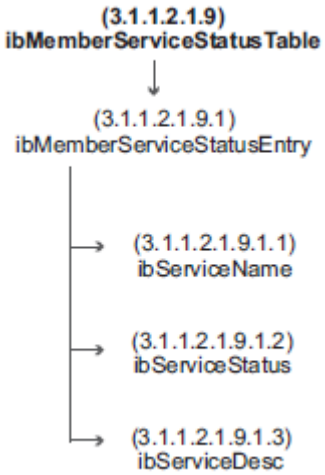
ibMemberServiceStatusTable

As shown in the figure below, ibMemberServiceStatusTable (object ID 3.1.1.2.1.2.9) has one subtree, ibMemberServiceStatusEntry, which contains the following objects:

- ibServiceName (String) reports the names of the Infoblox services.
- ibServiceStatus (Integer) reports the status of the Infoblox services.
- ibServiceDesc (String) describes the details of the status.

ibMemberServiceStatusTable displays the current status of the Infoblox services on the appliance that you query. For an HA pair, this table displays the service status of the active node. If the appliance you query is the passive node of an HA pair, this table reflects the service status of the passive node, which can be "inactive" or "unknown."
You can also query ibMemberNodeServiceStatusTable and ibMemberPassiveNodeServiceStatusTable that display system and hardware status on the queried appliance.

ibMemberServiceStatusTable Objects



Infoblox Services for ibMemberServiceStatusTable

The following table lists the values and descriptions of the Infoblox services that appear in ibMemberServiceStatusTable:

ibServiceName Values for ibMemberServiceStatusTable

Value	Description	Definition
1	dhcp	DHCP service
2	dns	DNS service
3	ntp	NTP service
4	tftp	File distribution using the TFTP service
5	http-file-dist	File distribution using the HTTP service
6	ftp	File distribution using the FTP service
7	bloxtools-move	Moving the bloxTools service
8	bloxtools	The bloxTools environment

Service Status

When you query the service status on an appliance, the response includes the status of the services. The below table shows the values and descriptions of the status. Note that for internal Grid operations, the NTP service is always in the "working" state even if it has been disabled through the Infoblox GUI.

ibServiceStates Values

Value	Description	Definition
1	working	The service is functioning properly.
2	warning	The service is having some issues. Check the service or hardware function and the syslog to identify the problem.
3	failed	The service failed. Review the syslog to identify the problem.
4	inactive	The service is disabled or out of service.
5	unknown	The appliance cannot detect the current stusof the service.

ibMemberNodeServiceStatusTable

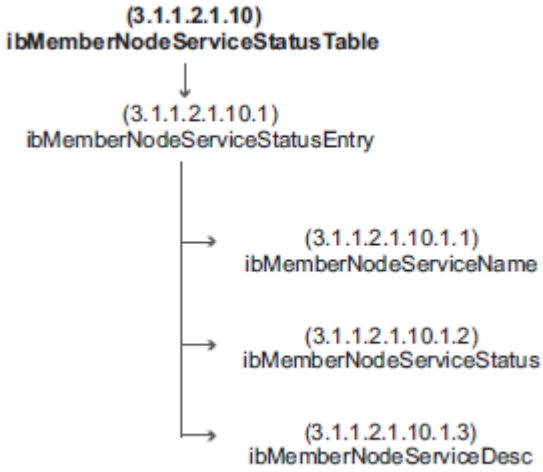
As shown in the below figure, ibMemberNodeServiceStatusTable (object ID 3.1.1.2.1.10) has one subtree, ibMemberNodeServiceStatusEntry, which contains the following objects:

- ibMemberNodeServiceName (String) reports the names of the system and hardware services.
- ibMemberNodeServiceStatus (Integer) reports the status of the services.
- ibMemberNodeServiceDesc (String) describes the details of the status.

ibMemberNodeServiceStatusTable displays the current status of the system and hardware services on the appliance that you query. For example, when you query an independent appliance, this table shows the information about the independent appliance. When you query the VIP of an HA pair, this table shows the information about the active node. For the active node of the HA pair, you can also query ibMemberPassiveNodeStatusTable to get the status of the passive node.

> ⚠ Note
> For an independent appliance and the passive node of an HA pair, no information is returned when you query ibMemberPassiveNodeServiceStatusTable.

ibMemberNodeServiceStatusTable Objects



Infoblox Services for ibMemberNodeServiceStatusTable

The following table lists the values and descriptions of the Infoblox services that appear in ibMemberNodeServiceStatusTable:

ibServiceName Values for ibMemberNodeServiceStatusTable

Value	Description	Definition
9	node-status	Member status
10	disk-usage	Disk usage
11	enet-lan	LAN port
12	enet-lan2	LAN2 port
13	enet-ha	HA port
14	enet-mgmt	MGMT port
15	lcd	LCD
16	memory	Memory
17	replication	Replication service
18	db-object	Database capacity in %

19	raid-summary	RAID array
20	raid-disk1	RAID Disk 1 (For appliances with RAID arrays)

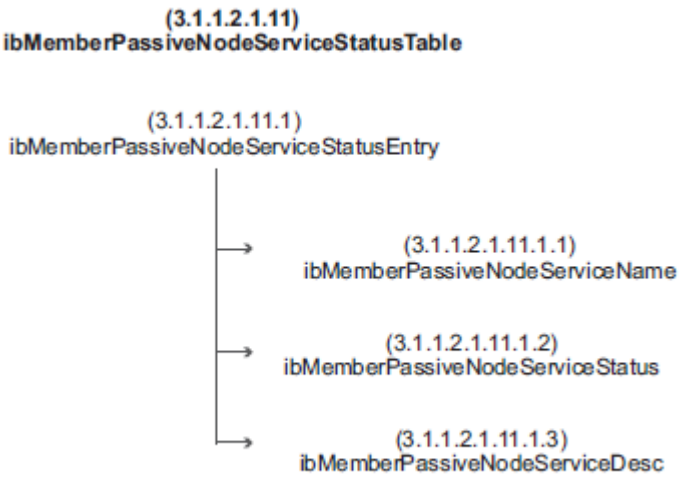
ibMemberPassiveNodeServiceStatusTable

As shown in the below figure, ibMemberPassiveNodeServiceStatusTable (object ID 3.1.1.2.1.2.11) has one subtree, ibMemberPassiveNodeServiceStatusEntry, which contains the following objects:

- ibMemberPassiveNodeServiceName (String) reports the names of the system and hardware services.
- ibMemberPassiveNodeServiceStatus (Integer) reports the status of the services.
- ibMemberPassiveNodeServiceDesc (String) describes details of the status.

ibMemberPassiveNodeServiceStatusTable displays the current status of the system and hardware services on the passive node of an HA pair when you query the VIP of the HA pair. For independent appliances and the passive nodes of HA pairs, this table does not display any status.

ibMemberPassiveNodeServiceStatusTable Objects



ibDHCPOne MIB

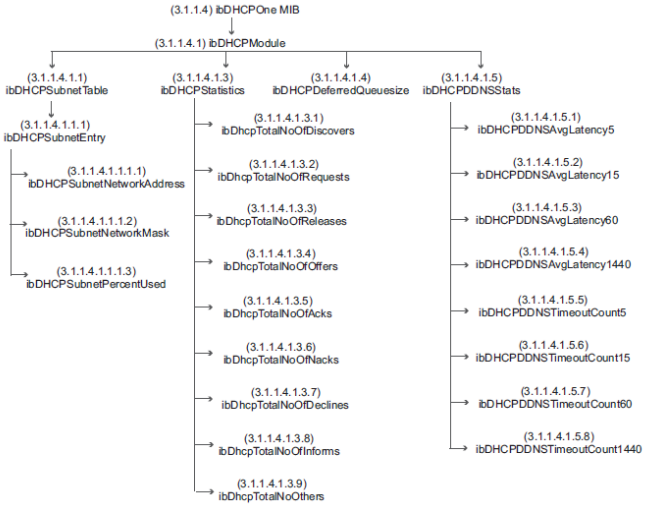
The ibDHCPOne MIB provides information about address usage within a subnet, DHCP lease statistics, and DHCP packet counts. It includes two modules, ibDHCPModule for IPv4 data and ibDHCPv6Module for IPv6 data.

ibDHCPModule

The below figure illustrates the structure of the ibDHCPModule. (Note that the OIDs shown in the illustration do not include the prefix .1.3.6.1.4.1.7779.) ibDHCPModule contains the following objects:

- ibDHCPSubnetTable provides statistical data about the DHCP operations of the appliance.
- ibDHCPStatistics maintains counters for different types of packets.
- ibDHCPDeferredQueuesize tracks the total number of deferred DDNS updates that are currently in the queue to be retried. When DDNS updates are deferred due to timeout or server issues, the DHCP server puts these updates in this queue.
- ibDHCPDDNSStats monitors the average latency for the DDNS updates in microseconds and the number of timeouts during different time intervals.

ibDHCPModule



ibDHCPSubnetTable provides statistical data about the DHCP operations of the appliance. It contains the following objects:

ibDHCPSubnetTable

Object (Type)	Description
ibDHCPSubnet Entry	File that contains the objects for monitoring DHCP operations on the appliance.
ibDHCPSubnetNetworkAddress (IbIpAddr)	The subnetworks, in IP address format, that have IP addresses for lease. A subnetwork may have many address ranges for lease.
ibDHCPSubnetNetworkMask (IbIpAddr)	The subnet mask in dotted decimal format.
ibDHCPSubnetPercentUsed (Integer)	The percentage of dynamic DHCP addresses leased out at this time for each subnet. The percentage of dynamic DHCP addresses that are leased out are calculated as the [Total number of active leases in the range + Fixed addresses (leased or unused) + DHCP reservation addresses + Host addresses with DHCP enabled inside the specified subnet]/[Total number of IP address available in the range + Number of Fixed address inside the subnet + Number of IPv4 reservation addresses + Host addresses] For example: Network: 10.192.16.0/24 Range: 10.192.16.10 – 10.192.16.20 (11 free IP addresses) Fixed addresses: 10.192.16.3 (outside DHCP range) and 10.192.16.11 (within DHCP range) There are 10 free IP addresses in the DHCP Range: 10.192.16.10 – 10.192.16.20 and one fixed address within the DHCP range IPv4 DHCP Utilization in Infoblox GUI: 16.6% (2/12) -> For this case, (1 fixed address outside range + 1 fixed address within range) / (fixed address outside DHCP range + number of IP addresses in the DHCP range which includes the fixed address within range)] * 100 = (2/12)*100 -> 17% SNMP output from the CLI of the server: Infoblox > show snmp variable .1.3.6.1.4.1.7779.3.1.1.4.1.1.1.3.11.49.48.46.49.57.50.46.49.54.46.48 IB-DHCPONE-MIB::ibDHCPSubnetPercentUsed."10.192.16.0" = INTEGER: 17

Following is an example of the table as viewed through a MIB browser:

MIBBrowserView1

	ibDHCPSubnetNetworkAddress	ibDHCPSubnetNetworkMask	ibDHCPSubnetPercentUsed
1	10.0.0.0	255.0.0.0	0.0000
2	20.0.0.0	255.255.255.0	0.0000
3	20.0.1.0	255.255.255.0	0.0000
4	20.0.2.0	255.255.255.0	0.0000
5	20.0.3.0	255.255.255.0	0.0000
6	20.0.4.0	255.255.255.0	0.0000
7	20.0.5.0	255.255.255.0	0.0000
8	20.0.6.0	255.255.255.0	0.0000
9	20.0.7.0	255.255.255.0	0.0000
10	20.0.8.0	255.255.255.0	0.0000

ibDHCPStatistics

ibDHCPStatistics maintains counters for different types of packets. The counters always start with zero when the DHCP service is restarted. Therefore, the numbers reflect the total number of packets received since the DHCP service was last restarted on the appliance. The ibDHCPStatistics module contains the following objects:

ibDHCPStatistics

Object (Type)	Description
ibDhcpTotalNoOfDiscovers (Counter)	The number of DHCPDISCOVER messages that the appliance received. Clients broadcast DHCPDISCOVER messages when they need an IP address and network configuration information.
ibDhcpTotalNoOfRequests (Counter)	The number of DHCPREQUEST messages that the appliance received. A client sends a DHCPREQUEST message requesting configuration information, after it receives the DHCPOFFER message.
ibDhcpTotalNoOfReleases (Counter)	The number of DHCPRELEASE messages that the appliance received from its clients. A client sends a DHCP release when it terminates its lease on an IP address.
ibDhcpTotalNoOfOffers (Counter)	The number of DHCPOFFER messages that the appliance has sent to clients. The appliance sends a DHCPOFFER message to a client. It contains an IP address and configuration information.
ibDhcpTotalNoOfAcks (Counter)	The number of DHCPACK messages that the appliance sent to clients. It sends a DHCPACK message to a client to confirm that the IP address offered is still available.
ibDhcpTotalNoOfNacks (Counter)	The number of DHCPNACK messages that the appliance sent to clients. It sends a DHCPNACK message to withdraw its offer of an IP address.
ibDhcpTotalNoOfDeclines (Counter)	The number of DHCPDECLINE messages that the appliance received. A client sends a DHCPDECLINE message if it determines that an offered IP address is already in use.
ibDhcpTotalNoOfInforms (Counter)	The number of DHCPINFORM messages that the appliance received. A client sends a DHCPINFORM message when it has an IP address but needs information about the network.
ibDhcpTotalNoOfOthers (Counter)	The total number of DHCP messages other than those used in negotiation, such as DHCPFORCERENEW, DHCPKNOWN, and DHCPLEASEQUERY.

ibDHCPDDNSStats

ibDHCPDDNSStats monitors the average latency for the DHCP DDNS updates in microseconds and the number of timeouts during different time intervals. The ibDHCPDDNSStats module contains the following objects:

ibDHCPStatistics

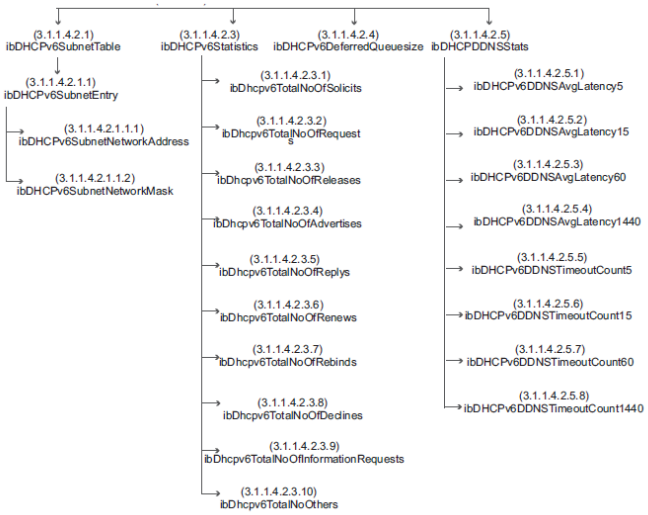
Object (Type)	Description
ibDHCPDDNSAvgLatency5 (Integer)	Indicates the average latency in microseconds of the DHCP DDNS updates in the last five minutes.
ibDHCPDDNSAvgLatency15 (Integer)	Indicates the average latency in microseconds of the DHCP DDNS updates in the last 15 minutes.
ibDHCPDDNSAvgLatency60 (Integer)	Indicates the average latency in microseconds of the DHCP DDNS updates in the last 60 minutes.
ibDHCPDDNSAvgLatency1440 (Integer)	Indicates the average latency in microseconds of the DHCP DDNS updates in the last 24 hours.
ibDHCPDDNSTimeoutCount5 (Integer)	The number of timeouts for the DHCP DDNS updates in the last five minutes.
ibDHCPDDNSTimeoutCount15 (Integer)	The number of timeouts for the DHCP DDNS updates in the last 15 minutes.
ibDHCPDDNSTimeoutCount60 (Integer)	The number of timeouts for the DHCP DDNS updates in the last 60 minutes.
ibDHCPDDNSTimeoutCount1440 (Integer)	The number of timeouts for the DHCP DDNS updates in the last 24 hours.

ibDHCPv6Module

The figure below illustrates the structure of the ibDHCPv6Module, which contains the following objects:

- ibDHCPv6SubnetTable provides statistical data about the DHCPv6 operations of the appliance.
- ibDHCPv6Statistics maintains counters for different types of packets.
- ibDHCPv6DeferredQueuesize tracks the total number of deferred DDNS updates that are currently in the queue to be retried. When DDNS updates are deferred due to timeout or server issues, the DHCP server puts these updates in this queue.
- ibDHCPv6DDNSStats monitors the average latency for the DDNS updates in microseconds and the number of timeouts during different time intervals.

ibDHCPv6Module



ibDHCPv6SubnetTable

ibDHCPSubnetTable provides statistical data about the DHCPv6 operations of the appliance. It contains the following objects:

ibDHCPSubnetTable

Object (Type)	Description
ibDHCPv6Subnet Entry	File that contains the objects for monitoring DHCPv6 operations on the appliance.
ibDHCPv6SubnetNetworkAddress (IbIpAddr)	The subnetworks, in IPv6 address format, that have IPv6 addresses for lease. A subnetwork may have many address ranges for lease.
ibDHCPv6SubnetNetworkMask (IbIpAddr)	The subnet mask in CIDR notation format.

ibDHCPv6Statistics

ibDHCPv6Statistics maintains counters for different types of packets. The counters always start with zero when the DHCP service is restarted. Therefore, the numbers reflect the total number of packets received since the DHCP service was last restarted on the appliance. The ibDHCPv6Statistics module contains the following objects:

ibDHCPv6Statistics

Object (Type)	Description
ibDhcpv6TotalNoOfSolicits (Counter)	The number of Solicit messages that the Grid member received, including Solicit messages embedded in Relay-Forward messages. A DHCP client sends a Solicit message to locate DHCP servers.

ibDhcpv6TotalNoOfRequests (Counter)	The number of Request messages that the Grid member received. A DHCP client sends a Request message to request one or more IP addresses and configuration parameters from a DHCP server.
ibDhcpv6TotalNoOfReleases (Counter)	The number of Release messages that the Grid member received. A DHCP client sends a Release message when it terminates its lease and releases its IP address.
ibDhcpv6TotalNoOfAdvertises (Counter)	The number of Advertise messages that the Grid member sent. When a DHCP server receives a Solicit message, it can respond with an Advertise message to indicate that the server is available for DHCP service.
ibDhcpv6TotalNoOfReplies (Counter)	The number of Reply messages that the Grid member sent. A DHCP server sends a Reply message that includes IP addresses and configuration parameters when it responds to Solicit, Request, Renew or Rebind message. It sends a Reply message with configuration parameters only when it responds to an Information-Request message.
ibDhcpv6TotalNoOfRenews (Counter)	The number of Renew messages that the Grid member received. A DHCP client sends a Renew message to a DHCP server to extend the lifetimes on the leases granted by the DHCP server and to update other properties.
ibDhcpv6TotalNoOfRebinds (Counter)	The number of Rebind messages that the Grid member received. A DHCP client sends a Rebind message to extend the lifetime of its lease and to update configuration parameters.
ibDhcpv6TotalNoOfDeclines (Counter)	The number of Decline messages that the Grid member received. A DHCP client sends a Decline message to a DHCP server when it discovers that the IP address offered by a DHCP server is already in use.
ibDhcpv6TotalNoOfInformationRequests (Counter)	The number of Information-Request messages that the Grid member received. A client sends an Information-Request message to retrieve configuration parameters, such as the IP addresses of DNS servers inthe network.
ibDhcpv6TotalNoOfOthers (Counter)	The total number of DHCP messages other than those used in negotiation.

ibDHCPv6DDNSStats

ibDHCPv6DDNSStats monitors the average latency for the DHCPv6 DDNS updates in microseconds and the number of timeouts during different time intervals. The ibDHCPv6DDNSStats module contains the following objects:
ibDHCPStatistics

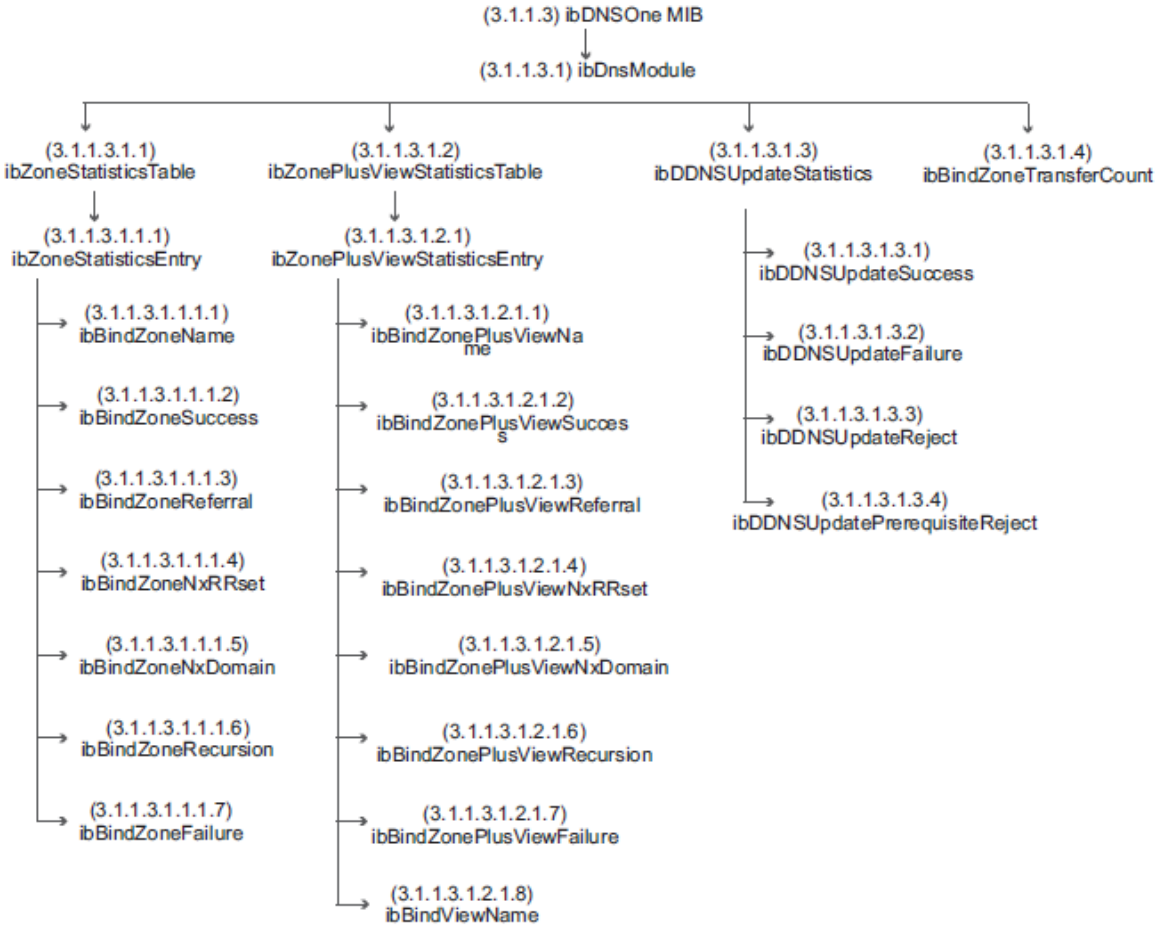
Object (Type)	Description
ibDHCPv6DDNSAvgLatency5 (Integer)	Indicates the average latency in microseconds of the DHCPv6 DDNS updates in the last five minutes.
ibDHCPv6DDNSAvgLatency15 (Integer)	Indicates the average latency in microseconds of the DHCPv6 DDNS updates in the last 15 minutes.
ibDHCPv6DDNSAvgLatency60 (Integer)	Indicates the average latency in microseconds of the DHCPv6 DDNS updates in the last 60 minutes.

ibDHCPv6DDNSAvgLatency1440 (Integer)	Indicates the average latency in microseconds of the DHCPv6 DDNS updates in the last 24 hours.
ibDHCPv6DDNSTimeoutCount5 (Integer)	The number of timeouts for the DHCPv6 DDNS updates in the last five minutes.
ibDHCPv6DDNSTimeoutCount15 (Integer)	The number of timeouts for the DHCPv6 DDNS updates in the last 15 minutes.
ibDHCPv6DDNSTimeoutCount60 (Integer)	The number of timeouts for the DHCPv6 DDNS updates in the last 60 minutes.
ibDHCPv6DDNSTimeoutCount1440 (Integer)	The number of timeouts for the DHCPv6 DDNS updates in the last 24 hours.

ibDNSOne MIB

The ibDNSOne MIB provides DNS statistics about all zones in all views. The figure below illustrates the structure of the ibDNSOne MIB. (Note that the OIDs shown in the illustration do not include the prefix 1.3.6.1.4.1.7779.) The ibDNSOne MIB contains four subtrees: ibZoneStatisticsTable (Counter64), ibZonePlusViewStatisticsTable (Counter64), ibDDNSUpdateStatistics (Counter64), and ibBindZoneTransferCount (Counter64).

ibDNSOne MIB



Using the DNS Zone Statistics Tables

ibZoneStatistcisTable and ibZonePlusViewStatisticsTable provide DNS statistics for all zones in all DNS views, including the default and all user-defined DNS views. You can use the information in these tables to calculate the total number of recursive queries on the DNS server. Depending on whether your DNS server is an authoritative or a caching-only server, you calculate the total number of recursive queries differently.

ibZoneStatisticsTable

ibZoneStatisticsTable contains DNS statistics of all zones in the default DNS view. DNS statistics of user-defined DNS views are captured in ibZonePlusViewStatisticsTable.
ibZoneStatisticsTable includes a "summary" zone that provides global statistics for the DNS server, including statistics for all zones in the default and user-defined DNS views.
The syntax of the objects in ibZoneStatisticsTable uses a Counter64 format. In some cases, the counter format may not be compatible with SNMP toolkits that use a 32-bit counter. Ensure that you reconfigure or update these tools to use the Counter64 format. ibZoneStatisticsTable contains the following objects:

ibZoneStatisticsTable

Object (Type)	Description
ibBindZoneName (IbString)	DNS zone name. The index name for global statistics is “summary.”
ibBindZoneSuccess (Counter64)	The number of successful responses since the DNS process started.
ibBindZoneReferral (Counter64)	The number of DNS referrals since the DNS process started.
ibBindZoneNxRRset (Counter64)	The number of DNS queries received for non-existent records.
ibBindZoneNxDomain (Counter64)	The number of DNS queries received for non-existent domains.
ibBindZoneRecursion (Counter64)	The number recursive queries received since the DNS process started.
ibBindZoneFailure (Counter64)	The number of failed queries since the DNS process started.

Following is an example of the table as viewed through a MIB browser:

MIBBrowserView

	ibBindZoneName	ibBindZoneSuccess	ibBindZoneReferral	ibBindZoneNxRRset	ibBindZoneNxDomain	ibBindZoneRecursion
1	parent	0	0	0	0	0
2	digzone	0	0	0	0	0
3	summary	1	3	0	0	0
4	ddnszone	0	0	0	0	0
5	reboottestzone	1	0	0	0	0
6	10.in-addr.arpa	0	0	0	0	0
7	20.in-addr.arpa	0	0	0	0	0
8	40.in-addr.arpa	0	0	0	0	0
9	zone-1-1-a.parent	0	0	0	0	0
10	zone-1-2-a.parent	0	0	0	0	0
11	zone-1-3-a.parent	0	0	0	0	0
12	zone-1-4-a.parent	0	0	0	0	0
13	zone-1-5-a.parent	0	0	0	0	0
14	zone-1-6-a.parent	0	0	0	0	0
15	zone-1-7-a.parent	0	0	0	0	0
16	zone-1-8-a.parent	0	0	0	0	0
17	zone-1-9-a.parent	0	0	0	0	0
18	zone-1-10-a.parent	0	0	0	0	0

ibZonePlusViewStatisticsTable

ibZonePlusViewStatisticsTable provides DNS statistics about all zones in user-defined DNS views. DNS statistics about zones in the default view are captured in ibZoneStatisticsTable. Note that information in ibZonePlusViewStatisticsTable is rolled up to the "summary" zone in ibZoneStatisticsTable.
The syntax of the objects in ibZonePlusViewStatisticsTable uses a Counter64 format. In some cases, the counter format may not be compatible with SNMP toolkits that use a 32-bit counter. Ensure that you reconfigure or update these tools to use the Counter64 format. ibZonePlusViewStatisticsTable contains the following objects:

ibZonePlusViewStatistics Table

Object (Type)	Description
ibBindZonePlusViewName (IbString)	The zone name.
ibBindZonePlusViewSuccess (Counter64)	The number of successful responses since the DNS process started.
ibBindZonePlusViewReferral (Counter64)	The number of DNS referrals since the DNS process started.
ibBindZonePlusViewNxRRset (Counter64)	The number of DNS queries received for non-existent records.
ibBindZonePlusViewNxDomain (Counter64)	The number of DNS queries received for non-existent domains.
ibBindZonePlusViewRecursion (Counter64)	The number of queries that caused recursion since the DNS process started.
ibBindZonePlusViewFailure (Counter64)	The number of failed queries since the DNS process started.
ibBindViewName (IbString)	The DNS view name.

Calculating Recursive DNS Queries

You can use the information in ibZoneStatisticsTable and ibZonePlusViewStatisticsTable to calculate the total number of recursive queries.
Following is an example of ibZoneStatisticsTable indexed by zone names in the default view:

```
index   ibBindZoneNameibBindZoneSuccessibBindZoneReferralibBindZoneNxRRset
        ibBindZoneNxDomainibBindZoneRecursionibBindZoneFailure
================================================================================
======================
 "abc.com"abc.com000
       0   0   0
 "summary"summary500
       0   0   0
 "internal.com"internal.com100
       0   0   0
```

Following is an example of ibZonePlusViewStatisticsTable indexed by zone names in all user-defined views:

```
index
ibBindZonePlusViewNameibBindZonePlusViewSuccessibBindZonePlusViewReferralibBindZ
onePlusViewNxRRset
        ibBindZonePlusViewNxDomainibBindZonePlusViewRecursionibBindZonePlusViewF
        ailureibBindViewName
================================================================================
======================
 "ext1.com"ext1.com100
        0  00  DNS1
 "ext2.com"ext2.com200
        0  00  DNS1
 "ext3.com"ext3.com000
        0  00  DNS2
```

Use the ibBindZoneSuccess object in both tables to determine the total number of recursive queries. If your DNS server is a caching-only server, the total number of recursive queries is the number indicated in the ibBindZoneSuccess object of the "summary" zone. In this example, for a caching-only server, the total number of recursive queries is 5.
If your DNS server is an authoritative server, add all the numbers in ibBindZoneSuccess for all zones in both tables, excluding the "summary" zone. In this example, the total is 4. You then subtract this number from the number in ibBindZoneSuccess of the "summary" zone. In this case, the total number of recursive queries is 1 for an authoritative DNS server.

ibDDNSUpdateStatistics

ibDDNSUpdateStatistics provides statistical data about DDNS updates. The counters always start with zero when the DNS service is restarted. They report the total numbers since the DNS service was last restarted. ibDDNSUpdateStatistics contains the following objects:

ibDDNSUpdateStatistics

Object (Type)	Description
ibDDNSUpdateSuccess (Counter64)	The number of successful dynamic DNS updates.
ibDDNSUpdateFailure (Counter64)	The number of all failed dynamic DNS updates, excluding those reported by the ibDDNSUpdateReject object.
ibDDNSUpdateReject (Counter64)	The number of dynamic DNS updates that failed because they were denied by the DNS server.
ibDDNSUpdatePrerequisiteReject (Counter64)	The number of dynamic DNS updates that failed because the prerequisites were not satisfied. This is also included in the total number of failures reported by the ibDDNSUpdateFailure object.

ibBindZoneTransferCount

ibBindZoneTransferCount (Counter64) provides the total number of successful zone transfers from an Infoblox primary or secondary DNS server to a DNS client, since the DNS service was last restarted. Note that this counter tracks the number of successful full zone transfers (AXFRs) and incremental zone transfers (IXFRs).

IB-DNSSERV-MIB

The IB-DNSSERV-MIB contains one object, ibDnsServConfig, which reports the DNS BIND version implemented by the NIOS software.

IB-DNSHITRATIO-MIB

The IB-DNSHITRATIO-MIB contains one object, ibDnsHitRatio, which provides information about the DNS cache hit ratio. Note that the MIB variable (ibDNSOne) for cache hit rate has an OID of 1.3.6.1.4.1.7779.3.1.1.3.1.5.0, where 1.3.6.1.4.1.7779 is the prefix.

IB-DNSQUERYRATE-MIB

The IB-DNSQUERYRATE-MIB contains one object, ibDnsQueryRate, which provides information about the DNS queries per second. Note that the MIB variable (ibDNSOne) for DNS query rate has an OID of 1.3.6.1.4.1.7779.3.1.1.3.1.6.0, where 1.3.6.1.4.1.7779 is the prefix.

IB-DHCPSERV-MIB

The IB-DHCPSERV-MIB contains one object, ibDhcpv4ServerSystemDescr, which provides the DHCP server name and its DHCP version.

Infoblox Reporting and Analytics

This section describes the Infoblox Reporting and Analytics solution and its features. It explains how to navigate through the user interface, view predefined dashboards, create personal reports and searches. It also provides best practices for customizing searches and setting permissions, and describes the reporting clustering feature and how to configure a reporting cluster.

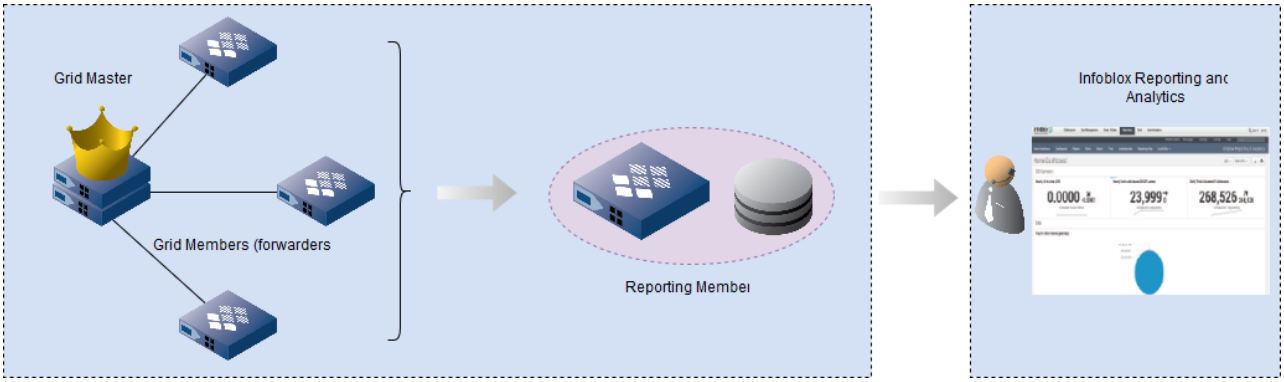
It contains the following sections:

The Infoblox Reporting and Analytics solution automates the collection, analysis, and presentation of core network service data that assists you in planning and mitigating network outage risks so you can manage your networks more efficiently. It provides predefined dashboards and reports that capture useful information about the activities and performance of core network services. It also provides an enhanced reporting interface so you can create custom dashboards, reports, and alerts.

> ⚠ **Note**
>
> For Reporting and Analytics to function properly, ensure that you **DO NOT** create a SHA-256 4096 SSL key for the HTTPS certificate in your Grid because Java does not support SHA-256 with a 4096 key size.

Through reporting clustering, you can combine and configure multiple reporting members in a cluster. These reporting members work together to provide greater performance with higher data throughput and indexing capacity. The cluster also efficiently scales storage and indexing capacity. Reporting data is replicated among these reporting appliances to ensure continuous service even if one of the servers fails. You can configure more reporting appliances in multiple locations (sites) so that reporting data and service can be recovered from catastrophic disasters. Thus, the reporting clustering solution increases scale, offers higher reporting performance and greatly improves the reliability of the Reporting and Analytics solution. For information about this feature, see *About Reporting Clustering*.

When you set up a reporting appliance with valid licenses in the Grid, the reporting server acts as an indexer that collects data from Grid members while the members are forwarders that transmit information to the reporting server. The reporting server indexes all raw data and transforms it into searchable events. Depending on your needs, you can enable certain Grid members as forwarders and disable others so the reporting server receives only the information you need from specific members. The following figure depicts the high-level configuration of the NIOS Reporting and Analytics solution:
Infoblox Reporting and Analytics Overview



The Infoblox reporting solution supports both IPv4 and IPv6 networks and you can configure a reporting member in IPv4, IPv6, or in dual mode (IPv4 and IPv6) network environment. An IPv4 reporting member uses IPv4 as the communication protocol, so you can add an IPv4 reporting member to an IPv4 or dual mode Grid. An IPv6 reporting member uses IPv6 as the Grid communication protocol, so you can add an IPv6 reporting member to an IPv6 or dual mode Grid. But a dual mode reporting member can use either IPv4 or IPv6 as the communication protocol, so you can add a dual mode reporting member to an IPv4, IPv6, or a dual mode Grid. For more information about how to set up the communication protocol, see *Changing the Communication Protocol for a Dual Mode Appliance*.

Related topic

Guidelines for Upgrading the Reporting and Analytics Solution

Setting Up Reporting and Analytics

To enable and start using the Infoblox reporting solution on supported reporting appliances, complete the following:

1. Install a valid Reporting license on the reporting appliance, as described in *Licensing Requirements*. Note that Infoblox now offer subscription licenses for the reporting solution.
2. Set administrative permissions, as described in *Administrative Permissions for Reporting and Analytics*.
3. Configure reporting properties, as described in *Grid Reporting Properties*.
4. Start the reporting service on the indexer and forwarders.

Supported Reporting Appliances and Storage Space

Infoblox provides several reporting appliances to address different reporting requirements.
The Report Categories, Related Data Sources, and Update Frequencies table lists the supported Trinzic Reporting platforms based on IP capacities and average DHCP leases and DNS queries per second, see *Configuring Reporting Clustering*. There will be an impact on the performance of your reporting server when you perform many searches, download PDF reports, and send reports through emails and alerts. It is important to consider the reporting server configuration and make sure that it can handle the overall workload. A reporting appliance uses up to 95% of the total reporting disk space. The usable hard disk space on different appliance models is shown in the table below.

Infoblox Reporting Appliances and their Usable Reporting Hard Disk Space

Enterprise Model	Supported Infoblox Model	Reporting Hard Disk Space	Usable Reporting Hard Disk Space (GB)	Daily Maximum Data Consumption*
Trinzic Reporting 5005 Appliance (User-configurable)	IB-V5005	User-defined hard disk space	User-defined hard disk space

	IB-VM-800 Hyper-V**	250 GB	237	1 GB

Note

The daily maximum data consumption includes all DNS, DDNS, IPAM, DHCP, Discovery, and system traffic or events from all members with data transmission enabled within the Grid. When data traffic exceeds the daily maximum, the reporting server sends an SNMP trap and email notification, if configured. After five (5) daily maximum warnings in a rolling period of 30 days, you cannot perform any reporting related functions. You must then contact Infoblox Technical Support to resolve the issue. Note that the reporting server continues to process incoming data during the violation state. However, you cannot view any reports or manage any reporting related functions until you fix the violation issue.
**support for Reporting appliance models IB-VM-800, IB-VM-1400 starts from Microsoft Windows 2012 R2. Appliance model IB-VM-800 and IB-VM-1400 (Reporting) is supported for Microsoft Windows 2012 R2.

For information about the Trinzic Reporting platforms, their specifications, and how to install them as reporting appliances, refer to the respective installation guides, available on the Infoblox Support site.

Licensing Requirements

You can install a valid Reporting license on a supported Trinzic Reporting platform and configure it as a reporting member solely for reporting purposes. You cannot add licenses to run other services, such as DNS and DHCP, on the reporting member. For information about Infoblox platforms that support reporting, see *Configuring Reporting Clustering*.
Infoblox offers perpetual and subscription licensing programs to meet your business needs. You must obtain a new replacement license from Infoblox if you want to transfer an existing license to another member.

Perpetual Licensing

A perpetual license is appliance-specific, meaning you can install only one perpetual license on each reporting appliance. There is no expiration date for this license type and you can use the Infoblox Reporting service for the lifetime of the appliance. However, you cannot install a perpetual license on an appliance that already has a valid DNS, DHCP, Microsoft Management, Query Redirection, or Multi-Grid Management license installed. You also cannot join a reporting member that has a perpetual license to a Grid that has a subscription license installed. A subscription license is a Grid-wide license and is not appliance-specific. Reporting members that have perpetual licenses can join a Grid that does not have a subscription license. For information about subscription licenses, see Subscription Licensing below.

Note

All reporting appliances come with a 500 MB trial license. You can use the set temp_license CLI command to install the trial license. Available indexing capacity for a perpetual license: 1, 2, 5, 10 and 20 GB.

If you plan to configure reporting clustering, note that the overall indexing capacity for a reporting cluster increases based on the total licensing capacity for all reporting members. For example, if your Grid has three reporting members with 2 GB licensing capacity each, the overall cluster indexing capacity for the cluster becomes 6 GB. However, the stacking indexing capacity does not apply to trial licenses. In other words, if the three reporting members in your Grid all have trial licenses, the total cluster indexing capacity remains at 500 MB. For information about reporting clustering, see *About Reporting Clustering*.
Note that you cannot install a perpetual reporting license on a Grid that has unrestricted reporting VMs as Grid members and vice versa. However, you can install a subscription license on a Grid that has unrestricted reporting VMs as Grid members. Unrestricted reporting VMs are reporting appliances for which you can arbitrarily configure CPU, memory, and disk size. You can arbitrarily configure CPU, memory, and disk size on IB-V5005 appliance.

Subscription Licensing

A subscription license is a Grid-wide license that you install on the Grid Master, and it is not appliance-specific. A subscription license can either be permanent or have an expiration date and Grid Manager (the Infoblox GUI) displays a 90-day and 30-day warning prior to the actual expiration date. The effective start date for a subscription license starts on the day you generate the license. Note that a reporting member that has a perpetual license is not allowed to join the

Grid that has a subscription license.
In a dynamic license pool, expiration warnings are based upon the expiration dates of the sub pools. When any licenses in a sub pool expire, the total available licenses for a pool drops accordingly. On the other hand, a perpetual static license allocated to an appliance does not expire. The appliance continues to run the feature for the lifetime of that appliance.
For more information about Managing Grid-wide Licenses, see *Managing Licenses*.

> **Note**
>
> Available indexing capacity for a subscription license: 1, 2, 5, 10, 20, 50, 100, 200, and 500 GB. Contact your Infoblox representative for pricing and availability information.

About License Violations

License violations occur when the reporting appliance exceeds the maximum allowed daily volume or when the indexed data type is not allowed for the license type. There might be an impact on the reporting service performance if violations occur. License violation is reported in the **Reporting** tab of Grid Manager. During the license violation period, the reporting server continues to index data but the search function will cease to be operational. This means that the **Reporting** tab is available with the following warning message displayed: "Reporting Service is unavailable." You can apply a **Reset** license to remove the violations. Contact Infoblox Technical Support to obtain a **Reporting Reset** license.
Note the following behavior for such violations:

- NIOS continues to index data; however, you will not be able to use the search feature.
- You can use the reporting search when the number of violations in the previous 30 days is within the limit. To obtain valid licenses, contact your Infoblox representative or Infoblox Technical Support.
- If there are five consecutive violations in five consecutive days, then the search feature is disabled for the next 25 days until a **Reset** license is installed. If necessary, contact Infoblox Technical Support to obtain a **ReportingReset** license so you can reset the current license violations.
- During a license violation, summary indexing does not work and reports that use the summary index will not display output. For information about reports that use the summary index, see *Reporting Data Model*.

Administrative Permissions for Reporting and Analytics

You must have the appropriate permissions to access, view, edit, and clone searches, dashboards, reports, and alerts that are available in the **Reporting** tab. NIOS synchronizes all users and admin groups as users and roles on the reporting server. In NIOS, admin groups may have the setting "superusers" enabled or disabled. NIOS groups that have "superusers" enabled will correspond to roles with administrative permissions on the reporting server. This documentation will refer to this role as a superuser role and the associated users as superusers. NIOS groups that do not have "superusers" enabled will not have administrative permissions on the reporting server. This role will be referred to as a non-superuser role and the associated users are limited-access users. The default NIOS admin group "admin-group" will have a superuser role on the reporting server called "infoblox-admin-role." The default NIOS admin named "admin" will have a user name on the reporting server called "infoblox-admin."

> **Note**
>
> When you enable the reporting service, the *splunk-reporting-group* is created automatically for authentication by the Reporting and Analytics App on the Grid. It is an internal admin group, so you must not add users to this group or rename it.

By default, superusers have full access to the Reporting and Analytics App and limited-access users do not. Superusers can grant permissions to limited-access users so they can access the Reporting and Analytics App. Limited-access users will not have access to the **Reporting** tab until superusers grant them this access. For information about Splunk roles, refer to the Splunk documentation. Note that the reporting service does not support non-ASCII characters in the names of admin groups and admin users. When you include ASCII characters and space in the admin user name, make sure that its length does not exceed 33 characters.

When configuring NIOS, only superuser and users with the Grid Reporting Properties permission can configure Grid Reporting Properties. Limited-access users can view the Grid Reporting Properties. When superusers create or delete any admin groups in NIOS, the corresponding roles are created or deleted on the reporting server. You cannot directly create or delete roles on the reporting server. If superuser permission is granted or removed from a NIOS group, this permission change will be reflected in the corresponding role on the reporting server. When you modify the name of an admin group on NIOS, make sure that you grant permissions again for all corresponding roles that are created on the Reporting and Analytics App for this renamed admin group. For information about granting permissions, see Granting Permissions below.

> **Note**
>
> Limited-access users cannot create, modify, and delete any user role for the Splunk App.

Granting Permissions

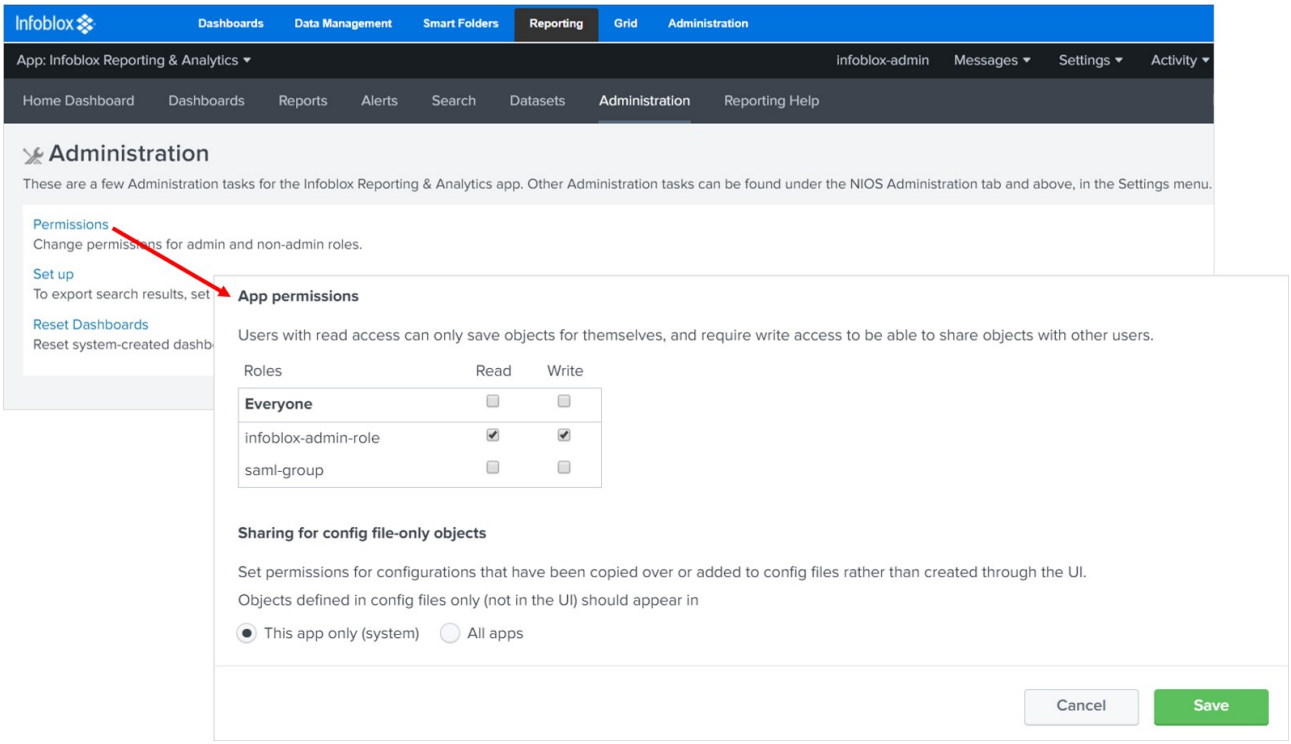
Superusers can grant App permissions to limited-access users. Permissions for all reporting objects are migrated to the new Reporting solution and managed through the new user interface after an upgrade. You may see some new built-in roles, such as **Everyone**, when configuring Reporting permissions. For best practices, do not alter permissions for these new built-in roles. In addition, Reporting Dashboard and Reporting Search global permissions have been removed. If an admin group or admin role was granted these permissions before an upgrade, the permissions will still be displayed after an upgrade. However, they won't take any effect. The Grid Reporting Properties permission is retained.

> **Note**
>
> The **App Permission** and **Edit Permissions** sections display only your assigned admin role on the reporting server. Therefore, you can only view the admin role to which your user name was assigned. Only the default system admin can view all admin roles.

To set permissions:

1. From the **Reporting** tab -> select the **Administration** tab.
2. Click **Permissions** to manage permissions.
3. In the **App permissions** dialog box, set permissions to **Read** and/or **Write** for the roles listed. You must have at least one permission (Read or Write) to execute a task on the **Reporting** tab.
4. Click **Save**.

Setting Permissions for Reporting and Analytics App



Editing Permissions

Users can edit permissions for objects where they are the owner, such as dashboards, reports, and alerts. When a user creates a new report, dashboard or an alert, It is only available to that user. To make that object available to other users, you can do the following (only if your permissions allow you to do so):

- Make an object available to all users.
- Restrict or expand access to all or specific objects by roles.
- Set Read or Write permissions at the Reporting level for roles. For information about users and roles, refer to the Splunk documentation.

To modify permissions:

1. From the **Reporting** tab -> select **Dashboards** or **Reports** or **Alerts**.
2. From the **Edit** drop-down list, select **Edit Permissions**.
3. Specify the following:
    - Display for **Owner**, **App**, or **All Apps**. For more information about **All Apps** permissions, refer to the Splunk documentation.
    - Read and write privileges for users. By default, the permissions are set on the object. You cannot remove the **Read** and **Write** permissions completely. However, you can change this permissions from **Read** to **Write** or vice versa, based on your permissions. For more information about permissions, refer to the Splunk documentation.
4. Click **Save**.

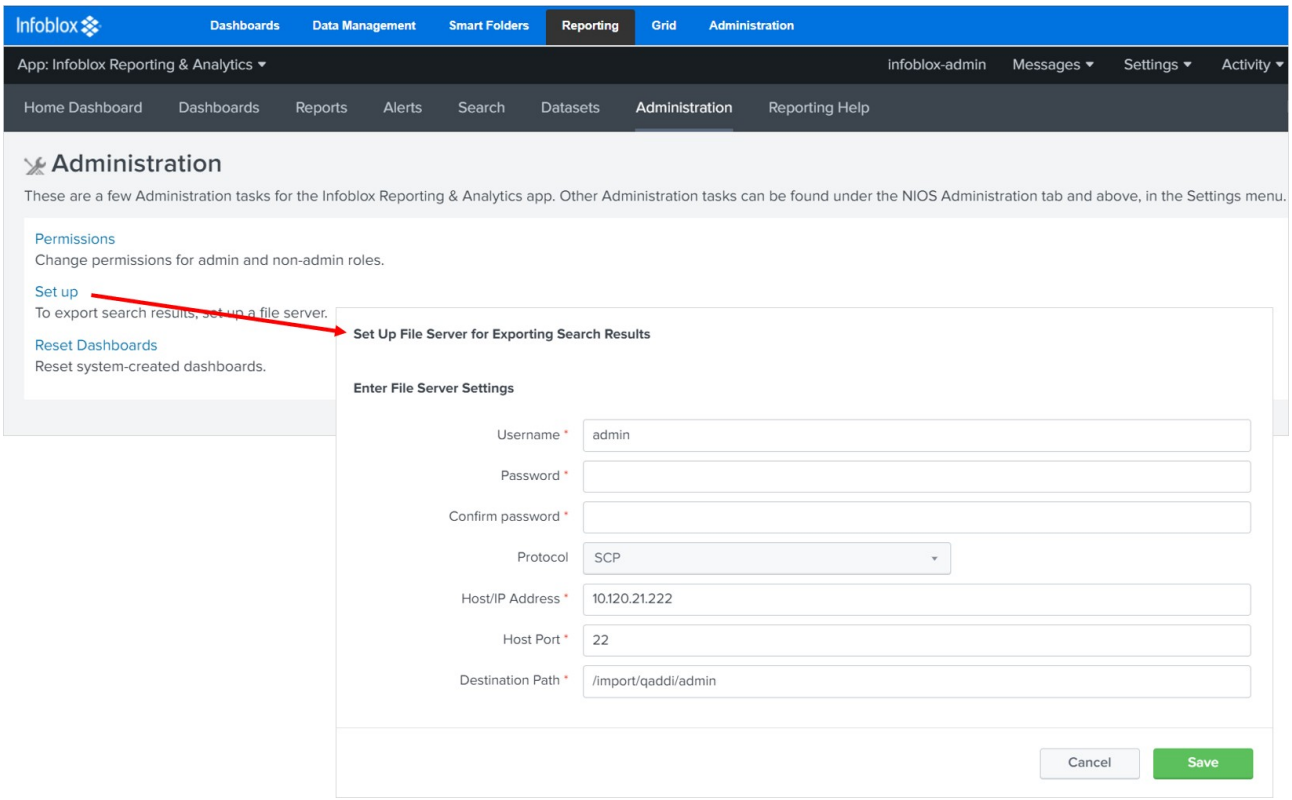
Configuring an External Server for Search Result Exports

You can configure an FTP, SCP, or TFTP server to which you plan to schedule the export of search results. Only superusers can configure the remote server and limited-access users cannot do so. When you upgrade to 7.3.x, make sure that you reconfigure an FTP, SCP, or TFTP server, even if you have already scheduled the export of search results. The **Set up** page to configure an FTP, SCP, or TFTP server is displayed for all new installations and upgrades if you have not previously scheduled the export of search results. If you have configured any scheduled export of search results in a

previous NIOS release, NIOS migrates one of the server settings to the Reporting and Analytics App. In this case, the **Set up** page is not displayed. However, you can still access the **Set up** page from the **Reporting** tab > **Administration** tab, as illustrated in Setup Page to specify Server for Exporting Search Results figure below.
To configure an FTP, SCP, or TFTP server:

1. From the **Reporting** tab -> select the **Administration** tab -> click **Set up**.
2. To configure a remote server, complete the following:
    - **Username**: Enter the username of your server account.
    - **Password**: Enter the password of your server account.
    - **Confirm Password**: Enter the same password.
    - **Protocol**: Select **FTP** or **SCP** or **TFTP** from the drop-down list.
    - **Host/IP Address**: Enter the host IP address.
    - **Host Port**: Enter the port number on the selected server.
    - **Destination Path**: Enter the path and the file name of the export file. For example, you can enter /export/Infoblox_2009_10_20_15_30 on a Linux server, or c:\export\Infoblox_2009_10_20_15_30 on a Microsoft Windows server.
3. Click **Save**.

Setup Page to specify Server for Exporting Search Results



Configuring Reporting Clustering

You can add higher scale, performance, and reliability to the Reporting and Analytics solution by using the reporting clustering feature. Through reporting clustering, you can combine and configure multiple reporting members in a cluster.

The reporting clustering feature offers high availability and disaster recovery. You can configure one or more reporting appliances in multiple locations (sites). Reporting data is replicated among these reporting appliances to ensure redundancies and continuous service even if one of the servers fails. For example, if one of the reporting members has

operational issues, reports and dashboards will use backup copies of the data on other reporting members in the cluster to ensure continuous reporting service. When a new reporting member joins the cluster, you do not need to reconfigure and restart your forwarders to send data to the new reporting member as the Grid Master automatically notifies all forwarders about the new member. In addition, data indexed on the new reporting member participates in searches that support reports and dashboards. Thus, the new reporting clustering solution increases scale, offers higher reporting performance and greatly improves the reliability of the Reporting and Analytics solution.

The reporting clustering feature is supported on appliances running NIOS version 7.3.200 and later. For new installations and upgrades from a previous NIOS release to NIOS 7.3.200 and later, the appliance is set to the single indexer mode by default. For more information about how reporting clustering works and the types of clustering mode, see Clustering Overview and Reporting Cluster Modes below.

> **Note**
>
> Reporting clusters are not supported in a Multi-Grid configuration.

Clustering Overview

The concept of reporting clustering is to set up a group of reporting members within one site (location) or across multiple sites. When you configure multiple reporting members within one site, you are setting up a single-site cluster. Configuring multiple reporting members across different sites gives you a multi-site cluster, as illustrated in the figure Sample Multi-Site Reporting Cluster Single-site clusters and multi-site clusters below, offer the benefits of high availability and disaster recovery. Without reporting clustering, a reporting member is known as a single indexer.
A reporting cluster, either single-site or multi-site, consists of the following components that work together to perform reporting and clustering activities:

- **Cluster Master**: The cluster master coordinates all clustering activities and always runs on the Grid Master.
- **Indexer** (also known as cluster peer): An indexer that collects, processes, and indexes reporting data. It can also function as the originating indexer (source peer) or a replication target (target peer).
- **Forwarder**: A forwarder sends reporting data to the indexer for processing.
- **Search Head**: A search head handles search queries and distributes search requests to indexers in the cluster. One of the reporting members in the cluster will have double duties of being the indexer and search head.
- **Replication Factor**: This factor defines the number of copies of reporting data the cluster replicates and maintains. This is set to 2 by default for both single-site and multi-site clusters so the clusters can tolerate one reporting member failure without losing any data (since there will still be another copy of data available in the cluster).
- **Search Factor**: This factor defines the number of copies of searchable data. This is set to 2 for single-site clusters and set to 1 for multi-site clusters so the cluster can tolerate one reporting member failure without impacting search results (since there will still be a searchable copy of data available in the cluster).
- **ReportingSite Extensible Attribute**: This is an extensible attribute that you associate with reporting members in a multi-site cluster. For more information, see ReportingSite Extensible Attribute below.

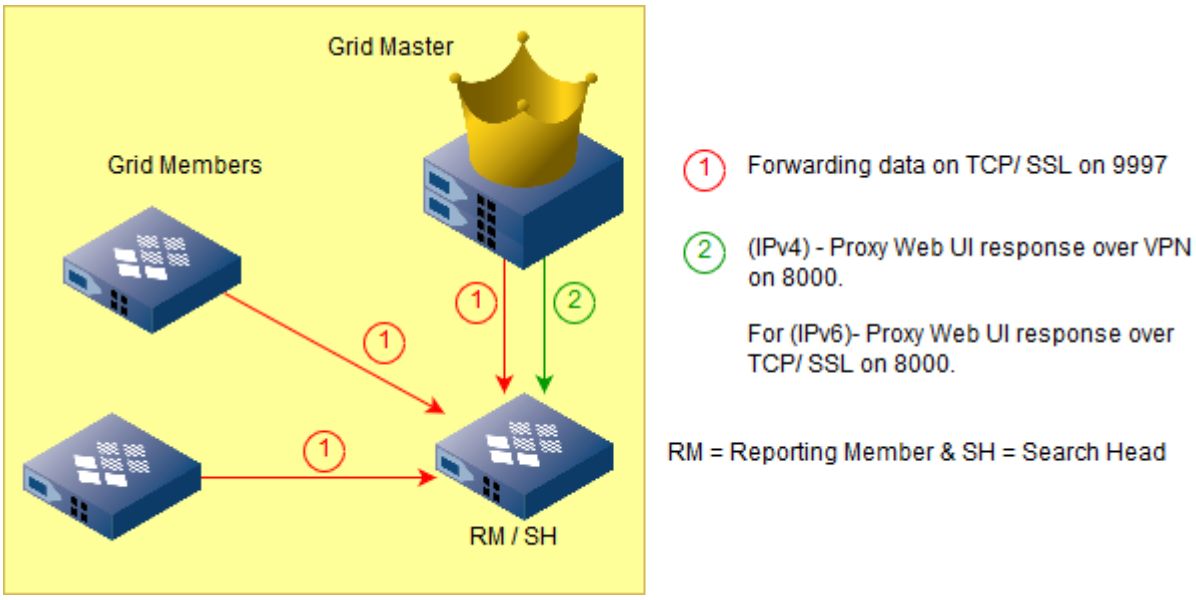
In a Grid that includes a reporting cluster, the Grid Master coordinates various activities across reporting members.
In the reporting cluster, a reporting member can act as an indexer and/or a search head. It also participates in peer-to-peer data replication.
To configure a reporting cluster, you must first set up all the reporting members and enable the reporting service in the Grid. You can then select the reporting clustering type for your cluster. For more information about cluster types, see Reporting Cluster Modes below. When you configure the reporting cluster, you must use an NTP server to synchronize the time of the Grid Master, Grid members and reporting members.

Reporting Cluster Modes

You must first enable the reporting service and configure one or more reporting members as needed before configuring the reporting cluster. When you enable reporting clustering, the Grid Master, forwarders, and reporting members use specific ports for network communication. Ports Required for IPv4 and IPv6 Single Indexer, Port Requirement for IPv4 and IPv6 Single-site Clustering, and Port Requirement for IPv4 and IPv6 Multi-site Clustering figures below illustrates whether the network communication is over TCP/SSL or VPN, and ports that you can use for the reporting service.

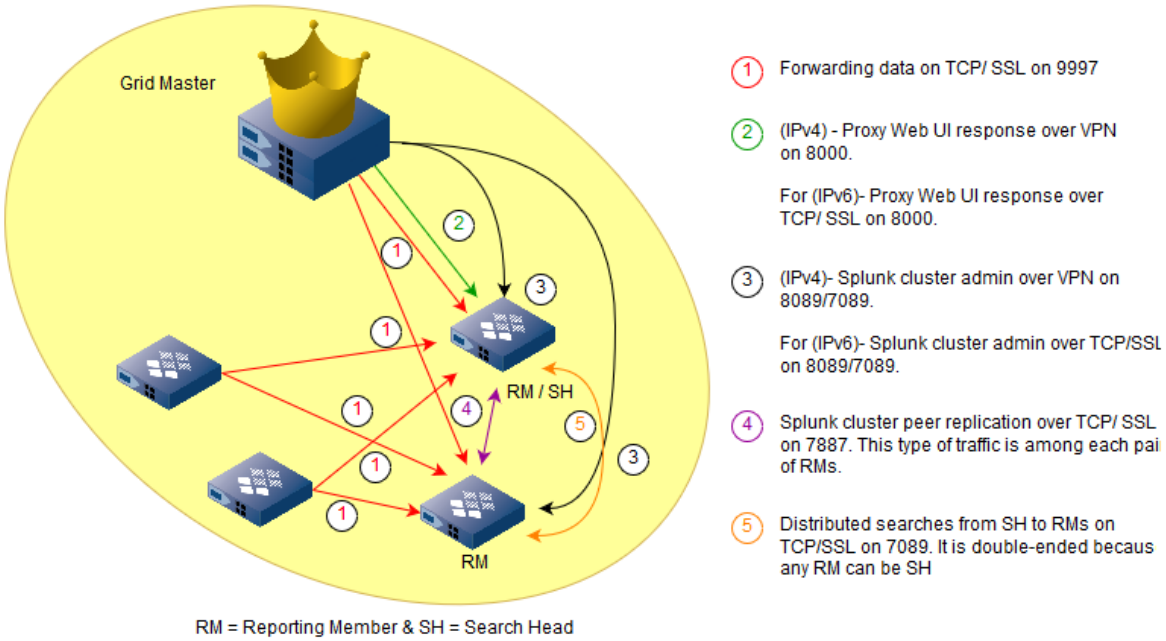
- **Single Indexer:** This is the traditional configuration that works on one reporting server (indexer). The forwarder sends reporting data to the indexer and the indexer indexes the data. This is the default configuration when you enable the reporting service for new installations and when you upgrade from a previous NIOS release to NIOS 7.3.200 and later.

Ports Required for IPv4 and IPv6 Single Indexer



- **Single-Site Cluster**: In a single-site cluster, the Grid Master is also the cluster master and all reporting members are cluster indexer peers. NIOS selects a peer and configures it as the search head to handle search queries. If the selected search head goes down, NIOS automatically selects another search head among the reporting members in the same site. All other Grid members (non-reporting members) are considered forwarders that send reporting data to the cluster peers for processing. You must configure at least two reporting members that are located in the same site (location). By default, the replication factor and search factor for a single-site cluster are set to 2. Note that you can upgrade your configuration from a single-site cluster to a multi-site cluster. However, once configured, you cannot change your configuration back to a single indexer. For information about how to configure a single-site cluster, see Configuring Reporting Clusters below.

Port Requirement for IPv4 and IPv6 Single-site Clustering



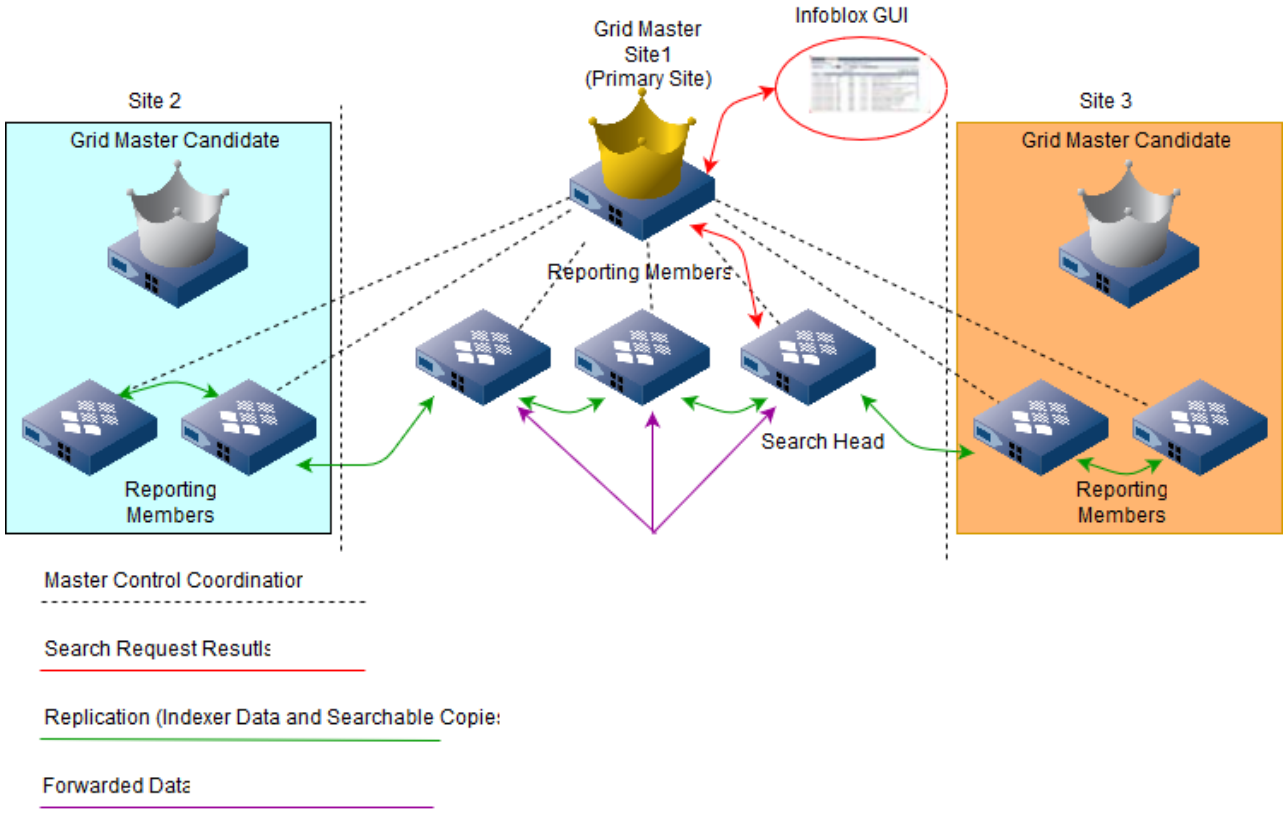
- **Multi-Site Cluster** - A multi-site clustering configuration is useful when you want to manage multiple reporting sites at different locations, with each site having its own set of indexers. The multi-site clustering configuration is valid only when you associate all the reporting members in the cluster with the predefined **ReportingSite** extensible attribute. For information about the ReportingSite extensible attribute, see ReportingSite Extensible Attribute below. In a multi-site cluster, you configure one of the sites as the primary site, and then plan other sites in a specific order. This order defines the next site of indexers to which the forwarders send data when the primary site is out of service. Note that all Grid members send data only to indexers in the primary site. You can designate a new primary site either by using the *Grid Reporting Properties* editor, or using the set promote_master CLI command. For more information about the CLI command, refer to the *Infoblox CLI Guide*. A multi-site cluster must have at least two sites with two reporting members in each site, as illustrated in the Sample Multi-Site Reporting Cluster figure. The first reporting site that you configure is the primary site, which also hosts the search head for the cluster. If the search head goes down, the Grid Master automatically chooses an available reporting member in the same site as the search head. If all the indexers in a site go down, or if you want to change the search head to another site, then you must manually redefine the primary site. Note that you must make one of the active sites as the primary site. In a multi-site cluster, the search factor (also known as the site search factor) determines both the number of searchable copies that the entire cluster maintains and the number of copies that each site maintains. By default, the search factor is set to 1 and the replication factor is 2 in a multi-site cluster.

> **Note**
>
> You can change your configuration from a single indexer to a single-site cluster or multi-site cluster and from a single-site cluster to a multi-site cluster. However, you cannot revert your configuration from a multi-site cluster to a single-site cluster or to a single indexer.

Clustering Data Replication

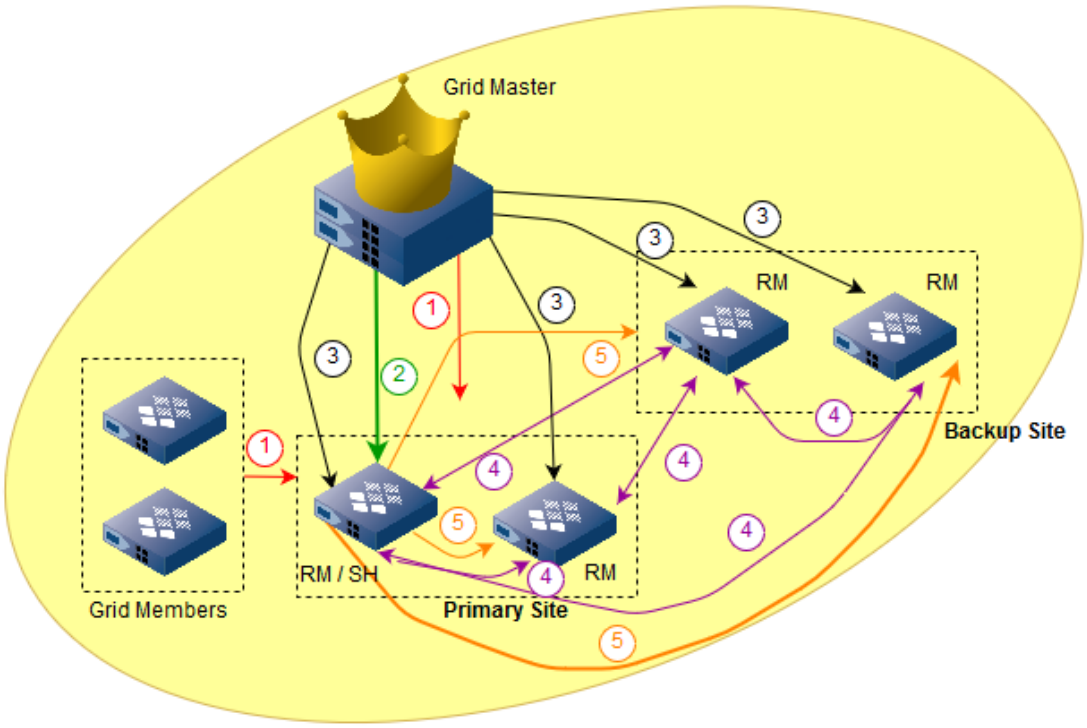
When you change the configuration from a single indexer to a single-site cluster or multi-site cluster and from a single-site cluster to a multi-site cluster, the replication of data will start only for the new data that are created after you have completed the cluster mode configuration. When you change the configuration, the replication of new data starts only after you have completed the clustering configuration. Any data created prior to switching are restored on the primary site and are not replicated on the secondary site. To manage your reporting clustering data efficiently, see *Guidelines for Deploying Reporting Clusters*.

Sample Multi-Site Reporting Cluster



For more information about how reporting cluster works, refer to the Splunk documentation at *https://docs.splunk.com/Documentation/Splunk/8.2.4/Indexer/Basicclusterarchitecture*.

Port Requirement for IPv4 and IPv6 Multi-site Clustering



1 Forwarding data on TCP/ SSL on 9997

2 (IPv4) - Proxy Web UI response over VPN on 8000.

For (IPv6)- Proxy Web UI response over TCP/ SSL on 8000.

3 (IPv4)- Splunk cluster admin over VPN on 8089/7089.

For (IPv6)- Splunk cluster admin over TCP/SSL on 8089/7089.

4 Splunk cluster peer replication over TCP/ SSL on 7887. This type of traffic is among each pai of RMs.

5 Distributed searches from SH to RMs on TCP/SSL on 7089. It is double-ended becaus any RM can be SH

RM = Reporting Member & SH = Search Head

ReportingSite Extensible Attribute

NIOS defines the ReportingSite extensible attribute for use by the multi-site cluster reporting configuration. You must associate a ReportingSite extensible attribute value with the reporting members defined in the cluster. For more information, see Assigning a Reporting Site EA Value to a Multi-Site Cluster below. Note that your multi-site cluster configuration is invalid unless you assign ReportingSite values to all the reporting members that are part of the cluster. You can add up to five ReportingSite extensible attributes, and view and edit the ReportingSite extensible attributes in the **Administration** tab -> **Extensible Attributes** tab in Grid Manager. You can view the **ReportingSite** extensible attribute values in the **Grid** -> **Grid Manager** -> **Members** tab in Grid Manager. The **ReportingSite** column is not available if you customize the Results table. You can enable the **ReportingSite** column by selecting **Columns** -> **Edit Columns**. For information about customizing tables, see *About the Grid Manager Interface*. You can also use the **Group Results** function to group reporting members that contain the same ReportingSite extensible attributes. For information about grouping members by extensible attributes, as described in Grouping Members by Extensible Attribute, see *Adding Grid Members*.

As illustrated in Sample Multi-Site Reporting Cluster above, the ReportingSite value "site1" is assigned to a site within a multi-site cluster and to the reporting members RM1, RM2 and RM3. The ReportingSite value "site2" is assigned to a different site in the cluster and to reporting members RM4, RM5 and RM6. If the search head goes down, the Grid Master automatically chooses an available reporting member in the same site to be the search head.

> **Note**
>
> When you modify the ReportingSite extensible attribute value for any indexers in a multi-site cluster, ensure that you validate the configuration again, as described in Validating Reporting Clustering Configuration below.

Monitoring Reporting Cluster Status

After you have set up reporting members and defined clustering type, you can monitor the cluster status through the following:

- View the reporting member service status, as described in Monitoring Grid Services, see *Monitoring Services*.
- Check license usage by the reporting member, as described in *Home Dashboards*.

Promoting the Grid Master Candidate in Multi-Site Clustering

If the Grid Master fails and all other reporting members are up and running in a multi-site reporting cluster, you must promote the Grid Master Candidate to the Grid Master by using the CLI command set promote_master. For information about the CLI command, refer to the *Infoblox CLI Guide*.

Reporting Categories and Related Data Sources

The reporting member uses two types of data sources to generate reports: file-based data sources and script-based data sources. When the reporting member is down or unreachable, file-based data sources are queued until the reporting member is up and running. However, the script-based data sources are lost if the size of the queued data exceeds 500 KB.
The amount of data in the queue is managed as follows:

- Rotates the reporting syslog files (extracted from /var/log/messages) at 120 MB retaining one older file. The data in the queue depends on the file size when the reporting member becomes unreachable.
- The CSV files overwrite the oldest data with the new data at regular intervals. So, the CSV file contains only the latest events.

  > **Note**
  >
  > If you desire older information to be kept, use any of the export methods to daily export this data to a file.

  The table below lists the reports provided by the reporting server, report categories, and the source type, data source type (file or script-based), and queue data update frequencies for each report:

Report Categories, Related Data Sources, and Update Frequencies

Report Category	Reports	Source Type	Data Source (file-based or scriptbased)	Update Frequency
Device	Inactive IP Addresses	ib:reserved 2	file-based (syslog)	Rotates at 120 MB; retains one older copy; queued data is between 120 MB and 240 MB

Report Category	Reports	Source Type	Data Source (file-based or scriptbased)	Update Frequency
	Port Capacity Utilization by Device Port Capacity Trend Port Capacity Delta by Device	ib:reserved2	file-based (csv)	Overwritten every 6 hours
	End Host History	ib:discovery:end_host_activity	file-based (csv)	Overwritten every 24 hours
	IP Address Inventory			
	Network Inventory			
	IPAMv4 Device Networks			
	Device Interface Inventory			
	Device Inventory	ib:reserved2	file-based (csv)	Overwritten every 24 hours
	Device Components			
	Device Advisor	ib:reserved2	file-based (csv)	Overwritten every 24 hours
DHCP Performance	DHCP Message Rate Trend	ib:dhcp:message	file-based (csv)	Overwritten every 1 minute
	DHCPv4 Usage Trend DHCPv4 Range Utilization Trend	ib:dhcp:range	file-based (csv)	Overwritten every 1 hour
DHCP Lease History	DHCP Lease History DHCP Top Lease Clients	ib:dhcp:lease_history	file-based (syslog)	Rotates at 120 MB; retains one older copy; queued data is between 120 MB and 240 MB
	Top Devices Identified Device Trend Device Class Trend Top Device Classes	ib:dhcp:lease_history	file-based (syslog)	Based on summary search report, which is updated during the 16th and 46th minutes of each hour
	Top Devices Denied an IP Address	ib:dhcp:lease_history	file-based (syslog)	Based on summary search report, which is updated during the 19th and 49th minutes of each hour
	Device Fingerprint Change Detected	ib:dhcp:lease_history	file-based (syslog)	Executed every 24 hours

Report Category	Reports	Source Type	Data Source (file-based or scriptbased)	Update Frequency
DNS Performance	DNS Response Latency Trend	ib:dns:perf	script-based	Executed every 1 minute
DNS Record Scavenging	DNS Scavenged Object Count Trend	ib:dns:reclamation	file-based (csv)	Updated whenever reclamation tasks are executed
DNS Query Capture	DNS Domain Query Trend DNS Domains Queried by Client Top DNS Clients by Query Type Top DNS Clients Querying MX Records	ib:dns:capture	file-based (csv)	Updated whenever the Data Collection VM collects capture query data from a Grid member
DDNS	DDNS Update Rate Trend	ib:ddns	file-based (syslog)	Rotates at 120MB; retains one older copy; queued data is between 120MB and 240MB.
DNS Traffic Control	DNS Traffic Control Resource Availability Trend	ib:dns:reserved	file-based (csv)	Based on summary search report, which is updated once per six hour at 47th minute of each hour. With each execution, it summarizes raw events indexed from 370 minutes ago to 10 minutes ago.
	DNS Traffic Control Resource Availability Status	ib:dns:reserved	file-based (csv)	Based on summary search report, which is updated once per six hour at 47th minute of each hour. With each execution, it summarizes raw events indexed from 370 minutes ago to 10 minutes ago.
	DNS Traffic Control Resource Pool Availability Trend	ib:dns:reserved	file-based (csv)	Based on summary search report, which is updated once per six hour at 23rd minute of each hour. With each execution, it summarizes raw events indexed from 370 minutes ago to 10 minutes ago.
	DNS Traffic Control Resource Pool Availability Status	ib:dns:reserved	file-based (csv)	Based on summary search report, which is updated once per six hour at 23rd minute of each hour. With each execution, it summarizes raw events indexed from 370 minutes ago to 10 minutes ago.
	DNS Traffic Control Response Distribution Trend	ib:dns:reserved	file-based (csv)	Based on summary search report, which is updated once per six hour at 37th minute of each hour. With each execution, it summarizes raw events indexed from 370 minutes ago to 10 minutes ago.
DDI Utilization	DHCPv4 Usage Statistics DHCPv4 Top Utilized Networks	ib:dhcp:network	file-based (csv)	Overwritten every 1 hour
	IPAM Network Usage IPAM Top Networks	ib:ipam:network	file-based (csv)	Overwritten every 1 hour
	DNS Zone Statistics Per DNS View	ib:dns:view	file-based (csv)	Overwritten every 24 hours

Report Category	Reports	Source Type	Data Source (file-based or scriptbased)	Update Frequency
	DNS Statistics per Zone	ib:dns:zone	file-based (csv)	Overwritten every 24 hours
	DNS Object Count Trend for Flex Grid License	ib:dns:ibflex_zone_counts	file-based (csv)	Generated once in 24 hours and average is calculated over 5 days

Ecosystem Publication	Publish Data	ib:reserved 1	file-based (csv)	Updated whenever there is a relevant RPZ, IPAM, and DHCP lease event occurs.
Cloud	VM Address History	ib:reserved 2	file-based (csv)	Updated immediately when there is a change related to the VM IP address. Rotates at 300MB and retains one older copy.
Audit Log	Audit Log Events	ib:audit	file-based (audit log)	Updated immediately when the audit log is updated.
	Audit Log WAPI Events	ib:audit	file-based (audit log)	Updated immediately when the audit log is updated.
Syslog	Syslog Events	ib:syslog	file-based (Syslog)	Updated immediately when alerts are logged in the syslog.

Configuring Reporting Clusters

You can configure a reporting single indexer, a single-site cluster, or a multi-site cluster. When you configure reporting clustering, make sure that you configure two or more reporting appliances and that all indexers are online.

> **Note**
>
> There is no action required if you see intermittent "Too many streaming errors" and "Skip indexing" messages in the **Messages** menu of the **Reporting** tab. This can be caused by network connectivity issues between the reporting nodes.
> During NIOS upgrade, when configuring reporting clusters, ignore the "Unable to establish a connection to peer" message displayed on the Reporting tab.

To configure a reporting cluster:

1. From the **Administration** tab -> **Reporting** tab, click **Grid Reporting Properties** from the Toolbar.
2. In the *Grid Reporting Properties* editor, select the **Reporting Clustering** tab and complete the following:
   - **Single Indexer**: Select this to configure only one reporting server. This is the default reporting cluster mode.

- **Single-Site Cluster**: Select this if you want to configure two or more reporting servers in the same site (location). The data is replicated on multiple reporting servers. You can upgrade your configuration to the multi-site clustering mode, but you cannot revert this configuration to a singer indexer mode.
- **Multi-Site Cluster**: Select this if you want to configure multiple reporting servers at different sites (locations). You must assign the ReportingSite extensible attributes to all the reporting members that you have configured in the same site within the cluster. You can configure the same ReportingSite extensible attribute with multiple reporting members. The reporting members that are configured with the same ReportingSite extensible attributes are tagged to the same site. Click the Add icon and select the ReportingSite extensible attribute that you have configured on the reporting member. The first site that you add is considered to be the primary site, which functions as the search head. You can change the order of the sites by clicking the up and down arrows.

For more information about the reporting cluster type, see Reporting Cluster Modes above.

> **Note**
>
> Your multi-site configuration is invalid if you do not add the correct ReportingSite extensible attribute values to the reporting members. You can validate your configuration as described in Validating Reporting Clustering Configuration below.

3. Click **Save & Close**.

Assigning a ReportingSite EA Value to a Multi-Site Cluster

The multi-site clustering configuration is valid only when you associate all the reporting members in the cluster with the specified **ReportingSite** extensible attribute values. Make sure that you select the ReportingSite values from those that are specified for the multi-site cluster in the *Grid Reporting Properties* editor. After you assign extensible attribute values to the reporting members, you can validate the multi-site cluster configuration as described in Validating Reporting Clustering Configuration below.
To associate the ReportingSite extensible attribute with the reporting member:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab -> *member* checkbox, and then click **Extensible Attributes** in the Toolbar.
2. Click the Add icon in the **Extensible Attributes** table to enter extensible attributes. The appliance adds a row to the table each time you click the Add icon. Select the row and the attribute name from the drop-down list, and then enter the value.
3. Optionally, select an extensible attribute and click **Delete** to delete it.
4. Click **Save & Close**.

Validating Reporting Clustering Configuration

After you have configured the reporting cluster mode, you can verify its validity. Whenever you make changes to the reporting configuration through Grid Manager or hardware replacement, make sure that you validate the configuration. When you verify a multi-site cluster configuration, NIOS validates the following:

- The extensible attribute ReportingSite is specified for all reporting members.
- The set of extensible attributes configured in the *GridReportingProperties* editor equals to the set of ReportingSite extensible attributes defined for the reporting members.
- For each ReportingSite extensible attribute, the number of reporting peers must be greater or equal to the replication factor in each site.
- For each ReportingSite extensible attribute, the search factor must be less than or equal to the replication factor in each site.

To verify the reporting cluster-mode configuration:

1. From the Grid tab -> **Grid Manager** tab, click the **Reporting** service.
2. In the vertical Toolbar, click **Verify Cluster Configuration**.
   The *Verify Reporting Cluster Configuration* dialog box displays an error message if the configuration is invalid.

Make sure that you associate the ReportingSite extensible attributes with all the reporting members that you have configured.

3. Click **OK** to close the dialog box.

Guidelines for Deploying Reporting Clusters

The following are a few guidelines to consider before you deploy reporting clustering:

- *Best Practices for Capacity Planning*
- *Monitor Volume and Storage Consumption*
- *Deployment and Service Monitoring*
- *Other Best Practices for Deploying Reporting Clusters*

Best Practices for Capacity Planning

- Forecast the usage of the reporting volume and disk size based on your business needs and estimate the future potential growth.
    - Work with the your Infoblox representatives to gather statistics and metrics of your Grid to estimate the expected potential reporting data volume and disk storage required to manage your reporting data. This helps you determine which tier of NIOS Reporting license you should purchase, the number of appliances, and the appliance models you might need.
    - Configure reporting appliances using the same hardware appliance models. The capacity of the whole cluster is limited by the weakest reporting member if you configure reporting members using different appliance hardware models.
    - Consider the future potential growth during the initial deployment of a reporting cluster. Scaling out the reporting cluster by adding more reporting members at a later time might result in a significant configuration change.
    - Unlike single-indexer reporting solution, there might be more than one solution to handle certain estimated license and disk size for the reporting cluster. To reduce the potential admin overhead, Infoblox recommends that you use a small number of high-end reporting appliances to form a cluster, rather than using a large number of low-end reporting appliance.
- When deploying a reporting cluster in a virtual environment, consider the following:
    - You can deploy clustering in a virtual environment as long as it provides adequate system resources and capacities. Refer to the following resource to help design the clustering deployments. This link provides information about best practices and consequences that you must be aware of when configuring the host environments:
        - *https://docs.splunk.com/Documentation/Splunk/8.2.4/Capacity/Referencehardware*
- If you expect to deploy the reporting cluster in multiple data centers to achieve disaster recovery in the future, then configure the multi-site reporting clustering for the first time, even if all reporting members are physically located in the same data center. You can move some of the reporting members to other data center at a later time as required, rather than deploying new reporting members and reconfiguring the multi-site cluster.
  Note: Be aware that the additional reporting members (the secondary site in the same data center) doesn't really increase the capacity of the reporting cluster.
- Reporting cluster can only tolerate single node failure.
    - By default, the replication factor is set to 2, which means that there are two copies for each bucket in the entire single-site cluster or each site for a multi-site cluster. Therefore, it can tolerate failure only on one node.
    - The cluster may not be able to tolerate double failure. For example, if node1 just recovered from a failure and if node2 fails before node1 is fully recovered (before turning everything to green). In such cases, there is a chance of losing some data.
- When you change the reporting cluster mode, be aware of the following:
    - The data indexed by a single-indexer is not replicated to other peers, even if upgraded to a single-site cluster. Similarly, the data indexed by a single-site cluster is not replicated to other sites, even if upgraded to a multi-site cluster. In other words, the single-indexer configuration does not support HA configuration and single-site data does not have disaster recovery measure. Note that when you restore the reporting

data created in a single-site cluster to a multi-site cluster, the data is restored only on the primary site of the cluster and are not replicated on the secondary site.

Monitor Volume and Storage Consumption

- Monitor the license volume usage on the reporting server regularly using the following dashboards:
  - Monitor the **Today's License Usage** (GB) and **License Usage Trend Per Member** panels available in the *Home Dashboards*.
  - For more information about the the following, see *Internal Dashboards:*
    - Reporting License Usage
    - Reporting Volume Usage Trend per Category
    - Reporting Volume Usage Trend per Member
- Configure alerts in the Infoblox Reporting and Analytics App to trigger actions when data volume reaches a specified limit.
- Monitor the disk usage: You can monitor the disk usage for each index in the *Grid Reporting Properties* editor and adjust the breakdown among indexes to make sure that the data is retained for the desired period of time.
- Take actions when the license volume or disk usage approaches the limit.
  - Choose to obtain licenses that can manage your data volume.
  - Expand the cluster with additional reporting members to increase the disk volume. If there is a surge of reporting data generation before you upgrade your license, you may reduce the inbound volume by turning off reporting on certain Grid members or certain reporting categories.
- Do not ignore license violation warnings, such as GUI yellow banner and SNMP traps.
  - When reporting license usage approaches the limit, NIOS displays the warning messages in the yellow banner, log messages, and SNMP traps (if configured).
  - When you receive five (5) violation notifications in a rolling period of 30 days, you cannot view reports or configure report related functions. To avoid reporting interruptions, promptly address any violation notifications by contacting Infoblox Technical Support.
    Note that the reporting server continues to process incoming data during the violation state. However, you cannot view any report or manage any report related functions until you fix the violation issue.

Deployment and Service Monitoring

- A reporting cluster requires that the Grid Master and reporting members have the same IPv4 or IPv6 configurations.
  - Use either IPv4 or IPv6 networks for all members. There might be an impact on the performance if you use both IPv4 and IPv6 networks. There are a few guidelines to consider before you deploy reporting clustering. For more information about the guidelines, see *Guidelines for Deploying Reporting Clusters*.
- Be aware of the time lag in displaying the actual state in the reporting service status.
  - NIOS reporting monitors all communication between Splunk cluster master (on the Grid Master) and reporting members, between Grid members (forwarders) and reporting members, and among reporting members.
  - Grid Manager displays the service status to indicate any network issues. However, the status is not real-time and there might be some time lag up to 5 minutes from the moment when the issues occur or recover.
- Regularly backup your reporting data even for a multi-site cluster deployment. Infoblox recommends that you perform reporting data backup before changing your configuration from a single indexer to a single-site cluster or multi-site cluster and from a single-site cluster to a multi-site cluster. For information about backing up reporting data, see *Managing Reporting Data*.
- Use the **Reporting Clustering Status** dashboard to monitor the reporting cluster status.
  - If the reporting cluster is functioning properly, then the overall status is green. The status turns red if there is any network outage or reporting member goes offline, which indicates that the replication factor or search factor is not met. It might take some time for Grid Manager to change the status to green even after you fix the issue because the cluster needs to replicate buckets among peers.
- There can be duplicated bucket data in the reporting backup FTP server.

    - In the cluster mode configuration, there is a chance of uploading multiple copies of the same bucket because reporting data backup takes data from multiple reporting members simultaneously. However, the reporting data restore process eliminates the duplicate copies of such buckets.
- It is a good practice to back up the Infoblox Reporting and Analytics App regularly, even though the appliance backs up data from the running search head to the Grid Master periodically. By doing this, it is easier to recover the data automatically by the new search head in case of a search head failure. For information about Backing Up and Restoring the Infoblox Reporting and Analytics App, see *Managing Reporting Data*.

Other Best Practices for Deploying Reporting Clusters

- When you plan a single site or multi-site reporting cluster, make sure that you join all the relevant reporting members to the cluster immediately. Any delays in adding the reporting members might cause some data loss because peers are unable to start indexing immediately. In addition, Infoblox recommends that you validate the reporting clustering configuration before you start the reporting service, as described in Validating Reporting Clustering Configuration, see *Configuring Reporting Clustering*.
- When you need to bring down any reporting members for reasons such as maintenance and the member will be back online soon, you can use the `set reporting_cluster_maintenance_mode` CLI command to suppress the cluster master to initiate any bucket fix-up activities. For more information about this command, refer to the *InfobloxCLIGuide*. After completing the maintenance, use the same (`set reporting_cluster_maintenance_mode`) CLI command to turn off the reporting cluster maintenance mode.
- When you upgrade from a previous release to NIOS 7.3.200 or later, the Grid will automatically be upgraded to the single indexer mode. You can change the reporting clustering configuration after the upgrade.
- When you upgrade from NIOS 7.3.200 to a later NIOS release, the Grid will retain the cluster type configured in NIOS 7.3.200.
- During a scheduled upgrade, reporting members will restart and become unavailable to receive events from other Grid members. To avoid the scenario that all reporting members might go offline about the same time, Infoblox suggests that you put reporting members in different upgrade groups and schedule different upgrade times for these upgrade groups. By doing so, there will always be some reporting members available to receive data from other Grid members. Thus, you can avoid potential data loss during scheduled upgrades.
- When you upgrade from a previous release to NIOS 7.3.200 or later, reporting data generated before you enable reporting clustering is replicated on all reporting members. Therefore, in cases when a reporting appliance is down or offline, you may experience some data loss (although this data will be captured in the reporting backup file). Infoblox recommends that you back up your reporting data before an upgrade or enabling reporting clustering.
- You cannot revert the NIOS software version after you have configured a single-site or multi-site cluster from the single indexer mode. For example, if you upgrade the Grid from NIOS 7.3.0 to NIOS 7.3.200 or later with reporting service enabled (only the single indexer mode is supported until NIOS 7.3.200), the Grid will automatically be upgraded to a single indexer mode. If you then configure a single-site or multi-site cluster after the upgrade, you cannot revert to a single indexer in the upgraded version. To configure a single indexer, you must revert the NIOS software version to NIOS 7.3.0, which may cause some data loss because not all data stored on different reporting members in the previous reporting cluster is consolidated to the single indexer.
- When you plan to move a reporting appliance from one Grid to another, you must first enable the reporting service in the new Grid and then join the reporting appliance.
- Infoblox recommends that you do not reboot the reporting appliance or restart the reporting service when performing reporting backups or restores. For information about Backing Up Reporting Data and Restoring the Reporting Database, see *Managing Reporting Data*.
- Infoblox recommends that you use appliance models with the same capacity as peers in a cluster. If you set up a reporting cluster using heterogeneous models, the appliance displays a warning message and limits the capacity of the entire cluster based on the peer that has the smallest capacity. For information about how to validate the reporting configuration, see *Configuring Reporting Clustering*. The following table provides example configurations for the single-site and multi-site clustering.

Clustering Configuration Examples

Clustering Types	Configuration Details	Validation
Single-site clustering (Replication Factor = Search Factor =2)	Forwarder volume = 2GB per day Licensing Master: 1 X 5G Primary Site: 2 X TR-1405 (5G)	Yes
	Forwarder volume: 5GB per day Licensing Master: 1 X 10G Primary Site: 2 X TR-2205	Yes
	Forwarder volume: 8GB per day Licensing Master: 2 X 10G Primary Site: 4 X TR-2205	Yes
	Forwarder volume: 8GB per day Licensing Master: 1 X 20G Primary Site: 2 X TR-4015	Yes
	Forwarder volume: 8GB per day Licensing Master: 1 X 10G Primary Site: 2 X TR-2205	No 8GB exceeds the effective capacity of 7GB.
	Forwarder volume: 5GB per day Licensing Master: 1 X 10G Primary Site: 4 X TR-2205	No A single 10G license makes this cluster underused.
Multi-site clustering (Replication Factor = 2 Search Factor =1)	Forwarder volume: 5GB per day Licensing Master: 1 X 10G Primary Site: 2 X TR-2205, Backup Site: 2 X TR-2205	Yes
	Forwarder volume: 5GB per day Licensing Master: 1 X 10G Primary Site: 2 X TR-2205, Backup Site: 1 X TR-2205	No Infoblox recommends that you configure at least two reporting members in each site (location).
	Forwarder volume: 8GB per day Licensing Master: 1 X 10G Primary Site: 4 X TR-2205, Backup Site: 2 X TR-2205	Yes
	Forwarder volume: 8GB per day Licensing Master: 1 X 10G Primary Site: 4 X TR-2205, Backup Site: 1 X TR-2205	No Because total volume 8GB from forwarders exceed the effective capacity of 7GB.

Grid Reporting Properties

After you set up a dedicated reporting appliance in your Grid, you must configure the Grid reporting properties so you can communicate with the reporting appliance and retrieve report data through the Grid Master. In addition, you must select the correct report categories in order for the reporting server to generate the correct data in corresponding reports, as described in Configuring Grid Reporting Properties below.

By default, only superusers can configure the Grid reporting properties. When you enable the Grid reporting service, all members transmit data to the reporting server. You can disable data transmission from specific members to the reporting server. Before using the reporting service, you must configure the remote server to export the search results, as described in Reporting (Index) Storage Space below. Once you configure the reporting server and enable the reporting service on Grid members, you can view and manage reports through the **Reporting** tab of Grid Manager.

> **Note**
>
> - When you reset the appliance using the `reset all` CLI command or reset the database using the r`eset database` CLI command, reporting configurations are not preserved. If you reset the appliance, you must configure Grid reporting properties and remote server settings to use the reporting service.
> - Expired cookies in a Splunk session are not removed in the Firefox browser by default. Expired cookies also cannot be reused. However, there is no impact on functionality.

Complete the following to set up your reporting solution:

1. Configure general reporting properties, including the selection of report categories, as described in Configuring Grid Reporting Properties below.
2. Specify the network port for reporting, as described in Setting the Network Port for Reporting below.
3. Specify email properties, as described in Configuring Email Notification Settings, *About Alerts*.
4. Configure the logo image for PDF delivery, as described in Configuring Logo Image in PDF Reports, see *About Reports*.

The properties you define in the *Grid Reporting Properties* editor apply to all the reporting members unless you override them at the specific member level. To override at the member level, see Modifying Member Reporting Properties below.

Configuring Grid Reporting Properties

After you configure the reporting server, you must enable the data indexing and select at least one reporting category to ensure that the reporting service functions properly.

> **Note**
>
> You must select the correct report categories in order for the reporting server to generate the correct data in corresponding reports.

Complete the following to configure the Grid reporting properties:

1. From the **Administration** tab -> **Reporting** tab, click **Grid Reporting Properties** from the Toolbar.
   or
   From the **Grid** tab, select the **Grid Manager** tab and click the **Services** tab. In the **Services** tab, select the **Reporting** tab and click **Edit** -> **Grid Reporting Properties** from the Toolbar.
2. In the *Grid Reporting Properties* editor, select the **General** -> **Basic** tab
3. Complete the following:
   a. **Reporting Server**: Grid Manager displays the name of the reporting server.
   b. **Enable Data Indexing**: Data transmission is disabled by default. You must select this checkbox to ensure that all Grid members transmit data to the reporting appliance. Enabling data transmissions for all members can affect the overall data consumption on the reporting server. For information about the daily maximum data consumption per day for your reporting appliance, see the Default Index Space Configured for Each Report Category table below.
   c. **Enable Time Based Retention**: Select this checkbox if you want the reporting data to be retained for a number of days you specify. You can specify the number of days in the **Retention in days** column. When you select this checkbox, NIOS displays a warning message indicating that the reporting data is deleted after the number of days specified in the **Retention in days** column. This checkbox is disabled by default. Note that the **Enable Time Based Retention** feature is not available for the IP Address Usage Report, the DNS QPS Usage Report, and the DHCP LPS Usage Report as the deletion of data after the retention period impacts the subscription count, which in turn generates inaccurate data in these reports.

d. **Report Category**: Select the reports you want the reporting server to generate. The reporting server automatically configures data sources and configurations required to generate the reports you select here. The required data is stored in the reporting server database. By default, no report categories are selected. For a list of report categories, see *Predefined Dashboards*. You must select at least one reporting category for the reporting service to start working.
    i. **Index%**: Displays the actual storage space allocated for a reporting index. You can modify this value between 0 and 100. When you enable an index category and leave it at 0%, the appliance displays an error message. Make sure that the total percentage of the index storage space for all report categories equals 100% or less than 100%. The appliance displays a warning message when the total percentage of the index storage space is less than 100%.
    ii. **Used%**: Displays the index storage space used by a reporting index.
    iii. **Retention in days**: Enter the number of days up to which you want the reporting data to be retained. The data will be permanently deleted after this number of days. You can enter a value between 7 and 365. The default value is **No Retention**.
    iv. **IndexName:** Displays the reporting index name, which is displayed on the *Reporting Index Usage Statistics* report.
    Note that if you back up the reporting data before the expiry of the retention period, then you can restore the data at a later date.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Caching Threat Category Information from the Cloud Services Portal

The threat category information (Threat indicator database and Threat description) is downloaded from the Cloud Services Portal and stored locally. The threat category information is then sent to the reporting server to augment RPZ hits and reports are generated. Caching threat category information from the Cloud Services Portal helps enhance the performance of threat reports as data is fetched from the cache that is stored locally.

You can configure the Cloud Services Portal credentials and schedule the entire threat indicator database download from the Cloud Services Portal. If you have already downloaded the entire threat indicator database, then consecutive full downloads take place only after 24 hours.

> ⚠ Note
>
> For the threat indicator caching feature to work on a Grid, the Grid must have at least one user with **can delete** permission set up on the Grid.

Limitations

Note the following limitations when you use the threat indicator caching feature:

- Enabling the threat indicator caching feature results in higher usage of network bandwidth and reduction of the reporting indexing capacity.
- Enabling the threat indicator caching feature impacts the performance of Grid Master as Splunk consumes significant bandwidth to forward the entries to indexers. It takes a few minutes for the entries to get forwarded and indexed completely based on the data size.
- If you enable the threat indicator caching feature, and then revert or upgrade the Grid to a version that does not support the feature, then the indexed threat indicator database data will still occupy disk space even though they are not searchable in the upgraded or reverted Grid version.
- The size of the downloaded threat indicator database file will be huge due to data retention in the following scenarios:
    - When you enable and disable the threat indicator caching feature a few times.
    - When you upgrade NIOS and then revert it to the prior version without disabling the threat indicator feature, and also when you upgrade NIOS again.
- When the threat indicator caching feature is enabled, threat details in the *DNS Top RPZ Hits* report does not show historic data. For more information about the *DNS Top RPZ Hits* report, see *DNS Top RPZ Hits*.

- For replication to work properly in cluster mode, Infoblox recommends that an appliance should have 12 cores CPU and 12 GB memory.

Configuring the Threat Indicator Caching Feature

Complete the following to configure the threat indicator caching feature:

1. From the **Grid** tab, select the **Grid Manager** tab and click the **Services** tab. In the **Services** tab, select the **Reporting** tab and click **Edit** -> **Grid Reporting Properties** from the Toolbar.
2. In the **Grid Reporting Properties** editor, select the **Threat Indicator Caching** tab-> **Basic** tab.
    a. **Enable Threat Indicator Caching**: Select the checkbox to enable the feature. Enabling this feature downloads the threat indicator information from the Cloud Services Portal to the Grid Master, and then the threat indicator information is indexed on the reporting members.
    Note that selecting this option results in higher indexing license usage, network bandwidth, and storage.
3. Complete the following:
    a. **Splunk Threat Indicator Caching Index Storage**: Specifies the disk storage allocation for the threat indicator caching feature. The minimum disk storage limit is 8 GB and the maximum disk space that it can be set to is 42 GB. By default, the disk storage space is set to 12 GB. The disk space that you allocate will reduce the storage limit for all other indexes. Set the required storage space based on the volume of data that you expect to be downloaded from the Cloud Services Portal and based on your indexing capacity. Grid Master downloads the threat indicator data and periodically forwards it to the reporting server for indexing.
    The indexing usage that is observed by Infoblox during the lab testing is, one full synchronization consumes ~600 to ~800 MB of indexing space and each incremental synchronization consumes ~60 MB of indexing space.
    Note that the indexing space usage varies on a daily basis based on data generated by the Cloud Services Portal. Therefore, do not consider the numbers stated here as standard guidelines.
    b. **Incremental Threat Indicator Caching Update Interval** (in hours): Enter the interval value in hours to download the incremental updates from the threat indicators of the Cloud Services Portal. For example, if you set the value as 2, after every two hours the incremental threat indicator is downloaded. The incremental threat indicator is downloaded only after the whole threat indicator is downloaded from the Cloud Services Portal.
    c. **Last Incremental Threat Indicator Caching Download Timestamp**: Displays the date and time of the last successful incremental threat database download.
    d. **Update Policy**: Select **Automatic** or **Manual**. You need to select any one of the following options in order to avoid huge data storage usage on Splunk.
        i. **Automatic**: Select this option if you want to automatically download the whole database after every seven days. By default, the value is set to seven days.
        ii. **Manual**: Select this option to schedule the whole database download manually. For more information on threat context locale cache scheduler, see Scheduling Threat Indicator Caching below.
        iii. **Test Connection**: Click **Test Connection** to test the connectivity between NIOS and the Cloud Services Portal. Then, enter the Cloud Services Portal credentials on the **BloxOne Threat Defense Cloud Integration** tab. For more information about Enabling the BloxOne Threat Defense Cloud Client, see *Configuring BloxOne Threat Defense Cloud Clients for Outbound*.
    e. **Last Whole Threat Indicator Caching Download Timestamp**: Displays the date and time of the last successful whole threat indicator download.
    f. **Scheduling**: Select to schedule the whole threat indicator download. You can select **Scheduling** only if the **Update Policy** is selected as **Manual**.
    g. **Last Threat Indicator Caching Failure Timestamp**: Displays the date and time of the last failed attempt that is made to download the threat indicators after five iterations.

Scheduling Threat Indicator Caching

You can schedule the download of the whole threat database daily, weekly or monthly. However, if you have already downloaded the whole threat indicator database and the scheduled date and time is near next, in that case the schedule is skipped. Based on the schedule the Incremental ThreatDB is downloaded from the Cloud Services Portal as per the set interval

Complete the following to schedule the threat indicator caching:

1. From the **Grid** tab, select the **Grid Manager** tab and click the **Services** tab. In the **Services** tab, select the **Reporting** tab and click **Edit** -> **Grid Reporting Properties** from the Toolbar.
2. In the **Grid Reporting Properties** editor, select the **Threat Indicator Caching**-> **Basic** tab
3. Select the **Enable Threat Indicator Caching** option.
4. In the *Complete ThreatDB Download Interval* section, select the **Update Policy** as **Manual**.
5. Click the Scheduling icon.
6. In the *Threat Indicator Caching Scheduler* dialog box, select the daily, weekly, or monthly option as follows: Note that the time zone for scheduling will be the same as the zone that is set for the Grid.
    a. To schedule a daily download:
        i. Select **Daily**.
        ii. In the *Schedule daily* section, in the **Time** field, set the time when the download must start. Ensure that you have sufficient space available as daily data indexing limits may get exhausted.
    b. To schedule a weekly download:
        i. Select **Weekly**.
        ii. In the *Schedule every week on* section select the day of the week when the download must happen every week.
        iii. In the **Time** field, set the time when the download must start.
    c. To schedule monthly download:
        i. Select **Monthly**.
        ii. In the *Schedule the day of the month* section, enter the day of the month when the download must happen. You can set the date from 1st to 28th of a month.
        iii. In the **Time** field, set the time when the download must start.
    d. Click **OK**.
7. Click **Save & Close**.

Reporting (Index) Storage Space

One key configuration aspect of the reporting appliance is index space. By default, some percentage of index space is allocated on the reporting server for each report category listed in *Report Categories, Related Data Sources, and Update Frequencies table*. For information about how to configure index space, see Configuring Grid Reporting Properties above. Each report category uses up to a certain percentage of the usable reporting hard disk space for index storage. For example, of the total 237 GB usable hard disk space of an IB-VM-800 appliance, the reporting category, **Device** uses 47.47%. For the list of default index space configured for each report category, see Default Index Space Configured for Each Report Category table. You can modify the index percentage value between 0 and 100. When you modify this value, make sure that the total percentage for the index storage space for all categories equals exactly 100%. You can set the index percentage to a value of less than 100% to reserve a certain percentage for future use. If the total percentage of the index space usage exceeds 100%, the appliance displays an error message. Note that the reporting appliance removes the oldest data when you reduce the index space percentage for a category to a value that is lower than the used percentage by the existing data. For information about the maximum index size and number of days the reporting data is retained, see *Reporting Indexes* table. Also, ensure that its host name has only alphanumeric characters, underscores, dots, and dashes.

Note

For usable reporting hard disk space for each appliance model, see *Infoblox Reporting Appliances and their Usable Reporting Hard Disk Space* table.

Default Index Space Configured for Each Report Category

Report Category	Default Index Space (%) Adjustable by User	Total Reporting Disk Space Used for Index Storage (GB)
Audit Log	0%	-
DNS Query DNS Performance DDNS DNS Record Scavenging	20%	Usable reporting hard disk space x 20%
DNS Query Capture	0%	-
DHCP Performance	20%	Usable reporting hard disk space x 20%
DHCP Fingerprint DHCP Lease History	39%	Usable reporting hard disk space x 39%
DDI Utilization	5%	Usable reporting hard disk space x 5%
Security Network User	1%	Usable reporting hard disk space x 1%
DNS Traffic Control	0%	Usable reporting hard disk space is broken down between ib_dtc and ib_dtc_summary internally.
Cloud	0%	-
System Utilization	15%	Usable reporting hard disk space x 15%
		-
Device	0%	-
Ecosystem Subscription Ecosystem Publication	0%	-
License	0%	-

Modifying Member Reporting Properties

To modify reporting properties for a reporting member:

1. From the **Grid** tab -> **Grid Manager** tab -> **Services** tab, select the **Reporting** service and click the *Grid_member* checkbox, and then click the Edit icon.

2. In the *Reporting Member Properties* editor, select the **General** tab and click **Override**.
3. Under **Reporting Settings**, complete the following:
    a. **Enable data forwarding to the indexer on this member**: Select this checkbox to enable data transmissions to the reporting server. If you do not select this checkbox, a member will not forward data to the indexer and reporting service is disabled on that member.
    b. **Select the data categories to forward**: Select the report categories for which you want this member to forward data to the reporting server. Clear the report categories for which you do not want this member to forward data to the reporting server.
    Note that the member configured as an indexer displays only the **Audit Log** category.
4. Save the configuration.

Defining Interface for Reporting Traffic

On a Grid member, you can define the network interface you want the member to use for sending reporting data to the reporting server.
To define network interface on the Grid member for reporting traffic, complete the following:

1. From the **Grid** tab -> **Grid Manager** tab -> **Services** tab, select the **Reporting** service and click the *Grid_member* checkbox, and then click the Edit icon.
2. In the *Reporting Member Properties* editor, select the **General** -> **Advanced** tab, and then complete the following:
    a. **Forwarding interface used for reporting traffic**: From the drop-down list, select the interface that you want this member to use to send reporting data. Note that you must properly configure the interfaces on the member for them to appear in the drop-down list. After a NIOS upgrade to version 8.1.x or later, if you had selected Any from the drop-down list, the LAN1 (or VIP for HA configurations) subnet is used as the static route except if the threat protection licenses are installed and ANY is selected from the drop-down, MGMT subnet is used as the static route. Select MGMT if you want to continue using the management port for grid communication. Selecting MGMT enables the MGMT subnet to be used as the static route.
    Note that after you start the reporting service on the reporting member, you cannot reset the interface set for the reporting traffic. You may have to configure the reporting member again to modify the interface for the reporting traffic.
3. Save the configuration.

Setting the Network Port for Reporting

All Grid members use port 9997 for reporting service by default. This port is used for data transmissions between the reporting member and other members. Ensure that you configure your firewall rules to allow traffic on this port. You can designate another network port for reporting purposes.

To set the network port for reporting, complete the following:

1. From the **Administration** tab, select the **Reporting** tab -> expand the Toolbar and click **Grid Reporting Properties**.
    Or
    From the **Grid** tab -> **Grid Manager** tab -> **Services** tab, select the **Reporting** service and click the *Grid_member* checkbox, and then click **Edit** -> **Grid Reporting Properties** from the Toolbar.
2. In the *Grid Reporting Properties* editor, select the **General** -> **Advanced** tab and complete the following:
    a. **Port**: Enter the port number you want to use for reporting purposes. The default port is 9997.
3. Save the configuration.

Specifying the Data Generation Interval for Reports

You can specify the time interval when the appliance generates data for the *DNS Statistics per View* and *DNS Statistics per Zone* reports. The default value for the data generation interval for these reports is one day (86400 seconds). You can specify different data generation intervals for the *DNS Statistics per View* and *DNS Statics per Zone* reports.

To specify the data generation interval for *DNS Statistics per View* and *DNS Statistics per Zone* reports, complete the following:

1. From the **Administration** tab, select the **Reporting** tab -> expand the Toolbar and click **Grid Reporting Properties**.
   or
   From the **Grid** tab -> **Grid Manager** tab and click the **Services** tab. In the **Services** tab, select the **Reporting** tab and click **Edit** -> **Grid Reporting Properties** from the Toolbar.
2. In the *Grid Reporting Properties* editor, select the **Data Generation Schedule** tab and complete the following:
   a. **Data Generation**: Enter the time in HH:MM:SS AM/PM format. You can also click the Clock icon to select a time from the drop-down list.
3. Save the configuration.

For more information about the reports DNS Statistics per DNS View and DNS Statistics per Zone, see *IPAMv4 Utilization Dashboards*.

Configuring Threat Protection Data

You can use this feature only if the Threat Protection and Threat Protection Update licenses are installed on the Infoblox Advanced Appliance. When you configure this feature, you receive threat protection events in the syslog. The events logged include threat protection rules and the source IPs that triggered the rules. For information about how to monitor these events using the syslog, see *Monitoring through Syslog*.

For certain threat protection reports, accumulated statistics for each unique IP/rule pair are collected. You can control the volume of data collected per member using the following options:

- **Top IP/Rule Statistics Collection Limit**: This option limits the collection of accumulated statistics to the top N unique IP/rule pairs.
- **IP/Rule Statistics Collection Interval (minutes)**: The interval at which the accumulated statistics for the top N unique IP/rule pairs are collected. The smaller the interval, the finer the granularity of the accumulated statistics in terms of time, but the data volume will be higher.

Based on your configuration, the reporting appliance displays data in the following threat protection reports, see *Security Dashboards*:

- Threat Protection Top Rules Logged
- Threat Protection Top Rules Logged by Source

Note

When threat details are missing for a non-local RPZ feed zone entry, it is recommended to check if the associated feed zone's TSIG key is configured.
To enable threat protection reports, you must select the **Security** report category in the **Grid Reporting Properties** editor. To select the **Security** checkbox, go to the **Reporting** tab -> **Grid Reporting Properties** -> **General** tab -> **Basic** tab -> select the **Security** checkbox under **Report Category**. Ensure that you set the Security Index% to an optimal level so the reporting database has enough storage space to accommodate all reporting data. For information about how to configure the Index%, see *Configuring Grid Reporting Properties*.

To configure the data collection limit, complete:

1. From the **Administration** tab, select the **Reporting** tab and click **Grid Reporting Properties** from the Toolbar.
   Or
   From the **Grid** tab, select the **Grid Manager** tab and click the **Services** tab. In the **Services** tab, select the **Reporting** tab and click Edit -> **Grid Reporting Properties** from the Toolbar.
2. In the *Grid Reporting Properties* editor, select the **Threat Protection** tab and complete the following:
   a. **Top IP/Rule Statistics Collection Limit**: Enter the maximum number of the top N unique source IP/rule pairs for data collection. For example, if you specify 20, the appliance collects data for the top 20 unique source IP/rule pairs.

b. **IP/Rule Statistics Collection Interval (minutes)**: Enter the time interval at which the reporting appliance updates data. For example, if you specify the interval as 60 minutes, the appliance updates data at a 60-minute interval.

3. Click **Save & Close**.

Monitoring DNS Client Queries

You can view the presence of clients in the network that are sending large numbers of queries to DNS zones or DNS domains. To monitor the top clients querying DNS zones, perform the following:

1. From the **Administration** tab, select the **Reporting** tab -> expand the Toolbar and click **Grid Reporting Properties**.
   Or
   From the **Grid** tab, select the **Grid Manager** tab and click the **Services** tab. In the **Services** tab, select the **Reporting** tab and click Edit -> **Grid Reporting Properties** from the Toolbar.
2. In the *Grid Reporting Properties* editor, select the **Basic** tab -> **DNS**.
3. Under **DNS Top Clients Per Domain**, select the **Monitor Queries made to the following zones** checkbox. Only authoritative zones are supported, to a limit of 1000 zones for monitoring purposes.
   a. To select zones one at a time, choose individual checkboxes. Click the Add icon and select **Add Domain** or **Bulk Add Domains** to add new zone information for excluding.
   b. To specify the number of clients to be listed, choose the **Top N Limit** value. The default value is 10.

Monitoring IP Block Group Queries

You can view the user defined IP block groups that are querying DNS domains. To monitor the IP Block Groups, perform the following:

1. From the **Administration** tab, select the **Reporting** tab -> expand the Toolbar and click **Grid Reporting Properties**.
   Or
   From the **Grid** tab, select the **Grid Manager** tab and click the **Services** tab. In the **Services** tab, select the **Reporting** tab and click **Edit** -> **Grid Reporting Properties** from the Toolbar.
2. In the *Grid Reporting Properties* editor, select the **Basic** tab -> **DNS**.
3. Under **DNS Query trend per IP Block**, select the **Monitor Queries made from the following groups** checkbox.
   a. Click the Add icon to add a group to the group table. From the drop-down list, click **Select Group** to select groups in the *Group Selector* dialog box, or click **Bulk Add Groups** to add multiple groups.
   b. To select all groups, select the **Group** checkbox. Or, select individual checkbox to select the group one at a time.
   c. To delete a group, select the group and click the Delete icon.

Configuring DNS RPZ Rule Hits

You can specify a limit to display the number of top clients, who receive re-written responses through the RPZ, in **DNS Top RPZ Hits**. You can also specify the total number of RPZ entries for each client.

1. From the **Administration** tab, select the **Reporting** tab -> expand the Toolbar and click **Grid Reporting Properties**.
   Or
   From the **Grid** tab, select the **Grid Manager** tab and click the **Services** tab. In the **Services** tab, select the **Reporting** tab and click **Edit** -> **Grid Reporting Properties** from the Toolbar.
2. In the *Grid Reporting Properties* editor, select the **Basic** tab -> **DNS**.
3. Under **DNS RPZ Rule Hit Configuration**, complete the following:
   a. Enter a value for **Top N Limit** to specify the maximum number of top clients that can be listed in the report.
   b. Specify the **Total RPZ Entries per Client**. This indicates the number of entries for each client in RPZ.

Note

You have to select the **Security** checkbox before you define values here. To select the checkbox, **Reporting** tab -> **Grid Reporting Properties** -> **General** tab -> **Basic** tab -> select the checkbox **Security** under **Report Category**.

Forwarding Syslog Data to the Reporting Server

You can control the kind of syslog data forwarded to the indexer from the Grid members. You can search for syslog events (search string) in the **Reporting** tab -> **Search** tab. The syslog events you see in the **Search** tab depend on the syslog categories that you specify in both the Grid Reporting and Member Reporting Properties. The **Search** tab displays syslog events for the selected syslog categories at both the Grid Reporting Properties and Member Reporting Properties.

To specify syslog data categories, complete the following:

1. From the **Administration** tab, select the **Reporting** tab -> expand the Toolbar and click **Grid Reporting Properties**.
   Or
   Member: From the **Grid** tab, select the **Grid Manager** tab and click the **Services** tab. In the **Services** tab, select the **Reporting** tab -> *member* checkbox and then click the Edit icon.
2. In the *Grid Reporting Properties* or *Reporting Member Properties* editor, select the **Syslog Data** tab and complete the following:
   Click **Override** in the *Reporting Member Properties* editor to override the settings configured at the Grid reporting level. To inherit the same properties as the Grid, click **Inherit**.
   a. **Source:** From the drop-down list, select which syslog messages the appliance sends to the external syslog server:
      i. **Any:** The appliance sends both internal and external syslog messages.
      ii. **Internal:** The appliance sends syslog messages that it generates.
      iii. **External:** The appliance sends syslog messages that it receives from other devices, such as syslog servers and routers.
   b. **Severity:** Choose a severity filter from the drop-down list. When you choose a severity level, the appliance sends log messages with the selected level and the levels above it. The severity levels range from the lowest, **debug**, to the highest, **emerg**. For example, if you choose **debug**, the appliance sends all syslog messages to the server. If you choose **err**, the appliance sends messages with severity levels **err**, **crit**, **alert**, and **emerg**.
      i. **emerg**: Panic or emergency conditions. The system may be unusable.
      ii. **alert**: Alerts, such as NTP service failures, that require immediate actions.
      iii. **crit**: Critical conditions, such as hardware failures.
      iv. **err**: Error messages, such as client update failures and duplicate leases.
      v. **warning**: Warning messages, such as missing keepalive options in a server configuration.
      vi. **notice**: Informational messages regarding routine system events, such as "starting BIND".
      vii. **info**: Informational messages, such as DHCPACK messages and discovery status.
      viii. **debug**: Messages that contain information for debugging purposes, such as changes in the latency timer settings and AD authentication failures for specific users.
   c. **Logging Category**: Select one of the following logging categories:
      i. **Send all**: Select this to log all syslog messages, irrespective of categories to which it belongs. When you select this option, the appliance logs syslog messages for all the events, including all DNS and Infoblox related events. However, the syslog messages are not prefixed when you select this option.
      ii. **Send selected categories**: Select this to configure logging categories from the list of available logging categories. Use the arrows to move logging categories from the **Available** table to the **Selected** table and vice versa. The appliance sends syslog messages for the categories that are in the **Selected** table. When you select this option, you must add at least one logging category. The syslog messages are prefixed with a category name to which it belongs. Also, the RPZ events logged in the syslog messages uses specific prefixes for the selected categories. Note that the syslog messages are prefixed when you set logging categories for at least one external syslog server, even if you set other external syslog servers as **Send All**.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring IP Blocks and IP Block Groups

You can configure IP addresses, subnets, or a mix of multiple IP addresses and subnets into IP blocks, and then assign them to IP block groups for monitoring and tracking queries made to specific IP blocks. For information about adding IP addresses, see Adding IP Blocks below. You can also configure as many groups as necessary and assign them to specific clients. Note that assigning more IP block groups results in monitoring more queries, which may affect the performance of the reporting server. You can generate a report to monitor queries made to these user-defined IP block groups or IP blocks. For information about DNS Query Trend per IP Block Group, see *Predefined Dashboards*.
Guidelines while configuring IP blocks:

- You cannot configure arbitrary IP address ranges, such as 192.168.0.1 to 192.168.0.100 as an IP block.
- You cannot add or modify an IP block that overlaps with another IP block in a different group. However, you can add an IP block that overlaps with another IP block in the same IP block group.

> **Note**
>
> The appliance restarts the DNS service after you assign or unassign an IP block group at the Grid or member level. Also, the appliance restarts the DNS service when you modify or delete an IP address or IP block group assigned to the Grid or member or when you add, modify, or delete an IP block in such IP block groups.

You can do the following in the Groups panel, as described in the following sections:

- Add IP block groups.
- Modify IP block groups.
- Add IP block.
- Modify IP blocks.
- Delete IP block groups and IP blocks.
- Print IP block groups and IP blocks.
- Export IP block groups and IP blocks.

In addition, you can also do the following:

- Use filters or the **Go to** function to navigate to a specific group. You can also create quick filters to save frequently used filter criteria. For information about how to use quick filters, see *Finding and Restoring Data*.
- Use Global Search to search for IP block groups and IP blocks. For information about Global Search, see *About the Grid Manager Interface*.
- Use Smart Folders to organize IP block groups and IP blocks. For information, see *Smart Folders*.
- Import and export groups in CSV format. For more information about CSV import feature, see *Importing and Exporting Data using CSV Import*.

Adding IP Block Groups

To add a new group:

1. From the **Administration** tab, select the **Reporting** tab -> *Group* -> Add.
   or
   From the **Administration** tab, select the **Reporting** tab, expand the Toolbar and click **Add** -> IP Block Group.
2. In the *Add IP Block Group* wizard, complete the following:
   - **Name**: Enter the name of the group.
   - **Comment**: Enter useful information about the group.
3. Do one of the following:
   - Click **Save & Close** to add the IP block group and close the wizard.
   - Click **Save & Edit** to add the IP block group and launch the editor. You can edit the details.
   - Click **Save & New** to add the IP block group and launch the wizard again to add another group.
   - Click **Save & Open** to add the IP block group and open the IP block group.

Modifying IP Block Groups

1. From the **Administration** tab, select the **Reporting** tab -> *Group* -> Edit.
2. In the **General** tab of the *IP Block Group* editor, you can modify the group name and comment.
3. Click **Save & Close** to save the configuration.

> **Note**
>
> You can perform inline editing by double-clicking the row of data that you want to modify. The appliance displays the inline editing editor in the selected row. Click **Save** after modifying the data.

Adding IP Blocks

In a group, you can add as many subnets/IP addresses as necessary. Note that adding more IP addresses results in monitoring more queries, which may affect the performance of the reporting server.

1. From the **Administration** tab, select the **Reporting** tab -> *Group* -> Add.
   or
   From the **Administration** tab, select the **Reporting** tab, expand the Toolbar and click **Add** -> IP Block.
2. In the *Add IP Block* wizard, complete the following:
   - **Group**: Click **Select** to select a group. When there are multiple groups, Grid Manager displays the *Group Selector* dialog box to select a group. Click a group name in the dialog box. You can use filters or the Go to function to narrow down the list.
   - **Address**: Enter the source IPv4/IPv6 addresses or the IPv4/IPv6 subnets.
   - **Comment**: Enter useful information about the IP block.
3. Do one of the following:
   - Click **Save & Edit** to add an IP address or IP block and launch the editor. You can edit the details.
   - Click **Save & New** to add an IP address or IP block and launch the wizard again to add another IP block.
   - Click **Save & Close** to add an IP address or IP block and close the wizard.

Modifying IP Blocks

1. From the **Administration** tab, select the **Reporting** tab -> *Group.*
2. Select an IP address or IP block you want to modify and click the Edit icon.
3. In the **General** tab of the *IP Block* editor, modify the IP address or comment.
4. Click **Save** to save the configuration.

> **Note**
>
> You can modify description by using inline editing. Double-click the row that you want to modify, the appliance displays the inline editing editor in the selected row. Click **Save** after modifying comment. You cannot modify IP address using inline editing editor.

Deleting IP Block Groups and IP Blocks

1. For IP block groups: From the **Administration** tab, select the **Reporting** tab -> *Group.*
2. For IP blocks: From the **Administration** tab, select the **Reporting** tab -> *Group* -> *IP block*.
3. Click the Delete icon.
4. In the *Delete Confirmation* dialog box, click **Yes**.

Exporting IP Block Groups and IP Blocks

You can export displayed data or you can export the group list in CSV (comma separated value) format. Exporting group lists or group data may take a few moments based on the amount of exported data.
To export displayed data:

1. For IP block groups: From the **Administration** tab, select the **Reporting** tab -> *Group.*
2. For IP blocks: From the **Administration** tab, select the **Reporting** tab -> *Group* -> *IP block.*
3. From the **Export** drop-down menu, select **Export visible data**. For more information on how to export, see *Importing and Exporting Data using CSV Import*.

To export all data to a CSV file:

1. For IP block groups: From the **Administration** tab, select the **Reporting** tab -> *Group.*
   For IP blocks: From the **Administration** tab, select the **Reporting** tab -> *Group* -> *IP block*.
2. From the Export drop-down menu, select **Export data in Infoblox CSV Import format**. For more information on how to export, see *Importing and Exporting Data using CSV Import.*

Printing IP Block Groups and IP Blocks

1. For IP block groups: From the **Administration** tab, select the **Reporting** tab -> *Group*. For IP blocks: From the **Administration** tab, select the **Reporting** tab -> *Group* -> *IP block.*
2. Click the Print icon. For more information on how to print from Grid Manager, see *About the Grid Manager Interface*.

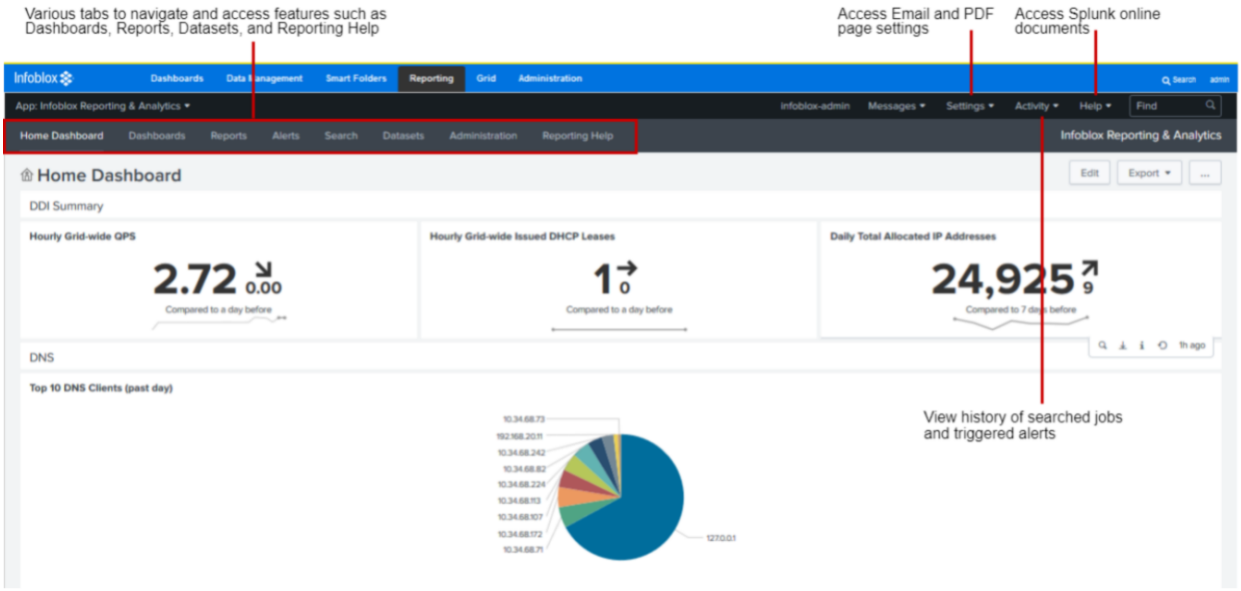
Reporting User Interface Overview

When you access the **Reporting** tab in Grid Manager, you can do the following:

- View and analyze all of your DNS, DHCP, and IPAM data.
- View the reporting data in the form of charts and tables.
- Use the **Search** tab to create or edit searches.

The key options in the **Reporting** tab are: **Home Dashboards**, **Dashboards**, **Reports, Alerts, Search**, **Datasets**, **Administration**, and **Reporting Help**. For more information about these options, refer the below table.

Reporting Tab Overview



The following table summarizes the different tabs and key options that are available on the **Reporting** tab:
Reporting Tab Overview

Tab Name	Purpose	Description
Settings	Email notification settings Server Logging	For information about Configuring Email Notification Settings, see *About Alerts*
Home Dashboard	Overall summary view for the reporting data in your Grid	For information, see *Home Dashboards*
Dashboard	Provide table and graph views for the reporting data in your Grid.	For information, see *About Dashboards*
Reports	Saved searches that retrieve specific type of reporting data	For information, see *About Reports*
Alerts	Set alerts to trigger actions when certain events occur	For information, see *About Alerts*
Search	Create a search interactively from scratch and save it as a dashboard panel, alert and report.	For information about About Searches, see *Home Dashboards*
Datasets	Refer to Splunk documentation for more information.	
Administration	• Set up • Permissions	For information, see *Reporting (Index) Storage Space* For information, see *Administrative Permissions*
Reporting Help	Quick help on some of the reporting topics.	

Hierarchy settings for all the navigation menu options (listed in the Reporting Tab Overview table above) are available in the *default.xml* file.

> **Warning**
>
> *Infoblox recommends that you do not modify the default.xml file. The navigation menu is built on a custom XML structure that is stored as default.xml in the navigation directory (from the **Reporting** tag, select the **Settings** tab -> **User Interface** -> **Navigation Menus** -> default). Editing this file changes the specific default settings for the reporting features and your changes become permanent. In addition, you might not be able to see the latest changes made by Infoblox. To restore the default settings, you must reset the NIOS appliance to its original factory settings. For Information, see Resetting a NIOS Appliance to Factory Settings.*

Predefined Dashboards

Grid Manager includes a list of predefined dashboards that provide summary views for most of the data and trends in your Grid. If you need to modify the settings of a default dashboard, you can either clone the default dashboard, or create a new one from scratch to create a user-defined dashboard that displays multiple reports that are relevant to the activities that you want to monitor. For more information about activities that you can perform on dashboards, see *About Dashboards*.

> **Warning**
>
> Infoblox recommends that you do not modify the predefined dashboards even if you have appropriate permissions. Editing the default dashboards changes the default settings and your changes become permanent. In addition, you might not be able to see the latest changes made by Infoblox. You can select a default dashboard and clone it to modify any of the settings, such as permissions, panels, and so on. For information about cloning dashboards, see *About Dashboards*.

You can apply filters and view the dashboards in table, stacked area, or in both views. The following table lists the dashboard categories and their corresponding dashboards. The dashboards have been explained in detail in the later sections.

Dashboard Categories

Dashboard Category	Corresponding Dashboard	Displays IDNs in Punycode (Yes/No)
Audit Log Events	See the following dashboard categories at *Audit Log Events Dashboards*	
	For Audit Log Events	Yes
	For Audit Log WAPI Events	Yes
IPAMv4 Utilization	See the following dashboard categories at *IPAMv4 Utilization Dashboards*:	
	DHCPv4 Top Utilized Networks	Yes
	DNS Statistics per DNS View	Yes
	DNS Statistics per Zone	Yes

Dashboard Category	Corresponding Dashboard	Displays IDNs in Punycode (Yes/No)
	IPAMv4 Network Usage Statistics	Yes
	IPAMv4 Network Usage Trend	Yes
	IPAMv4 Top Utilized Networks	Yes
	Managed DDI Peak IP Usage Trend	NA
	DNS Object Count Trend for Flex Grid License	NA
	IP Address Usage Report	NA
	VLAN Conflict	NA
	License Pool Utilization	No
	IPAM Prediction Dashboard	No
Devices (Discovery)	See the following dashboard categories at *Devices (Discovery) Dashboards*:	
	Inactive IP Addresses	Yes
	Port Capacity Delta by Device	Yes
	Port Capacity Trend	Yes
	Port Capacity Utilization by Device	Yes
	IP Address Inventory	Yes
	Network Inventory	Yes
Network Insight	End Host History	Yes
	Device Interface Inventory	Yes
	Device Inventory	Yes
	Device Components	Yes
	IPAMv4 Device Networks	Yes
	Device Advisor	Yes

Dashboard Category	Corresponding Dashboard	Displays IDNs in Punycode (Yes/No)
DHCP Dashboards	See the following dashboard categories at *DHCP Dashboards:*	
DHCP Fingerprints	Device Trend	Yes
	Device Class Trend	Yes
	Top Devices Identified	Yes
	Top Devices Denied an IP Address	Yes
	Top Device Classes	Yes
	Device Fingerprint Change Detected	Yes
DHCP Lease	DHCP Lease History	Yes
	DHCP Top Lease Clients	IDN is not supported
	DHCP LPS Usage Report	NA
DHCP Performance	DHCPv4 Range Utilization Trend	Yes
	DHCPv4 Usage Trend	Yes
	DHCP Message Rate Trend	Yes
	DHCPv4 Usage Statistics	No
Cloud Dashboards		
	VM Address History	Yes
System Utilization	See the following dashboard categories at *System Utilization Dashboards*	
	CPU Utilization Trend	Yes
	Memory Utilization Trend	Yes
	Traffic Rate by Member	Yes
	SPLA Grid Licensing Features Enabled	NA
	Managed DDI Features Enabled	Yes

Dashboard Category	Corresponding Dashboard	Displays IDNs in Punycode (Yes/No)
DNS Dashboards	See the following dashboard categories at *DNS Dashboards*	
DDNS Query	DDNS Update Rate Trend	Yes
DNS Performance	DNS Response Latency Trend	Yes
	Managed DNS Peak Usage Trend	NA
	DNS QPS Usage Report	NA
DNS Query	DNS Top Requested Domain Names	Yes
	DNS Top Clients	Yes
	DNS Top Clients Per Domain	Yes
	DNS Query Rate by Query Type	Yes
	DNS Query Rate by Member	Yes
	DNS Replies Trend	Yes
	DNS Response Latency Trend	Yes
	DNS Top Clients Per Domain	Yes
	The DNS Top NXDOMAIN / NOERROR (no data)	Yes
	DNS Top SERVFAIL Errors Sent	Yes
	DNS Top SERVFAIL Errors Received	Yes
	DNS Top Timed-out Recursive Queries	Yes
	DNS Query Trend per IP Block Group	Yes
	DNS Effective Peak Usage Trend for SPLA Grid License	Yes
	DNS Daily Peak Hour Query Rate by Member	No
	DNS Daily Query Rate by Member	No
	DNS Cache Hit Rate Trend	No

Dashboard Category	Corresponding Dashboard	Displays IDNs in Punycode (Yes/No)
System Capacity	System Capacity Prediction Trend	No
Internal Dashboards	See the following dashboard categories at *Internal Dashboards*	
	Reporting Index Usage Statistics	NA
	Reporting License Usage	No
	Reporting Volume Usage Trend per Category	NA
	Reporting Volume Usage Trend per Member	NA
License Dashboards	*License Pool Utilization*	No
DNS Capture	DNS Domain Query Trend	Yes
	DNS Domains Queried by Client	Yes
	DNS Top Clients by Query Type	No
	DNS Top Clients Querying MX Records	No
DNS Traffic Control	DNS Traffic Control Resource Availability Status	No
	DNS Traffic Control Resource Availability Trend	No
	DNS Traffic Control Resource Pool Availability Status	No
	DNS Traffic Control Resource Pool Availability Trend	No
	DNS Traffic Control Resource SNMP Trend	No
	DNS Traffic Control Response Distribution Trend	No
DNS Reclamation	DNS Scavenged Object Count Trend	Yes
Security Dashboards	See the following dashboard categories at *Security Dashboards*	
	FireEye Alerts	Yes
	DNS Top RPZ Hits	Yes
	DNS Top RPZ Hits by Clients	Yes

Dashboard Category	Corresponding Dashboard	Displays IDNs in Punycode (Yes/No)
	Threat Protection Event Count Dashboard	Yes
	Threat Protection Top Rules Logged	Yes
	DNS Top Tunneling Activity	Yes
	DNS Tunneling Traffic by Category	Yes
	Top Malware and DNS Tunneling Events by Client	Yes
	Detailed RPZ Violations by Subscriber ID	NA
	DNS RPZ Hits Trend by Mitigation Action	Yes
	DNS Firewall Executive Threat Report	No
	Top DNS Firewall Hits	No
	Malicious Activity by Client	Yes
Ecosystem Dashboards	See the following dashboard categories at *Ecosystem Dashboards*	
	User Login History Report	Yes
	Subscription Data	Yes
	Publish Data	Yes

Note

To view RPZ-related reports or dashboards, you must enable RPZ logging on the **Logging** tab in the *Grid DNS Properties* editor.

Home Dashboards

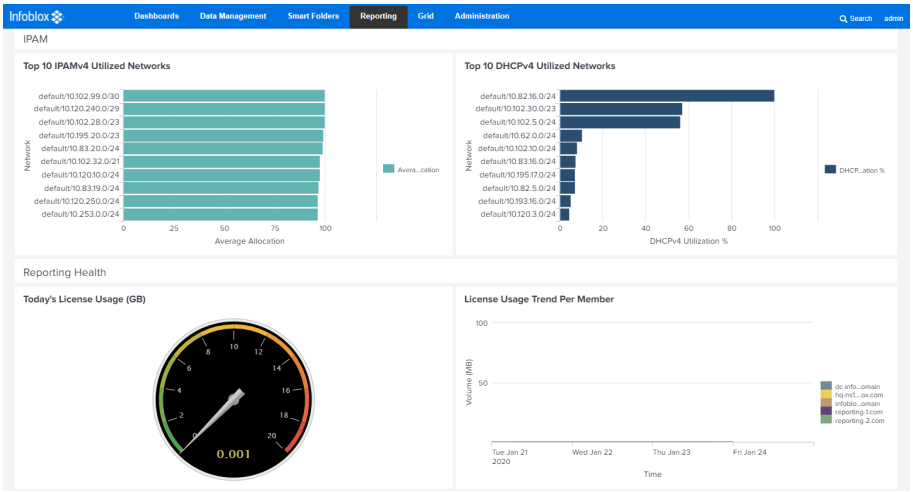
You can view the overall summary of DNS, DHCP, and IPAM activities in the **Home Dashboard** page. This page presents a summary view of the following:

- **DDI Summary**: Presents statistical information about the DNS, DHCP, and IPAM activities of all Grid members.
- **DNS**: Displays the statistical summary of DNS activities. You can export the search results, open in search, and refresh.
- **DHCP**: Displays the statistical summary of DHCP activities. You can export the search results, open in search, and refresh.
- **IPAM**: Displays the summary of the *Top 10 IPAMv4 Utilized Networks* dashboard.
- **Reporting Health**: You can view the license usage by the reporting server:
  - **Today's License Usage**: Current license usage by the indexer.

- **License Usage Trend per Member**: License usage by the indexer per member.

> **Note**
>
> When you click **Open in Search** for a report, dashboard, or alert, the content of the entire page is encoded and displayed in the **Search** page. To avoid encoding, go to **Activity** tab -> **Jobs**. The **Jobs** page lists the search job history in the form of links. The top one is the latest search job executed by the alert or dashboard or report. The search string is not encoded when you click this link to run the search.

Reporting Home Dashboard



On the Home Dashboard, you can also work with searches as described in the following sections:

- About Searches
- Best Practices for Customizing Searches
- Creating Reports from a Search
- Saving a Search as a Dashboard Panel
- Exporting Search Results
- Saving Search as Alerts

About Searches

Searches are criteria that the reporting server uses to save reports and dashboard panels. Each predefined report has an associated search. For more information, refer to the official Splunk documentation: *http://docs.splunk.com/Documentation*.
To run a search:

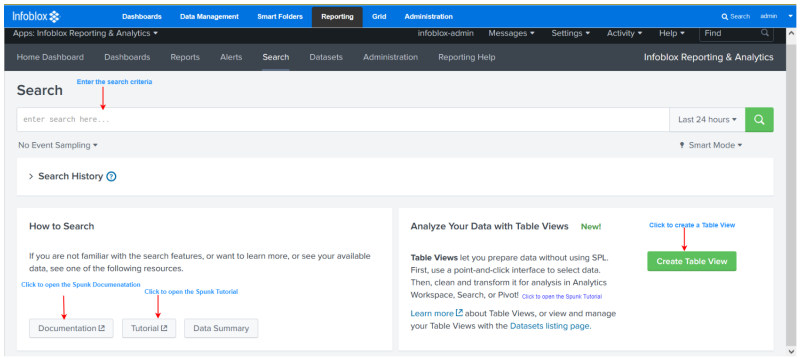
1. From the **Reporting** tab, select the **Search** tab.
2. Enter the search criteria. Use the auto-open search tips from Splunk.
3. If necessary, select a time range in the time range picker at the end of the search bar. By default, it is set to **Last 24 Hours**.
4. Click the Search icon.

The search results are based on the most seen events for the dashboards listed in the table below. To know more about dedup searches, reports, or dashboards, refer to *https://docs.splunk.com/Documentation/Splunk/8.2.4/SearchReference/Dedup*.

Dashboards and Deduplicate Key(s)

Dashboard	Deduplicate Key(s)
Inactive IP Addresses, for more information see *Devices (Discovery) Dashboards* .	Network view + IP address
For more information about these dashboards, see *IPAMv4 Utilization Dashboards* .	
DHCPv4 Top UtilizedNetworks	Network view + network
DNSStatistics per DNSView	DNS view
DNSStatisticsperZone	DNS view + DNS zone
IPAMv4 Network Usage Statistics	Network view + Network
IPAMv4 Top UtilizedNetworks	Network view + Network

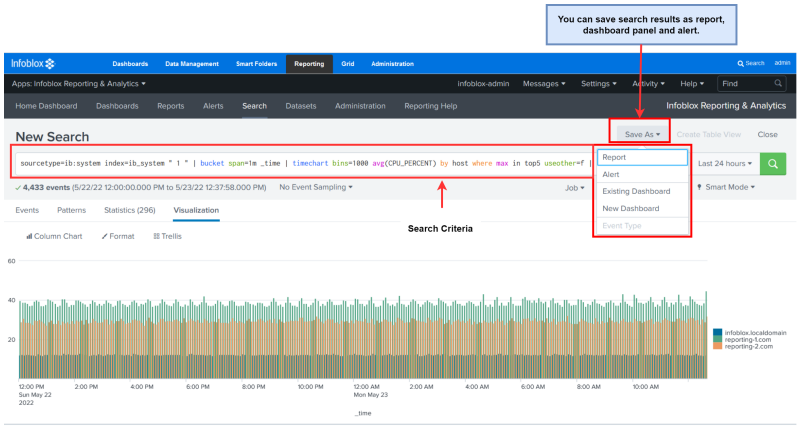
Sample Search Summary



The search results are displayed in the **New Search** panel, as illustrated in the *New Search View*. In the **New Search** panel, you can save search results as **Report**, **Dashboard Panel**, and **Alert**.

When you deploy reporting clustering, we enable Splunk configuration to prevent data loss from forwarders, which may cause duplicated events in the indexer under certain circumstances. When you view reports and dashboards, the events that are already deduped are not duplicated again. However, if you view raw search events (such as write your own search against the indexed data directly), you may still see the duplicated events.

New Search View



Best Practices for Customizing Searches

You can optimize the performance of your reporting server and more efficiently view and manage your reports. Depending on the type of search and the data you want to search for, Infoblox recommends that you use the following guidelines:

- Specify shorter start and end times whenever possible.
    - Time range is one of the most important factors for search performance. Depending on the number of events that need to be loaded from the disk, it might take a long time when you specify a wider time range as it involves a large amount of data.
- Be specific about the fields you use.
    - Rare searches are faster than dense searches, so be specific whenever possible.
    - Start a search from a smaller dataset and then gradually apply it to bigger dataset.
    - When experimenting searches, start with a small date and time range, and then apply it to a bigger time range only when it is optimized.
- If a search is running for a long time, you can use the **Pause** and **Stop** buttons.
    - You can tune the search criteria and run it again if you stop an ongoing search job.
- Configure the panels to display data only if you have specific input instead of adding too many panels to the dashboard.
- Scheduling expensive searches.
    - You can configure reports and dashboards by scheduling searches because prefetched search results are displayed each time the reports and dashboards are opened. This reduces the workload on the reporting server without data freshness.
- Stagger scheduled searches.

Try to stagger your searches whenever possible. When you define how often the reporting server runs a search, be aware of other searches that the server is running. When you schedule the server to run many searches at the same time, the server performance can be negatively affected.

Creating Reports from a Search

You can create reports by saving a search as a report. To save a search as a report:

1. From the **Reporting** tab, select the **Search** tab.
2. Enter the search criteria and then click the Search icon. The search results are displayed in the **New Search** panel.
3. From the **Save As** drop-down list, click **Report** to generate a report.
4. Enter title and description.
5. Click **Save**.
6. Do one of the following in the *Your report has been created* dialog box:
    - Click **View** to view your report on the Report page.
    - Click **Continue Editing** to edit.

- Click **Add to Dashboard** to add new report to the dashboard panel.

You can also complete the following settings in the *Your report has been created* dialog box:

- **Permissions**: Click this to edit permissions for your report, as described in Editing Permissions, see *Administrative Permissions*.
- **Schedule**: Click this to schedule a report. For information about scheduling reports, see *About Reports.*
- **Acceleration**: For more information, refer to the Splunk documentation.

Saving a Search as a Dashboard Panel

You can save a search as a dashboard panel.
Do the following to save a search as a dashboard panel:

1. On the **Reporting** tab, select the **Search** tab.
2. Enter the search criteria and then click the Search icon. The search results are displayed in the **New Search** panel.
3. From the **Save As** drop-down list, choose **New Dashboard** to create a dashboard panel, or, you can choose **Existing Dashboard** to save the search to an existing dashboard panel.
4. In the *Save Panel to New Dashboard* dialog box, complete the following:
    a. In the **Dashboard Title** field, enter a title.
    b. Click **Edit ID** to modify the **Dashboard ID** field. It should only contain letters, numbers, and underscores.
    c. In the **Description** field, type a description.
    d. Select **Classic Dashboards**, or select **Dashboard Studio** and choose **Absolute** or **Grid** layout to create a dashboard.
    Classic Dashboards type of dashboard is the traditional splunk dashboard builder.
    Dashboard Studio type of dashboards are new type of dashboards available with the latest splunk version.
    e. Click **Save to Dashboard**.
5. When prompted, click **View Dashboard** to view the dashboard in the **Dashboard** panel. For more information, see *About Dashboards.*

> ⚠ Note
>
> There are no pre-defined dashboards available for the **Dashboard Studio**.

Exporting Search Results

You can export the data in the selected search in CSV (comma separated value) or XML format. Note that this may take a long time depending on the amount of data you want to export. To schedule the export of search results to an FTP, SCP, or TFTP server configured on the **Set up** page, select **File Transfer Action** when creating a scheduled alert, as described in Creating Scheduled Alerts, see *About Alerts*.
To export data in a selected search:

1. From the **Reporting** tab, select the **Search** tab.
2. Enter the search criteria and then click the Search icon. The search results are displayed in the **New Search** panel.
3. Click the Export icon

    to export search results.
4. In the *Export Results* dialog box, complete the following:
    - **Format**: Select **CSV**, **XML** or **JSON** from the **Format** drop-down list.
    - **File Name**: Specify a file name for the export file. This is optional.
    - **Number of Results**:(**Limited** or **Unlimited**). If you select **Limited**, enter the number of results to be exported in the **Max Results** field.
5. Click **Export**.

Saving Search as Alerts

To save a search as an alert:

1. From the **Reporting** tab, select the **Search** tab.
2. Enter the search criteria and then click the Search icon.
3. From the **Save As** drop-down list, click **Alert**.
4. In the **Save As Alert** dialog box, specify all alert settings. For information about creating scheduling alerts, see *About Alerts.*
5. Click **Save**.

About Alerts

You can configure alerts to trigger actions when certain events occur. When you set up an alert, search results trigger an alert action if they match the alert conditions. You can configure an alert to send an email notification, SNMP trap, and log a message in the syslog. Note that alerts are executed based on update frequencies for each corresponding search. For example, *DHCP Lease History* alerts are executed every 10 minutes, and Device Trend alerts are executed every 30 minutes at the 17th and 47th minutes of each hour (one minute after the search updates). For information about search indexes and update time intervals, see *About Reports* . You can also throttle an alert if you want to change its frequency. For more information, refer to the Splunk documentation.
You can do the following in the **Alerts** page:

- Create scheduled alerts, as described in CreatingScheduledAlerts below.
- Edit permissions, as described in Editing Permissions, see *Administrative Permissions*.
- Edit alert type, trigger condition, and alert actions, as described in EditingAlerts below.
- Clone an alert, as described in Cloning Alerts below.

Creating Scheduled Alerts

You can schedule an alert to notify when a scheduled report returns results that meet a specific condition. The appliance sends an alert when it encounters the trigger condition.

1. From the **Reporting** tab, select the **Alerts** tab -> select an *alert* and click **Open in Search**.
2. From the **Save As** drop-down list, click **Alert**.
3. In the *Save As Alert* dialog box, complete the following:
    - Specify the title and description.
    - **Alert Type**: Select Scheduled
    - **Time Range**: Specify the time range. For example, you can select **Run Every Day**.
    - **Schedule At**: Specify the time.
    - **Trigger Condition**: Specify trigger conditions. For more information, refer to the Splunk documentation.
    - **Trigger Actions**: Click this to configure alert actions. You can select the following:
        - **Send SNMP Trap**: Select this to enable SNMP traps. For information about how to trigger SNMP traps for reporting event types, see *Configuring SNMP*.
        - **Send email**: Select this to send alert notification through email. You can specify email address in the **To** text box.
        - **Send to Syslog**. Select this to log a message in the syslog. If you configure this option with an alert, the message goes to the syslog on the reporting member or indexer.
        - **File Transfer Action**: Select this to upload the search results to an FTP or SCP or TFTP server configured on the **Set up** page. For information about Reporting (Index) Storage space, see *Grid Reporting Properties*.
4. Click **Save**.

Editing Alerts

You can edit alert type, trigger condition, and alert actions, as follows:

1. From the **Reporting** tab, select the **Alerts** tab -> select an *alert*.
2. From the **Edit** drop-down list, choose **Edit Alert** to edit the alert settings. In the *Edit Alert* dialog box, make the required changes.
3. Click **Save**.

Cloning Alerts

1. From the **Reporting** tab, select the **Alerts** tab.
2. Select an alert you want to clone, click **Edit** -> **Clone**.
3. Enter a title and a description. Click **Clone Alert**.

> ⚠ Note
>
> Infoblox recommends that you save the cloned alerts only in the Infoblox Reporting & Analytics (infoblox) app.

Configuring Email Notification Settings

You can enable the appliance to send email messages to specified recipients when the alert is triggered. You can configure email settings for alerts, scheduled reports, and scheduled PDF delivery.
To configure email properties for alerts and PDF delivery:

1. From the **Reporting** tab -> **Settings** tab -> click **Server settings**.
2. Click **Email settings**.
3. Specify the mail host. The default is local host.
4. Optionally, you can specify username and password.
5. Specify **Email Format**.
6. In the **Specify PDF Report** Settings, specify the paper size, paper orientation, and also the path to logo image.
7. Click **Save**.

> ⚠ Note
>
> You can configure email addresses when scheduling dashboard PDFs, scheduling reports, and creating alerts.

About Reports

Infoblox provides reports that are named by core network service functions, such as DNS query and system utilization. Reports contain predefined search criteria that retrieve specific data from the reporting database. Each report is associated with a search. It is not recommended to modify predefined reports. However, when you run a search, you can save it as reports and share it with other users. You can also create a new report by cloning an existing report, and then modify the search criteria.
You can also create a personal report in two different ways:

- Clone a report, as described in the Cloning Reports section below.
- Saving a search as a report, as described in the Creating Reports from a Search section below.

> **Note**
>
> IDNs are not supported on the reporting server. The reporting server manages IDNs in punycode. The reports generated by collecting reporting data from the DNS server displays all the data in punycode only.

When you upgrade to 7.3.x, all NIOS Global reports are migrated to the **Dashboards** panel without filters. However, the filter conditions configured in NIOS are reflected in the **Dashboards** panel. All NIOS System and Global searches are migrated to the **Reports** panel.
You can do the following in the **Reports** tab:

1. From the **Reporting** tab, select the **Reports** tab -> select a report.
2. In the **Reports** panel, you can do the following:
    - Open a report in the **Search** page and edit the report using the **Save As** menu. For information about Searches, see *Home Dashboards*.
    - You can do the following using the **Edit** drop-down list:
        - Edit Description
        - Edit Permissions, as described in the Editing Permissions section, see *Administrative Permissions*.
        - Edit Schedule, as described in the Scheduling Reports section below.
        - Clone a report, as described in the Cloning Reports section below.

Reporting Indexes and Update Time Intervals

The Reporting Indexes table below lists the search indexes that the reporting server uses to generate reports. It contains information about the frequency of the summary report updates for each report and the percentage of the total index space allocated for each report category. Use this information to plan your reporting strategy for the Grid so you can optimize the performance of the reporting server.
Each summary report or search has its own update frequency. For example, the *DNS Top Requested Domain* report updates its data every 30 minutes, starting at the 4**th** minute of each half hour. It collects report data during the first 30 minutes of the previous 60 minutes. For example, if the report starts an update at 6:04 a.m., the data it collects is from 5:04 a.m. to 5:34 a.m.
The reporting server also uses this information to generate alerts. For example, once configured, Top Devices Identified alerts are executed at the 17**th** and 47**th** minutes of each hour (one minute after each update), regardless of whether DHCP fingerprint detection is enabled or disabled. For information about alerts, see *About Alerts*

> **Note**
>
> The maximum retention period for the reporting data is 136 years. However, the data is removed from the database if the data exceeds the maximum limit for a reporting index and when the data crosses the retention period (after 136 years).

Reporting Indexes

Indexes	Reports/Searches	Summary Report Data Updates	Default Maximum Index Size (% of Total Index Storage)	
Device (Discovery)			0%	
	Inactive IP Addresses	N/A		
	Port Capacity Utilization by Device	N/A		

Indexes	Reports/Searches	Summary Report Data Updates	Default Maximum Index Size (% of Total Index Storage)	
	Port Capacity Trend	N/A		
	Port Capacity Delta by Device	N/A		
	IP Address Inventory	N/A		
	Network Inventory	N/A		
	IPAMv4 Device Networks	N/A

	IPAMv4 Network Usage Statistics (Detailed)	N/A		
	DNS Statistics per DNS View (Detailed)	N/A		
	DNS Statistics per Zone (Detailed)	N/A		
	IPAMv4 Top Utilized Networks (Detailed)	N/A		
	DNS Object Count Trend for Flex Grid License	Data is generated once every 24 hours		

Indexes	Reports/Searches	Summary Report Data Updates	Default Maximum Index Size (% of Total Index Storage)	
DNS			10%	
	DDNS Update Rate Trend	N/A		
	DNS Response Latency Trend (Summary)	N/A		
	DNS Cache Hit Rate Trend	N/A		
	DNS Query Rate by Query Type	N/A		
	DNS Query Rate by Server (Detailed)	N/A		
	DNS Replies Trend	N/A		
	DNS Query Trend Per IP Block Group	N/A		
	FireEye Alerts	N/A		
DNS Summary			10%	
	DDNS Update Rate Trend (Summary)	Every 30 minutes, starting at the 6**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Response Latency Trend (Summary)	Every 30 minutes, starting at the 20th minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Top Requested Domain Names (Summary)	Every 30 minutes, starting at the 4**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Cache Hit Rate Trend (Summary)	Every 30 minutes, starting at the 8**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Effective Peak Usage Trend for SPLA Grid License	NA		

Indexes	Reports/Searches	Summary Report Data Updates	Default Maximum Index Size (% of Total Index Storage)	
	DNS Top Clients (Summary)	Every 30 minutes, starting at the 2**nd** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Query Rate by Query Type (Summary)	Every 30 minutes, starting at the 10**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Query Rate by Member (Summary)	Every 30 minutes, starting at the 12**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Daily Query Rate by Member (Summary)	Every day, starting at 00:32 each day. Data covers from 00:00 of yesterday to 00:00 of today.		
	DNS Daily Peak Hour Query Rate by Member (Summary)	Every 60 minutes, starting at the 34**th** minute of each hour. Data covers from the top of last hour to the top of current hour.		
	DNS Replies Trend (Summary)	Every 30 minutes, starting at the 18**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Top Clients Per Domain (Summary)	Every 30 minutes, starting at the 3**rd** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Top NXDOMAIN / NOERROR (no data) (Summary)	Every 30 minutes, starting at the 5**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Top SERVFAIL Errors Sent (Summary)	Every 30 minutes, starting at the 6**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Top SERVFAIL Errors Received (Summary)	Every 30 minutes, starting at the 7**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DNS Top Timed-Out Recursive Queries (Summary)	Every 30 minutes, starting at the 8**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		

Indexes	Reports/Searches	Summary Report Data Updates	Default Maximum Index Size (% of Total Index Storage)	
	DNS Top RPZ Hits (Summary)	Every 10 minutes, starting at the 2**nd** minute of each 10 minute. Data covers from 20 minute ago to 10 minute ago.		
	DNS Top RPZ Hits by Clients (Summary)	Every 10 minutes, starting at the 2**nd** minute of each 10 minute. Data covers from 20 minute ago to 10 minute ago.		
	DNS Scavenged Object Count Trend	Every 30 minutes, starting at every 21**st** and 51**st** minute of each hour.		
	DHCP			2 Months
		DHCPv4 Usage Statistics (Detailed)	N/A	
		DHCPv4 Range Utilization Trend (Summary)	N/A	
		DHCP Message Rate Trend (Detailed)	N/A	

Indexes	Reports/Searches	Summary Report Data Updates	Default Maximum Index Size (% of Total Index Storage)	
DHCP Summary			24 Months	
	Device Trend (Summary)	Every 30 minutes, starting at every 16**th** and 46th minutes of each hour. Data covers the first 30 minutes of the previous 60 minutes.		
	Device Class Trend (Summary)	Every 30 minutes, starting at every 16**th** and 46th minutes of each hour. Data covers the first 30 minutes of the previous 60 minutes.		
	Top Devices Identified (Summary)	Every 30 minutes, starting at every 16**th** and 46th minutes of each hour. Data covers the first 30 minutes of the previous 60 minutes.		
	Top Devices Denied an IP Address (Summary)	Every 30 minutes, starting at every 19**th** and 49th minutes of each hour. Data covers the first 30 minutes of the previous 60 minutes.		
	Top Device Classes (Summary)	Every 30 minutes, starting at every 16**th** and 46th minutes of each hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DHCP Top Lease Clients (Summary)	Every 30 minutes, starting at the 16**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	DHCPv4 Range Utilization Trend (Summary)	Every 8 hours, starting at the 24**th** minute of each half hour. Data covers the first 8 hours of the previous 8.25 hours.		
	DHCPv4 Usage Trend (Summary)	Every 8 hours, starting at the 22**nd** minute of each half hour. Data covers the first 8 hours of the previous 8.25 hours.		
	DHCP Message Rate Trend (Summary)	Every 30 minutes, starting at the 14**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
DHCP Lease History			39%	
	DHCP Lease History (Detailed)	N/A		

Indexes	Reports/Searches	Summary Report Data Updates	Default Maximum Index Size (% of Total Index Storage)	
	Device Fingerprint Change Detected (Detailed)	N/A		
Security			1%	
	Threat Protection Event Count By Severity Trend (Summary)	N/A		
	Threat Protection Event Count By Member Trend (Summary)	N/A		
	Threat Protection Event Count By Rule (Summary)	N/A		
	Threat Protection Event Count By Category (Summary)	N/A		
	Threat Protection Event Count By Time (Summary)	N/A		
	Threat Protection Event Count By Member (Summary)	N/A		
	Threat Protection Top Rules Logged (Summary)	N/A		
	Threat Protection Top Rules Logged by IP (Summary)	N/A		
	DNS Top Tunneling Activity (Summary)	Every 30 minutes, starting at every 11**th** and 41st minute of each hour.		
	DNS Tunneling Traffic by Category (Summary)	Every 30 minutes, starting at every 11**th** and 41st minute of each hour.		
	Top Malware and DNS Tunneling Events by Client (Summary)	Every 30 minutes, starting at every 11**th** and 41st minute of each hour.		
Cloud	VM Address History (Detailed)	N/A	0%	
Audit Log	Audit Log Events (Detailed)	N/A	0%	

Indexes	Reports/Searches	Summary Report Data Updates	Default Maximum Index Size (% of Total Index Storage)	
	Audit Log WAPI Events	N/A	0%	
Ecosystem	Ecosystem Subscription Ecosystem Publication	N/A		
License	License Pool Utilization	N/A	1%	
System Utilization			15%	
	Memory Utilization Trend (Summary)	Every 30 minutes, starting at the 26**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes		
	Memory Utilization Trend (Detailed)	N/A		
	Traffic Rate (Detailed)	N/A		
	Traffic Rate by Member (Summary)	Every 30 minutes, starting at the 28**th** minute of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	CPU Utilization Trend (Summary)	Every 30 minutes, starting at the top of each half hour. Data covers the first 30 minutes of the previous 60 minutes.		
	SPLA Grid Licensing Features Enabled	Every 24 hours for all IB-FLEX members in the Grid.		

⚠ When you filter a dashboard by a time frame that is larger than the maximum retention period, the reporting server returns data within the maximum retention period. For example, when you try to view data of the *CPU Utilization Trend* report for the past six months, the server only returns data up to the last two months.

Cloning Reports

1. From the **Reporting** tab, select the **Reports** tab.
2. Select the report you want to modify, click **Edit** -> **Clone**.
3. Enter a new title and description.
4. Set its permissions. Select **Private** if you do not want to share the cloned report with other users. Select **Clone** if you want the cloned report to have the same permissions as the original report.
5. Click **Clone Report**.
6. Optionally, you can do the following:
   - Edit the permissions as described in the Editing Permissions section, see *Administrative Permissions*.
   - Click **View** to view the cloned report.
   - Click **Add to Dashboard** to add the cloned report to the dashboard.

Click **Open in Search** to open the cloned report in the **Search** page.

> ⚠ Note
>
> Infoblox recommends that you save the cloned reports only in the Infoblox Reporting & Analytics (infoblox) app.

Deleting Reporting Data

To selectively delete reporting data from NIOS, you must first enable the `delete` permission for the local admin with superuser permission by using the *set reporting_user_capabilities* command in the NIOS CLI. Then, complete the following:

1. From the **Reporting** tab, select the **Search** tab.
2. Enter the search criteria in the search bar that returns the events you want to delete and click the **Search** icon.
3. After you confirm that the search results contain only those events that you want to delete, pipe the search to the `delete` command.

   Example:
   ```
   <Splunk_Query> | delete
   ```

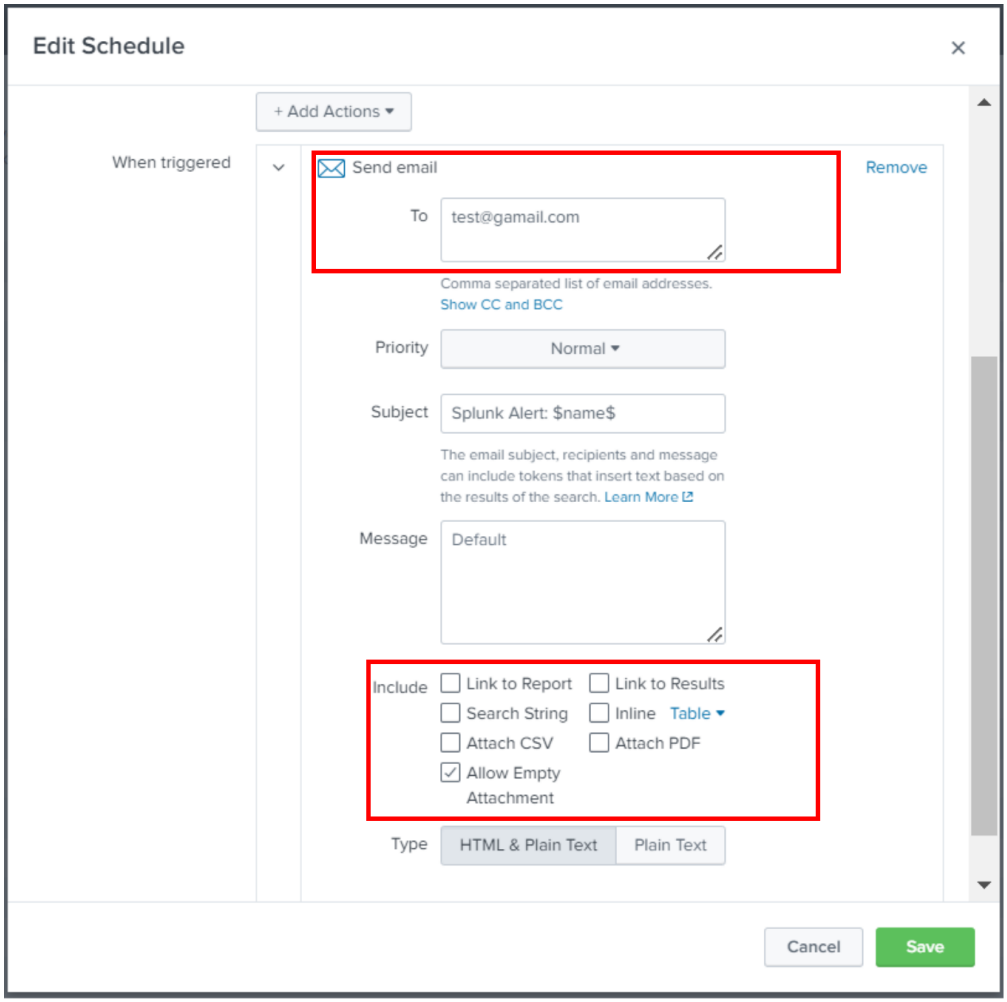
   For more information, see the Splunk documentation.

> ⚠ Notes
>
> - You cannot retrieve the data once it is deleted.
> - You cannot visualize the deleted data.
> - The deleted data does not reduce any disk space.
> - Frequent deletion of data may affect the search performance.
> - You must not delete any of the `ib_threatdb*` index files as it results in loss of threat events data.

Scheduling Reports

You can schedule a report to run on a scheduled interval and trigger an action each time it runs. When scheduling a report, you can set up an action to send an email to receive report results. In addition, you can export results in CSV (comma separated value) or XML format.
To schedule a report:

1. From the **Reporting** tab, select the **Reports** tab.
2. Select the report you want to schedule, click **Edit** -> **Edit Schedule**.
   Note that you can schedule a report when you save search results as reports. When you set the paper size to **A5**, the logo image and report name may overlap in the footer of the downloaded reports or reports sent through email.
3. In the *Edit Schedule* dialog box, select the **Schedule Report** checkbox.
4. Enter the **Schedule** and **Time Range**. For more information about how to use the **Schedule** and **Time Range** options, refer to the Splunk documentation.
5. Click **Add Actions**, and then to set an action for the scheduled reports, select **Send Email** to send an email that contains report results in text format, or as CSV or PDF attachments to a specified set of recipients.
   - Enter the email address in the **To** text box. To send the email message to multiple recipients, type a comma between email addresses.
     Edit Schedule



- In the **Include** section, select one of the following: **Inline Table**, **Attach CSV**, **Attach PDF**. Selecting **Attach PDF** or **Attach CSV** attaches the results of the report in the form of a CSV file or a PDF. You can also select the **Allow Empty Attachment** for attachment-based include options. Ensure that you specify this information.

6. Click **Save**.

Infoblox recommends that you do not select Link to Report, Link to Results, Search String in the Include section. These links might not work in your environment. Do not select the Run a Script option because there is no script to run.

Configuring Logo Image in PDF Reports

All reports display the Infoblox logo by default. You can customize reports by removing the Infoblox logo, or by replacing it with your own company logo. The reporting server uses the latest image file that you have uploaded. Make sure that you upload a logo file that is in PNG format and has a file size that is smaller than 500 KB. Note that the image file name must be *pdf_logo_image.png*. Do not change the logo image file name. You can configure your PDF reports and schedule to send them through emails. For information about scheduling the delivery of reports, see Scheduling Reports below.

> **Note**
>
> In the footer of the report, you can view the logo image (if uploaded), panel name, and the timestamp when the report was downloaded. When there is no data in a single panel report, the downloaded PDF displays "No Results Found" along with "Last Updated" information. However, a report with multiple panels, displays only the panel name for the panel that does not have any data.

To upload logo image:

1. From the **Administration** tab, select the **Reporting** tab -> expand the Toolbar and click **Grid Reporting Properties**.
   or
   From the **Grid** tab, select the **Grid Manager** tab and click the **Services** tab. On the **Services** tab, select the **Reporting** tab and click **Edit** -> **Grid Reporting Properties** from the Toolbar.
2. In the Grid Reporting Properties editor, select the **PDF** tab and complete the following:
   Logo Image: Click **Upload** to open the *Upload* dialog box. Click **Select** to navigate to where the image file is located and click **Open**. Click **Upload** to upload the file. The appliance displays a preview of how it will appear on reports after you successfully upload the logo file. You can click **Clear** to remove the logo and upload a new one. Make sure that the file format and size meet the requirements; otherwise, the appliance displays an error message. You can click **Clear** to remove the uploaded image file.
3. Click **Save & Close**.

About Dashboards

Dashboards provide summary views for most of the data and trends in your Grid. Grid Manager includes a list of default dashboards. For more information, see *Predefined Dashboards*. Infoblox recommends not to modify the default dashboards. If you need to modify the settings of a default dashboard, you can either clone a default dashboard, or create a new dashboard from scratch and then add panels and reports. For example, you can create a new dashboard called "DNS and DHCP Activities," and then add DNS report, add DHCP related reports, such as DHCP Top Lease Clients and DHCP Lease History, to the new dashboard. When you save the "DNS and DHCP Activities" dashboard, the reporting server saves all the reports added to the dashboard and displays dashboard with updated data. By doing this, user-defined dashboards can provide single point of access to review multiple reports that are relevant to the activities you want to monitor. If you modify a default dashboard, you can reset to its default settings. Each dashboard comes with a set of filters to further refine report data.

When you upgrade to 7.3.0 or later, all your system reports are migrated to **Reporting** tab -> **Dashboards**.

> **Warning**
>
> Infoblox recommends that you do not modify the predefined dashboards even if you have appropriate permissions. Editing the default dashboards changes the default settings and your changes become permanent. In addition, you might not be able to see the latest changes made by Infoblox. You can select a default dashboard and clone it to modify any of the settings such as permissions, panels, and so on. For more information, see Cloning Dashboards below.

In the **Dashboard** panel, you can do the following using the **Edit** drop-down list:

- Edit panels as described in the Editing Dashboards section below.
- Edit source, title, and description.
- Edit permissions as described in the Editing Permissions section below.
- Clone a dashboard as described in the Cloning Dashboards section below.
- Reset dashboards, as described in the Resetting Dashboards section below.

> **Note**
>
> You cannot set any dashboard as the home dashboard. The **Set as Home Dashboard** option available in the **Edit** drop-down list does not add a dashboard to the **Home Dashboard** tab.

Creating New Dashboards

When you add a new dashboard, Grid Manager displays it in the **Reporting** -> **Dashboards** tab. You can add multiple panels and reports to the new dashboard.
To create a new dashboard:

1. From the **Reporting** tab -> select the **Dashboards** tab.
2. Click **Create New Dashboard**.
3. Complete the following:
   - **Dashboard Title**: Enter the dashboard title.
   - **Description**: Enter the dashboard description.
   - **Permissions**: Click **Shared in App** to share a dashboard to other users. Depending on their permissions, other users can edit the dashboard. When **Private** is selected, the dashboard is available only to the user who creates it. You can change permissions later while editing a dashboard.
   - Select **Classic Dashboards** or **Dashboard Studio** and choose **Absolute or Grid layout to create a dashboard in Dashboard Studio.**
     Classic Dashboards type of dashboard is the traditional Splunk dashboard builder.
     Dashboard Studio type of dashboards are new type of dashboards available with latest version of Splunk. For details on Splunk Dashboard Studio, please refer *https://docs.splunk.com/Documentation/Splunk/8.2.4/DashStudio/IntroFrame*.
4. Click **Create**.

> **Note**
>
> - Uploading a background image or icons to **Dashboard Studio** type dashboards is not supported.
> - There are no pre-defined dashboards available for **Dashboard Studio**.

Cloning Dashboards

It is not recommended to modify default dashboards. You can select a default dashboard and clone it to modify any of the settings, such as permissions, panels, and so on.

> **Note**
>
> You do not need any permission to create, modify, and delete your own personal dashboard. However, limited-access users need **Read** and **Write** permissions to modify cloned dashboards. For information about administrative permissions, see *Administrative Permissions.*

When you clone a dashboard, you can do the following:

- View and set permissions, as described in Editing Permissions, see *Administrative Permissions.*
- Schedule PDF delivery, as described in Scheduling PDF Delivery for Dashboards below.
- Edit panels, as described in Editing Dashboards below.

To create a personal dashboard:

1. From the **Reporting** tab, select the **Dashboards** tab.
2. Select the dashboard you want to modify, click **Edit** -> **Clone**.
3. Enter a new title, ID, and description.
4. Set its permissions. Select **Private** if you do not want to share the cloned dashboard with other users. Select **Clone** if you want the cloned dashboard to have the same permissions as the original dashboard.
5. Click **Clone Dashboard**.
6. Optionally, you can edit permissions, as described in Editing Permissions, see *Administrative Permissions* or click **View** to view the cloned dashboard.

Resetting Dashboards

Infoblox recommends not to modify default dashboards. However, when you make changes to the default dashboards, you can reset to its default settings.
To reset a dashboard:

1. From the **Reporting** tab -> select the **Administration** tab.
2. Click **Reset Dashboards**.
3. Select the checkbox of the dashboard or Select all to select all the dashboards.
4. Click **Reset selected dashboards**.

The dashboard you have modified will reset to its default settings.

Editing Dashboards

To edit the panels and filters of a dashboard, it is recommended to clone the default dashboard, and then add panels, filters and reports to the cloned dashboard. When you add a report to the panel, Grid Manager generates the corresponding dashboard in the panel. When you save the dashboard, Grid Manager updates reports in each panel. Alternatively, you can edit the XML source code to add filters and panels to a cloned dashboard, as described in Editing the XML Source Code of a Dashboard below.
To add panels and filters to a dashboard:

1. From the **Reporting** tab -> select the **Dashboards** tab -> select a *dashboard*.
2. From the **Edit** drop-down list, select **Edit Panels**.
3. In the **Edit: <Dashboard>** pane, you can click **Add Panel** or **Add Input** or **Edit Source**.
   Note that you cannot modify or delete the default values set for the dashboard filters. For example, you cannot delete or modify the filter All set for Members. When you add a new input using the editor, make sure that you edit the source and refer to the token for the input in the search string. By doing so, the search is updated when you change the input value. For information editing source, refer to Splunk documentation.
4. Optionally, you can click  to delete a filter. When you delete a filter, make sure that you delete the filter information from the XML source code as well. For information, see Editing the XML Source Code of a Dashboard below.
5. Expand the panel categories and select the panel you want to add. For detailed information about how to add panel categories, refer to the Splunk documentation.
6. Click **Add to Dashboard**.

Editing the XML Source Code of a Dashboard

Note

Before editing dashboards, forms, and panel files in simple XML source code, you should be familiar with the basic layout of dashboards and the XML elements that define them. Infoblox recommends that you save a copy of the source code of the dashboard before making any modifications.

To edit the XML source code for a dashboard:

1. From the **Reporting** tab, select the **Dashboards** tab.
2. Select a dashboard you want to edit the XML source code, click **Edit** -> **Edit Source**.

   You can add filters, such as checkbox, drop-down list, radio button, and text box. For information about how to edit the XML source code, refer to the Splunk documentation.

Example - Adding an extensible attribute filter

If your reporting data contains the "location" extensible attributes associated to members, adding the following sample XML code to the XML source code will create an extensible attribute filter, **Member Location**:

```
<input type="dropdown" token="ea_location">
       <label>Member Location</label>
       <choice value="All">All</choice>
       <default>All</default>
       <search>
         <query>| inputlookup __grouping_by_ea_tag_lookup
                | spath input=EA path=Location output=EA_Location
                | stats count by EA_Location </query>
         <earliest>$time.earliest$</earliest>
         <latest>$time.latest$</latest>
      </search>
      <fieldForLabel>EA_Location</fieldForLabel>
      <fieldForValue>EA_Location</fieldForValue>
      <change>
        <condition value="All">
          <set token="ea_location_str"> | noop </set>
        </condition>
        <condition value="*">
         <set token="ea_location_str"> | spath input=EA path=Location
output=EA_Location
                                       | where EA_Location="$value$"</set>
        </condition>
      </change>
```

```
    </input>

    <search id="base_search">
       <query>index=ib_system_summary report=si_cpu_usage
              $members$
              $ea_site_str$
              $ea_location_str$
              $group_by_str$
              $group_by_stats$
            | timechart bins=1000 $calculation_method$(CPU_PERCENT) by
$time_chart_field$
    where max in $topn$ useother=f
             | interpolate 1200</query>
       <earliest>$time.earliest$</earliest>
       <latest>$time.latest$</latest>
    </search>
```

Scheduling PDF Delivery for Dashboards

To schedule PDF delivery for dashboards, you must first create a new dashboard. Ensure that email notification settings are configured prior to scheduling PDF delivery. For more information about Configuring Email Notification Settings, see *About Alerts*. To schedule PDF delivery, you can use the dashboard **Edit** drop-down list. You can access the **Edit** drop-down list directly from a dashboard or from the **Dashboards** page.

> ⚠ Note
>
> Scheduled PDF delivery is not available for dashboards that include forms.

Do the following if the **Schedule PDF Delivery** option is disabled:

1. Open the dashboard for which you want to schedule PDF delivery.
2. Click **Open in Search** icon available at the bottom of the dashboard panel.
3. From the **Save As** menu, click **Dashboard Panel**.

To set up PDF delivery for the dashboard with a single panel:

1. From the **Reporting** tab, select the **Dashboards** tab.
2. Do one of the following:
    - Select the dashboard you want to schedule, click **Edit** -> **Schedule PDF Delivery**. If the **Schedule PDF Delivery** option is disabled, follow the steps as described above.

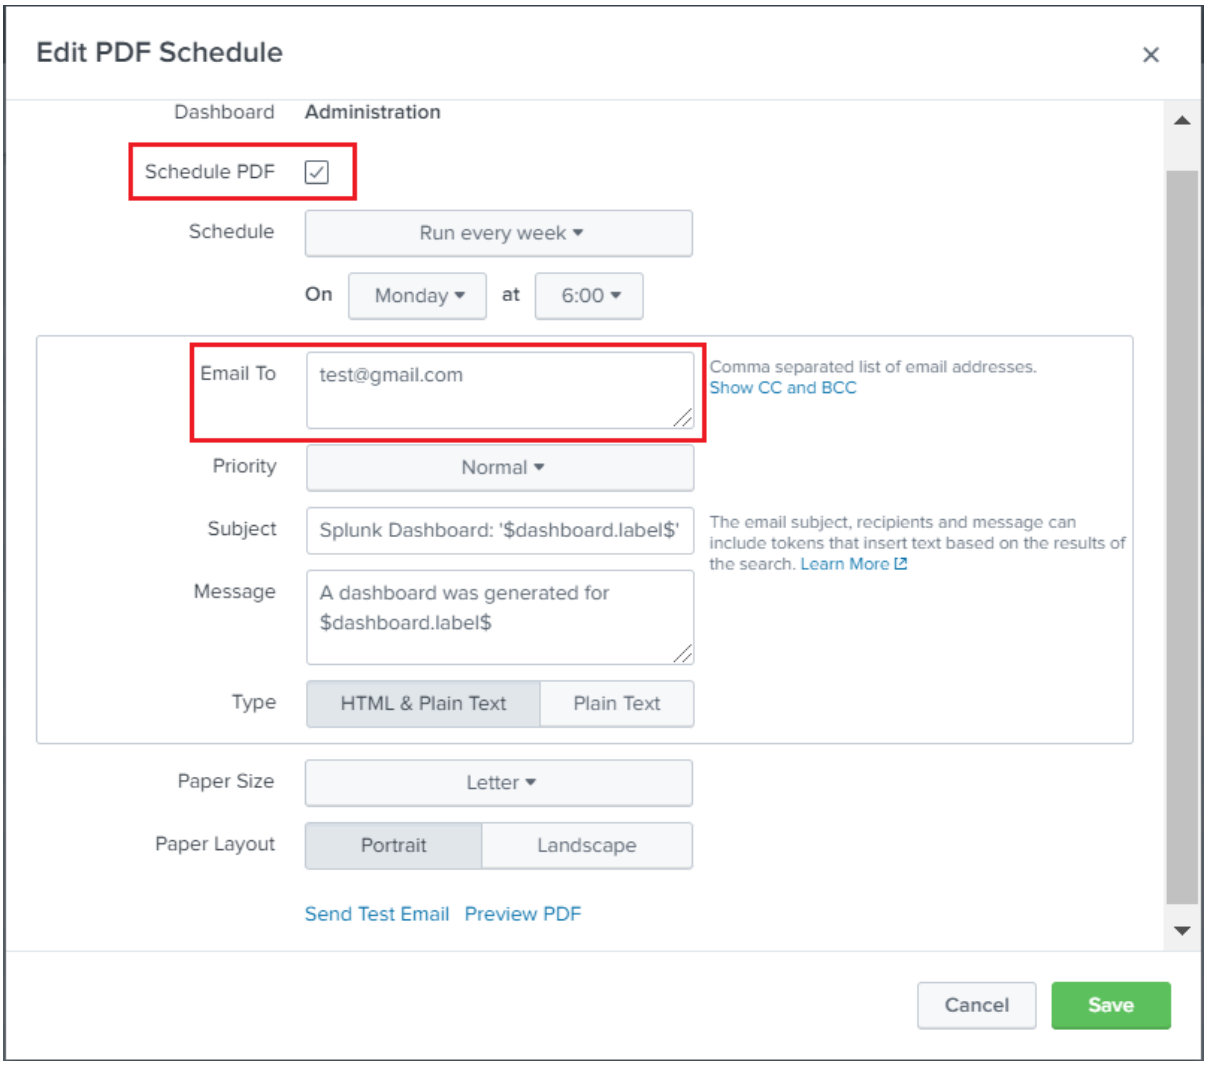
- Open the dashboard in the **Dashboards** page and click **Schedule PDF Delivery** from the **Edit** drop-down list.

3. In the *Edit PDF Schedule* dialog box, do the following:
   - Select the **Schedule PDF Delivery** checkbox to enable PDF delivery.
   - Select a schedule. For more information, refer to the Splunk documentation.
   - In the **Email To** text box, specify email address.
   - Select paper size and paper layout. You can change the paper size and paper layout, if data is not displayed properly in the PDF delivery.
   - To receive dashboard PDFs immediately, click **Send Test Email**.

4. Click **Save**.

> **Note**
>
> To set up PDF delivery for the dashboard with multiple panels, repeat the above steps from step 1 to step 4 and add other panels to the dashboard created for the first panel.

Edit PDF Schedule dialog box



Click **Send Test Mail** to receive Dashboard PDFs Immediately.

About Dashboard Filters

You can apply different filters to control the data displayed in the dashboards. The data on the dashboard is displayed based on the various filter criteria you select.
To apply a filter:

1. From the **Reporting** tab, select the **Dashboards** tab -> select a *dashboard*.
2. Apply filter criteria appropriately and click **Submit**.
   The dashboards display results based on the filters that you apply.

The most common filters are as follows:

- **Time**
- **Top N**: Topmost filter options. The default is 10. You can select from a set of fixed values for the TopN filter setting: 5, 10, 20, 50, 100, 200, 250, or 500.
- **Members**: Grid members configured on the appliance.
- **Network**
- **Member Site**, as described in Applying Extensible Attribute Filters below.

Applying Time Filters

You can generate a dashboard for a specific time interval by applying time filters. You can filter results by preset time ranges, create custom time ranges, specify time ranges based on dates or date and time, or work with advanced features in the time range picker. For information about Time range picker, refer to the Splunk documentation.
The date and time displayed in the **Time** filters are based on the time zone set in your user profile by default. For more information about how to configure a time zone, see Setting the Browser Time Zone in *Setting Login Options*.
However, the timestamp displayed in the results for a dashboard is based on the time zone configured on the reporting server.

Note

The NIOS reporting data is updated at a certain time interval, rather than updating continuously. Therefore, the **Real-time** option in the **Time** filter might not work for most of the dashboards. For information about update time intervals, see Reporting Indexes and Update Time Intervals in *About Reports*.

Applying Extensible Attribute Filters

You can use extensible attribute filters to narrow down the search by including only members that contain certain extensible attribute values. An extensible attribute added to a member is displayed in the **Extensible Attribute** filter. For information about managing extensible attributes, see *Managing Extensible Attributes*. When you configure group-by-extensible-attribute search and apply the **Extensible Attribute** filter, the dashboard displays results for grouped members that have the same extensible attribute value for the **Site** extensible attribute. If you have configured multiple attribute values for a member, then applying the **Extensible Attribute** filter displays all the attribute values associated with that member. For example, if member 1 has predefined attribute **Site** with attribute values `member a` and `member b` an d member 2 has predefined attribute **Site** with attributes values `member c` and `member d`, then the dashboard displays `member a` and `member b` when you apply the **Member Site <member 1>** filter.
In addition, you can apply **Group By EA Tag** filter and group members with the same extensible attribute value so that instead of displaying data per member, the reports display data per group of members with the same value for the **Site** extensible attribute. When you apply **Group By EA Tag** filter, you can set the data calculation method to decide which statistic value [Aggregate, Average, or Maximum] you want to be displayed for grouped members. You can group by Active Directory Sites for the *IPAMv4 Network Usage Statistics* report, *IPAMv4 Top Utilized Networks* report, and *DHCPv4 Network Usage Statistics* report.
To apply an extensible attribute and group by EA tag/field filters:

1. From the **Reporting** tab, select the **Dashboards** tab -> select a dashboard.
2. In the filter section, complete the following:
    - **Member <Extensible Attribute>:** Select an extensible attribute configured for a member. If you need an additional extensible attribute filter, you must first clone the default dashboard, and then add an extensible attribute filter by editing the XML source code. For information, see Editing the XML Source Code of a Dashboard above.
    - **Group By EA Tag/Field**: Select an extensible attribute to enable the reporting server to group networks by members that have certain extensible attribute tags or fields. Note that this option is available for specific dashboards only.
      Note that if you use special characters in the extensible attribute name, the appliance replaces these special characters with equivalent values. For example, the extensible attribute **Site In London** is displayed as Site20In20London in the **Group By EA Tag/Field** drop-down list. In this example, space is replaced with 20. If you add the extensible attribute **London@**, it is displayed as **London40** in the **Group By EA Tag/Field** drop-down list.
    - **Calculation Methods**: This field is enabled only when you select the **Group by EA Tag/Field** checkbox. The displayed result varies based on your search definitions. The result values can contain information such as event counts, DNS queries, traffic rate, and usage trends. For example, when you select **Maximum**, the *DNS Query Rate by Member* dashboard shows all the members that have the same extensible attributes and members with the maximum DNS queries, and the *Threat Protection Event Count By Member* dashboard shows the members that have the same extensible attributes and maximum event counts. Select one of the following methods:
        - **Aggregate**: Displays the sum of values for individual members in a group.
        - **Average**: Displays the mathematical average of a group. This value is obtained by adding values for all members in a group and then dividing the total by the number of members.
        - **Maximum**: Displays the maximum value among the members in a group.

> **Note**
>
> When you apply **GroupByEATag/Field** in Active Directory Sites supported reports, the values displayed in these reports are aggregated sum of absolute values (sum of values of individual networks in a group) and utilization% is the mathematical average of the group.

You can configure the group-by-extensible-attribute filter and data calculation methods for the following dashboards only. For more information about these dashboards, see *Predefined Dashboards*.

- CPU Utilization Trend (Detailed)
- IPAMv4 Network Usage Statistics
- IPAMv4 Top Utilized Networks
- IPAMv4 Network Usage Trend
- DDNS Update Rate Trend
- DHCPv4 Usage Statistics
- DNS Daily Query Rate by Member
- DNS Query Rate by Member
- DNS Daily Peak Hour Query Rate by Member
- DNS Response Latency Trend
- DNS Cache Hit Rate Trend
- DNS Traffic Control Resource Availability Trend
- DNS Traffic Control Resource Pool Availability Trend
- DNS Traffic Control Response Distribution Trend
- Memory Utilization Trend
- Traffic Rate by Member
- Threat Protection Event Count By Member
- Threat Protection Event Count By Member Trend

Reporting Data Model

This section contains information about fields that are included in the reports and dashboards. You can find the commonly extracted fields and their specifications such as data source and range, which can help you better define your dashboards and searches.

Splunk default fields

Splunk server adds the following default fields to each event in every index.

Field Name	Description	Values/Range
date_hour	Indicates the hour when an event occurred. To narrow your search for specific event timestamps, you can use the default datetime fields. Click *here* for more information on datetime fields.	Range: 0-23
date_mday	Indicates the day of the month when the event occurred	Range: 1-31
date_minute	Indicates the exact minute when the event occurred	Range: 0-59
date_month	Indicates the month during which an event occurred	
date_second	Indicates the second in which an event occurred	Range: 0-59
date_wday	Indicates the day of the week in which an event occurred	Example: Sunday, Monday, etc.
date_year	Indicates the year in which an event occurred	
date_zone	Indicates the time for the local timezone of an event, expressed as hours in Unix Time	
eventtype	Indicates events of the same type based on a given search. Click *here* for more information.	Example: splunkd-log
host	Contains information about the originating hostname or a network IP address that generates the event	Example: reporting-1.com
index	Contains the name of the index with which a given event is indexed	Example: ib_dns_summary
linecount	Contains information about the number of lines in an event before it is indexed	Example: 1

punct	Contains information about the pattern of the first thirty punctuation characters in the first line of the event with which it is associated. It shows how an event looks when all letters, numbers, and spaces are removed and contains characters such as periods, colons, parentheses, quotes, question marks, dashes, and underscores. Click *here* for more information.	Example: -_::._\[\]:___.../_=
source	Contains the name of the file, stream, or other input details from which the event originates	Example: si-search-dns-query-reply
sourcetype	Specifies the format of data input from which the event originates	Stash
splunk_server	Contains the name of the Splunk server that comprises the event	Example: reporting-2.com-2-<*secondary server*>
splunk_server_group	Contains the name of the Splunk server group	String

Commonly Extracted Fields

Field Name	**Description**	**Values/Range**
EA	Specifies the extensible attribute	String
HWTYPE	Specifies the hardware type	Example: IB-4015
MAX_DB_OBJECTS	Specifies the maximum objects in the database for a host	eg: 8000000
MAX_DHCP_LPS	Specifies the maximum number of DHCP leases per second for a host	Example: 15.0
MAX_DNS_QPS	Specifies the maximum DNS queries per second for a host	Example: 1000000.0
MEMBER_IP	Specifies the IP address of the member	IP address
timeendpos	Specifies the byte at which the timestamp ends. These values are based on the TIME_FORMAT that is specified for a sourcetype.	Example: 26
timestartpos	Specifies the byte at which the timestamp starts	Example: 0

Indexes and Extracted Data

Infoblox Audit Logs

Most of the fields in this index are extracted directly from the **audit.log** file. Some of them are mentioned in the table below:

Extracted Field Name	Description of the field	Values/Range	Source of Data
ACTION	Indicates the action taken	String. Example: Called	Infoblox audit logs
ADMIN	Indicates the name of the admin	String. Example: root	Infoblox audit logs
EA	Common Extracted Fields		
EXEC_STATUS	Indicates the execution status	String. Example: Pending Approval	Infoblox audit logs
HWTYPE	Common Extracted Fields		
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
MESSAGE	Indicates the message	String. Example: to=Serial 040Console apparently_via=Direct auth=Local group=.admin-group	Infoblox audit logs
OBJECT_NAME	Indicates the object name	String. Example: RequestRestartServiceStatus	Infoblox audit logs
OBJECT_TYPE	Indicates the object type	String. Example: Shared AAAA Record	Infoblox audit logs
TIMESTAMP	Indicates the timestamp	Timestamp. Example: 2017-01-31 01:57:05	Infoblox audit logs
action	Indicates the action	Example: update, insert	Infoblox audit logs
address		Example: 10.0.0.0	Infoblox audit logs
auth		Example: Local	Infoblox audit logs
cidr		Example: 8	Infoblox audit logs

code		Example: created	Infoblox audit logs
comment		String	Infoblox audit logs
date_hour	Splunk Default field		
date_mday	Splunk Default field.		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
eventtype	Splunk Default field		
group		Example: admin-group	Infoblox audit logs
host	Splunk Default field		
index	Splunk Default field		
linecount	Splunk Default field		
member		Example: Member:infoblox.localdomain	Infoblox audit logs
network_view		Example: default	Infoblox audit logs
punct	Splunk Default field		
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
user		Example: admin	Infoblox audit logs

Response_Time		Example: 0.1659	Infoblox audit logs
URI		Example: v2.10/record:host	Infoblox audit logs
InData		Example: {'comment': 'this is my one.xyz comment', 'name': 'user.zone.com', 'ipv4addrs': [{'configure_for_dhcp': False, 'mac': 'aa:0:0:0:1:cc', 'ipv4addr': '1.1.1.0'}], 'view': 'default'}	Infoblox audit logs

Infoblox DNS Query, DNS Performance, DDNS, DNS Record Scavenging

Extracted Field Name	Description of the field	Values/Range	Source of Data
CLIENT	Indicates the DNS client	String	Infoblox DNS query
COUNT	Indicates the count	Integer	Infoblox DNS query and DNS Record Scavenging
EA	Common Extracted Fields		
FQDN	Indicates the FQDN	String	Infoblox DNS query
HITS	Indicates the DNS cache hits count	Integer	Infoblox DNS query
HNAME	Indicates the HNAME	String	Infoblox DNS query
HWTYPE	Common Extracted Fields		
LATENCY	Indicates the latency count	Integer	Infoblox DNS performance
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER	Specifies the member	String	DNS Record Scavenging
MEMBER_IP	Common Extracted fields		
MISSES	Specifies DNS cache miss count	Integer	Infoblox DNS query
QCOUNT	Specifies query count	Integer	Infoblox DNS query
REST	REST	String	Infoblox DDNS

SOURCE	SOURCE	String	Infoblox DDNS
SOURCEA	SOURCEA	IP address	Infoblox DDNS
TLD	Specifies the top-level domain name	String	Infoblox DNS query
TYPE	RR Type	String. Example: nxdomain	Infoblox DNS query and DNS Record Scavenging
TYPEA	TYPEA	String. Example: Success	Infoblox DDNS
VIEW		String	Infoblox DNS query
ZONE	Indicates the name of the zone	String	Infoblox DDNS
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
display_name	Specifies the name of the DNS view	String	.
eventtype	Splunk Default field		
failure	Specifies the DNS FAILURE query count	Integer	
host	Splunk Default field		
index	Splunk Default field		
linecount	Splunk Default field		
nxdomain	Specifies the DNS NXDOMAIN query count	Integer	
nxrrset	Specifies the DNS NXRRSET query count	Integer	

other	Specifies the DNS other query count	Integer	
punct	*Splunk Default field*		
referral	Specifies the DNS REFERRAL query count	Integer	
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
success	Specifies the DNS success query count		
timeendpos	Common Extracted Fields		
timestartpos	Common Extracted Fields		

Infoblox DNS Query Capture

Extracted Field Name	Description of the field	Values/Range	Source of Data
EA	Common Extracted Fields		
HWTYPE	Common Extracted Fields		
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
answer_count	Specifies the answer count	Integer	Infoblox DNS query capture
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		

date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
display_name	Specifies the DNS view	String	
eventtype	Splunk Default field		
flag_aa	Flag AA	Boolean. Example: Y	Infoblox DNS query capture
flag_ad	Flag AD	Boolean. Example: Y	Infoblox DNS query capture
flag_edns	Flag EDNS	Boolean. Example: Y	Infoblox DNS query capture
flag_recursion	Flag Recursion	Boolean. Example: Y	Infoblox DNS query capture
host	Splunk Default field		
host_class	Specifies the host class	Example: IN	Infoblox DNS query capture
host_type	Specifies the host type	Example: PTR	Infoblox DNS query capture
index	Splunk Default field		
linecount	Splunk Default field		
message_type	Specifies the message type	Example: Query or Response	Infoblox DNS query capture
name	Specifies the name	Host name. Example: 1.0.0.127.in-addr.arpa	Infoblox DNS query capture
query	Specifies the query	Host name. Example: 213.31.102.10.in-addr.arpa	Infoblox DNS query capture
query_class	Specifies the query class	Example: IN	Infoblox DNS query capture
query_count	Specifies the query count	Integer. Example: 1	Infoblox DNS query capture
query_source	Specifies the query source	Example: I, E	Infoblox DNS query capture
query_type	Specifies the DNS query type	Example: PTR	Infoblox DNS query capture

rdata	RDATA	String. This value depends on the query type.	Infoblox DNS query capture
reply_code	Specifies the reply code	String. Example: ServFail, NoError	Infoblox DNS query capture
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
src_ip	Specifies the source IP	IP Address	Infoblox DNS query capture
src_port	Specifies the source port	Integer	Infoblox DNS query capture
time_msec	Specifies time in milliseconds	Integer	Infoblox DNS query capture
timeendpos	Common Extracted Fields		
timestamp	Indicates the timestamp	Integer	Infoblox DNS query capture
timestartpos	Common Extracted Fields		
transport	Specifies the mode of transport	Example: UDP, TCP	Infoblox DNS query capture
ttl	Specifies the TTL	Integer. Example: 3600	Infoblox DNS query capture
view	Specifies the view	Example: 1, 2	Infoblox DNS query capture

Infoblox DHCP Performance

Extracted Field Name	**Description of the field**	**Values/Range**	**Source of Data**
EA	Common Extracted Fields		
HWTYPE	Common Extracted Fields		
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		

MEMBER_IP	Common Extracted Fields		
NETWORK	Specifies the network address	Example: 10.0.0.0/8	
address	Specifies the DHCP client address	IP address	Infoblox DHCP performance
address_total	Specifies the total number of addresses	Integer	Infoblox DHCP performance
cidr	Specifies the CIDR	Example: 24	Infoblox DHCP performance
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
dhcp_hosts	Specifies the DHCP hosts count	Integer	Infoblox DHCP performance
dhcp_utilization	Specifies the DHCP utilization	Integer	Infoblox DHCP performance
dhcp_utilization_status	Specifies the DHCP utilization status	String	Infoblox DHCP performance
dhcpv4ack	Specifies the DHCPv4 ACK message count	Integer	Infoblox DHCP performance
dhcpv4decline	Specifies the DHCPv4 decline message count	Integer	Infoblox DHCP performance
dhcpv4discover	Specifies the DHCPv4 discover message count	Integer	Infoblox DHCP performance
dhcpv4inform	Specifies the DHCPv4 inform message count	Integer	Infoblox DHCP performance
dhcpv4leaseactive	Specifies the DHCPv4 lease active message count	Integer	Infoblox DHCP performance

dhcpv4leasequery	Specifies the DHCPv4 lease query message count	Integer	Infoblox DHCP performance
dhcpv4leaseunassigned	Specifies the DHCPv4 lease unassigned message count	Integer	Infoblox DHCP performance
dhcpv4leaseunknown	Specifies the DHCPv4 lease unknown message count	Integer	Infoblox DHCP performance
dhcpv4nak	Specifies the DHCPv4 NAK message count	Integer	Infoblox DHCP performance
dhcpv4offer	Specifies the DHCPv4 offer message count	Integer	Infoblox DHCP performance
dhcpv4release	Specifies the DHCPv4 release message count	Integer	Infoblox DHCP performance
dhcpv4request	Specifies the DHCPv4 request message count	Integer	Infoblox DHCP performance
dhcpv6advertise	Specifies the DHCPv6 advertise message count	Integer	Infoblox DHCP performance
dhcpv6confirm	Specifies the DHCPv6 confirm message count	Integer	Infoblox DHCP performance
dhcpv6decline	Specifies the DHCPv6 decline message count	Integer	Infoblox DHCP performance
dhcpv6information_request	Specifies the DHCPv6 information request message count	Integer	Infoblox DHCP performance
dhcpv6leasequery	Specifies the DHCPv6 lease query message count	Integer	Infoblox DHCP performance
dhcpv6leasequery_reply	Specifies the DHCPv6 lease query reply message count	Integer	Infoblox DHCP performance
dhcpv6rebind	Specifies the DHCPv6 rebind message count	Integer	Infoblox DHCP performance
dhcpv6reconfigure	Specifies the DHCPv6 reconfigure message count	Integer	Infoblox DHCP performance
dhcpv6relay_forward	Specifies the DHCPv6 relay forward message count	Integer	Infoblox DHCP performance
dhcpv6relay_reply	Specifies the DHCPv6 relay reply message count	Integer	Infoblox DHCP performance
dhcpv6release	Specifies the DHCPv6 release message count	Integer	Infoblox DHCP performance

dhcpv6renew	Specifies the DHCPv6 renew message count	Integer	Infoblox DHCP performance
dhcpv6reply	Specifies the DHCPv6 reply message count	Integer	Infoblox DHCP performance
dhcpv6request	Specifies the DHCPv6 request message count	Integer	Infoblox DHCP performance
dhcpv6solicit	Specifies the DHCPv6 solicit message count	Integer	Infoblox DHCP performance
display_name	Specifies the DNS View	String	
dynamic_hosts	Specifies the dynamic hosts count	Integer	Infoblox DHCP performance
end_address	Specifies the end IP address	IP address	Infoblox DHCP performance
eventtype	Splunk Default field		
host	Splunk Default field		
index	Splunk Default field		
linecount	Splunk Default field		
members	Specifies the DHCP member	Example: infoblox.localdomain	Infoblox DHCP performance
ms_servers	Specifies the MS servers	IP address	Infoblox DHCP performance
protocol	Specifies the DHCP protocol	Example: IPV4	
punct	Splunk Default field		
ranges	Specifies the DHCP ranges count	Integer	Infoblox DHCP performance
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
start_address	Specifies the start IP address	IP address	Infoblox DHCP performance
static_hosts	Specifies the static hosts count	Integer	Infoblox DHCP performance

timeendpos	Common Extracted Fields		
timestamp	Specifies the timestamp of the event	Example: 2017-02-04 03:45:53	Infoblox DHCP performance
timestartpos	Common Extracted Fields		
View	Specifies the network view	Example: default	Infoblox DHCP performance

Infoblox DHCP FingerPrint, DHCP Lease History

Extracted Field Name	Description of the field	Values/Range	Source of Data
ACTION	Specifies the action	String. Example: Issued	Infoblox DHCP lease history
CIDR	Specifies the CIDR	Integer	Infoblox DHCP lease history
DEVICE_CLASS	Specifies the device class	String. Example: Linux	
EA	Common Extracted Fields		
END_EPOCH	Specifies the end epoch time	Integer	Infoblox DHCP lease history
FP	Specifies the name of the DHCP fingerprint	String. Example: No Match	Infoblox DHCP lease history
FP_CIDR	Specifies the fingerprint CIDR	Integer. Example: 8	Infoblox DHCP lease history
FP_NW	Specifies the fingerprint network	Network address. Example: 10.0.0.0	Infoblox DHCP lease history
FP_RANGE	Specifies the fingerprint range	Network range. Example: 10.0.0.1-10.0.0.200	Infoblox DHCP lease history
FP_VIEW	Specifies the fingerprint view	String. Example: default	Infoblox DHCP lease history
HWTYPE	Common Extracted fields		
LEASE_IP	Specifies the lease IP address	IP address	Infoblox DHCP lease history
MAC_DUID	Specifies the MAC address	MAC address	Infoblox DHCP lease history
MAX_DB_OBJECTS	Common Extracted fields		
MAX_DHCP_LPS	Common Extracted fields		

MAX_DNS_QPS	Common Extracted fields		
MEMBER_IP	Common Extracted fields		
MS Server	Specifies the MS server	IP Address	Infoblox DHCP lease history
NW	Specifies the network	Network address. Example: 10.0.0.0	Infoblox DHCP lease history
OPTION12HOST	Specifies the host name that is sent using DHCP Option 12	String. Example: Fedora21	Infoblox DHCP lease history
OS_NUMBER	Specifies the OS number	Integer	Infoblox DHCP lease history
PROTO	Specifies the protocol	String. Example: dhcpd	Infoblox DHCP lease history
SFP	SFP	String. Example: Ubuntu/Debian 5/ Knoppix 6	Infoblox DHCP fingerprint
START_EPOCH	Specifies the start epoch time	Integer	Infoblox DHCP lease history
VIEW	Specifies the view		Infoblox DHCP lease history
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
display_name	Specifies the DNS view	String	
eventtype	Splunk Default field		
host	Splunk Default field		
index	Splunk Default field		

linecount	Splunk Default field		
punct	Splunk Default field		
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
timeendpos	Common extracted fields		
timestartpos	Common extracted fields		

Infoblox DDI Utilization

Extracted Field Name	Description of the field	Values/Range	Source of Data
EA	Common Extracted Fields		
HWTYPE	Common Extracted Fields		
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
address_alloc	Specifies the address allocation count	Integer	Infoblox DDI utilization
address_assignable	Specifies the address assignable count	Integer	Infoblox DDI utilization
address_assigned	Specifies the address assigned count	Integer	Infoblox DDI utilization
address_conflicts	Specifies the address conflicts count		Infoblox DDI utilization
address_reserved	Specifies the address reserved count	Integer	Infoblox DDI utilization
address_total	Specifies the total number of addresses	Integer	Infoblox DDI utilization

address_unalloc	Specifies the address unallocation count	Integer	Infoblox DDI utilization
address_unmanaged	Specifies the address unmanaged count	Integer	Infoblox DDI utilization
allocation	Allocation	Integer	Infoblox DDI utilization
cidr	Specifies the CIDR	Example: 24	Infoblox DDI utilization
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
discovered_name	Specifies the discovered name	String	Infoblox DDI utilization
display_name	Specifies the DNS view	String	
eventtype	Splunk Default field		
first_discovered_timestamp	Specifies the first discovered timestamp	Timestamp	Infoblox DDI utilization
host	Splunk Default field		
hosts	Specifies the address hosts count	Integer	Infoblox DDI utilization
index	Splunk Default field		
ip_address	Specifies the IP address	IP Address	Infoblox DDI utilization
last_discovered_timestamp	Specifies the last discovered timestamp	timestamp	Infoblox DDI utilization
linecount	Splunk Default field		

managed	Indicates if managed or not	Boolean	Infoblox DDI utilization
management_platform	Specifies the management platform	String	Infoblox DDI utilization
members	Specifies the DHCP members	Example: infoblox.localdomain	Infoblox DDI utilization
ms_primary	Specifies the MS primary	String	Infoblox DDI utilization
port_vlan_name	Specifies the VLAN port name	String	Infoblox DDI utilization
port_vlan_number	Specifies the VLAN port number	Integer	Infoblox DDI utilization
network_view	Specifies the network view	String	Infoblox DDI utilization
primary	Primary	FQDN	Infoblox DDI utilization
protocol	Specifies the DHCP protocol	Example: IPV4	Infoblox DDI utilization
punct	Splunk Default field		
rr_a	Specifies the resource record A count	Integer	Infoblox DDI utilization
rr_aaaa	Specifies the resource record AAAA count	Integer	Infoblox DDI utilization
rr_cname	Specifies the resource record CNAME count	Integer	Infoblox DDI utilization
rr_dhcid	Specifies the resource record DHCID count	Integer	Infoblox DDI utilization
rr_dname	Specifies the resource record DNAME count	Integer	Infoblox DDI utilization
rr_dnskey	Specifies the resource record DNSKEY count	Integer	Infoblox DDI utilization
rr_ds	Specifies the resource record DS count	Integer	Infoblox DDI utilization
rr_lbdn	Specifies the resource record LBDN count	Integer	Infoblox DDI utilization
rr_mx	Specifies the resource record MX count	Integer	Infoblox DDI utilization
rr_naptr	Specifies the resource record NAPTR count	Integer	Infoblox DDI utilization
rr_ns	Specifies the resource record NS count	Integer	Infoblox DDI utilization

rr_nsec	Specifies the resource record NSEC count	Integer	Infoblox DDI utilization
rr_nsec3	Specifies the resource record NSEC3 count	Integer	Infoblox DDI utilization
rr_nsec3param	Specifies the resource record NSEC3PARAM count	Integer	Infoblox DDI utilization
rr_other	Specifies the resource record OTHER count	Integer	Infoblox DDI utilization
rr_ptr	Specifies the resource record PTR count	Integer	Infoblox DDI utilization
rr_rrsig	Specifies the resource record RRSIG count	Integer	Infoblox DDI utilization
rr_soa	Specifies the resource record SOA count	Integer	Infoblox DDI utilization
rr_srv	Specifies the resource record SRV count	Integer	Infoblox DDI utilization
rr_tlsa	Specifies the resource record TLSA count	Integer	Infoblox DDI utilization
rr_total	Specifies the resource record TOTAL count	Integer	Infoblox DDI utilization
rr_txt	Specifies the resource record TXT count	Integer	Infoblox DDI utilization
signed	Indicates whether signed or not	Boolean	Infoblox DDI utilization
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
timeendpos	Common Extracted Fields		
Timestamp	Specifies the timestamp of the event	Example: 2017-02-04 03:45:53	Infoblox DDI utilization
timestartpos	Common Extracted Fields		
utilization	Specifies the address utilization count	Integer	Infoblox DDI utilization

view	Specifies the network view	Example: default	Infoblox DDI utilization
zone_format	Specifies the zone format	String. Example: Forward-Mapping	Infoblox DDI utilization
zone_name	Specifies the zone name	String. Example: member1.com	Infoblox DDI utilization
zones_forward	Specifies the zone forward count	Integer	Infoblox DDI utilization
zones_ipv4	Specifies the IPv4 count of the zone	Integer	Infoblox DDI utilization
zones_ipv6	Specifies the IPv6 count of the zone	Integer	Infoblox DDI utilization
zones_signed	Specifies the signed count of the zone	Integer	Infoblox DDI utilization

Infoblox Discovered Devices Related Dashboards/Reports

Extracted Field Name	Description of the field	Values/Range	Source of Data
ADM_DN_OP_DN_COUNT	Admin-Down/Operation-DownPort Count	Integer	Infoblox discovered devices related dashboards/reports
ADM_UP_OP_DN_COUNT	Admin-Up/Operation-UpPort Count	Integer	Infoblox discovered devices related dashboards/reports
ADM_UP_OP_UP_COUNT	Admin-Up/Operation-DownPort Count	Integer	Infoblox discovered devices related dashboards/reports
COMPONENT_NAME	Specifies the component name	String. Example: DELL-PC8024F	Infoblox discovered devices related dashboards/reports
COMPONENT_TYPE	Specifies the component type	String. Example: Switch-Router	Infoblox discovered devices related dashboards/reports
COMPONENT_PORT	Specifies the component port	String. Example: Gi1/0/24	Infoblox discovered devices related dashboards/reports
DEVICE_MGMT_IP	Specifies the device management IP address	IP address	Infoblox discovered devices related dashboards/reports
DEVICE_MODEL	Specifies the device model	String. Example: EX2200	Infoblox discovered devices related dashboards/reports

DEVICE_NAME	Specifies the device name	String. Example: Cisco_434f44	Infoblox discovered devices related dashboards/reports
DEVICE_TYPE	Specifies the device type	String. Example: Switch, Router	Infoblox discovered devices related dashboards/reports
DEVICE_VENDOR	Specifies the device vendor	String. Example: Avaya	Infoblox discovered devices related dashboards/reports
DISCOVERED_MAC_DUID	Specifies the discovered MAC DUID	MAC address	Infoblox discovered devices related dashboards/reports
DISCOVERED_NAME	Specifies the discoverd name	Example: dev_view1.yahoo.com	Infoblox discovered devices related dashboards/reports
EA	Common Extracted Fields		
HWTYPE	Common Extracted Fields		
IN_USE_FLAG	In use flag	Integer. Example: 1	Infoblox discovered devices related dashboards/reports
IPADDR	Specifies the IP address	IP Address. Example: 11.11.11.11	Infoblox discovered devices related dashboards/reports
IPADDR_MASK	Specifies the IP address mask	Integer. Example: 128	Infoblox discovered devices related dashboards/reports
MAC_DUID	Specifies the MAC address	MAC address	Infoblox discovered devices related dashboards/reports
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
NETWORK_VIEW	Specifies the network view	String. Example: default	Infoblox discovered devices related dashboards/reports
NON_NULL_NAME	Specifies the non-null name	String. Example: DELL-PC8024F	

NON_NULL_PORT	Specifies the non-null port	String. Example: Gi1/0/24	
TIMESTAMP	Specifies the timestamp	Timestamp. Example: 2017-02-15 15:56:27	Infoblox discovered devices related dashboards/reports
TIMESTAMP_USER_HOST_ PROCESS_PID_INFO_PREFIX	Specifies the timestamp userhost process pid info prefix	String. Example: 2017-02-15T11:02:53+00:00 user infoblox.localdomain <ac:structured-macro ac:name="unmigrated-wiki-markup" ac:schema-version="1" ac:macro-id="e5d51f7e-f354-4235-870a-9e02f49b3d41"><ac:plain-text-body><![CDATA[python[]: info ipaddr-activity-rpt	Infoblox discovered devices related dashboards/reports
TOTAL_AVAIL_COUNT	Specifies the total available count	Integer	Infoblox discovered devices related dashboards/reports
Type	Specifies the type	String. Example: Discovery	
ap_bss_mac	Access Point BSS MAC	MAC address	Infoblox discovered devices related dashboards/reports
ap_ip_dotted	Access Point IP dotted	String	Infoblox discovered devices related dashboards/reports
ap_mac	Access Point MAC	MAC address	Infoblox discovered devices related dashboards/reports
ap_name	Access Point name	String	Infoblox discovered devices related dashboards/reports
ap_associated_ssid	Access Point associated SSID	String	Infoblox discovered devices related dashboards/reports
asset_type	Specifies the asset type	String. Example: Physical Device	Infoblox discovered devices related dashboards/reports
class	Specifies the class name	String. Example: port	Infoblox discovered devices related dashboards/reports
component_name	Specifies the component name	String. Example: GigabitEthernet1/0/1	Infoblox discovered devices related dashboards/reports
date_hour	Splunk Default field		

date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
Description	Specifies the description	String. Example: Gigabit Ethernet Port	Infoblox discovered devices related dashboards/reports
device_id	Specifies the device ID	Integer	Infoblox discovered devices related dashboards/reports
device_ip_address	Specifies the device IP address	IP address	Infoblox discovered devices related dashboards/reports
device_model	Specifies the device model	String. Example: catalyst37xxStack	Infoblox discovered devices related dashboards/reports
device_name	Specifies the device name	String. Example:DELL-PC8024F	Infoblox discovered devices related dashboards/reports
device_os_version	Specifies the device OS version	String. Example: 4.14.6M	Infoblox discovered devices related dashboards/reports
device_type	Specifies the device type	String. Example: Switch	Infoblox discovered devices related dashboards/reports
device_vendor	Specifies the device vendor	String. Example: Cisco	Infoblox discovered devices related dashboards/reports
device_version	Specifies the device version	String. Example: 5.1.2.3	Infoblox discovered devices related dashboards/reports
display_name	Specifies the DNS view	String	Infoblox discovered devices related dashboards/reports

end_host_addl_info	Specifies additional information about the end host	String	Infoblox discovered devices related dashboards/reports
end_host_device_model	Specifies the device model of the end host	String. Example: catalyst37xxStack	Infoblox discovered devices related dashboards/reports
end_host_device_type	Specifies the device type of the end host	String. Example: Switch-Router	Infoblox discovered devices related dashboards/reports
end_host_device_vendor	Specifies the device vendor of the end host	String. Example: Cisco	Infoblox discovered devices related dashboards/reports
end_host_first_discovered	Specifies the first occasion when the end host was first discovered	Integer	Infoblox discovered devices related dashboards/reports
end_host_ip_address	Specifies the IP address of the end host	IP address	Infoblox discovered devices related dashboards/reports
end_host_last_discovered	Indicates when was end host last discovered	Integer	Infoblox discovered devices related dashboards/reports
end_host_mac_address	Specifies the MAC address of the end host	MAC address	Infoblox discovered devices related dashboards/reports
end_host_name	Specifies the name of the end host	String. Example: WS-C3750X-24P	Infoblox discovered devices related dashboards/reports
end_host_network_view	Specifies the network view of the end host	String. Example: custom view	Infoblox discovered devices related dashboards/reports
end_host_os_version	Specifies the version of the end host OS	String. Example: 15.2(1)E2	Infoblox discovered devices related dashboards/reports
eventtype	Splunk Default field		
firmware_rev	Indicates firmware revision	String. Example: 15.2(1)E2	Infoblox discovered devices related dashboards/reports
first_seen	First seen timestamp	Integer	Infoblox discovered devices related dashboards/reports
hardware_rev	Specifies revision of the hardware	String. Example: V05	Infoblox discovered devices related dashboards/reports
host	Splunk Default field		
index	Splunk Default field		
interface_admin_status	Specifies the interface admin status	String. Example: up	Infoblox discovered devices related dashboards/reports

interface_description	Specifies the interface interface description	String	Infoblox discovered devices related dashboards/reports
interface_ip_address	Specifies the interface IP address	IP address	Infoblox discovered devices related dashboards/reports
interface_name	Specifies the interface name	String. Example: Fa0	Infoblox discovered devices related dashboards/reports
interface_port_status	Specifies the interface port status	String. Example: up	Infoblox discovered devices related dashboards/reports
interface_speed	Specifies the interface speed	Integer. Example: 1000000000	Infoblox discovered devices related dashboards/reports
interface_type	Specifies the interface type	String. Example: tunnel	Infoblox discovered devices related dashboards/reports
interface_vlan	Specifies the interface VLAN ID	Integer Example: 16	Infoblox discovered devices related dashboards/reports
interface_vlan_name	Specifies the interface VLAN name	String. Example: VLAN1014	Infoblox discovered devices related dashboards/reports
ip_address	Specifies the IP address	IP address	Infoblox discovered devices related dashboards/reports
is_trunk_port	Specifies if it is a trunk port or not	Boolean	Infoblox discovered devices related dashboards/reports
last_seen	Specifies the last seen timestamp	Integer	Infoblox discovered devices related dashboards/reports
linecount	Splunk Default field		
model	Specifies the model name	String. Example: DCS-7048T-A	Infoblox discovered devices related dashboards/reports
network_view	Specifies the network view	String. Example: custom view	Infoblox discovered devices related dashboards/reports
port_last_changed_at	The timestamp when the port was last changed	Timestamp	Infoblox discovered devices related dashboards/reports
punct	Splunk Default field		
serial_number	Specifies the serial number	String. Example: JPE12440180	Infoblox discovered devices related dashboards/reports
software_rev	Specifies the software revision	String. Example: 15.2(1)E2	Infoblox discovered devices related dashboards/reports

source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
switch_interface	Specifies the switch interface	String. Example: Gi0/47	Infoblox discovered devices related dashboards/reports
switch_ip_address	Specifies the switch IP Address	IP Address	Infoblox discovered devices related dashboards/reports
switch_model	Indicates the switch model	String. Example: cat3560x48	Infoblox discovered devices related dashboards/reports
switch_name	Specifies the switch name	String. Example: ni-mri-sw4.inca.infoblox.com	Infoblox discovered devices related dashboards/reports
switch_os_version	Specifies the OS version of the switch	String. Example: 12.2(53)SE2	Infoblox discovered devices related dashboards/reports
switch_type	Specifies the switch type	String. Example: Switch	Infoblox discovered devices related dashboards/reports
switch_vendor	Specifies the vendor of the switch	String. Example: Cisco	Infoblox discovered devices related dashboards/reports
switch_vlan	Specifies the switch VLAN	Integer. Example: 18	Infoblox discovered devices related dashboards/reports
timeendpos	Common Extracted Fields		
timestamp	Indicates the timestamp	Integer	Infoblox discovered devices related dashboards/reports
timestamp_user_host_process_pid_info_prefix	Specifies the prefix	String	Infoblox discovered devices related dashboards/reports
timestartpos	Common Extracted Fields		
user_id	Specifies the User ID		Infoblox discovered devices related dashboards/reports
View	Specifies the DNS view	String	Infoblox discovered devices related dashboards/reports
virtual_ind	Specifies the virtual indicator	Integer	

Infoblox Threat Protection Related Dashboards/Reports

Extracted Field Name	Description of the field	Values/Range	Source of Data
ACOUNT	ACOUNT	Integer	Infoblox threat protection related dashboards/reports
ACTIVE_COUNT	Specifies the active count	Integer	Infoblox threat protection related dashboards/reports
ALERT_ID	Specifies the alert ID	Integer	Infoblox threat protection related dashboards/reports
ALERT_TYPE	Specifies the alert type	String	Infoblox threat protection related dashboards/reports
BLOCK_END	Specifies the block end IP address	Integer	Infoblox threat protection related dashboards/reports
BLOCK_START	Specifies the block start IP address	Integer	Infoblox threat protection related dashboards/reports
CATEGORY	Specifies the category	String. Example: OSPF	Infoblox threat protection related dashboards/reports
CLIENT	Specifies the client	String	Infoblox threat protection related dashboards/reports
COUNT	Specifies the count	Integer	Infoblox threat protection related dashboards/reports
DCOUNT	Specifies the DCOUNT	Integer	Infoblox threat protection related dashboards/reports
DNST_CATEGORY	Specifies the destination category	String	Infoblox threat protection related dashboards/reports
DOMAIN_NAME	Specifies the domain name	String	Infoblox threat protection related dashboards/reports
EA	Common Extracted Fields		
FIREEYE_APPLIANCE	Specifies the FireEye appliance	String	Infoblox threat protection related dashboards/reports
HWTYPE	Common Extracted Fields		
LOG_SEVERITY	Specifies log severity	String	Infoblox threat protection related dashboards/reports
MAX_DB_OBJECTS	Common Extracted Fields		

MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
MESSAGE	Specifies the message	String. Example: DROP OSPF unexpected	Infoblox threat protection related dashboards/reports
MITIGATION_ACTION	Specifies the mitigation action	String	Infoblox threat protection related dashboards/reports
NAT_STATUS	Specifies the NAT status	String	Infoblox threat protection related dashboards/reports
RECORD_DATA	Specifies the record data	String	Infoblox threat protection related dashboards/reports
RPZ_QNAME	Specifies the RPZ QNAME	String	Infoblox threat protection related dashboards/reports
RULE_DESCRIPTION	Specifies the rule description	String. Example: This rule drops any unexpected OSPF packets when OSPF is disabled.	
RULE_NAME	Specifies the rule name	String. Example: DROP OSPF unexpected	
RULE_SID	Specifies the rule SID	Integer	Infoblox threat protection related dashboards/reports
SEVERITY	Specifies the severity	String. Example: INFORMATIONAL	Infoblox threat protection related dashboards/reports
SID	Specifies the SID	Integer	Infoblox threat protection related dashboards/reports
SOURCE_IP	Specifies the source IP	IP address	Infoblox threat protection related dashboards/reports
SOURCE_PORT	Specifies the source port	Integer	Infoblox threat protection related dashboards/reports
TIMESTAMP	Indicates the timestamp	Timestamp	Infoblox threat protection related dashboards/reports
TOTAL_COUNT	Specifies the total count	Integer	Infoblox threat protection related dashboards/reports
VIEW	Specifies the DNS view	String	Infoblox threat protection related dashboards/reports

date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
eventtype	Splunk Default field		
host	Splunk Default field		
index	Splunk Default field		
linecount	Splunk Default field		
punct	Splunk Default field		
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
timestartpos	Common extracted fields		

Infoblox DNS Traffic Control

Most of the fields in this index are extracted directly from the **syslog_filtered.log** file. Some of them are mentioned in the table below:

Extracted Field Name	Description of the field	Values/Range	Source of Data
EA	Common Extracted Fields		
HWTYPE	Common Extracted Fields		

MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
available	*Specifies the available count*	Integer	Infoblox DNS traffic control
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
eventtype	Splunk Default field		
host	Splunk Default field		
index	Splunk Default field		
linecount	Splunk Default field		
monitor	Specifies the DNS Traffic Control SNMP health monitor	String	Infoblox DNS traffic control
pool	Specifies the pool	String	Infoblox DNS traffic control
punct	Splunk Default field		
resource	Specifies the resource	String	Infoblox DNS traffic control
response_count	Specifies the response count	Integer	Infoblox DNS traffic control
source	Splunk Default field		

sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
timeendpos	Common Extracted Fields		
timestamp	Indicates the timestamp of the event	Example: 2017-02-04 03:45:53	
timestartpos	Common Extracted Fields		
unavailable	Specifies the unavailable count	Integer	Infoblox DNS traffic control

Infoblox Cloud Related Dashboards/Reports

Extracted Field Name	Description of the field	Values/Range	Source of Data
ACTION	Specifies the action	String. Example: Allocated	
EA	Common Extracted Fields		
HWTYPE	Common Extracted Fields		
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
TENANT_NAME	Specifies the name of the tenant associated with the VM	String	
action	Specifies the action count	Integer	Infoblox cloud related dashboards/ reports
address	Specifies the IP address	IP address	Infoblox cloud related dashboards/ reports
address_type	Specifies the type of address	Integer	Infoblox cloud related dashboards/ reports
application_type	Specifies the application type		Infoblox cloud related dashboards/ reports

cidr	Specifies the CIDR	Example: 24	Infoblox cloud related dashboards/ reports
cnames	Specifies the common name	String	Infoblox cloud related dashboards/ reports
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
display_name	Specifies the DNS view	String	
elastic_address	Specifies the elastic IP address	IP address	Infoblox cloud related dashboards/ reports
eventtype	Splunk Default field		
Fqdn	Specifies the FQDN	String	Infoblox cloud related dashboards/ reports
host	Splunk Default field		
index	Splunk Default field		
interface_name	Specifies the interface name	String	Infoblox cloud related dashboards/ reports
is_primary_ifc	Indicates if primary IFC or not	Example: 0 (not primary)	Infoblox cloud related dashboards/ reports
linecount	Splunk Default field		
location	Specifies the location		Infoblox cloud related dashboards/ reports
mac_address	Specifies the MAC address	Example: 00:11:22:33:44:55	Infoblox cloud related dashboards/ reports

mgmt_platform	Specifies management platform	Example: vm132ctest	Infoblox cloud related dashboards/ reports
network	Specifies the network address	Example: 10.0.0.0/8	Infoblox cloud related dashboards/ reports
network_view	Specifies the network view	Example: default	Infoblox cloud related dashboards/ reports
port_id	Specifies the port ID	Integer	Infoblox cloud related dashboards/ reports
private_address	Specifies the private address	IP address	Infoblox cloud related dashboards/ reports
private_hostname	Specifies the private hostname	String	Infoblox cloud related dashboards/ reports
public_address	Specifies the public address	IP address	Infoblox cloud related dashboards/ reports
public_hostname	Specifies the public hostname	String	Infoblox cloud related dashboards/ reports
punct	Splunk Default field		
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
tenant_id	Specifies the tenant ID	Integer	Infoblox cloud related dashboards/ reports
timeendpos	Common Extracted Fields		
timestamp	Indicates the timestamp of the event	Example: 2017-02-04 03:45:53	Infoblox cloud related dashboards/ reports
timestartpos	Common Extracted Fields		
view	Specifies the DNS view	String	
vlan_id	Specifies the VLAN ID	Integer	Infoblox cloud related dashboards/ reports

vm_hostname	Specifies the hostname of the VM	String	Infoblox cloud related dashboards/ reports
vm_name	Specifies the name of the VM	Example: 99	Infoblox cloud related dashboards/ reports
vm_vpc_address	Specifies the VPC address of the VM	IP address	Infoblox cloud related dashboards/ reports
vm_vpc_cidr	Specifies the VPC CIDR of the VM	Example: 24	Infoblox cloud related dashboards/ reports
vm_vpc_id	Specifies the VPC ID of the VM	Integer	Infoblox cloud related dashboards/ reports
vm_vpc_name	Specifies the VPC name of the VM	Integer	Infoblox cloud related dashboards/ reports
vpc_addr	Specifies the VPC address	IP address	Infoblox cloud related dashboards/ reports

Infoblox Syslog

Most of the fields in this index are extracted directly from the **syslog_filtered.log** file. Some of them are mentioned in the table below:

Extracted Field Name	Description of the field	Values/Range	Source of Data
BOOT_IMAGE		Example: /boot/bzImage	Infoblox syslog file
CPUs		Integer. Example: 8	Infoblox syslog file
EA	Common Extracted Fields		
HWTYPE	Common Extracted Fields		
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		

date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
eventtype	Splunk Default field		
group		Example: admin-group	Infoblox syslog file
hits		Integer	Infoblox syslog file
host	Splunk Default field		
index	Splunk Default field		
linecount	Splunk Default field		
misses		Integer	Infoblox syslog file
punct	Splunk Default field		
size		Integer	Infoblox syslog file
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
timeendpos	Common Extracted Fields		
timestartpos	Common Extracted Fields		

System Capacity

Extracted Field Name	Description of the field	Values/Range	Source of Data
COUNT	Specifies the count	Integer	System capacity

EA	Common Extracted Fields		
HWTYPE	Common Extracted Fields		
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
PERCENT	Specifies the percentage	Integer	System capacity
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	*Splunk Default field*		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
eventtype	Splunk Default field		
host	Splunk Default field		
index	Splunk Default field		
linecount	Splunk Default field		
punct	Splunk Default field		
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		

splunk_server_group	Splunk Default field		
timeendpos	Common Extracted Fields		
timestartpos	Common Extracted Fields		

Infoblox System Utilization (CPU, Memory, Network Traffic) Related Dashboards/Reports

Extracted Field Name	Description of the field	Values/Range	Source of Data
CPU_PERCENT	Specifies the CPU percentage	Integer value within 0-100	Infoblox system utilization related dashboards/reports
EA	Common Extracted Fields		
HWTYPE	Common Extracted Fields		
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
MEMORY_PERCENT	Specifies the memory percentage	Integer. Value within 0-100	Infoblox system utilization related dashboards/reports
TRAF_VALUE	Specifies the traffic value	Integer	Infoblox system utilization related dashboards/reports
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		

eventtype	Splunk Default field		
host	Splunk Default field		
index	Splunk Default field		
linecount	Splunk Default field		
punct	Splunk Default field		
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
sys_report_id	Specifies the report ID based on whether inbound or outbound	Integer	Infoblox system utilization related dashboards/reports
timeendpos	Common Extracted Fields		
timestartpos	Common Extracted Fields		

Infoblox Ecosystem Subscription

Extracted Field Name	Description of the field	Values/Range	Source of Data
EA	Common Extracted Fields		
HWTYPE	Common Extracted Fields		
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
cisco_ise_endpoint_profile	Specifies the Cisco ISE endpoint profile	String	Infoblox ecosystem subscription
cisco_ise_security_group	Specifies the Cisco ISE security group		Infoblox ecosystem subscription

cisco_ise_session_state	Specifies the Cisco ISE session state	String. Example: STARTED	Infoblox ecosystem subscription
cisco_ise_ssid	Specifies the Cisco ISE SSID	String	Infoblox ecosystem subscription
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
domainname	Specifies the domain name	String	Infoblox ecosystem subscription
ea_eps_status	Specifies the EPS status of the extensible attribute	String	Infoblox ecosystem subscription
eventtype	Splunk Default field		
guid	Specifies the GUID	String	Infoblox ecosystem subscription
host	Splunk Default field		
index	Splunk Default field		
ip_address	Specifies the IP address	IP address	Infoblox ecosystem subscription
last_discovered_timestamp	Specifies the last discovered timestamp	Integer	Infoblox ecosystem subscription
linecount	Splunk Default field		
port_vlan_name	Specifies the VLAN name of the port	String	Infoblox ecosystem subscription
port_vlan_number	Specifies the VLAN number of the port	Integer	Infoblox ecosystem subscription
punct	Splunk Default field		

source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
timeendpos	Common Extracted Fields		
timestamp	Specifies the timestamp of the event	Example: 2017-02-04 03:45:53	Infoblox ecosystem subscription
timestartpos	Common Extracted Fields		
username	Specifies the username	String	Infoblox ecosystem subscription

Infoblox Ecosystem Publication

Extracted Field Name	Description of the field	Values/Range	Source of Data
EA	Common Extracted Fields		
HWTYPE	Common Extracted Fields		
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
contents	Specifies the content	String. Example: {'LEASE_STATE': 'STARTED', 'Lease_Start_Time': '2017-03-01T07:00:00Z', 'MAC_OR_DUID': '80:3c:3e:29:84:cc', 'Fingerprint': 'No Match', 'Lease_End_Time': '2017-03-01T07:02:00Z', 'IPAddress': '10.0.0.20', 'Infoblox_Member': '10.35.205.6'}	Infoblox ecosystem publication
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		

date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
eventtype	Splunk Default field		
host	Splunk Default field		
index	Splunk Default field		
ip_address	Specifies the IP address	IP address	Infoblox ecosystem publication
linecount	Splunk Default field		
notification_action	Specifies the notification action	Example: CISCOISE_PUBLISH_IPAM	Infoblox ecosystem publication
notification_target	Specifies the notification target	IP address	Infoblox ecosystem publication
punct	Splunk Default field		
source	Splunk Default field		
sourcetype	Splunk Default field		
splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
timeendpos	Common Extracted Fields		
timestamp	Specifies the timestamp of the event	Example: 2017-02-04 03:45:53	Infoblox ecosystem publication
timestartpos	Common Extracted Fields		

Reporting License Usage

Extracted Field Name	Description of the field	Values/Range	Source of Data
EA	Common Extracted Fields		

HWTYPE	Common Extracted Fields		
MAX_DB_OBJECTS	Common Extracted Fields		
MAX_DHCP_LPS	Common Extracted Fields		
MAX_DNS_QPS	Common Extracted Fields		
MEMBER_IP	Common Extracted Fields		
date_hour	Splunk Default field		
date_mday	Splunk Default field		
date_minute	Splunk Default field		
date_month	Splunk Default field		
date_second	Splunk Default field		
date_wday	Splunk Default field		
date_year	Splunk Default field		
date_zone	Splunk Default field		
display_name	Specifies the DNS view	String	
eventtype	Splunk Default field		
host	Splunk Default field		
index	Splunk Default field		
license_count	Specifies the license count	Integer	Reporting license usage
license_pool	Specifies the license pool	String. Example: cloud_api.0	Reporting license usage
linecount	Splunk Default field		
punct	Splunk Default field		
source	Splunk Default field		
sourcetype	Splunk Default field		

splunk_server	Splunk Default field		
splunk_server_group	Splunk Default field		
timeendpos	Common Extracted Fields		
timestamp	Indicates the timestamp	Timestamp	Reporting license usage
timestartpos	Common Extracted Fields		
utilization	Specifies the utilization	Integer	Reporting license usage
view	Specifies the DNS view	String	

Summary Indexes

Summary Indexes Frequency

The field frequencies of all fields for each summary index are as mentioned below:

Summary Index	Report	Frequency	Cron Schedule	Earliest Time	Latest Time
ib_dns_summary	si_dns_reclaimed_object_count_trend	At every 30th minute from 21 through 59	21-59/30 * * * *	30m@m	60m@m
	si_dns_top_clients	At every 30th minute from 2 through 59	2-59/30 * * * *	30m@m	60m@m
	si_dns_query_reply	At every 30th minute from 18 through 59	18-59/30 * * * *	30m@m	60m@m
	si_top_servfail_received_queries	At every 30th minute from 7 through 59	7-59/30 * * * *	30m@m	60m@m
	si_dns_response_latency_trend	At every 30th minute from 20 through 59	20-59/30 * * * *	30m@m	60m@m
	si_dns_member_qps_trend_per_hour	At minute 34	34 * * * *	@h	-1h@h
	si_top_nxdomain_query	At every 30th minute from 5 through 59	5-59/30 * * * *	30m@m	60m@m
	si_dns_member_qps_trend_per_day	Every day 32 minutes past midnight	32 0 * * *	@d	-1d@d
	si_dns_member_qps_trend	At every 30th minute from 12 through 59	12-59/30 * * * *	30m@m	60m@m

	si_dns_requested_domain	At every 30th minute from 4 through 59	4-59/30 * * * *	30m@m	60m@m
	si_dns_qps_trend	At every 30th minute from 10 through 59	10-59/30 * * * *	30m@m	60m@m
	si_top_servfail_sent_queries	At every 30th minute from 6 through 59	6-59/30 * * * *	30m@m	60m@m
	si_ddns_update	At every 30th minute from 6 through 59	6-59/30 * * * *	30m@m	60m@m
	si_dns_cache_hit_ratio	At every 30th minute from 8 through 59	8-59/30 * * * *	30m@m	60m@m
	si_top_timeout_queries	At every 30th minute from 8 through 59	8-59/30 * * * *	30m@m	60m@m
	si_dns_rpz_hits	At every 10th minute from 2 through 59	2-59/10 * * * *	10m@m	20m@m
	si_top_clients_per_domain	At every 30th minute from 3 through 59	3-59/30 * * * *	30m@m	60m@m
ib_dhcp_summary	si_dhcp_message	At every 30th minute from 14 through 59	14-59/30 * * * *	30m@m	60m@m
	si_dhcp_usage_trend	At 22 minutes past every 8th hour	22 */8 * * *	15m@m	495m@m
	si_dhcp_top_lease_client	At every 30th minute from 16 through 59	16-59/30 * * * *	30m@m	60m@m
	si_devices_denied_an_ip_address	At every 30th minute from 19 through 59	19-59/30 * * * *	30m@m	60m@m
	si_dhcp_range_utilization_trend	At 24 minutes past every 8th hour	24 */8 * * *	15m@m	495m@m
	si_dhcp_top_os_by_network	At every 30th minute from 16 through 59	16-59/30 * * * *	30m@m	60m@m
ib_dtc_summary	si_dtc_response_distribution	At 37 minutes past every 6th hour	37 */6 * * *	10m@m	370m@m
	si_adns_resource_pool_availability	At 23 minutes past every 6th hour	23 */6 * * *	10m@m	370m@m
	si_smart_dns_resource_snmp	At 47 minutes past every 6th hour	47 */6 * * *	10m@m	370m@m

	si_smart_dns_resource_availability	At 47 minutes past every 6th hour	47 */6 * * *	10m@m	370m@m
ib_system_summary	si_index_disk_usage	At 37 minutes past every 6th hour	37 */6 * * *	10m@m	370m@m
	si_memory_utilization	At every 30th minute from 26 through 59	26-59/30 * * * *	30m@m	60m@m
	si_traffic_rate	At every 30th minute from 28 through 59	28-59/30 * * * *	30m@m	60m@m
	si_cpu_usage	At every 30th minute	*/30 * * * *	30m@m	60m@m
ib_security_summary	si_dns_tunneling_activity	At every 3030th th minute from 11 through 59	11-59/30 * * * *	30m@m	60m@m

Note:

- **cron schedule** - cron time scheduled to execute a search
- **earliest time** - specifies the earliest time for a search
- **latest time** - specifies the latest time for a saved search

Common fields in summary indexes

Splunk server adds the following fields to every event in each summary index.

Field Name	Description of the field	Values/Range	Remarks
info_max_time	The **info_*** fields are added to each event when you use the **addinfo** command. This command is primarily an internally-used component of Summary Indexing. Click *here* for more information. The latest time boundary for the search.	Integer	Splunk added special field
info_min_time	Specifies the earliest time boundary for search	Integer	Splunk added special field
info_search_time	Specifies the time when search was initiated	Integer	Splunk added special field
search_name	Specifies the name of the saved search	Example: si-search-dns-query-reply	Splunk added special field
search_now	Specifies the time when search was scheduled to run	Integer	Splunk added special field

Infoblox DNS Summary

Note: *psrsvd* stands for *prestats reserved{*}. Syntax is psrsvd_\[type\]_\[fieldname\]. These special fields are added by Splunk to summary index data that begins with *psrsvd* when you initiate search using the *si** command to populate a summary index. See *List of available psrsvd types* from Splunk docs.

Extracted Field Name	Description of the field	Reports	Values/Range	Source of Data	Remarks
CLIENT	Specifies the IP address of the DNS client		Example: 10.39.18.60		
COUNT	Specifies the count of DNS queries	si_dns_top_clients	Integer		
	Specifies the count of SERVFAIL errors that are received for DNS clients	si_top_servfail_received_queries	Integer		
	Specifies the count of NXDOMAIN/NOERROR replies for DNS clients	si_top_nxdomain_query	Integer		
	Specifies the count of DNS domain name requests	si_dns_requested_domain	Integer		
	Specifies the count of DNS queries per second	si_dns_qps_trend	Integer		
	Specifies the count of DNS SERVFAIL errors that are sent for DNS queries	si_top_servfail_sent_queries	Integer		
	Specifies the count of DNS timed-out recursive queries	si_top_timeout_queries	Integer		
	Specifies the average count of DNS RPX hits	si_dns_rpz_hits	Integer		
	Specifies the count of DNS clients per domain	si_top_clients_per_domain	Integer		
EA	Common Extracted Fields				
FQDN	Specifies the fully qualified domain name	si_dns_requested_domain and si_top_clients_per_domain	Example: 213.31.102.10.in-addr.arpa		
HWTYPE	Common Extracted Fields				
MAX_DB_OBJECTS	Common Extracted Fields				

MAX_DHCP_LPS	Common Extracted Fields				
MAX_DNS_QPS	Common Extracted Fields				
MEMBER	Specifies the member		String	Infoblox DNS Summary	
MEMBER_IP	Common Extracted Fields				
TLD	Specifies top level domain names	si_dns_requested_domain	Example: arpa		
TYPE	Specifies the DNS response type	si_dns_query_reply, si_dns_qps_trend, and si_ddns_update	SUCCESS/ NOERROR **OR** REFERRAL **OR** NXRRSET **OR** NXDOMAIN **OR** REFUSED **OR** OTHER		
VIEW	It refers to the DNS view key to map DNS view through lookup. See display_name field.	si_dns_requested_domain, si_dns_top_clients, si_dns_member_qps_trend_per_hour, si_dns_member_qps_trend_per_day, si_dns_member_qps_trend, si_dns_qps_trend, si_ddns_update, si_dns_cache_hit_ratio, si_dns_rpz_hits, si_top_clients_per_domain, si_top_timeout_queries, si_top_servfail_sent_queries, si_top_nxdomain_query, and si_top_servfail_received_queries	Example: _default		
date_hour	Splunk Default field				
date_mday	Splunk Default field				
date_minute	Splunk Default field				
date_month	Splunk Default field				
date_second	Splunk Default field				
date_wday	Splunk Default field				
date_year	Splunk Default field				

date_zone	SplunkReporting Data Model				
display_name	Specifies the DNS view	si_dns_requested_domain, si_dns_top_clients, si_dns_member_qps_trend_per_hour, si_dns_member_qps_trend_per_day, si_dns_member_qps_trend, si_dns_qps_trend, si_ddns_update, si_dns_cache_hit_ratio, si_dns_rpz_hits, si_top_clients_per_domain, si_top_timeout_queries, si_top_servfail_sent_queries, si_top_nxdomain_query, and si_top_servfail_received_queries	Example: default.MS-2016		
eventtype	Splunk Default field				
host	Splunk Default field				
index	Splunk Default field				
info_max_time	Common summary index fields				
info_min_time	Common summary index fields				
info_search_time	Common summary index fields				
linecount	Splunk Default field				
orig_host	Specifies the host name of the data source		Example: infoblox.com		Splunk added default field
psrsvd_ct_COUNT	Here, ct = count. It contains the count information for the COUNT field.	si_dns_query_reply and si_dns_qps_trend			Splunk added special field
psrsvd_ct_LATENCY	Contains the count information for the LATENCY field	si_dns_response_latency_trend			Splunk added special field

psrsvd_ct_QCOUNT	Contains the count information for the QCOUNT field	si_dns_member_qps_trend_per_hour, si_dns_member_qps_trend_per_day, and si_dns_member_qps_trend			Splunk added special field
psrsvd_gc	Here, gc = group count. It indicates the count for stats grouping and it is not scoped to a single field.	si_dns_query_reply, si_dns_response_latency_trend, si_dns_member_qps_trend_per_hour, si_dns_member_qps_trend_per_day, si_dns_member_qps_trend, and si_dns_qps_trend			Splunk added special field
psrsvd_nc_COUNT	Here, nc = numerical count. It indicates the number of numerical values and contains the numerical count information for the COUNT field.	si_dns_query_reply and si_dns_qps_trend			Splunk added special field
psrsvd_nc_LATENCY	Contains the numerical count information for the LATENCY field	si_dns_response_latency_trend			Splunk added special field
psrsvd_nc_QCOUNT	Contains the numerical count information for the QCOUNT field	si_dns_member_qps_trend_per_hour, si_dns_member_qps_trend_per_day, and si_dns_member_qps_trend			Splunk added special field
psrsvd_nx_QCOUNT	Here, nx = maximum numerical value. It contains the maximum numerical value information for the QCOUNT field.	si_dns_member_qps_trend_per_hour and si_dns_member_qps_trend_per_day			Splunk added special field
psrsvd_sm_COUNT	Here, sm = sum. It contains the sum information for the COUNT field.	si_dns_query_reply and si_dns_qps_trend			Splunk added special field
psrsvd_sm_LATENCY	Contains the sum information for the LATENCY field.	si_dns_response_latency_trend			Splunk added special field
psrsvd_sm_QCOUNT	Contains the sum information for the QCOUNT field	si_dns_member_qps_trend_per_hour, si_dns_member_qps_trend_per_day, and si_dns_member_qps_trend			Splunk added special field

psrsvd_sx_QCOUNT	Here, sx = maximum lexicographical value. It contains the maximum lexicographical value information for the QCOUNT field	si_dns_member_qps_trend_per_hour and si_dns_member_qps_trend_per_day			Splunk added special field
psrsvd_v	Here, v = version. This is not scoped to a single field.	si_dns_query_reply, si_dns_response_latency_trend, si_dns_member_qps_trend_per_hour, si_dns_member_qps_trend_per_day, si_dns_member_qps_trend, and si_dns_qps_trend			Splunk added special field
psrsvd_vt_COUNT	Here, vt = value type. It contains precision of the associated field. This field contains precision of the COUNT field.	si_dns_query_reply and si_dns_qps_trend			Splunk added special field
psrsvd_vt_LATENCY	Contains precision of the LATENCY field	si_dns_response_latency_trend			Splunk added special field
psrsvd_vt_QCOUNT	Contains precision of the QCOUNT field	si_dns_member_qps_trend_per_hour, si_dns_member_qps_trend_per_day, and si_dns_member_qps_trend			Splunk added special field
report	**Contains the name of the report that populates the summary index**				
	DNS Scavenge Object Count Trend data	si_dns_reclaimed_object_count_trend			
	DNS Top Clients report data	si_dns_top_clients			
	DNS Replies Trend data	si_dns_query_reply			
	DNS Top SERVFAIL Errors Received Report data	si_top_servfail_received_queries			
	DNS Response Latency Trend data	si_dns_response_latency_trend			
	DNS Daily Peak Hour Query Rate by Member Report data	si_dns_member_qps_trend_per_hour			

	DNS Top NXDOMAIN / NOERROR (no data) Report data	si_top_nxdomain_query			
	DNS Daily Query Rate by Member Report data	si_dns_member_qps_trend_per_day			
	DNS Query Rate by Member Report data	si_dns_member_qps_trend			
	DNS Top Requested Domain Names Report data	si_dns_requested_domain			
	DNS Queries Per Second Trend data	si_dns_qps_trend			
	DNS Top SERVFAIL Errors Sent Report data	si_top_servfail_sent_queries			
	DDNS Update Rate Trend data	si_ddns_update			
	DNS Cache Hit Rate Trend data	si_dns_cache_hit_ratio			
	DNS Top Timed-Out Recursive Queries Report data	si_top_timeout_queries			
	DNS RPZ Hits Reports data	si_dns_rpz_hits			
	DNS Top Clients per Domain Report data	si_top_clients_per_domain			
search_name	Common summary index fields				
search_now	Common summary index fields				
source	Splunk Default field				
sourcetype	Splunk Default field				
splunk_server	Splunk Default field				
splunk_server_group	Splunk Default field				
timeendpos	Common Extracted Fields				

timestartpos	Common Extracted Fields				

Infoblox DHCP Summary

Extracted Field Name	Description of the field	Reports	Values/Range	Source of Data	Remarks
ACTION	Specifies the action		String. Example: Issued	Infoblox DHCP summary	
DEVICE_CLASS	Specifies the device class		String. Example: Linux		
DHCP_RANGE	Specifies the DHCP range		Network range. Example: 10.0.0.1-10.0.0.200		
EA	Common Extracted fields				
FP	Specifies the fingerprint data		String. Example: No Match	Infoblox DHCP summary	
HWTYPE	Common Extracted Fields				
LEASED_IP	Specifies the lease IP address		IP address	Infoblox DHCP summary	
MAC_DUID	Specifies the MAC address		MAC address	Infoblox DHCP summary	
MAX_DB_OBJECTS	Common Extracted Fields				
MAX_DHCP_LPS	Common Extracted Fields				
MAX_DNS_QPS	Common Extracted Fields				
MEMBER_IP	Common Extracted Fields				
Protocol	Specifies the DHCP protocol		String. Example: IPV4	Infoblox DHCP summary	
SFP	Specifies the SFP		String. Example: Ubuntu/Debian 5/ Knoppix 6		

VIEW	It refers to the DNS view key to map the DNS view through lookup. See display_name field		String		
date_hour	*Splunk Default field*				
date_mday	Splunk Default field				
date_minute	Splunk Default field				
date_month	Splunk Default field				
date_second	Splunk Default field				
date_wday	Splunk Default field				
date_year	Splunk Default field				
date_zone	Splunk Default field				
dhcp_utilization_status	Specifies the DHCP utilization status		String	Infoblox DHCP summary	
display_name	Specifies the DNS view		String		
end_address	Specifies the end IP address		IP address	Infoblox DHCP summary	
eventtype	Splunk Default field				
host	Splunk Default field				
index	Splunk Default field				
info_max_time	Common summary index fields				

info_min_time	Common summary index fields				
info_search_time	Common summary index fields				
linecount	Splunk Default field				
members	Specifies the DHCP member		String. Example: infoblox.localdomain	Infoblox DHCP summary	
ms_servers	Specifies the MS servers		IP address	Infoblox DHCP summary	
orig_host	Specifies the host name of the data source		Example: infoblox.com		Splunk added default field
psrsvd_ct_FREE_ADDRESSES	Specifies the count information for FREE_ADDRESSES field	si_dhcp_usage_trend			Splunk added special field
psrsvd_ct_dhcp_utilization	Specifies the count for dhcp_utilization field	si_dhcp_range_utilization _trend			Splunk added special field
psrsvd_ct_dynamic_hosts	Specifies the count for dynamic_hosts field	si_dhcp_usage_trend			Splunk added special field
psrsvd_ct_static_hosts	Specifies the count for static_hosts field	si_dhcp_usage_trend			Splunk added special field
psrsvd_ct_v4ack	Specifies the count for v4ack field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v4decline	Specifies the count for v4decline field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v4discover	Specifies the count for v4discover field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v4inform	Specifies the count for v4inform field	si-search-dhcp-message			Splunk added special field

psrsvd_ct_v4leaseactive	Specifies the count for v4leaseactive field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v4leasequery	Specifies the count for v4leasequery field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v4leaseunassigned	Specifies the count for v4leaseunassigned field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v4leaseunknown	Specifies the count for v4leaseunknown field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v4nak	Specifies the count for v4nak field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v4offer	Specifies the count for v4offer field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v4release	Specifies the count for v4release field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v4request	Specifies the count for v4request field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6advertise	Specifies the count for v6advertise field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6confirm	Specifies the count for v6confirm field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6decline	Specifies the count for v6decline field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6information_request	Specifies the count for v6information_request field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6leasequery	Specifies the count for v6leasequery field	si-search-dhcp-message			Splunk added special field

psrsvd_ct_v6leasequery_ reply	Specifies the count for v6leasequery_reply field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6rebind	Specifies the count for v6rebind field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6reconfigure	Specifies the count for v6reconfigure field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6relay_forward	Specifies the count for v6relay_forward field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6relay_reply	Specifies the count for v6relay_reply field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6release	Specifies the count for v6release field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6renew	Specifies the count for v6renew field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6reply	Specifies the count for v6reply field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6request	Specifies the count for v6request field	si-search-dhcp-message			Splunk added special field
psrsvd_ct_v6solicit	Specifies the count for v6solicit field	si-search-dhcp-message			Splunk added special field
psrsvd_gc	Here, gc = group count. The count for stats grouping and not scoped to a single field.				Splunk added special field
psrsvd_nc_FREE_ADDRESSES	Specifies the numerical count for FREE_ADDRESSES field	si_dhcp_usage_trend			Splunk added special field

psrsvd_nc_dhcp_utilization	Specifies the numerical count for dhcp_utilization field	si_dhcp_range_utilization_trend			Splunk added special field
psrsvd_nc_dynamic_hosts	Specifies the numerical count for dynamic_hosts field	si_dhcp_usage_trend			Splunk added special field
psrsvd_nc_static_hosts	Specifies the numerical count for static_hosts field	si_dhcp_usage_trend			Splunk added special field
psrsvd_nc_v4ack	Specifies the numerical count for v4ack field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v4decline	Specifies the numerical count for v4decline field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v4discover	Specifies the numerical count for v4discover field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v4inform	Specifies the numerical count for v4inform field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v4leaseactive	Specifies the numerical count for v4leaseactive field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v4leasequery	Specifies the numerical count for v4leasequery field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v4leaseunassigned	Specifies the numerical count for v4leaseunassigned field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v4leaseunknown	Specifies the numerical count for v4leaseunknown field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v4nak	Specifies the numerical count for v4nak field	si-search-dhcp-message			Splunk added special field

psrsvd_nc_v4offer	Specifies the numerical count for v4offer field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v4release	Specifies the numerical count for v4release field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v4request	Specifies the numerical count for v4request field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6advertise	Specifies the numerical count for v6advertise field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6confirm	Specifies the numerical count for v6confirm field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6decline	Specifies the numerical count for v6decline field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6information_request	Specifies the numerical count for v6information_request field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6leasequery	Specifies the numerical count for v6leasequery field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6leasequery_reply	Specifies the numerical count for v6leasequery_reply field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6rebind	Specifies the numerical count for v6rebind field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6reconfigure	Specifies the numerical count for v6reconfigure field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6relay_forward	Specifies the numerical count for v6relay_forward field	si-search-dhcp-message			Splunk added special field

psrsvd_nc_v6relay_reply	Specifies the numerical count for v6relay_reply field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6release	Specifies the numerical count for v6release field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6renew	Specifies the numerical count for v6renew field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6reply	Specifies the numerical count for v6reply field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6request	Specifies the numerical count for v6request field	si-search-dhcp-message			Splunk added special field
psrsvd_nc_v6solicit	Specifies the numerical count for v6solicit field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_FREE_ADDRESSES	Specifies the sum for FREE_ADDRESSES field	si_dhcp_usage_trend			Splunk added special field
psrsvd_sm_dhcp_utilization	Specifies the sum for dhcp_utilization field	si_dhcp_range_utilization_trend			Splunk added special field
psrsvd_sm_dynamic_hosts	Specifies the sum for dynamic_hosts field	si_dhcp_usage_trend			Splunk added special field
psrsvd_sm_static_hosts	Specifies the sum for static_hosts field	si_dhcp_usage_trend			Splunk added special field
psrsvd_sm_v4ack	Specifies the sum for v4ack field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v4decline	Specifies the sum for v4decline field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v4discover	Specifies the sum for v4discover field	si-search-dhcp-message			Splunk added special field

psrsvd_sm_v4inform	Specifies the sum for v4inform field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v4leaseactive	Specifies the sum for v4leaseactive field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v4lease query	Specifies the sum for v4leasequery field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v4leaseunassigned	Specifies the sum for v4leaseunassigned field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v4leaseunknown	Specifies the sum for v4leaseunknown field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v4nak	Specifies the sum for v4nak field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v4offer	Specifies the sum for v4offer field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v4release	Specifies the sum for v4release field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v4request	Specifies the sum for v4request field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6advertise	Specifies the sum for v6advertise field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6confirm	Specifies the sum for v6confirm field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6decline	Specifies the sum for v6decline field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6information_ request	Specifies the sum for v6information_request field	si-search-dhcp-message			Splunk added special field

psrsvd_sm_v6leasequery	Specifies the sum for v6leasequery field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6leasequery_reply	Specifies the sum for v6leasequery_reply field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6rebind	Specifies the sum for v6rebind field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6reconfigure	Specifies the sum for v6reconfigure field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6relay_forward	Specifies the sum for v6relay_forward field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6relay_reply	Specifies the sum for v6relay_reply field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6release	Specifies th sum for v6release field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6renew	Specifies the sum for v6renew field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6reply	Specifies the sum for v6reply field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6request	Specifies the sum for v6request field	si-search-dhcp-message			Splunk added special field
psrsvd_sm_v6solicit	Specifies the sum for v6solicit field	si-search-dhcp-message			Splunk added special field
psrsvd_v	Here, v = version. This is not scoped to a single field.	si_dhcp_usage_trend, si_dhcp_top_lease_client, si_dhcp_range_utilization_trend, si_dhcp_top_os_by_network, and si-search-dhcp-message			Splunk added special field

psrsvd_vt_FREE_ADDRESSES	Contains precision of the FREE_ADDRESSES field	si_dhcp_usage_trend			Splunk added special field
psrsvd_vt_dhcp_utilization	Contains precision of the dhcp_utilization field	si_dhcp_range_utilization_trend			Splunk added special field
psrsvd_vt_dynamic_hosts	Contains precision of the dynamic_hosts field	si_dhcp_usage_trend			Splunk added special field
psrsvd_vt_static_hosts	Contains precision of the static_hosts field	si_dhcp_usage_trend			Splunk added special field
psrsvd_vt_v4ack	Contains precision of the v4ack field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v4decline	Contains precision of the v4decline field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v4discover	Contains precision of the v4discover field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v4inform	Contains precision of the v4inform field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v4leaseactive	Contains precision of the v4leaseactive field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v4leasequery	Contains precision of the v4leasequery field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v4leaseunassigned	Contains precision of the v4leaseunassigned field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v4leaseunknown	Contains precision of the v4leaseunkown field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v4nak	Contains precision of the v4nak field	si-search-dhcp-message			Splunk added special field

psrsvd_vt_v4offer	Contains precision of the v4offer field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v4release	Contains precision of the v4release field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v4request	Contains precision of the v4request field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6advertise	Contains precision of the v6advertise field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6confirm	Contains precision of the v6confirm field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6decline	Contains precision of the v6decline field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6information_request	Contains precision of the v6information_request field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6leasequery	Contains precision of the v6leasequery field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6leasequery_reply	Contains precision of the v6leasequery_reply field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6rebind	Contains precision of the v6rebind field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6reconfigure	Contains precision of the v6reconfigure field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6relay_forward	Contains precision of the v6relay_forward field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6relay_reply	Contains precision of the v6relay_reply field	si-search-dhcp-message			Splunk added special field

psrsvd_vt_v6release	Contains precision of the v6release field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6renew	Contains precision of the v6renew field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6reply	Contains precision of the v6reply field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6request	Contains precision of the v6request field	si-search-dhcp-message			Splunk added special field
psrsvd_vt_v6solicit	Contains precision of the v6solicit field	si-search-dhcp-message			Splunk added special field
report	**Name of the report that is populating the summary index**				
	DHCP Message Rate Trend data	si-search-dhcp-message			
	DHCPv4 Usage Trend data	si_dhcp_usage_trend			
	DHCP Top Lease Clients report data	si_dhcp_top_lease_client			
	Top Devices Denied an IP Address report data	si_devices_denied_an_ip_address			
	DHCPv4 Range Utilization Trend	si_dhcp_range_utilization_trend			
	Device and Device Classes reports data	si_dhcp_top_os_by_network

Managing Reporting Data

You can do the following to manage the Reporting and Analytics App:

- *Upgrading Reporting and Analytics App*
- *Backing Up and Restoring the Infoblox Reporting and Analytics App*
- *Best Practices for Backing Up Reporting Data*
- *Reports with Data Synchronized from Microsoft Servers*

Upgrading Reporting and Analytics App

> **Note**
> All the updates for Infoblox Reporting & Analytics App are available with the NIOS upgrade. Therefore, as a part of NIOS upgrade, no further steps are required for upgrading the Infoblox Reporting & Analytics App.

You can download the latest version of the Infoblox Reporting and Analytics App from the Infoblox Support site. You can then upgrade this App on your reporting server.
To upgrade the Reporting and Analytics App:

1. Check your current version of the App in the **Reporting Help** tab.
2. Check if there is a later version that is available on the Infoblox Support site.
3. Download the `.bin2` file from Infoblox Support site.
4. From the **Administration** tab, select the **Reporting** tab.
5. Click **Upgrade Reporting & Analytics App** from the Toolbar.
6. In the *Upgrade Reporting & Analytics App* dialog box, click **Select**. In the *Upload* dialog box, click **Select**, navigate to the `.bin2` file, select it, and then click **Upload**.
7. After the Reporting and Analytics App is upgraded, click **Restart** to restart the Reporting service.

Backing Up and Restoring the Infoblox Reporting and Analytics App

To back up the Reporting and Analytics App, go to the **Grid** tab, select **Backup** -> **Grid Backup** -> **Manual Backup** from the Toolbar, and then select **Infoblox Reporting & Analytics App** to back up the app. When you back up the Reporting and Analytics App, the backup file is a .bak file that contains the reporting settings configured in the Grid Reporting Properties.
To restore the Reporting and Analytics App, go to the **Grid** tab, select **Restore** -> **Restore Grid** from the Toolbar, and then select **Infoblox Reporting & Analytics App** to restore the app.

Backing Up Reporting Data

Before you back up the reporting database, ensure that the reporting service is enabled on the reporting server. You cannot perform or schedule a backup if the reporting service is disabled on the reporting server. If you want to upgrade your reporting server, back up all the data before you power down the server. During an upgrade, the reporting server is automatically upgraded after the Grid Master. You cannot control or schedule when to upgrade the reporting server. For information about upgrades and upgrade groups, see *Managing Upgrade Groups*.
Note that reporting data backups are incremental backups, which means that backup files are copied to the designated file server only when there are new events generated since the last backup. Backing up of the reporting database to an FTP or SCP server using IPv4 or IPv6 is supported. The backup file is a .tar.gz file that contains the reporting data.
If you stop an ongoing backup process, backup files are still being copied to the designated file server. When you perform a subsequent backup, the appliance appends incremental data to these backup files.

You can manually back up the reporting database or schedule a backup, but you cannot perform both at the same time. The backup process starts when the indexed data rolls from the hot bucket to the warm bucket. The hot bucket includes all inbound events and actively written data. Indexed data moves to the warm bucket when one of the following conditions is met:

- The size of the reporting data reaches 1 GB
- Data is 90 days old
- The reporting server restarts

You can perform the following reporting data backups:

- Manual backups, as described in Backing Up the Reporting Database Manually below.
- Scheduled backups, as described in Scheduling the Backup of the Reporting Database below.

Backing Up the Reporting Database Manually

- From the **Grid** tab, select **Backup** -> **ReportingBackup** -> **ManualBackup** from the Toolbar.
- In the *ManualReportingBackup* editor, complete the following:
  - **Status**: Displays the status of the backup process of the last operation.
  - **Backupto**: Select the destination of the backup file from the drop-down list:
    - **FTP**: Back up the reporting database to an FTP server.
      - **Filepath**: Enter the directory path. For example, you can enter **/archive/backups/Infoblox/**.
      - **IP Address of FTP Server**: The IP address of the FTP server.
      - **Username**: Enter the username of your FTP account.
      - **Password**: Enter the password of your FTP account.
    - **SCP**: Back up the reporting database to an SSH server that supports SCP.
      - **Filepath**: Enter the directory path. For example, you can enter **/archive/backups/Infoblox/**.
      - **IP Address of SCP Server**: The IP address of the SCP server.
      - **Username**: Enter the username of your SCP account.
      - **Use Keys**: If you select this checkbox, you can back up files to SCP without entering the password. The first time you select the checkbox, you need to enter the password. However, during subsequent times, the Infoblox server verifies whether Infoblox keys are available on the SCP server. If they are available, you can click the **Backup** button without entering the password. If Infoblox keys are not available on the SCP server, the following message is displayed:

        ```
        Reporting backup has failed.
        ```
      - **Password**: Enter the password of your SCP account.
      - **Keys Type**: Select the SSH key type to be uploaded. At present, only ECDSA and RSA keys are supported. Click **Upload Keys** to upload the keys to the SCP server. If the keys are not available, click **Download Keys** to download the keys and manually add them to the SCP server.

⚠ Notes

- If you are using Fedora, ECDSA keys are supported only on Fedora versions later than Fedora 12.
- When you select **FTP** or **SCP**, ensure that you have a valid user name and password on the server prior to backing up the files. Also ensure that the target SSH server has the required permissions for an SCP backup. The permission must be 755 and the target server must have write permission to the directory to which you upload the backup file.
- For an SCP backup, ensure that you are logged in as the user for whom the key was created. Also ensure that the .ssh directory on the server and the files it contains, have the correct permissions: `chmod 600 ~/.ssh/authorized_keys && chmod 700 ~/.ssh/`
- If you promote a Grid Master or perform an HA failover, you must upload the SSH key once again for a successful SCP backup using keys.

Scheduling the Backup of the Reporting Database

- From the **Grid** tab, select **Backup** -> **ReportingBackup** -> **ScheduleBackup** from the Toolbar.
- In the *ScheduleReportingBackup* editor, complete the following:
  - **Status**: Displays the status of the backup process of the last operation. Select the destination of the backup file from the **Backupto** drop-down list**:**
  - **FTP**: Back up the reporting database files to an FTP server.
    - **IP Address of FTPServer**: The IP address of the FTP server.
    - **Directory Path**: Enter the directory path. For example, you can enter **/archive/backups**. The directory path cannot contain spaces. The folder or directory you enter here must already exist on the specified server. Do not include the file name in the directory path.
    - **Username**: Enter the username of your FTP account.
    - **Password**: Enter the password of your FTP account.

- **Recurrence**: Select how often you want to back up the files. You can select **Weekly**, **Daily**, or **Hourly** from the drop-down list. When you select **Weekly**, complete the following:
  - **Every:** Choose a day of the week from the drop-down list.
  - **Time**: Enter a time in the hh:mm:ss AM/PM format. You can also click the clock icon and select a time from the drop-down list. The Grid Master creates a backup file on the selected day and time every week.
    When you select **Daily**, enter a time in the hh:mm:ss AM/PM format. You can also select a time from the drop-down list.
    When you select **Hourly**, complete the following:
  - **Minutes after the Hour**: Enter the minute after the hour when the Grid Master creates a backup file. For example, enter 5 if you want the Grid Master to create a backup file five minutes after the hour every hour.
- **Disable Scheduled Backup:** Select this if you want to disable automatic backups from occurring now, but want to save the settings for future use.

- **SCP**: Back up the reporting database to an SSH server that supports SCP.
  - **IP Address of SCP Server**: The IP address of the SCP server.
  - **Directory Path**: Enter the directory path of the file. For example, you can enter **/archive/backups**. The directory path cannot contain spaces. The folder or directory you enter here must already exist on the specified server. Do not include the file name in the directory path.
  - **Username**: Enter the username of your SCP account.
  - **Use Keys**: If you select this checkbox, you can back up files to SCP without entering the password. The first time you select the checkbox, you need to enter the password. However, during subsequent times, the Infoblox server verifies whether Infoblox keys are available on the SCP server. If they are available, you can click the **Backup** button without entering the password. If Infoblox keys are not available on the SCP server, the following message is displayed:
    `Reporting backup has failed.`
  - **Password**: Enter the password of your SCP account.
  - **Keys Type**: Select the SSH key type to be uploaded. At present, only ECDSA and RSA keys are supported. Click **Upload Keys** to upload the keys to the SCP server. If the keys are not available, click **Download Keys** to download the keys and manually add them to the SCP server.
  - **Recurrence**: Select how often the scheduled backups should occur. You can select **Weekly**, **Daily**, or **Hourly**. For information, see the FTP section.
  - **Disable Scheduled Backup:** Select this if you want to disable automatic backups from occurring now. You can still save the settings for future use.

⚠ Notes
- If you are using Fedora, ECDSA keys are supported only on Fedora versions later than Fedora 12.
- When you select **FTP** or **SCP**, ensure that you have a valid user name and password on the server prior to backing up the files. Also ensure that the target SSH server has the required permissions for an SCP backup. The permission must be 755 and the target server must have write permission to the directory to which you upload the backup file.
- For an SCP backup, ensure that you are logged in as the user for whom the key was created. Also ensure that the .ssh directory on the server and the files it contains, have the correct permissions: `chmod 600 ~/.ssh/authorized_keys && chmod 700 ~/.ssh/`
- If you promote a Grid Master or perform an HA failover, you must upload the SSH key once again for a successful SCP backup using keys.

Restoring the Reporting Database

Restoring the reporting database may take a long time to perform, and the reporting service is unavailable during a restore. Ensure that you back up the reporting database before you perform the operation. Restoring of reporting database from an FTP or SCP server using IPv4 or IPv6 is supported.
Note the following during a restore:

- The reporting service is unavailable.
- Existing reporting data is removed from the reporting server.

- Backup data is restored up to the amount the reporting server can accommodate.
  The Volume Used Today displayed in the Device Information section will not be updated after restoring the data. Also, when you restore data or execute the CLI command reset reporting_data, the volume violation count will be reset to zero on the second day.

1. From the **Grid** tab, select **Restore** -> **Restore Reporting** from the Toolbar.
2. In the *Restore* dialog box, complete the following:
   - **Status**: Displays the status of the restore process, if in progress.
     Select the destination of the backup file from the **Restore from** drop-down list**:**
   - **FTP**: Restore the reporting backup files from an FTP server.
     - **Filepath**: Enter the directory path. For example, you can enter **/archive/backups/Infoblox/**.
     - **IP Address of FTP Server**: The IP address of the FTP server.
     - **Username**: Enter the username of your FTP server account.
     - **Password**: Enter the password of your FTP server account.
   - **SCP**: Restore the reporting backup files from a SCP server.
     - **Filepath**: Enter the directory path. For example, you can enter **/archive/backups/Infoblox/**.
     - **IP Address of SCP Server**: The IP address of the SCP server.
     - **Username**: Enter the username of your SCP server account.
     - **Password**: Enter the password of your SCP server account.
3. Click **Restore**.

Best Practices for Backing Up Reporting Data

The following are some best practices that you must implement when backing up reporting data:

Best Practices for Backing Up

- The first backup of the reporting data is a full backup. Subsequent backups irrespective of scheduled or manual are incremental backups. Infoblox recommends that you do not change the backup directory for each backup.
- Reporting data backups are incremental. Any modification or deletion of the backed up data can create an impact when the data is restored.
- If you upgrade or replace the Reporting server, Infoblox recommends that you back up the reporting data and the Infoblox Reporting and Analytics App.
- Once the reporting data is restored on a Grid, subsequent backups include only the new data.

Best Practices for Upgrading or Replacing the Reporting Server (Single Indexer)

- After you upgrade or replace the Reporting server, restore the Infoblox Reporting and Analytics App to restore any custom reports or Grid settings.
- After you upgrade or replace the Reporting server, restore the reporting data from the reporting backup to view the historic reporting data.

Best Practices for Upgrading or Replacing the Reporting Server (Single or Multi-Site Cluster)

- If the Grid has a reporting configuration updated from a single indexer to a single or multi-site cluster, data replication starts only for the data indexed after clustering. If you upgrade or replace the old reporting server, you may lose the data indexed before clustering. Infoblox recommends that you restore the reporting backup to view historic data.

Reports with Data Synchronized from Microsoft Servers

Note: The DNS reports listed in the following table displays data synchronized from the Microsoft servers only when you have enabled synchronization of reporting data for the Grid or the Microsoft servers. For information about enabling synchronization of DNS reporting data from the Microsoft server, see *Synchronizing DNS Reporting Data*.

Infoblox supports the following versions of Microsoft Windows servers in displaying reporting data from both NIOS and the Microsoft servers:

- DNS Reports: Microsoft Windows 2012 R2, Microsoft Windows 2016 and Microsoft Windows 2019.
- DHCP Reports: Microsoft Windows 2008, Microsoft Windows 2008 R2, Microsoft Windows 2012, Microsoft Windows 2012 R2, Microsoft Windows 2016 and Microsoft Windows 2019.
- IPAM Reports: Microsoft Windows 2008, Microsoft Windows 2008 R2, Microsoft Windows 2012, Microsoft Windows 2012 R2, Microsoft Windows 2016 and Microsoft Windows 2019.

The following reports display data from both NIOS and the Microsoft servers. For detailed information about these reports, see *Predefined Dashboards*.

DNS Reports

- *DNS Top Requested Domain Names*
- *DNS Top Clients*
- *DNS Top Clients Per Domain*
- *DNS Query Rate by Query Type*
- *DNS Query Rate by Member*
- *DNS Daily Query Rate by Member*
- *DNS Daily Peak Hour Query Rate by Member*
- *DNS Top NXDOMAIN /NOERROR (no data)*
- *DNS Top SERVFAIL Errors Sent*
- *DNS Top SERVFAIL Errors Received*
- *DNS Top Timed-out Recursive Queries*
- *DNS Query Trend per IP Block Group*
- *DDNS Update Rate Trend*

Following DNS reports are generated if a Data Collector VM is registered with the Grid:

- *DNS Domain Queried by Client*
- *DNS Domain Query Trend*
- *DNS Top Clients by Query Type*
- *DNS Top Clients Querying MX Records*

DHCP Reports

- *DHCPv4 Usage Trend*
- *DHCPv4 Usage Statistics*
- *DHCPv4 Range Utilization Trend*
- *DHCPv4 Top Utilized Networks*
- *DHCP Lease History*
- *DHCP Top Lease Clients*
- *DHCP Message Rate Trend*

IPAM Reports

- *IPAMv4 Network Usage Statistics*
- *IPAMv4 Network Usage Trend*
- *IPAMv4 Top Utilized Networks*

Infoblox Infrastructure Security

The mission-critical DNS infrastructure can become a vulnerable component in your network when it is inadequately protected by traditional security solutions and consequently used as an attack surface. Compromised DNS services can result in catastrophic network and system failures. To fully protect your network in today's cyber security threat environment, Infoblox sets a new DNS security standard by offering scalable, enterprise-grade, and integrated protection for your DNS infrastructure.

While your external (internet-facing) DNS server can be subject to cyber attacks such as DNS DDoS (Distributed Denial of Service) and others, threats can also come from the inside of your firewalls. Today's targeted attacks pose risk to both data and infrastructure inside an enterprise. You could have an endpoint infected with malware or threats trying to communicate with C&C (Command-and-Control) servers that use DNS as a protocol. You could also have a malicious

insider trying to steal valuable digital assets by opening a DNS tunnel or embedding data in DNS queries. Depending on how you want to protect your mission-critical DNS infrastructure, you can configure your Infoblox appliance to mitigate against external, internal, or both (external and internal) DNS threats.

This section contains information about the Infoblox infrastructure security features that protect external DNS from cyber DNS attacks and internal DNS from infrastructure attacks, data exfiltration, and APTs (Advanced Persistent Threats) and malware. It covers the following topics:

Infoblox Advanced DNS Protection

The Infoblox Advanced DNS Protection solution employs hardware-accelerated security rules to detect, report upon, and stop attacks such as DDoS, DNS reflection, DNS amplification, DNS hijacking, and other network attacks targeting DNS authoritative applications. This security solution helps minimize "false positives" and ensures that your mission-critical DNS services continue to function even when under attack. For more information, see *Infoblox Advanced DNS Protection*.

Infoblox DNS Firewall

Infoblox DNS Firewall uses DNS RPZs (Response Policy Zones) for allowing reputable sources to dynamically communicate reputation domain names so you can implement policy controls for DNS lookups. For more information, see *Infoblox DNS Firewall*.

Infoblox Threat Insight

The Infoblox Threat Insight solution defenses against data exfiltration through DNS tunneling for ultimate network protection. For more information, see *Infoblox Threat Insight*.

Security Ecosystem

The Infoblox security ecosystem comprises FireEye integrated RPZs for detecting malware and APTs and the TAXII (Trusted Automated eXchange of Indicator Information) service for mitigating cyber attacks. For more information, see *Infoblox DNS Firewall*.
For best practices in securing your networks, you can also set up DNS blacklists or configure a security banner. When you enable DNS Integrity Check for top-level authoritative zones, the appliance verifies DNS data in the NS RRsets and glue records, and reports any data discrepancies so you can mitigate possible DNS domain hijacking.
Following are other DNS security features for your network security:

Access Control (Named ACLs)

To effectively manage your core network services, you can grant legitimate hosts access to specific operations on the appliance using an ACL (access control list) or anonymous ACEs (access control entries). You can also configure a named ACL and apply it to multiple operations, such as file distribution and DNS zone transfers. For more information, see *Configuring Access Control*.

DNS blacklists

Your organization can prevent customers or employees from accessing certain Internet resources, particularly web sites, by prohibiting a recursive DNS member from resolving queries for domain names that you specify. You can configure a recursive DNS member to redirect the DNS client to predefined IP addresses or return a REFUSED response code (indicating that resolution is not performed because of local policy), depending on the domain name. For more information, see *Blacklists*.

Security Banner

You can configure and publish a notice and consent banner as the first login screen that includes specific terms and conditions you want end users to accept before they log in to the Infoblox Grid. When you enable the notice and consent banner, users must accept the terms and conditions displayed on the consent screen before accessing the login screen of Grid Manager. For more information about configuring notice and consent banner, see *Managing a Grid*.

DNS Integrity Check

DNS domain hijacking or domain theft is the act of changing the registration of a domain name without the permission of its original registrant. In some cases, hijackers change the DNS data of a domain after gaining control of it. They consequently redirect users to a fraudulent site, instead of the legitimate site, on the Internet. To protect your authoritative DNS servers against this type of domain hijacking, you can configure the appliance to monitor NS records and glue records for top-level authoritative zones. Based on your configuration, the appliance periodically checks the DNS data for the zones and compares the data with that in the appliance database. The severity in data discrepancies can help identify possible domain hijacking. For more information about this feature, see *Configuring DNS Integrity Check for Authoritative Zones*.

About Infoblox Advanced DNS Protection

The Infoblox Advanced DNS Protection solution employs threat protection rules to detect, report upon, and stop DoS (Denial of Service), DDoS (Distributed Denial of Service) and other network attacks targeting DNS authoritative applications. Infoblox Advanced DNS Protection helps minimize "false positives" and ensures that your mission-critical DNS services continue to function even when under attack. For information about possible DNS threats, see *DNS and Network-Flood Threats*.

You can deploy the Advanced DNS Protection solution on hardware-accelerated appliances (physical appliances only) as well as software-based appliances (both physical and virtual) in the Grid. Depending on the appliances you deploy, you must install applicable hardware-based licenses or Software ADP subscription licenses. For information about supported Infoblox appliances for Advanced DNS Protection and the applicable licenses, see *Supported Threat Protection Appliances and Licensing Requirements*.

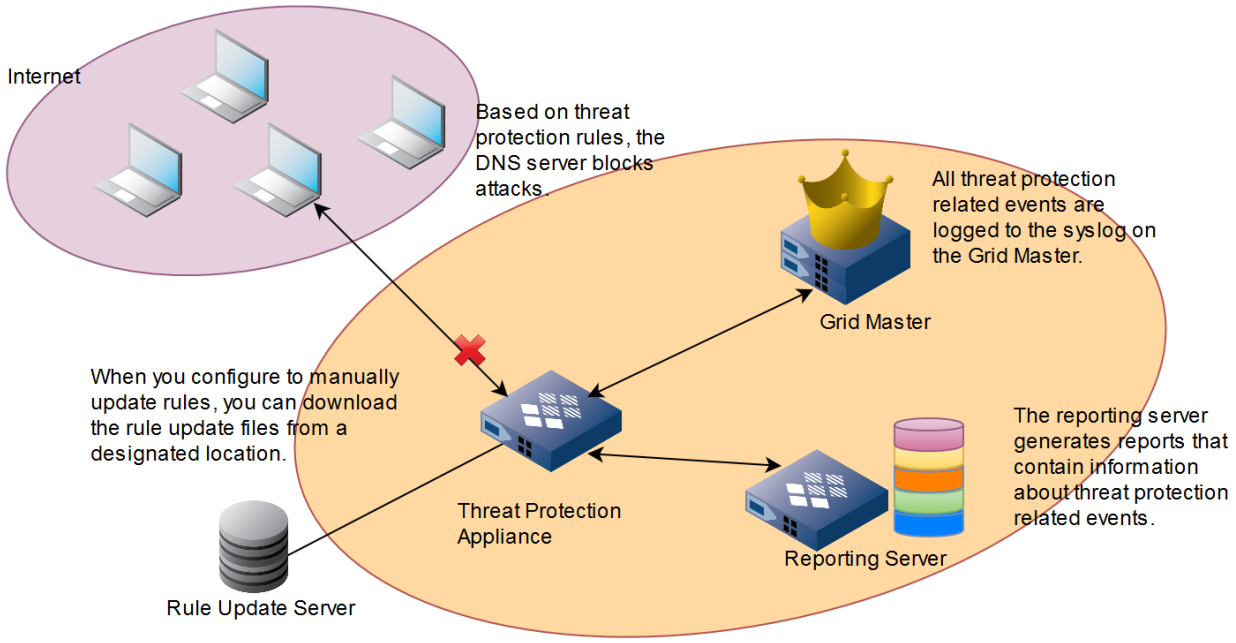
Infoblox Advanced DNS Protection is designed to provide visibility and protection against network floods and DNS attacks. It detects DNS attacks through predefined and custom threat protection rules, and mitigates DNS threats by dropping problematic packets while responding only to legitimate traffic. With valid licenses installed, you can subscribe to automatic rule updates that deliver near real-time protection against new and emerging attacks. You may also manually perform the rule update process based on your configuration. For information about threat protection rules, see *Understanding Threat Protection Rulesets and Rules*.

Infoblox Advanced DNS Protection supports a set of predefined threat protection rules that detect and mitigate possible DNS threats. You can modify some of the parameters and assign actions such as logging events and applying mitigation to these rules. You can also create custom rules to suit your security needs. For more information, see *Understanding Threat Protection Rulesets and Rules*.

As illustrated in the figure below, the threat protection appliance, acting as an authoritative DNS server, is added to the Grid. After installing valid threat protection licenses and configuring the appliance to serve as an Advance Appliance, it can now detect DNS threats and mitigate DNS threats based on threat protection rules. All threat protection related events, conformed to CEF (Common Event Format), are logged in the syslog on the Grid Master. To perform further

investigation about possible threats, the reporting server generates specific threat protection related reports. For information about how to monitor threat protection related events and reports, see *Monitoring Threat Protection Events*.

Infoblox Advanced DNS Protection Solution



Limitations for Threat Protection Appliances

Hardware-based appliances support all existing DNS features (including HA support) that are applicable to DNS caching and authoritative applications, except the following:

- Configuration of multiple interfaces on the same subnet
- 10/100-Mbps gigabit Ethernet mode and fixed speed/duplex settings

> **Note**
>
> The MGMT interface must be configured and Infoblox strongly recommends that the MGMT interface be used for Grid traffic.

Consider the following when the threat protection service is enabled on advanced appliances:

For Hardware ADP

- Protected interfaces (LAN1 and LAN2) are limited to DNS traffic, protocols in support of DNS anycast (BGP and OSPF) and the standard IP protocols such as ICMP, as well as connections to NTP servers.
- The MGMT interface is used for other traffic, such as Grid, SSH, SNMP, NTP, and it will not be protected against DDoS attacks.
- You cannot run other services, such as FTP, TFTP, and HTTP, on the Advance Appliances.
- The appliance terminates TCP connections for incoming DNS requests after handling the initial request through each TCP connection. The exception for this default Grid setting is for an SOA query sent by a client that is accepted in the allow-transfer ACL. In the case of an SOA query, the TCP connection remains open for subsequent DNS requests. This exception also covers the case in which an AXFR query follows the SOA query

through the same TCP connection. For more information about how to override this default Grid setting, see *Enabling Multiple DNS Requests through a Single TCP Session*.

For Software ADP

- When you use IB-FLEX for Software ADP, it supports a standalone or a Grid member with threat protection enabled, but it does not support a Grid Master with threat protection enabled. For more information about the IB-FLEX virtual appliance model, see *About IB-FLEX*.
- IB-FLEX applies threat protection rules to all traffic on LAN1, LAN2 and HA interfaces, but bypasses the traffic on the MGMT interface.
- The threat protection profiles used for Software ADP members support ADP NAT settings.

On all vNIOS appliances that support vDCA (virtual DNS Cache Acceleration) or vADP (virtual Advanced DNS Protection), you must run vDCA or vADP on a single virtual NUMA node. If the configuration of the virtual NUMA node and physical NUMA node are not the same, it may result in performance degradation.

Configuring Infoblox Advanced DNS Protection

To enable and configure Infoblox Advanced DNS Protection on supported Infoblox appliances, complete the following:

1. Obtain valid Threat Protection, Threat Protection (Software add-on) and Threat Protection Update licenses from Infoblox and install them on the Infoblox Advance Appliances. For information about license requirements, see *Supported Threat Protection Appliances and Licensing Requirements*.
2. Optionally, you can set up an HA pair using the same appliance models for both the active and passive nodes. For information about HA pairs, see *About HA Pairs*. Note that you cannot configure Advance Appliances as an HA Grid Master or HA Grid Master candidate.
3. Enable threat protection service, as described in *Starting and Stopping Threat Protection Service*. For an HA pair, enable the service on both the active and passive nodes.
4. Configure threat protection rule settings for the Grid, including automatic or manual rule updates, as described in *Configuring Grid Security Properties*. If your network configuration requires rule updates to go through a proxy server, you can configure the appliance to use a proxy server to send rule updates. For more information, see *Configuring Proxy Servers*. You can also delegate ruleset updates to specific Grid members and change the default interface to an alternate interface, as described in Configuring Members and Interfaces for Automatic Updates, see *Configuring Proxy Servers*. Define threat protection profiles for the Grid or specific members, as described in *Configuring Threat Protection Profiles*.
5. Optionally, you can do the following:
    - Override the default Grid setting that disables multiple DNS requests through one TCP session, as described in *Enabling Multiple DNS Requests through a Single TCP Session*.
    - Direct incoming DNS queries to be handled by DNS Cache Acceleration before being passed to Threat Protection, as described in *Handling DNS Queries Through DNS Cache Acceleration*.
    - Modify system rules, as described in *Modifying System and Auto Rules*.
    - Create custom rules using rule templates, as described in creating custom rules, see *Custom Rules*.

After you have successfully set up Infoblox Advanced DNS Protection, you can do the following:

- View the current threat protection rules, as described in *Viewing Threat Protection Rules*.
- Modify system and custom threat protection rules, as described in *Managing Threat Protection Rules*.
- Manually upload rule updates, as described in *Manually Uploading Rulesets*.
- Publish uploaded rule updates, as described in *Publishing Rule Updates*.
- For manual updates, compare differences between two rulesets and merge parameter changes from an old ruleset into a new one, as described in *Comparing and Merging Rulesets*.
- Monitor threat protection related events and reports, as described in *Monitoring Threat Protection Events*.
- Set the threat protection service in monitor mode, as described in *Enabling and Disabling Monitoring Mode*.
- Add threat protection profiles, as described in *Adding Threat Protection Profiles*.
- Clone threat protection profiles, as described in *Cloning Threat Protection Profiles*.
- Modify threat protection profiles, as described in *Modifying Threat Protection Profiles*.
- Merge threat protection profiles, as described in *Merging Threat Protection Profiles*.
- Inherit Grid rule settings for a threat protection profile, as described in *Inheriting Grid Rule Settings*.

- Delete a threat protection profile, as described in *Deleting Threat Protection Profiles*.
- View the current threat protection profiles, as described in *Viewing Threat Protection Profiles*.

Administrative Permissions

Superusers can configure all threat protection related tasks. You can assign **Security Permissions** to specific admin groups and roles. You can also add a global permission for managing Grid security properties or add an object permission for managing member security properties.
To perform any action on the rulesets and rules, you must have a Read-write permission for *Grid Security properties* and *Member Security properties* at the Grid level and the member level respectively. For more information about security permissions, see *Administrative Permissions for DNS Threat Protection*.

Administrative Permissions for Advanced DNS Protection

Superusers can configure all threat protection related tasks. You can assign **Security Permissions** to specific admin groups and roles. You can also add a global permission for managing Grid security properties or add an object permission for managing member security properties.
To perform any action on the rulesets and rules, you must have a Read-write permission for *Grid Security properties* and *Member Security properties* at the Grid level and the member level respectively. For more information about security permissions, see *Administrative Permissions for DNS Threat Protection*.

Supported Threat Protection Appliances and Licensing Requirements

The Infoblox Advanced DNS Protection solution offers the following licenses: **Threat Protection, Threat Protection (Software add-on),** and **Threat Protection Update**. The following are descriptions for each of these licenses:

- **Threat Protection**: Install this license on the physical or hardware-based threat protection appliances. With valid licenses installed, Infoblox Advanced DNS Protection supports both IPv4 and IPv6.
  You can configure two appliances of the same model to form an HA pair for high availability configuration. For more information about how to configure an HA pair for Infoblox Advanced DNS Protection and its limitations, see *About HA Pairs*. You can configure hardware-based appliances in either IPv4, IPv6, or dual mode (IPv4 and IPv6) network environment.

> ⚠ Note
> Reverting to an earlier NIOS release that does not support HA configuration for these appliances could cause a service outage.

- **ThreatProtection(Softwareadd-on)**: The Software ADP license is a subscription license. Grid Manager displays a warning message when the license expires. You must renew the license to use the Software ADP service. To renew the license, contact your Infoblox representative or Infoblox Technical Support. Before you obtain your permanent license, you can install a temporary license for **Threat Protection (Software add-on)** using the `set temp_license` CLI command. For more information, refer to the *InfobloxCLIGuide.* Infoblox supports **ThreatProtection(Softwareadd-on)** and **ThreatProtectionUpdate** licenses for elastic scaling. For more information, see *About Elastic Scaling*.

> ⚠ Note
> You cannot install Multi-Grid Management and Microsoft Management licenses if you install **ThreatProtection** or **ThreatProtection(Softwareadd-on)** licenses on the NIOS appliance.

- **Threat Protection Update**: To receive initial and subsequent threat protection rules and rule updates, you must have the **Threat Protection Update** license installed. You can then configure NIOS to automatically download and publish threat protection rules or you can manually complete the process. For information, see *Manually Uploading Rulesets* and *Publishing Rule Updates*.

With valid licenses installed, the threat protection appliance can be used as a DNS caching or DNS authoritative server. You can join the appliance to the Grid and treat it as a Grid member. Note that if you install a Threat Protection license on a member, you can enable threat protection only on this member. Contact your Infoblox representative to obtain the **Threat Protection**, **Threat Protection Update** and **Threat Protection (Software add-on)** licenses. For information about licenses, see *Managing Licenses*.

The following table lists all the supported threat protection appliance models and licenses that you can install on them to activate threat protection:

Threat Protection Appliance Models and Appliances

Threat Protection Appliance Model	Physical or Virtual	Required License	Comments

IB-FLEX	Virtual	Threat Protection (Software add-on) and Threat Protection Update	IB-FLEX

You can install the **Threat Protection (Software add-on)** license on the following hypervisors:

- VMware ESXi with or without SR-IOV enabled
- OpenStack with KVM with or without SR-IOV enabled
- KVM with or without SR-IOV enabled

For more information about these appliances, refer to the respective installation guides under the **Tech Docs** tab on the Infoblox Support site at *https://support.infoblox.com*.

Starting and Stopping Threat Protection Service

After you install the Threat Protection licenses on the appliance, you can start the threat protection service so you can monitor and mitigate DNS threats on that appliance.
To start or stop threat protection service:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Services** tab, click the Threat Protection service link, and then select the *member* checkbox.
2. From the Toolbar, click **Start** to start the service or **Stop** to stop the service.

Note that when you stop threat protection service, the appliance does not provide visibility or protection against network floods or DNS threats. After you enable threat protection service, you can configure rule settings, add custom rules, and evaluate system rules to ensure that mitigation to DNS threats is handled properly. You can also temporary disable the threat protection service when necessary. For information about how to configure Grid security settings, see *Configuring Grid Security Properties*.

> **Note**
>
> Starting the threat protection service may cause a change in BIND behaviour in handling multiple TCP DNS queries from the same client. To avoid this, you can disable multiple DNS requests by selecting the **Disable multiple DNS requests via single TCP session** checkbox. For more information see, *Enabling Multiple DNS Requests through a Single TCP Session*.

Note that under normal circumstances when the system is not experiencing any attack, enabling the threat protection service may have a significant performance impact. When the system is under attack, enabling the threat protection service may have a higher performance impact. You might also notice a significant increase in the memory usage due to the threat protection service. You cannot replicate Grid, member, and profile by level threat protection configuration changes during a scheduled full upgrade.

Enabling and Disabling Monitoring Mode

To ensure that blocking certain DNS queries and packets through threat protection rules does not cause unintended effect on your appliance, you can set the threat protection service in monitor mode. You can also put your appliance in this mode to rule out the possibility that the DNS server is dropping DNS queries. When monitor mode is enabled, the appliance logs DNS packets (instead of dropping them) that would have been blocked by threat protection rules. This

information is recorded in the syslog.
When the Threat Protection service is in monitor mode, the service status changes from **Threat Protection Service is working** to **Threat Protection is working in monitor mode** and the status color changes from green to yellow. The status appears in both the **Data Management** tab -> **Security** tab -> **Members** tab and in the **Grid** tab -> **Grid Manager** tab -> **Services** tab. Note that when one of the members is in monitor mode, the overall status for the Threat Protection service changes from green to yellow. For more information about viewing service status, see *Monitoring Services*.
You can enable or disable the monitor mode for individual Grid members through the CLI command **set smartnic monitor-mode**. You cannot set this configuration at the Grid level. To enable or disable monitor mode for both hardware and Software ADP profiles, you can use the command set adp monitor-mode on/off. The show adp command displays the status of the monitor mode. Grid Manager displays a warning if the threat protection profile is running in monitor mode. For more information about this command, refer to the *Infoblox CLI Guide*. Note that the **set smartnic monitor-mode** command is recorded in the audit log while the threat protection events are recorded in the syslog. For information about the audit log and syslog, see *Monitoring Tools*.

Understanding Threat Protection Rulesets and Rules

To fully implement Infoblox Advanced DNS Protection , ensure that you import the latest threat protection ruleset. To import rulesets, you must have the **Threat Protection Update** license installed on the appliance. For more information, see *Supported Threat Protection Appliances and Licensing Requirements*. A ruleset comprises all threat protection rules, including system and auto-generated rules, rule templates, custom rules (if any), and parameter definitions and values. For detailed information about threat protection rules, refer to the *Infoblox Threat Protection Rules* available on the Support web site. Infoblox supports a common threat protection ruleset for both hardware and Software ADP members. This ruleset supports all rules and templates. You can also manually upload your rulesets or download rulesets automatically from the IT server.
Infoblox Advanced DNS Protection supports the following threat protection rules:

- Predefined system and auto-generated rules, as described in *System and Auto Rules*.
- Custom rules, as described in *Custom Rules*.

Each threat protection rule belongs to a rule category. When you import a ruleset, the appliance publishes the system and auto rules in their respective categories. NIOS automatically manages rule categories and you cannot add, delete, or modify them. It also provides rule templates for creating custom rules. During a ruleset update, some categories and rules may be added or removed. These actions are performed without intervention after the updates are authorized or automatically executed. You cannot add or delete system and auto rules, but you can create custom rules through predefined rule templates and delete them when necessary.

> ⚠ **Note**
>
> You can recover only custom rules from the Recycle Bin, if enabled. Rules, rule templates and categories that are removed through ruleset updates are permanently deleted and cannot be restored from the Recycle Bin.

To obtain initial rules and subsequent rule updates, you can configure the appliance to automatically download and publish rulesets or you can manually download them from the Infoblox Support web site and then publish them. For information about how to configure automatic and manual rule settings, see *Configuring Grid Security Properties*. Note that only the Grid Master receives rules and rule updates. Grid member receives rules and updates through standard Grid replication from the Grid Master. Ruleset data is not replicated to Grid members that do not have the Threat Protection services enabled.
Infoblox recommends that you configure the appliance to automatically receive ruleset updates so your appliance receives the latest rules periodically. If you prefer to manually download and publish rulesets, ensure that you download them frequently to receive the most updated rules. The appliance can store up to nine ruleset versions, and you can select up to five rulesets and switch between these versions for the Grid or members when necessary. For more information about ruleset versions and updates, see *About Ruleset Versions and Updates*.

Using the Events Per Second Rule Setting

The **Events per second** setting allows for disabling or throttling of event logs for specific threat protection rules. The default value is one and the maximum value is 700. NIOS displays an error message when you enter a value greater than the maximum value. You can override this event filter at the member level.

Setting the **Events per second** parameter to zero disables logging for that rule. Setting the parameter to any other number enables threat protection logging for that specific rule. For information about how to configure this, see *Configuring Grid Security Properties*.

Make note of the following guidelines when you enter a value in the **Events per Second per Rule** field:

- The value of this field is applicable only for rules that do not have `event-filter` as part of their format. The following is an example of a rule that has `event-filter` in its format:
  `drop udp any any -> any 53 (msg:"EARLY DROP UDP DNS named author attempts"; content:"|07|authors|04|bind|00|"; offset:12; sid:110100100; rev:1;) event_filter gen_id 1, sig_id 110100100, type limit, track by_src, count 1, seconds 1`
- For rules that have `event-filter` as part of their format, the event-filter precedes the value in the **Events per Second per Rule** field.
- Therefore, for rules that have `event-filter` as part of their format, to disable event logging for Threat Protection, you must disable it at the rule-level by modifying the syslog file. For rules that do not have `event-filter` as part of their format, to disable event logging for Threat Protection, set 0 in the **Events per Second per Rule** field.

Custom Rules

Based on your security needs, you can define custom rules using predefined rule templates. Custom rules are typically whitelisting or blacklisting rules. You can create up to 500 custom rules for each rule template offered by Infoblox Advanced DNS Protection . The appliance logs a syslog message if there are more than 500 rules for a specific rule category. You can remove some rules in order to create new ones for that category.

> **Note**
>
> Before upgrading from an earlier NIOS release to NIOS 6.11.x, ensure that you have less than 500 custom rules for each template. Otherwise, the upgrade may fail.

You can add or delete custom rules for the Grid only. You cannot add or delete them for members, but you can enable, disable, and modify certain rule parameters at the member level.
When you create custom rules, NIOS automatically generates the rule ID from the template used. Note that custom rules do not support IDNs (Internationalized Domain Names). You must first convert IDNs into punycode before entering the data. For information about how to create custom rules, see Creating Custom Rules below.
When you create custom rules, you are essentially creating whitelisting and blacklisting entries that utilize rate limiting to detect suspicious UDP and TCP traffic. Infoblox Advanced DNS Protection supports a series of rule templates for defining new custom rules. For information about rule templates, see the following Custom Rule Templates section.
Whitelisting rules define a list of allowed resources before they are blocked by the configured rate limit settings. They provide for only a selected set of entities to access the protected environment. Examples include company offices and their associated internal network services, which presumably use access control systems to enforce them. In effect, addresses or networks that do not match the whitelisting entries are automatically blocked.
Blacklisting rules define a list of disallowed resources through FQDN lookups as well as rate limiting. Blacklists typically allow a far broader base of access to many more entities, and cite a list of specific entities or people that do not have access. Otherwise, any devices or users theoretically have access to the protected environment.
For whitelist entries, the matching values are mandatory, in which the IP address or network of the rule is expressly

permitted access. Blacklist entries are forbidden, in which the IP address or network of the rule is expressly denied access. In essence, blacklisting is convenience while whitelisting is more secure.

> **Note**
>
> You can create DNS-specific blacklists under the **Data Management** tab **–> DNS** tab. However, you cannot use this blacklist feature as part of DNS threat protection.

Custom Rule Templates

Infoblox Advanced DNS Protection supports a few custom rule templates from which you create new custom rules. Note that when you use a specific rule template to create custom rules, the new rules reside in their respective rule categories. For information about creating custom rules, see Creating Custom Rules below.
For each rule you create, you can define the **Events per second** value to determine the number of events per second that will be logged for the rule. You can also define specific rule parameters for custom rules, as follows:
When you create custom rules that involve FQDN lookups, the appliance automatically verifies the FQDN syntax and format that you enter in the **Value** field. It properly translates escaped sequences and special characters that are used to represent specific characters in the FQDN. For example, \032 is interpreted as a space (hex 20), and \" is interpreted as the double quote (hex 22). The appliance sends an error message when it detects invalid characters in the FQDN.

> **Note**
>
> Custom rules do not support IDNs (Internationalized Domain Names). To use IDNs for custom rules, you must first convert the IDNs into punycode. You can use the **IDN Converter** from the **Toolbar** for the conversion.

- **BLACKLIST FQDN lookup TCP**: Use this rule template to create custom rules for blacklisting DNS queries by FQDN lookups on TCP. In the Rule Parameters table, complete the following:
  - **Blacklisted FQDN:** Enter the FQDN that you want the appliance to block over TCP traffic. NIOS supports an exact match or subdomain matches for the FQDN specified in the rule. For example, if "test.com" is specified as a custom rule, NIOS blocks “test.com” or “abc.test.com” but “abctest.com” will not be blocked.
- **BLACKLIST FQDN lookup UDP**: Use this rule template to create custom rules for blacklisting DNS queries by FQDN lookups on UDP. In the Rule Parameters table, complete the following:
  - **Blacklisted FQDN**: Enter the FQDN that you want the appliance to block over UDP traffic. NIOS supports an exact match or subdomain matches for the FQDN specified in the rule. For example, if "test.com" is specified as a custom rule, NIOS blocks “test.com” or “abc.test.com” but “abctest.com” will not be blocked.
- **BLACKLIST IP TCP Drop prior to rate limiting**: Use this rule template to create rules for blocking IPv4 or IPv6 addresses on TCP before the appliance drops the packets based on rate limiting rules you have defined using the **BLACKLIST IP TCP Drop prior to rate limiting** template. In the Rule Parameters table, complete the following:
  - **Blacklisted IP address/network**: Enter the IPv4 or IPv6 address from which packets sent are dropped before any relevant rate limiting rules take effect. Note that all TCP traffic from the specified Ipv4 and IPv6 addresses and networks will be blocked. Enter network addresses in address/CIDR format.
- **BLACKLIST IP UDP Drop prior to rate limiting**: Use this rule template to create rules for blocking IPv4 or IPv6 addresses on UDP before the appliance drops the packets based on rate limiting rules you have defined using the **BLACKLIST IP UDP Drop prior to rate limiting** template. In the Rule Parameters table, complete the following:
  - **Blacklisted IP address/network**: Enter the IPv4 or IPv6 address from which packets sent are dropped before any relevant rate limiting rules take effect. Note that all UDP traffic from the specified Ipv4 and IPv6 addresses and networks will be blocked. Enter network addresses in address/CIDR format.
- **RATELIMITED FQDN lookup TCP**: Use this template to create custom rules that contains rate limiting restrictions for blocking DNS queries by FQDN lookups on TCP traffic. In the Rule Parameters table, complete the following:
  - **Packets per second**: Enter the number of packets per second to define the rate limit for this rule. You define this value to control the rate of TCP traffic that consists of DNS lookups for the FQDN defined in this rule. The default is 5.
  - **Drop interval**: Enter the number of seconds for which the appliance drops packets.
  - **Blacklist rate limited FQDN**: Enter the FQDN that is affected by the rate limit value configured for this rule. The appliance drops the packets sent by this FQDN when the TCP traffic of DNS lookups for this FQDN exceeds the configured rate limit value.

- **RATELIMITED FQDN lookup UDP**: Use this rule template to create custom rules that contains rate limiting restrictions for blocking DNS queries by FQDN lookups on UDP traffic. In the Rule Parameters table, complete the following:
  - **Packets per second**: Enter the number of packets per second to define the rate limit for this rule. You define this value to control the rate of UDP traffic that consists of DNS lookups for the FQDN defined in this rule. The default is 5.
  - **Drop interval**: Enter the number of seconds for which the appliance drops packets.
  - **Blacklist rate limited FQDN**: Enter the FQDN that is affected by the rate limit value configured for this rule. The appliance drops the packets sent by this FQDN when the UDP traffic of DNS lookups for this FQDN exceeds the configured rate limit value.

> **Note**
>
> Make sure that you enter a valid FQDN. Example: *test.com*, *foo.com*, etc. The appliance does not display an error message when you enter an invalid FQDN. However, the Threat Protection dashboard displays a warning message for the invalid FQDNs. For information about threat protection status for Grid, see *Status Dashboard*.

- **RATELIMITED IP TCP**: Use this rule template to create custom rules that contains rate limiting restrictions for blacklisting IP addresses on TCP. If there are certain IP addresses that you want to block before its traffic reaches the rate limit restrictions, you can create a rule using the **RATELIMITED IP TCP** template. In the Rule Parameters table, complete the following:
  - **Packets per second**: Enter the number of packets per second to define the rate limit for this rule. You define this value to control the rate of TCP traffic that consists of DNS lookups for the IP address or network defined in this rule. The default is 5.
  - **Drop interval**: Enter the time interval in seconds the appliance drops IP packets sent by the rate limited IP address or network defined for this rule. The default is 30 seconds.
  - **Rate limited IP address/network**: Enter the IP address or network that is affected by the rate limit value configured for this rule. The appliance drops the packets sent by this IP address based on the drop interval when the TCP traffic of DNS lookups for this IP address exceeds the configured rate limit value.
- **RATELIMITED IP UDP**: Use this rule template to create custom rules that contains rate limiting restrictions for blacklisting IP addresses on UDP. If there are certain IP addresses that you want to block before its traffic reaches the rate limit restrictions, you can create a rule using the **RATELIMITED IP UDP** template. In the Rule Parameters table, complete the following:
  - **Packets per second**: Enter the number of packets per second to define the rate limit for this rule. You define this value to control the rate of UDP traffic that consists of DNS lookups for the IP address or network defined in this rule. The default is 5.
  - **Drop interval**: Enter the time interval in seconds the appliance drops IP packets sent by the rate limited IP address or network defined for this rule. The default is 30 seconds.
  - **Rate limited IP address/network**: Enter the IP address or network that is affected by the rate limit value configured for this rule. The appliance drops the packets sent by this IP address based on the drop interval when the TCP traffic of DNS lookups for this IP address exceeds the configured rate limit value.
- **WHITELIST IP TCP Pass prior to rate limiting**: Use this rule template to create custom rules for allowing certain IP addresses on TCP before the appliance drops the packets based on rate limiting rules you have defined using the **RATELIMITED IP TCP** template. In the Rule Parameters table, complete the following:
  - **Whitelisted IP address/network**: Enter the IPv4 or IPv6 address from which packets sent are allowed before any relevant rate limiting rules take effect.
- **WHITELIST IP UDP Pass prior to rate limiting**: Use this rule template to create custom rules for allowing certain IP addresses on UDP before the appliance drops the packets based on rate limiting rules you have defined using the **RATELIMITED IP UDP** template. In the Rule Parameters table, complete the following:
  - **Whitelisted IP address/network**: Enter the IPv4 or IPv6 address from which packets sent are allowed before any relevant rate limiting rules take effect.
- **WHITELIST TCP Domain**: Use this rule template to create custom rules to allow DNS queries by FQDN lookups on TCP. In the Rule Parameters table, complete the following:
  - **Whitelist FQDN**: Enter the FQDN that you want the appliance to allow over TCP traffic. NIOS supports an exact match or subdomain matches for the FQDN specified in the rule. For example, if "test.com" is specified as a custom rule, NIOS blocks “test.com” or “abc.test.com” but “abctest.com” will not be blocked.

- **WHITELIST UDP Domain**: Use this rule template to create custom rules to allow DNS queries by FQDN lookups on UDP. In the Rule Parameters table, complete the following:
    - **Whitelist FQDN**: Enter the FQDN that you want the appliance to allow over UDP traffic. NIOS supports an exact match or subdomain matches for the FQDN specified in the rule. For example, if "test.com" is specified as a custom rule, NIOS blocks “test.com” or “abc.test.com” but “abctest.com” will not be blocked.
- **BLACKLIST TCP FQDN lookup for DNS Message Type**: Use this rule template to create custom rules for blacklisting FQDN lookups on TCP for the specified DNS message type. In the Rule Parameters table, complete the following:
    - **DNS Record Type**: Select the DNS record type from the drop-down list or enter a valid ENUM for the DNS record. You can enter a value between 1 and 65534. The following DNS resource records are not supported by this rule template: MD (3), MF (4), MB (7), MG (8), MR (9), WKS (11), HINFO (13), MINFO (14), IXFR (251), and AXFR (252) record.
    - **Blacklisted FQDN substring**: Enter the FQDN from which the packets received are blocked over TCP for the specified DNS message type.
- **BLACKLIST UDP FQDN lookup for DNS Message Type**: Use this rule template to create custom rules for blacklisting FQDN lookups on UDP for the specified DNS message type. In the Rule Parameters table, complete the following:
    - **DNS Record Type**: Select the DNS record type from the drop-down list or enter a valid ENUM for the DNS record. You can enter a value between 1 and 65534. The following DNS resource records are not supported by this rule template: MD (3), MF (4), MB (7), MG (8), MR (9), WKS (11), HINFO (13), MINFO (14), IXFR (251), and AXFR (252) record.
    - **Blacklisted FQDN substring**: Enter the FQDN from which the packets received are blocked over UDP for the specified DNS message type.
- **Pass TCP DNS MessageT ypes**: Use this rule template to create custom rules to allow TCP DNS packets that contain the specified DNS record type. In the Rule Parameters table, complete the following:
    - **DNS Record Type**: Select the DNS record type from the drop-down list or enter a valid ENUM for the DNS record. You can enter a value between 1 and 65534. The following DNS resource records are not supported by this rule template: MD (3), MF (4), MB (7), MG (8), MR (9), WKS (11), HINFO (13), MINFO (14), IXFR (251), and AXFR (252) record.
- **Pass UDP DNS Message Types:** Use this rule template to create custom rules to allow UDP DNS packets that contain the specified DNS record type. In the Rule Parameters table, complete the following:
    - **DNS Record Type**: Select the DNS record type from the drop-down list or enter a valid ENUM for the DNS record. You can enter a value between 1 and 65534. The following DNS resource records are not supported by this rule template: MD (3), MF (4), MB (7), MG (8), MR (9), WKS (11), HINFO (13), MINFO (14), IXFR (251), and AXFR (252) record.
- **RATE LIMITED TCP DNS Message Type**: Use this rule template to create custom rules that contain rate limiting restrictions for blacklisting TCP DNS packets that contain the specified DNS record type. In the Rule Parameters table, complete the following:
    - **Packets per second**: Enter the number of packets per second to define the rate limit for this rule. You define this value to control the rate of TCP traffic that consists of DNS packets with the DNS record type defined in this rule. The default is 5.
    - **DNS Record Type**: Select the DNS record type from the drop-down list or enter a valid ENUM for the DNS record. You can enter a value between 1 and 65534. The following DNS resource records are not supported by this rule template: MD (3), MF (4), MB (7), MG (8), MR (9), WKS (11), HINFO (13), MINFO (14), IXFR (251), and AXFR (252) record.
    - **Drop interval**: Enter the number of seconds for which the appliance drops packets.
- **RATE LIMITED UDP DNS Message Type**: Use this rule template to create custom rules that contain rate limiting restrictions for blacklisting UDP DNS packets that contain the specified DNS record type. In the Rule Parameters table, complete the following:
    - **Packets per second**: Enter the number of packets per second to define the rate limit for this rule. You define this value to control the rate of UDP traffic that consists of DNS packets with the DNS record type defined in this rule. The default is 5.
    - **DNS Record Type**: Select the DNS record type from the drop-down list or enter a valid ENUM for the DNS record. You can enter a value between 1 and 65534. The following DNS resource records are not supported by this rule template: MD (3), MF (4), MB (7), MG (8), MR (9), WKS (11), HINFO (13), MINFO (14), IXFR (251), and AXFR (252) record.
    - **Drop interval**: Enter the number of seconds for which the appliance drops packets.

Creating Custom Rules

Infoblox Advanced DNS Protection provides a few rule templates from which you can create custom rules. For information about the list of rule templates that you can use, see *Custom Rule Templates*.
To create a custom rule:

1. From the **Data Management** tab, select the **Security** tab -> **Threat Protection Rules** tab -> *Ruleset* link, and then click **Add Custom Rule** from the Toolbar.
2. In the *Add Custom Rule* editor, complete the following:
    - **Template**: From the drop-down list, select the blacklisting or whitelisting rule template from which you want to create the new rule. For more information about the rule templates, see the previous section, Custom Rule Templates.
    - **Description**: Displays the description of the rule that you are about to create. You cannot modify this.
    - **Comment**: Enter comments to describe the new rule.
    - **Disable**: Select this if you want to keep the new rule disabled for later use.
3. Click **Next** and complete the following to configure rule parameters:
    - **Description**: Displays the description of the rule that you are about to create. You cannot modify this.
    - **Action**: Displays the operation the appliance performs when an event related to this rule occurs. Some rules are restricted to specific actions. For example, the action for all blacklisting rules is set to **Drop**, where the appliance drops IP packets when such an event occurs. The action for all whitelisting rules is set to **Pass**, where the appliance passes IP packets when such an event occurs.
    - **Log Severity**: Select **Critical**, **Major**, **Warning** or **Informational**. The log severity you select here determine the severity of the message triggered by a match against the rule.

      In the Rule Parameters section, do the following:
    - Click the **Value** field for **Events per second** to enter the maximum number of events per second that will be logged for this rule. Use a nonzero value if you want matches against the current rule to log events. Setting a value to 0 (zero) disables the appliance from logging events associated with this rule.
    - Depending on the template you have selected, click the **Value** field and enter the appropriate parameters to configure the rule. For descriptions about the parameters for each rule template and System and Auto Rule Categories, see *System and Auto Rules*. Note that when you create custom rules that involve FQDN lookups, the appliance automatically verifies the FQDN syntax and format that you enter in the **Value** field. It properly translates escaped sequences and special characters that are used to represent specific characters in the FQDN. For example, \32 is interpreted as a space (hex 20), and \" is interpreted as the double quote (hex 22). The appliance sends an error message when it detects invalid characters in the FQDN.
4. Click **Save & Close**.

The new rule, with an automatically assigned rule ID, is created and placed in its corresponding rule category.

System and Auto Rules

System rules are predefined threat protection rules that are built into the Advance Appliances. New system rules are added through rule updates. You can enable an entire category of system rules as well as individual rules. Note that you cannot add or delete system rules, though you can change some parameters. For most system rules, you can modify the **Action** and **Log Severity**. For more information, see *Modifying System and Auto Rules*.
Auto-generated rules are firewall rules that are automatically defined by NIOS for blocking traffic for disabled services and ports. They do not support functionality such as rate limiting. These rules can be grouped into different rule categories and are enabled or disabled by default. You cannot enable or disable auto rules in this release of Infoblox Advanced DNS Protection , though you can set log severity and control logging for these rules. Note that auto rules are automatically enabled or disabled and reconfigured based on the current running services and configuration on the appliance.

System and Auto Rule Categories

The appliance supports the following system and auto rule categories. For detailed descriptions about each system and auto rule, refer to the Threat Protection Rules document available on the Infoblox Support site.

- **BGP**: Contains auto rules that mitigate attacks that target BGP (Border Gateway Protocol) routing parameters, such as invalid attribute lengths or invalid message types.
- **DNS Amplification and Reflection**: Contains system and auto rules that can be used to mitigate the commonly used methods of DDoS attacks. For information about DNS amplification and reflection, see *DNS Reflection and Amplification Attacks*.
- **DNS Cache Poisoning**: Contains rate limiting rules that assign bandwidth restrictions rules used to mitigate DNS cache poisoning (on UDP and TCP) that is performed by sending a large volume of fake replies to a recursive server, which can result in hundreds or thousands of redirects. For more information about DNS cache poisoning, see *DNS Cache Poisoning*.
- **DNS Malware**: Contains rules that protect against DNS malware that posts serious threats to the DNS infrastructure. For information about DNS malware threats, see *DNS Malware*.
- **DNS DDoS**: Contains system rules that are used to mitigate DNS DDoS attacks on your Advance Appliance. These rules rate limits clients that trigger following DNS responses: NXDOMAIN, NXRRSET, and SERVFAIL.
- **DNS Message Type**: Contains DNS system rules that can be used to filter requests that query specific DNS flags in the DNS message header.
- **DNS Protocol Anomalies**: Contains auto rules that address general DNS protocol attacks such as invalid DNS queries.
- **DNS Tunneling**: Contains auto rules that mitigate against DNS tunneling attacks. For more information, see *Inside-Out Attacks*.
- **Default Drop**: Contains system rules that automatically drop IP packets when unusual UDP, TCP, and ICMP traffic is detected.
- **General DDoS**: Contains auto rules that address general DDoS (Distributed Denial of Service) attacks such as loopback address spoofing, and UDP or TCP packets that contain the same source and destination addresses.
- **HA Support**: Contains auto rules that are used to pass packets that go through the Virtual Router Redundancy Protocol (VRRP) and Internet Group Management Protocol (IGMP) for HA (High Availability) support.
- **ICMP**: Contains auto rules that mitigate ICMP and ICMPv6 ping attacks. ICMP ping size (for IPv4 and IPv6) for these rules is limited to 792 bytes. For information about ICMP, see *Internet Control Message Protocol (ICMP) Flood*.
- **NTP**: Contains auto rules that mitigate attacks that target the NTP (Network Time Protocol). These rules include support for NTP requests and responses, NTP IPv4 and IPv6 ACLs (Access Control Lists), and private mode 7 packets.
- **OSPF**: Contains auto rules that mitigate attacks that target OSPF (Open Shortest Path First) routing parameters, such as invalid attribute lengths or invalid message types.
- **Potential DDoS Related Domains**: Contains system rules the appliance uses to blacklist domains that may have been the targets or subjects in NXDOMAIN or DDoS attacks. These rules block all FQDN lookups on UDP for domains that have been observed to be used as targets in DDoS attacks, and they are enabled by default.
- **Reconnaissance**: Contains auto rules that mitigate network reconnaissance attacks, in which unauthorized remote attackers attempt to access networks by exploiting network standards and communications.
- **TCP/UDP Floods**: Contains DNS system rules that are used to mitigate DNS TCP and UDP floods. For information about TCP/UDP floods, see *UDP DNS Flood*.

About Ruleset Versions and Updates

Infoblox periodically releases updated rulesets. After an automatic update, the new ruleset is automatically applied to the Grid members that are using the Grid wide ruleset. After a manual update, you can manually apply the new ruleset to the Grid or individual Grid members. Before you manually publish a ruleset, you can view differences between the current ruleset and the newly downloaded one. You can also modify some changed parameters and then merge the changes from the old version to the new one. For more information, see *Comparing and Merging Rulesets*. For information on applying rulesets based on profiles, see *Adding Threat Protection Profiles*.
You can view the current ruleset version (displayed in the **Version** column) in one of the following tabs:

- **Grid**: From the **Data Management** tab, select the **Security** tab -> **Threat Protection Rules** tab.
- **Member**: From the **Data Management** tab, select the **Security** tab -> **Members** tab.
- **Profile**: From the **Data Management** tab, select the **Security** tab -> **Profiles** tab.

In a Grid, you can run different versions of rulesets on different Grid members. For example, Grid member 1 can use revision 1 and Grid member 2 can use revision 2 of the ruleset. You can also switch back to a previous ruleset version when necessary, but you cannot change the version number for individual rules.
The appliance retains up to nine (9) rulesets at any given time: five (5) old rulesets, one (1) newly downloaded ruleset

and three (3) "Do Not Delete" rulesets. You can configure rulesets as "Do Not Delete" at the Grid level. The appliance retains these rulesets and they cannot be deleted during an automatic or manual ruleset update. To allow a ruleset to be deleted during an update, you must first disable the "Do Not Delete" flag for these rulesets. Note that you cannot delete a ruleset that is used by the Grid or any members. For information about how to configure the "Do Not Delete" flag, see *Modifying Rulesets*.
For more information about how to add, modify, and delete a ruleset, see *Managing Threat Protection Rulesets*.

Ruleset Update Behavior

Consider the following behavior during a ruleset update:

- If you have configured the rule update policy as **Automatic**, the following occurs:
  - For each rule that exists in the current ruleset and is used by a Grid member, the appliance automatically copies all customized parameter values from the current ruleset to the corresponding rules in the new ruleset. For rule templates that exist in the current ruleset and are used by any member in the Grid, the appliance automatically copies the rule instances from the current version to the new ruleset.
  - The appliance automatically compares and integrates all rule changes into the new ruleset. For manual ruleset update, you can view the differences between the current ruleset and the newly downloaded ruleset, select specific rules and make modifications to customized parameters, and then merge the changes into the new ruleset before applying it to the Grid and members. For more information about how to view the rule differences and merge changes, see *Comparing and Merging Rulesets*.
  - The new ruleset is applied to the Grid and only members that use the same ruleset version as the Grid through inheritance from the Grid security properties. For members that use the same ruleset version as the Grid but has parameter overrides for certain rules, the overridden values will be copied to the new ruleset.

  For information about how to configure the rule update policy, see *Configuring Grid Security Properties*.
- When there are a total of nine (9) rulesets stored in the database, the ruleset that is not used by the appliance and is not marked as "Do Not Delete" will be replaced by the newly downloaded ruleset.
- If there are more than one ruleset that can be replaced, the appliance selects the oldest version based on the version number.
- If a specific system or auto rule from the current ruleset version does not exist in the new ruleset, it will not be migrated to the new ruleset.
- If a specific template from the current ruleset version does not exist in the new ruleset, all of its custom rules will not be migrated to the new ruleset.

Packet Flow for Threat Protection Rules

Threat protection rules are designed to work together to provide maximum protection for your environment. This section describes how these rules are being applied and how you can tune some of them to suit your system setup and network environment.
Threat protection rules are grouped by rule categories, and most of them have one or more associated rule parameters. All threat protection rules contain rule parameters that you may or may not be able to configure. Rule parameters are predefined with default values that generally suit most network environments. However, there are times when you have special setups or configurations in your environment that require special attention. In these cases, you may need to change some of the rule parameters to obtain optimal protection without sacrificing system performance. For detailed information about all threat protection rules and how to tune them when necessary, refer to the *Infoblox Threat Protection Rules* available on the Support web site.
Depending on the rules, you may or may not be able to override default values for the following rule parameters (when applicable):

- **Packets per second**: This parameter defines the rate limit or the number of packets per second that the appliance processes before it performs a triggered action, such as sending warnings or blocking traffic.
- **Drop interval**: This is the time period (in seconds) for which the appliance blocks traffic from the client or traffic that matches a certain pattern beyond the rate limit. Based on how you want to handle the traffic that exceeds the rate limit, you can configure this interval to work with the **Rate Algorithm** parameter.
- **Rate algorithm**: This parameter defines how the appliance handles incoming traffic when the traffic exceeds the rate limit (defined in **Packets per second**). You can set this to "blocking" or "rate limiting." The default is "rate limiting." When you set this to "blocking," the appliance allows client traffic to go through until it hits the rate limit.

It then blocks all traffic for the duration of the drop interval. If client traffic continuously exceeds the rate limit, the appliance continues to block all traffic for subsequent drop intervals without letting through any traffic, which could result in an indefinite traffic blockage. When you set this to "rate limiting," the appliance allows client traffic to go through until traffic hits the rate limit. It then blocks all traffic for the rest of the drop interval. The appliance re-evaluates client traffic at the beginning of each drop interval and repeats the same behavior for subsequent intervals.

To avoid resource exhaustion and limit frauds, you can limit the query rate for each source IP, and then set **Dropinterval** to one second and **Ratealgorithm** to "rate limiting," which results in a rate-limiting behavior that allows some traffic to go through before the rest of the traffic is blocked. In this case, the appliance re-evaluates the client behavior every second. If the client traffic exceeds the rate limit, the appliance processes only queries up to the rate limit and drops all excessive queries for the remainder of the second.
For more information about how to configure **Ratealgorithm**, **Packetspersecond** and **Dropinterval**, see the following section, Configuration Examples.

Note

Starting with NIOS 6.12.4, the default for **Ratealgorithm** has been changed from "blocking" to "rate limiting."

- **Events per second**: The number of events logged per second for the rule. Setting a value to 0 (zero) disables the appliance from logging events for the rule. Most rules have this parameter, and the default value is 1.
- **Packet size**: DNS packet size. If the DNS packet size exceeds a certain value, the corresponding rule will be triggered.

Configuration Examples

Depending on how you want the appliance to handle incoming traffic, you can configure applicable parameters so they work hand-in-hand to deliver desired results. Following are some examples that demonstrate how you can use the **Rate algorithm**, **Packets per second** and **Drop interval** parameters.

Example 1

If source IP 100.10.10.1 sends queries at a rate of 100 packets per second, and you have the following configuration for a threat protection rule:

Packets per second = 40

Drop interval = 3

Rate algorithm = blocking

The appliance handles incoming traffic in the following manner:

1st second: 40 packets are allowed; all other packets are blocked

2nd second: All traffic from 100.10.10.1 is blocked

3rd second: All traffic from 100.10.10.1 is blocked

4th second: All traffic from 100.10.10.1 is blocked

5th second: All traffic from 100.10.10.1 is blocked

6th second: All traffic from 100.10.10.1 is blocked

In this example, the appliance evaluates historic data of the client behavior. If the client traffic exceeds the limit, then the appliance continuously drops traffic, which may result in an indefinite traffic blockage for a client that continuously violates the rate limit.

Example 2

Source IP 100.10.10.1 sends queries at a rate of 100 packets per second for a duration of two seconds. It then sends 30 packets per second for three seconds and 50 packets afterwards; and you have the following configuration for a threat protection rule:

Packets per second = 40

Drop interval = 1

Rate algorithm = rate limiting

The appliance handles incoming traffic in the following manner:

1st second: 40 packets are allowed; all other packets are blocked for the remainder of the second

2nd second: 40 packets are allowed; all other packets are blocked for the remainder of the second

3rd second: All traffic from 100.10.10.1 is allowed

4th second: All traffic from 100.10.10.1 is allowed

5th second: All traffic from 100.10.10.1 is allowed

6th second: 40 packets are allowed; all other packets are blocked for the remainder of the second

In this case, the appliance re-evaluates the client behavior every second. If client traffic exceeds the rate limit, the appliance processes queries up to the rate limit and drops all excessive queries for the remainder of the second.

Configuring Grid Security Properties

After you have installed valid threat protection licenses, you can configure rule update settings for the Grid. The Grid settings apply to all members in the Grid. You can select to use an existing threat protection ruleset or use a threat protection profile. A threat protection profile defines specific security settings and ruleset that you want to apply to a specific member or a group of members. For more information about rulesets, see *Understanding Threat Protection Rulesets and Rules*. For information about threat protection profiles, see *Configuring Threat Protection Profiles*. You can override only the global **Event per second** filter (in the **Basic** tab) and the **Disable multiple DNS requests via single TCP session** option (in the **Advanced** tab) in the *Member Security Properties* editor by selecting a member and clicking Edit.
To configure rule settings for the Grid or an individual member:

1. **Grid**: From the **Data Management** tab, select the **Security** tab, and then click **Grid Security Properties** from the Toolbar.
2. In the *Grid Security Properties* editor, select the **Threat Protection** tab -> **Basic** tab, and complete the following:
    - **Active Ruleset Version**: To activate and apply a specific ruleset to the Grid, select the ruleset from the drop-down list.
    - **Active Ruleset Comment**: Displays information about the selected ruleset from the **Comment** field of the ruleset.
      In the *Threat Protection Ruleset Updates* section, define the rule update policy. The appliance automatically performs rule updates by default. You can choose to manually publish rule updates. For information about how to manually update rules, see *Manually Uploading Rulesets* and *Publishing Rule Updates*.
    - **Latest Available Ruleset**: Displays the version string of the last published ruleset. This field changes each time when the ruleset is updated.
    - **Last Checked For Updates**: Displays the timestamp and time zone when you manually upload a ruleset file or automatically download the latest rule update file from the Infoblox rule update server. This field changes the timestamp only when there is a change in the ruleset. The appliance does not update this field if there is no change in the ruleset for the manual upload or automatic download.
    - **Rule Update Policy**: Select the rule update policy from the drop-down list to determine whether updates are being applied automatically or manually. When you select **Automatic**, the appliance automatically switches to the newly downloaded ruleset and publishes the changes when a ruleset update is applied. This schedule is recurrent and occurs every 24 hours. Note that the download happens either 15 minutes before or after the time specified. Select **Manual** to manually download updated rulesets and publish them. Note that you must have a valid Threat Protection Update license installed in order to perform ruleset updates. For information about how to perform a manual update, see *Manually Uploading Rulesets* and *Publishing Rule Updates*.

- **Enable Automatic Ruleset Downloads**: Select this to enable automatic ruleset downloads. Note that starting with NIOS 8.0.0, ruleset downloads might take longer than previous releases; but there is no functional impact during the downloads.

> ⚠ Note
>
> When you select this, ensure that you configure and enable a valid DNS resolver for the Grid in the *Grid Properties* editor so the appliance can successfully access the updated ruleset file.

If your network environment does not allow direct HTTP or HTTPS communication with the Internet through a firewall from a secure location in which the Grid Master or the standalone appliance resides, you can configure the Advance Appliance to use a proxy server so you can receive automatic threat protection updates through this connection. Configured proxy settings are for the entire Grid. You cannot configure proxy settings for individual members. For information about how to configure proxy servers, see *Configuring Proxy Servers*.

- **Test Connection**: Click this to test the connectivity between the Advance Appliance and the server from which you receive the rule update files. Grid Manager displays a message indicating whether the connection is successful.
- **Download Rules Now**: Click this to immediately download the latest rule update file from the Infoblox rule update server, provided that the connection between the appliance and the server is successful.
  In the Schedule section, define the schedule for automatic ruleset downloads. The following options are enabled only when you have selected **Enable Automatic Ruleset Downloads**:
  - **Default**: Select this to set the default schedule settings for automatic ruleset downloads. When you select the default schedule, download starts anywhere between 12 AM and 6 AM local time.
  - **Custom**: Select this to schedule downloads at a later date and time. Click the Calendar icon to select the date and time.

> ⚠ Note
>
> When you schedule automatic ruleset downloads, the downloads are performed within 15 minutes before or after the scheduled time. If you have multiple Grid members configured for downloads, the same offset time applies to all members when the first member is unreachable. Downloads to the next reachable member do not happen right after a download fails on the unreachable member. The offset time is put in place to prevent all members from performing downloads at the same time.

In the Threat Protection Logging section, define the events per second per rule value to allow the appliance to log events in the syslog:

- **Events per Second per Rule**: Specify the number of events logged per second per rule. The default value is one and the maximum value is 700. Setting the value to 0 (zero) disables NIOS from logging events for the rules. NIOS displays an error message when you enter a value greater than the maximum value. You can override this event filter at the member level. For guidelines about using this setting, see *Using the Events Per Second Rule Setting*.

3. To save the configuration, click **Save & Close**. To publish changes, click **Publish** if it appears at the top of the screen. Note that NIOS does not require restarting of the threat protection service after rule updates.

> ⚠ Note
>
> When you enable the **Enable Automatic Ruleset Downloads** option and set the **Rule Update Policy** to Manual, and download a new ruleset manually, you need to click **Save & Close** to retain the existing customized rules. If you click **Cancel** or close the wizard, the existing customized ruleset will be replaced by the downloaded ruleset.

Enabling Multiple DNS Requests through a Single TCP Session

The advanced appliance inspects only one DNS request sent over a single TCP connection. To avoid accepting possible malicious data following a valid DNS request, the appliance terminates the TCP connection after handling the initial DNS request over TCP. You can modify this default Grid setting at the Grid or member level.
To modify this setting, do the following:

1. **Grid**: From the **Data Management** tab, select the **Security** tab, and then click **Grid Security Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **Security** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
   Profiles: From the **Data Management** tab, select the **Security** tab -> **Profiles** tab -> *profile* checkbox, and then click the Edit icon.
2. In the *Grid Security Properties* or *Member Security Properties* editor, select the **Threat Protection** tab -> **Advanced** tab, and complete the following:
   - **Disable multiple DNS requests via single TCP session**: This is selected by default to avoid accepting possible malicious data following a valid DNS request. When this is selected, the appliance handles the initial DNS request through TCP and then terminates the TCP session to block subsequent DNS traffic, except for an SOA query sent by a client that is accepted in the allow-transfer ACL. This exception covers the case in which an AXFR query follows the SOA query through the same TCP connection. This field is read-only when you use a threat protection profile instead of a ruleset. For more information, see *Configuring Grid Security Properties*.
3. Save the configuration.

> ⚠ Note
> The **Disable multiple DNS requests via single TCP session** checkbox is enabled by default when Advanced DNS Protection is enabled.

Handling DNS Queries Through DNS Cache Acceleration

By default, Threat Protection rules are applied on all DNS queries and packets before they are passed on to DNS Cache Acceleration. However, you can configure such that DNS queries and packets are first passed on to DNS Cache Acceleration. If the query is valid and the answer is in the cache, the query is answered by DNS Cache Acceleration. Only if the answer is not in the cache, Threat Protection rules are applied to the query.

Passing DNS queries and packets to DNS Cache Acceleration first betters the performance for recursive DNS queries.

To handle DNS Queries Through DNS Cache Acceleration, do the following:

1. **Grid**: From the **Data Management** tab, select the **Security** tab, and then click **Grid Security Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **Security** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *Grid Security Properties* or *Member Security Properties* editor, select the **Threat Protection** tab -> **Advanced** tab, and complete the following:
   Enable DNS responses from acceleration cache before applying Threat Protection rules: Select this checkbox for incoming DNS queries to be first handled by DNS Cache Acceleration. This checkbox is disabled by default.
3. Save the configuration.

Guidelines for Enabling DNS Responses from DNS Cache Acceleration

The following guidelines apply when you select the **Enable DNS responses from acceleration cache before applying Threat Protection rules** checkbox:

- This checkbox is available only on IB-FLEX platforms which are capable of both Advanced DNS Protection and DNS Cache Acceleration.
- You do not need to restart the DNS service or publish Threat Protection rules for the setting to take effect.

Limitation of Enabling DNS Responses from DNS Cache Acceleration

If you select the **Enable DNS responses from acceleration cache before applying Threat Protection rules** checkbox, rate-limiting or response based rules will not be triggered if the FQDNs queries are being cached.

Configuring NAT Mapping Properties

If you are operating in an environment where you need to aggregate multiple users (such as mobile users) behind one IP address, you might want to consider using NAT (Network Address Translation) Mapping to avoid the potential of service denial to a large group of users if threat protection rules are being applied to the same IP address.
NAT detection is essential to enforce the correct threat protection rule on source IP addresses. The Infoblox NAT Mapping feature allows you to designate individual IP addresses, networks, or ranges along with the source port ranges to denote NAT'ed clients. Any UDP or TCP traffic that originates from an IP address within the NAT IP range and uses a source port within the NAT port mapping is considered as a NAT'ed client. It is important to align the NIOS NAT mapping configuration with the NAT gateway configuration to avoid mis-classification of NAT IPs. Traffic that originates from a given source port block that falls within the configured NAT IP and port range is considered as the same NAT'ed client and traffic that originates from a different port block that falls within the same NAT IP and port range is considered to be a different NAT'ed client. If the traffic originates from the same source IP address, but from a different port block that falls outside the configured port range, then they are considered as a non-NAT'ed client.
NIOS NAT detection is designed to work with a specific form of NAT where multiple clients are NAT'ed onto a single public IP address using a single port block for each client at a time. Some NAT vendors refer to this scheme as PBA (Port Block Allocation) with fixed size port blocks. The NAT device cannot re-use the same NAT IP address for a different client for at least the drop interval of the threat protection rule that is currently running. Note that the client idle timeout duration of the NAT device must be larger than the drop interval of the threat protection rule that is currently running.
You can configure NAT Mapping rules on Advance Appliances by mapping a source IP address, network, or range of IP addresses with a range of ports and specifying the port block size to divide each port range into chunks of port blocks. Each port block represents a single NAT'ed client source port. The IP addresses and the port blocks specified in a NAT Mapping rule may be assigned to the clients in any order, either fixed, sequential, or random.
The appliance logs information about NAT'ed clients to the syslog. Following is an example of the threat detection event log message in the syslog for NAT'ed clients:

```
2015-06-01T22:57:22+00:00 daemon infoblox.localdomain threat-protect-
log[12192]: err
CEF:0|Infoblox|NIOS Threat|7.2.0-283371|120303001|Blacklist:block.com|7|
src=3.0.0.100
spt=1221 dst=1.1.6.2 dpt=53 act="DROP" cat="BLACKLIST UDP FQDN lookup" nat=1
nfpt=1124
nlpt=1223
```

The following values in the threat detection event log message are specific for NAT'ed clients:

- **nat=1**: Indicates that the syslog event is logged for a NAT'ed client.
- **nfpt**: Indicates the first port in the port block.
- **nlpt**: Indicates the last port in the port block.

For information about the syslog and how to use it, see *Viewing the Syslog*. Note the following about the NAT Mapping feature:

- A single NAT'ed client cannot use multiple source IP addresses or multiple port blocks simultaneously, otherwise NIOS might consider the same NAT'ed client as different clients.
- NIOS does not support traffic originating from both NAT'ed and non-NAT'ed clients using the same source IP address.
- NAT mapping supports only IPv4 addresses, networks and ranges and any traffic originating from an IPv6 address, network, or range is considered as a non-NAT'ed client.
- NAT mapping is applicable only for traffic that uses UDP or TCP source port.

- NIOS cannot determine the pre-NAT IP address of a client. However, you can use the NIOS threat protection logs and the threat protection reports in conjunction with the NAT device logs for the same interval to determine the pre-NAT IP address of a NAT'ed client.
- The NAT mapping configuration in the NIOS appliance must be aligned with the actual NAT device configuration to ensure correct NAT detection.
- NAT mapping is not available for members that use Software ADP.

You can enable the NAT Mapping feature and configure NAT Mapping rules on the Infoblox-4030 10GE appliances and the following hardware-based appliances: PT-1405, PT-2205 and PT-2205-10GE. Note that you can enable this feature only when threat protection service is enabled on the appliance.

Configuring NAT Mapping Rules

To enable the NAT Mapping feature and to configure NAT Mapping rules for a Grid or a member:

1. **Grid**: From the **Data Management** tab, select the **Security** tab, and then click **Grid Security Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **Security** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *Grid Security Properties* or *Member Security Properties* editor, select the **NAT Mappings** tab -> **Basic** tab, and then complete the following:
   The member inherits the NAT mapping settings from the Grid, by default. To override the settings, click **Override**. To retain the same settings as the Grid, click **Inherit**. Note that if you choose to override the Grid settings, you must override the entire setting; you cannot override partial setting.
   - **Enable tracking for NAT mappings**: This checkbox is disabled by default. When you select this checkbox, you can configure certain addresses, networks, and ranges for NAT tracking. When the NAT Mapping feature is enabled or disabled for the Grid, all members in the Grid inherit this setting.
   - **NAT Mappings**: To define the NAT Mapping rule, click the Add icon and select one of the following:
     - **Address**: Select this to configure a single NAT address. For example, if you have only one single NAT client or a single NAT source IP, select this.
     - **Network**: Select this if you want to configure an entire subnet for NAT.
     - **Range**: Select this if you want to configure a partial subnet for NAT.

       After you select the NAT mapping type, the appliance adds a new row to the table and displays the type in the table (you cannot modify this in the table). In the **Address/Network/Range** column of the new row, enter a single NAT address, if you have selected **Address**. You can also configure a network address as a single NAT address. Enter a subnet if you have selected **Network**; or enter the partial subnet if you have selected **Range**. Note that IPv6 address, network, or range entry is not supported.
       Click **+** beside the NAT mapping type, and then click the cell of the following fields in the new row to enter information:
       - **Start Port**: Enter the first source port in the port range. For example, if the port range is 1000-2000, you can enter 1000 as the start port.
       - **End Port**: Enter the end source port in the port range. For example, if the port range is 1000-2000, you can enter 2000 as the end port.
       - **Block size**: Enter the port block size. This determines the number of port blocks and each port block is considered as a logical NAT client. Based on the port block size, the port range is divided into port blocks. For example, if the start port is 1000 and the end port is 2000, and if you enter the port block size as 100, then 1000-1099 is the first port block, 1100-1199 is the second port block, 1200-1299 is the third port block, and so on.

         You can create a separate NAT Mapping rule for each source IP address, network, or range. You can add a maximum of 32 NAT Mapping rules and a maximum of 32 port ranges for each rule.

> **Note**
>
> The combination of the source IP address, network, or range and the port blocks configured for each NAT'ed client must be unique and it should not overlap.

3. Save the configuration.

> **Note**
>
> If you change the NAT Mapping rule after you have configured the NAT Mapping rule or if you enable or disable the NAT Mapping feature, you must publish the changes by clicking **Publish Changes** from the Toolbar. For information, see *Publishing Rule Updates*.

Managing Threat Protection Rulesets

You can do the following after the initial setup, including uploading the initial ruleset:

- Review the list of threat protection members, as described in *Listing Members*.
- Look at rulesets that are currently installed on your system, as described in *Viewing Threat Protection Rules*.
- Upload new rulesets to the system when you have selected to manually apply rule updates, as described in *Manually Uploading Rulesets*.
- Publish rule updates that you have uploaded to the system, as described in *Publishing Rule Updates*.
- Modify the **Comment** and **Do Not Delete** parameters for an existing ruleset, as described in *Modifying Rulesets*.
- View differences between an old and a new rulesets and optionally merge rule parameter changes from the old ruleset into the new one, as described in *Comparing and Merging Rulesets*.
- Configure proxy settings for the Grid if you need to use a proxy server for ruleset updates, as described in *Configuring Proxy Servers*.
- Delegate ruleset updates to a Grid member and select an alternate interface for downloading the updates, as described in Configuring Members and Interfaces for Automatic Updates, see *Configuring Proxy Servers*.

Publishing Rule Updates

You can publish rule updates at any time after you have uploaded the ruleset. For information about uploading ruleset files, see *Manually Uploading Rulesets*.
To publish rule updates:

1. From the **Data Management** tab, select the **Security** tab -> **Threat Protection Rules** tab, and then click **Publish Changes** from the Toolbar.
2. In the *Publish Changes* dialog box, complete the following:
    - **Publish Changes on all Members**: Select one of the following:
        - **Simultaneously**: Publish changes on all of the members in the Grid at the same time.
        - **Sequentially**: Publish changes on each Grid member according to the number of seconds you enter in the **Sequential every (seconds)** field. For example, if you enter every 10 seconds, the system update changes on the first member, and 10 seconds later on the second member. This is the default option.
    - **Impacted Members and Services**: Click the Poll Members icon to display the affected members in that Grid. Grid Manager displays the member names and whether each member is configured for the threat protection service:
        - **Yes**: The service is active and the system will publish rule updates on this member upon execution of this task.
        - **No**: The service is not active and the system will not publish rule updates on this member.
        - **Disabled**: The service is currently disabled on this member.

        To schedule this task, click the Schedule icon at the top of the dialog box. In the Schedule Change panel, complete the following:
        - **Now**: Publish rule updates upon clicking **Publish**.
        - **Later**: Enter the following information to schedule publishing updates at a certain date and time:
            - **Start Date**: Enter a date in YYYY-MM-DD (year-month-day) format. The appliance displays today's date. You can also click the calendar icon to select a date from the calendar widget.

- **Start Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. When you enter the time in a 24-hour format such as 23:00, Grid Manager displays 11:00:00 PM. You can also select a time from the drop-down list by clicking the time icon.
- **Time Zone**: Select a time zone for the scheduled date and time from the drop-down list. This field displays the time zone of the browser that the admin uses to log in to Grid Manager.

3. Click **Publish** to publish changes immediately or click **Schedule Publish** to schedule the publish.

Manually Uploading Rulesets

You can download a threat protection ruleset any time when you select to manually perform ruleset updates. You can choose to download rule updates but not immediately deploy them. NIOS archives and tracks up to nine ruleset versions, allowing for switching and merging between these versions when necessary. After uploading a ruleset, you can apply it by publishing it to the Grid and individual members. For more information, see *Publishing Rule Updates*.
Ruleset updates do not require restart of the DNS or threat protection service in the Grid, and they do not affect ongoing services. However, the appliance deploys updated rulesets only when you publish the changes. Note that all threat protection rule update events are logged in the syslog on the Grid Master only.

> **Note**
>
> By default, threat protection ruleset updates are automatic. Infoblox recommends that you retain this setting. For information about how to configure this setting, see *Configuring Grid Security Properties*.

To manually upload a ruleset file:

1. Access the Infoblox KB article # 2646 by logging in to the Infoblox Support site at *https://support.infoblox.com*, and then download the ruleset file in the KB article.
2. From the **Data Management** tab, select the **Security** tab -> **Threat Protection Rules** tab, and then click the Add icon.
3. In the *Rule File Upload* dialog box, do the following:
   - **File**: Click **Select** to navigate to the ruleset file location, and then click **Upload**. Grid Manager displays the file name in this field.
   - Click **Test** to check the changes that will occur during the rule update, without actually applying the update. You can view the update details in the Syslog Viewer. The appliance preserves the uploaded file if you do not click **Update** to update the rules. When you manually upload rulesets the next time, this file will be displayed in the dialog. You can then choose to apply the update from this file or upload a new file before performing the update.
   - Click **Update** to update the rules.
   - Click **View Update Results** to view the updated rules in the Syslog Viewer. All threat protection rule updates are logged in the syslog on the Grid Master.

Comparing and Merging Rulesets

After you manually download a ruleset and before you publish it, you can view differences between the old ruleset and the new one. The appliance shows you the system-level changes, including new rules, deleted rules, and rule syntax, between the two rulesets. It also shows you the customized parameter changes between the two versions. You can then select the changes you want to merge into the new ruleset. You can also modify some of these customized changes before you merge them into the new ruleset. Note that the modifications you make to the customized rule parameters will be added only to the new ruleset. When merging rulesets, all rules in the old ruleset and new ruleset are compared and identified by their rule IDs.
To merge rules from an older ruleset version to a newer ruleset:

1. From the **Data Management** tab, select the **Security** tab -> **Threat Protection Rules** tab, click **Merge** from the Toolbar, and then select **Ruleset** from the drop-down list.
2. In the *Merge Changes Into Ruleset* editor, complete the following:
   - **Old Ruleset**: From the drop-down list, select the ruleset version from which you want to merge changes into the new ruleset. The **Comment** field displays additional information about the ruleset.

- **New Ruleset**: From the drop-down list, select the ruleset version to which you want the changes to be merged. The **Comment** field displays additional information about the ruleset.
- **Get Differences**: Click this to display a list of differences between the selected old and new ruleset versions. The appliance displays system-level changes in the **System changes from old ruleset (x items)** table, where x is the total number of changed rules between the old and new ruleset versions. The appliance merges all system-level changes listed in this table into the new ruleset.

  The table displays the following information for each changed rule:
- **Rule ID**: The rule ID of the changed rule. You can click the rule link and modify parameters in the rule editor.
- **Rule Name**: The name of the rule.
- **Type**: Indicates whether the rule is a newly added rule or it has been deleted.
- **Old Ruleset Value**: Displays the old value that has been changed.
- **New Ruleset Value**: Displays the newly changed value.

  The **Customizations from old ruleset (x items)** table displays customized rule parameter changes between the old and new rulesets, where x is the total number of changed rules. You can select all or specific changed rules in this table to be merged into the new ruleset. You can also modify parameter for selected rules before merging the changes into the new ruleset. This table displays the following information for each rule:
- **Member**: The Grid member on which this rule is currently running.
- **Rule ID**: The rule ID of the changed rule. You can click the rule link and modify parameters in the rule editor.
- **Rule Name**: The name of the rule.
- **Old Ruleset Value**: Displays the old value that has been changed.
- **New Ruleset Value**: Displays the newly changed value.
- **Action**: Displays what the appliance will do to changes in this rule when you merge the rulesets.

3. Click **Merge Changes** to copy all the selected rules and changes you made to specific rules to the new ruleset. Note that you must select a rule from the **Customizations from old ruleset (x items)** table to activate the merging operation.

You can do the following in the *Merge Changes Into Ruleset* editor:

- Click **Export** to export all the changes listed in both tables to one CSV file. You can export this data after you click **Get Differences** and Grid Manager displays changes in both tables.
- Perform another ruleset merge by selecting another old ruleset and new ruleset.
- Click **Close** to exit the editor. Note that the editor does not close automatically after a merge.

Modifying Rulesets

To modify parameters for an existing ruleset:

1. From the **Data Management** tab, select the **Security** tab -> **Threat Protection Rules** tab.
2. In the Grid Threat Ruleset table, select the ruleset checkbox, and then click the Edit icon.
3. In the *Threat Ruleset* editor, select the **General** tab -> **Basic** tab to modify the following:
   - **Comment**: Enter information about the ruleset.
   - **Mark as Do Not Delete**: When you select this, the ruleset cannot be deleted during an update. You can select up to three rulesets and mark them as **Do Not Delete**.

     You can also view the following information (but you cannot modify it):

   - **Version**: Displays the ruleset version in YYYYMMDD-x format, where YYYY is the year, MM the month, DD the date, and x the ruleset engine version number.
   - **Active On**: Displays the Grid or the name of the Grid member on which the ruleset is currently running. This can be **Grid**, a Grid member name, or **None**. When this displays **None**, the ruleset is not being used.
   - **Added On**: Displays the timestamp when the ruleset was uploaded to the Grid Master in this format: YYYY-MM-DD HH:MM:SS, plus time zone.

Overriding the Grid Ruleset

You can override the Grid ruleset for individual members. Note that when a member uses a different ruleset than the Grid, it does not receive a ruleset update if the Grid automatically receives the next update. For information about how to activate a ruleset for the Grid, see *Configuring Grid Security Properties*.
To override the Grid ruleset:

1. From the **Data Management** tab, select the **Security** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.
2. In the *Member Security Properties* editor, select the **Threat Protection** tab -> **Basic** tab, and complete the following:
    - **Use ruleset**: Click this radio button to edit the ruleset. You can inherit or override a ruleset. When you select to use a ruleset, select an active ruleset from the **Threat Protection Ruleset Version** drop-down list.
    - **Use profile**: Click this radio button to edit the threat protection profile. Click **Select Profile** to select a threat protection profile from the *Threat Protection Profile Selector* dialog box. For more information about threat protection profiles, see *Adding Threat Protection Profiles*.
    - **Active Ruleset Version**: Click **Override** and select a ruleset from the drop-down list. The appliance activates and applies this ruleset to the member. In the confirmation dialog, click **Yes** and the member switches to the selected ruleset. This field is read-only at the member level.
    - **Active Ruleset Comment**: Displays information about the selected ruleset from the **Comment** field. This field is read-only at the member level.

Activating a Ruleset

The appliance can store up to nine (9) versions of rulesets. You can switch between these versions and activate one of them as the default ruleset.
To activate a specific ruleset:

1. **Grid**: From the **Data Management** tab, select the **Security** tab -> **Threat Protection Rules** tab.
   Member: From the **Data Management** tab, select the **Security** tab -> **Members** tab -> *member* link.
2. In the Grid Threat Rulesets or Member Rulesets table, click the Action icon  and select **Activate** from the menu. In the confirmation dialog, select **Yes** to proceed. The appliance installs the ruleset and uses it as the default ruleset for the Grid or the member.

Viewing Threat Protection Rulesets

Grid Manager displays all the rulesets that have been automatically or manually uploaded to the Grid Master. You can drill down to each ruleset to review individual rules in each rule category. To view the current threat protection rulesets and rules:

1. **Grid**: From the **Data Management** tab, select the **Security** tab -> **Threat Protection Rules** tab.
   Member: From the **Data Management** tab, select the **Security** tab -> **Members** tab -> *member* link.
   Profile: From the **Data Management** tab, select the **Security** tab -> **Profiles** tab -> *profiles* link.
2. In the **Threat Protection Rules** or the **Members** tab or the **Profiles** tab, Grid Manager displays current rulesets that are stored in the system. It displays the following information for each ruleset:

> ⚠ Note
>
> If the member is associated with a profile, the rules become read-only and you cannot edit them when you drill down the ruleset from the **Members** tab. However, you can still edit the rules if you drill down the ruleset from the **Profiles** tab even though Grid members are associated with the selected profile.

- **Version**: Displays the ruleset version in YYYYMMDD-x format, where YYYY is the year, MM the month, DD the date, and x the rule engine version number. You can click a version link to view rule categories and individual rules in each category for that specific ruleset.

- **Active On**: Displays the Grid or the name of the Grid member on which the ruleset is currently running. This can be **Grid**, a Grid member name, or **None**. When this displays **None**, the ruleset is not being used.
- **Do Not Delete**: Indicates whether this ruleset can be deleted or not during a ruleset update.
- **Added On**: Displays the timestamp when the ruleset was uploaded to the Grid Master in this format: YYYY-MM-DD HH:MM:SS, plus time zone.
- **Add Type**: Indicates whether the ruleset was uploaded automatically or manually.
- **Comment**: Additional information about this ruleset.

You can also do the following when you left click the Action icon  :

- Mark a ruleset as do not delete.
- Activate, open, or edit a specific ruleset.
- Click **Reset to defaults** to globally reset all the rule definitions to their default settings in the selected ruleset. When you reset the ruleset to defaults, all member rulesets will be reset as well. In the *Ruleset Reset* dialog, you can also select **Delete all custom rules in selected ruleset** to remove all the custom rules in the ruleset. You can reset to defaults at the rule category and rule levels. Note that the **Reset to defaults** option is not available if you upgrade to NIOS 7.3.x from a previous release.

To view rules in a specific ruleset version, click the **Version** link and Grid Manager displays the threat protection rules by categories. You can also select the checkbox of a ruleset and click the Open icon to view the rules in the ruleset.
You can also do the following in this panel:

- Manually upload a ruleset by clicking the Add icon. For more information, see *Manually Uploading Rulesets*.
- Modify some of the data in the table. Double click a row, and you can modify the **Do Not Delete** and **Comment** columns. Click **Save** to save the changes. Note that other fields are read-only.
- Select the checkbox of a ruleset and click the Delete icon to delete a ruleset, if it is not marked as **Do Not Delete**.
- Print or export the data.

> **Note**
> When you delete a ruleset that was recently downloaded through automatic downloads, the appliance cannot retrieve or automatically download this ruleset version again. You must manually download the ruleset and then manually deploy it to the Grid. For information about manual downloads, see *Manually Uploading Rulesets*.

Listing Members

This panel displays the following information about each Grid member:

- **Name**: The hostname of the Grid member.
- **Status**: The status of the DDoS service running on the Grid member.
- **Version**: Displays the threat protection ruleset version that is currently running on this member. This is displayed in YYYYMMDD-x format, where YYYY is the year, MM the month, DD the date, and x the rule engine version number.
- **Comment**: Comments that were entered for the Grid member.
- **Profile**: Displays the threat protection profile that is associated with this member.
- **Site**: Values that were entered for this pre-defined attribute. You can do the following:
- Sort the data in ascending or descending order by column.
- Select a member and click the Edit icon to modify the data.
- Click the Action icon  next to the respective member and:
  - select **Permissions** from the menu to define permissions for the member.
  - select **Clone to new profile** from the menu to create a new threat protection profile by cloning the settings from a member to the new profile. Note that this option is enabled only when the selected member is not associated with a profile.
- Print and export the data in this tab.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria:
  a. In the filter section, click **Show Filter** and define filter criteria for the quick filter.
  b. Click **Save** and complete the configuration In the Save Quick Filter dialog box.

The appliance adds the quick filter to the quick filter drop-down list in the panel. Note that global filters are prefixed with [G], local filters with [L], and system filters with [S].

Delegating Rule Updates to Grid Members

You can delegate ruleset updates to other Grid members if desired. You can also configure the interface you want to use for automatic updates on the members. For information about how to configure the Members and Interfaces for Automatic Updates, see *Configuring Proxy Servers*.

Configuring Threat Protection Profiles

When you configure the Grid or Member security properties, you have an option to select an active ruleset or a threat protection profile. A threat protection profile defines specific security settings and ruleset that you want to apply to a specific member or a group of members. Infoblox uses event filters to limit the amount of logs that are generated due to the threat protection events. It drops packets for services or ports that are not enabled on the card.
If you want to use the same threat protection rulesets and settings for multiple members, you can create a threat protection profile and associate it with multiple members so you do not have to configure them individually. You can configure threat protection profiles for both hardware and Software ADP appliances.
Infoblox automatically migrates threat protection profile settings when:

- you update an active ruleset at the Grid level and if a profile has inherited the respective active ruleset from the Grid.
- the profile inherits an active ruleset from the Grid and you override the active ruleset that is associated with the profile.
- the profile is set to override an active ruleset and you change an active ruleset for the profile.

You can do the following to configure threat protection profiles:

- Create threat protection profiles by associating rulesets, event filters and configuring multiple DNS requests over a single TCP session, as described in *Adding Threat Protection Profiles*.
- Clone threat protection profiles, as described in *Cloning Threat Protection Profiles*.
- Modify threat protection profiles, as described in *Modifying Threat Protection Profiles*.
- View differences between an old and a new rulesets and merge changes from an old threat protection profile into the new one, as described in *Merging Threat Protection Profiles*.
- Inherit Grid rule settings for a threat protection profile, as described in *Inheriting Grid Rule Settings*.
- Delete a threat protection profile, as described in *Deleting Threat Protection Profiles*.
- View the list of threat protection profiles, as described in *Viewing Threat Protection Rulesets*.

Viewing Threat Protection Profiles

To view the list of threat protection profiles:

1. From the **Data Management** tab, select the **Security** tab, and then click the **Profiles** tab. Grid Manager displays the following information:
    - **Name**: The name of the threat protection profile. Click the *profile* name to view the rules that are associated with the selected threat protection profile. For more information about rules, see *Viewing Threat Protection Rulesets*.
    - **Version**: The version of the threat protection profile.
    - **Members**: Displays the member associated with the threat protection profile. You can sort the values in this column.
    - **Comment**: Displays information that you specified for the threat protection profile.
    - **Site**: The location to which the member belongs. This is one of the predefined extensible attributes.

The **Disabled** column indicates whether the rule is enabled or disabled. The **Rule ID** column is set to grey for all rules that are disabled. The blue background for some parameters indicates that these parameters have been inherited from the Grid ruleset.

You can also do the following:

- Use **Global Search** to search for threat protection profiles by name, comment or object type. For information, see *Using Global Search*.
- Use **Smart Folders** to organize threat protection profiles by name, comment or object type. For information, see *Smart Folders*.
- To export the entire list of threat protection profiles in a csv format, click the Export icon and choose **Export Data in Infoblox CSV Import Format**. It also exports the customized rules for the profile. For more information, see *Exporting Data to Files*. To export all data in a different format, click the Export icon and choose **Export Visible Data**. For more information, see *Exporting Displayed Data*.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria:
    a. In the filter section, click **Show Filter** and define filter criteria for the quick filter.
    b. Click **Save** and complete the configuration In the *Save Quick Filter* dialog box.

The appliance adds the quick filter to the quick filter drop-down list in the panel. Note that global filters are prefixed with [G], local filters with [L], and system filters with [S].

Deleting Threat Protection Profiles

When you select this option, NIOS deletes the selected threat protection profile from the database. When you delete a threat protection profile or a profile rule, the appliance puts them in the Recycle Bin, if enabled. You can restore them if necessary. Note the following about threat protection profiles:

- When you delete a profile that contains an active ruleset, which is overridden at the profile level, you can restore the profile including the configuration if the ruleset exists on the Grid. You cannot restore the profile if the ruleset is deleted.
- When you delete a profile that inherits ruleset from the Grid, and if the same ruleset is still active on the Grid, you can restore the profile including the configuration for profile rules. If the ruleset is deleted or if the active ruleset on the Grid has changed, the appliance restores the profile from the Grid along with the profile rule settings for the current active ruleset.

To delete a threat protection profile, from the **Data Management** tab, select the **Security** tab -> **Profiles** tab, select the threat protection profile that you want to delete, click the Action icon and then select **Delete**. Click **Yes** in the confirmation dialog box to delete.

Inheriting Grid Rule Settings

When you select this option, NIOS automatically inherits the rule settings of the Grid for the respective profile. For example, if you update a rule at the Grid level, you can select this option to reflect the same changes in the profile. To inherit Grid rule settings for the selected profile, from the **Data Management** tab, select the **Security** tab -> **Profiles** tab, select the threat protection profile, click the Action icon and then select **Inherit Grid Rule Settings**. Click **Yes** in the confirmation dialog box to inherit the settings.

Merging Threat Protection Profiles

You can merge the threat protection rulesets from one profile to another before you publish it. The following rules are applicable when you update a ruleset that is assigned to a profile and migrate the profile settings to a new ruleset:

- NIOS migrates the profile settings of the rule to the new ruleset when you override a rule, which exists in both the old and the new ruleset, at the profile level.
- The profile ruleset continues to inherit the settings from the Grid if you do not override a rule that exists in both the old and the new ruleset.
- NIOS removes the profile settings for a rule when you override the rule settings for a profile and the rule does not exist in the new ruleset.
- When a rule exists only in a new ruleset, it inherits the settings from the Grid by default.
- Parameters for custom rules are migrated only when the same custom rule exists in the new ruleset.

You can view differences between the old profile and the new one before you publish the changes. The appliance shows you the system-level changes, including new rules, deleted rules, and rule syntax, between the two rulesets and customizations from the old profile. You can then select the changes you want to merge into the new profile. You can also modify some of these customized changes before you merge them into the new profile. When merging profiles, all rules in the old ruleset and new ruleset are compared and identified by their rule IDs.
To merge a threat protection profile:

1. From the **Data Management** tab, select the **Security** tab -> select either **Threat Protection Rules** or **Members** or **Profiles** tab, click **Merge** from the Toolbar, and then select **Profile** from the drop-down list.
2. In the *Merge Changes Into Profile Ruleset* editor, complete the following:
    - **Old Profile**: From the drop-down list, select the threat protection profile from which you want to merge changes into the new profile. The **Comment** field displays additional information about the profile and **Ruleset version** displays the ruleset version.
    - **New Profile**: From the drop-down list, select the threat protection profile to which you want to merge changes. The **Comment** field displays additional information about the profile and **Ruleset version** displays the ruleset version.
    - **Get Differences**: Click this to display a list of differences between the old and new profiles. The appliance displays system-level changes in the **System changes from old profile (x items)** table, where x is the total number of changed rules between the old and new profiles. The appliance merges all system-level changes listed in this table into the new profile.

      The table displays the following information for each changed rule:
    - **Rule ID**: The rule ID of the changed rule. You can click the rule link and modify parameters in the rule editor.
    - **Rule Name**: The name of the rule.
    - **Type**: Indicates whether the rule is a newly added rule or it has been deleted.
    - **Old Ruleset Value**: Displays the old ruleset value.
    - **New Ruleset Value**: Displays the new ruleset value.

      The **Customizations from old profile (x items)** table displays customized rule parameter changes between the old and new profile, where x is the total number of changed rules. You can select all or specific changed rules in this table to be merged into the new profile. You can also modify the parameters for selected rules before merging the changes into the new profile. This table displays the following information for each rule:
    - **Member/Profile**: The Grid member on which this rule is currently running.
    - **Rule ID**: The rule ID of the changed rule. You can click the rule link and modify parameters in the rule editor.
    - **Rule Name**: The name of the rule.
    - **Old Ruleset Value**: Displays the old ruleset value.
    - **New Ruleset Value**: Displays the new ruleset value.
    - **Action**: Displays what the appliance will do to changes in this rule when you merge the profiles.
3. Click **Merge Changes** to copy all the selected rules and changes you made to specific rules to the new profile. Note that you must select a rule from the **Customizations from old profile (x items)** table to activate the merging operation.

   You can do the following in the *Merge Changes Into Profile Ruleset* editor:
    - Click **Export** to export all the changes listed in both tables to one CSV file. You can export this data after you click **Get Differences** and Grid Manager displays changes in both tables.
    - Perform another profile merge by selecting another old profile and new profile.
    - Click **Close** to exit the editor. Note that the editor does not close automatically after a merge.

Modifying Threat Protection Profiles

You can modify the details associated with a threat protection profile. You can edit the rules when you drill down to the ruleset even though a member is associated with the profile.
To modify a threat protection profile:

1. From the **Data Management** tab, select the **Security** tab -> **Profiles** tab, select the threat protection profile that you want to modify, click the Action icon  and then select **Edit**.

2. The *Threat Protection Profile* editor contains the following tabs from which you can modify information:
   - **General**: All fields are automatically propagated with available information. You can modify the values in the **Basic** and **Advanced** tabs. For more information, see *Adding Threat Protection Profiles*.
   - **Member Assignment**: Add or delete members that are associated with the respective threat protection profile. Click the Add icon to associate a member with the selected profile. In the *Threat Protection Member Selector* dialog box, select the member you want to associate with the profile. For information, see *Listing Members*. To delete a member that is associated with the profile, select the checkbox next to the respective member and click the Delete icon.
   - **Extensible Attributes**: Add and delete extensible attributes that are associated with the template. You can also modify the values of the extensible attributes. For information, see as described in *Modifying Extensible Attributes*.
3. Save the configuration.

You must publish the changes after modifying a threat protection profile. For more information about publishing changes, see *Publishing Rule Updates*.

> ⚠ **Note**
>
> By default, all ruleset versions, events per second per rule, and disable multiple DNS requests via single TCP session are inherited from the Grid unless you click **Override** to change the Grid settings.

Cloning Threat Protection Profiles

You can create a new threat protection profile by cloning an existing one. The appliance creates a new profile with the settings that are copied from the source profile. You can also associate extensible attributes with the profile. Note that members in the source profile are not carried over to the cloned profile. You must associate new members with the newly cloned profile.
To clone a threat protection profile:

1. From the **Data Management** tab, select the **Security** tab -> **Profiles** tab, select the threat protection profile that you want to clone, click the Action icon  and select **Clone**.
2. In the *Clone Threat Protection Profile Wizard*, enter a name for the threat protection profile and modify the details. For more information, see *Adding Threat Protection Profiles*.
3. Associate extensible attributes and members with the threat protection profile.
4. Save the configuration.

Adding Threat Protection Profiles

You can create a threat protection profile and associate an active ruleset with it. Infoblox supports common threat protection rulesets for both hardware and Software ADP members. You can either upload a ruleset or download rulesets from a server. You can create any number of threat protection profiles, but you can select only a maximum of five rulesets in combination at the Grid, member and profile levels. For more information about rulesets, see *Understanding Threat Protection Rulesets and Rules*.
The threat protection profile allows you to create your own set of rules for either a member or a group of members that experience a similar kind of traffic. After you define a profile, you can clone it and test the copied settings for a new ruleset on one member before publishing the changes for a group of members that are associated with the profile.
To define threat protection profiles:

1. From the **Data Management** tab, select the **Security** tab -> **Profiles** tab and then click the *Add* icon.
2. In the *Add Threat Protection Profile Wizard*, add the following:
   - **Name**: Enter a name for the threat protection profile.
   - **Comment**: Enter information about the threat protection profile.
   - **Active Ruleset Version**: Select a value from the drop-down list. This indicates the current ruleset that is used for the respective threat protection profile. If you inherit a ruleset from the Grid and later change the respective ruleset at the Grid level, the new ruleset is not reflected in the profile. You must manually change the selected ruleset for the profile. For more information about active rulesets, see *Understanding Threat Protection Rulesets and Rules*.

- **Active Ruleset Comment**: Click **Override** to override the comment.
- **Events per Second per Rule**: Click **Override** to override the values. This indicates the number of events that is logged per second per rule to allow the appliance to log events to the syslog. Specify the number of events logged per second per rule. The default value is one and the maximum value is 700. Setting the value to 0 (zero) disables the appliance from logging events for the rules. The appliance displays an error message when you enter a value greater than the maximum value. You can override this event filter at the member level. For more information, and guidelines about using this setting, see *Using the Events Per Second Rule Setting*.
- **Disable multiple DNS requests via single TCP session:** Click **Override** to override the values. This determines if multiple DNS responses through TCP connection are disabled. For more information, see *Enabling Multiple DNS Requests through a Single TCP Session*.

3. Click **Next** to add extensible attributes.
4. Save the configuration.

> ⚠ Note
> A member associated with a threat protection profile can neither modify **Events per Second per Rule** and **Disable multiple DNS requests via single TCP session** settings at the member level nor enable or disable rules and change rule parameters at the member level.

Managing Threat Protection Rules

You can modify any previously defined custom rules, or some of the parameters for system and auto rules. For most system and auto rules, you may change the **Action** and **Log Severity**. You can also enable or disable individual rules or an entire category of rules.
If you have selected to manually update threat protection rules, you must download updated rules from the Infoblox Support web site and then publish them to the system.
When a member is associated with a profile, it automatically uses the ruleset that is associated with the profile. When you delete the associated profile, member uses the ruleset that was previously associated with it.
You can do the following after the initial setup, including uploading the initial ruleset:

- Look at rules that are currently installed on your system, as described in *Viewing Threat Protection Rulesets*.
- Enable and disable certain rules, as described in *Enabling and Disabling Rules*.
- Upload rule updates to the system when you have selected to manually apply rule updates, as described in *Modifying System and Auto Rules*.
- Publish rule updates that you have uploaded to the system, as described in *Publishing Rule Updates*.
- Modify existing system rules, as described in *Modifying System and Auto Rules*.
- Modify custom rules, as described in *Modifying Custom Rules*.

Modifying Custom Rules

1. From the **Data Management** tab, select the **Security** tab -> **Threat Protection Rules** tab.
2. In the Grid Rules table, expand the category to which the rule belongs, select the checkbox, and then click the Edit icon.
3. In the Custom Rule editor, select the **General** tab -> **Basic** tab to modify the following:
   - **Comment**: Enter information about the custom rule.
   - **Disable**: Select this checkbox to disable the custom rule.

     You can also view the following information (but you cannot modify it):

   - **Template**: Displays the name of the template the custom rule uses.
   - **Rule ID**: Displays the rule ID of the custom rule.
   - **Name**: Displays the name of the rule.
   - **Category**: Displays the category to which the custom rule belongs.
   - **Description**: Displays the description of the custom rule.
4. In the Custom Rule editor, select the **Settings** tab -> **Basic** tab to modify the following:

- **Log Severity**: Select the log severity level from the drop-down list. You can select **Critical**, **Major**, **Warning**, or **Informational**. Log severity may have an effect on how other Grid services respond to particular events. The selection here corresponds to the severity levels you can configure for logging in the syslog.
- **Rule Parameters**: In the Rule Parameters table, the **Description** column displays the rule parameters. Click the row and enter the corresponding values for the rule parameters in the **Value** column.
- **Action**: Displays the operation which the appliance performs when this event occurs. Some rules are restricted to specific actions. For example, the action for all blacklisting rules is set as **Drop** where the appliance drops the packets and logs the activity when such an event occurs. The action for all whitelisting rules is set as **Pass**, where the appliance silently passes the packets without logging when such an event occurs.

5. Save the configuration.

Modifying System and Auto Rules

1. From the **Data Management** tab, select the **Security** tab -> **Threat Protection Rules** tab.
2. In the Grid Rules table, expand the category to which the rule belongs, select the checkbox, and then click the Edit icon.
3. In the *System Rule* or *Auto Generated Rule* editor, select the **General** tab -> **Basic** tab to modify the following:
   - **Comment**: Enter information about the system rule.
   - **Disable**: Select this checkbox to disable the system rule. You cannot disable auto rules. You can also view the following information (but you cannot modify it):
   - **Rule ID**: Displays the rule ID of the system rule.
   - **Name**: Displays the name of the rule.
   - **Category**: Displays the category to which the system rule belongs.
   - **Description**: Displays the description of the system rule.
   - **Order**: Displays the number that indicates the order in which the rule will be executed by the appliance. The rule order can change during a ruleset update.
4. In the *System Rule* or *Auto Generated Rule* editor, select the **Settings** tab -> **Basic** tab. Depending on the rule, you may or may not be able to modify the following:
   - **Action**: Displays one of the following: **Alert**, **Drop** or **Pass**. Some rules are restricted to specific actions. For example, the action for all blacklisting rules is set as **Drop**, where the appliance drops the packets and logs the activity when such an event occurs. The action for all whitelisting rules is set as **Pass**, where the appliance silently passes the packets without logging when such an event occurs.
     - **Alert**: Logs the activity, and passes the packet.
     - **Drop**: Logs the activity and drops the packet.
     - **Pass**: Silently passes the packet without logging.
   - **Log Severity**: Select the log severity level from the drop-down list. You can select **Critical**, **Major**, **Warning**, or **Informational**. The selection here corresponds to the severity levels you configure for logging in the syslog.
   - **Rule Parameters**: In the Rule Parameters table, the **Description** column displays the rule parameters. Click the row and enter the corresponding values for the rule parameters in the **Value** column. Depending on the rule, this table displays only the parameters that are relevant to the system or auto rule.
5. Save the configuration.

Enabling and Disabling Rules

By default, all activated threat protection rules apply across the entire Grid. Enabling or disabling a rule category will enable or disable all rules contained in that category. You can also enable or disable individual rules.
To enable or disable all rules in a category, do the following:

1. Grid: From the **Data Management** tab, select the **Security** tab **–> Threat Protection Rules** tab, and then click the ruleset link.
   Member: From the **Data Management** tab, select the **Security** tab **–> Members** tab, and then select a member and click the ruleset link.
2. In the Threat Ruleset table, click the Action icon  next to the rule category, and choose **Enable All Rules in Category** or **Disable All Rules in Category**. Either option can be disabled depending on the current state of the rules in the category. For members, you can select **Inherit Grid Rule Settings in Category** to inherit rule settings from the Grid.

To enable or disable individual rules, do the following:

1. Grid: From the **Data Management** tab, select the **Security** tab **–> Threat Protection Rules** tab, and then click the ruleset link.
   Member: From the **Data Management** tab, select the **Security** tab **–> Members** tab, and then select a member and click the ruleset link.
2. Click the arrow beside a rule category to expand all rules in a rule category.
3. Click the Action icon next to a rule and choose **Enable** or **Disable** from the menu. Either option can be disabled depending on the current state of the rule.

> ⚠ **Note**
>
> Depending on the nature of the rules, you may or may not be able to disable or enable certain rules.

Viewing Threat Protection Rules

You can view the threat protection rules in one of the following views:

- Click **Toggle Flat View** to display a flat list of all the threat protection rules. In the flat view, each of the custom, system, and auto rules are listed separately.
- Click **Toggle Tree View** to display only the category of threat protection rules. You can expand the category of rule to view individual rules listed in each category.

To view rules categories and individual rules in a specific ruleset version:

1. **Grid**: From the **Data Management** tab, select the **Security** tab -> **Threat Protection Rules** tab. **Member**: From the **Data Management** tab, select the **Security** tab -> **Members** tab -> *member* link. **Profile**: From the **Data Management** tab, select the **Security** tab -> **Profiles** tab -> *profile* link.
2. In the Grid Security or Member Security table, click the **Version** link and Grid Manager displays the threat protection rules by categories. The **Category** column lists all the category to which rules belong.
3. To view individual rules listed in each category, expand the list by clicking the arrow beside the checkbox. You can view the following information for each rule:
   - **Category**: The category to which the rule belongs.
   - **Order**: The number that indicates the order in which the rule will be executed by the appliance. The rule order can change during a ruleset update.
   - **Rule ID**: The ID of the rule.
   - **Rule Name**: The name of the rule. This can contain up to 255 characters.
   - **Type**: The rule type. This can be **Custom**, **System**, or **Auto**. For more information about each rule type, see *Understanding Threat Protection Rulesets and Rules*.
   - **Disabled**: Displays whether the rule is disabled. A disabled rule does not perform any mitigation functions.
   - **Comment**: Comments that were entered for the rule. This can contain up to 255 characters.
   - **Action**: The operation that the appliance performs when the event occurs. This can be one of the following:
     - **Alert**: The appliance passes the packets and logs the event.
     - **Drop**: The appliance drops the packets and logs the event.
     - **Pass**: The appliance passes the packets but does not log the event.
   - **Description**: Description about the rule. This can contain up to 255 characters.
   - **Rule Parameters**: Displays the rule parameters that are configured for the rules and the corresponding values for the rule parameters.
   - **Log Severity**: Log severity level. This can be **Critical**, **Major**, **Warning**, or **Informational**.
     You can also do the following in this panel:
   - Click the Action icon 

     and select one of the following actions for a rule category:
     - **Enable All Rules in Category**: Select this to enable all the rules in the selected category. For a Grid member, this action overrides the Grid rule settings.
     - **Disable All Rules in Category**: Select this to disable all rules in the selected category. For a Grid member, this action overrides the Grid rule settings.

- **Inherit Grid Rule Settings in Category**: Select this to inherit Grid rule settings for the selected category. This appears only for member settings.
- Modify some of the data in the rules table. Double click a row, and modify the data. Click **Save** to save the changes. Note that some fields are read-only.
- Select the checkbox of a rule and click the Edit icon to modify the properties of the rule.
- Select the checkbox of a custom rule and click the Delete icon to delete a custom rule.
- Print or export the data.
- Publish changes you make to the rules by clicking **Publish Changes** from the Toolbar. For more information, see *Publishing Rule Updates*.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.

⚠ Note
When you use the **Go to** function to search for specific rules, Grid Manager may return duplicates of the same rules due to the paging mechanism currently used for displaying information.

- Create a quick filter to save frequently used filter criteria. For more information about using quick filters, see the following section.

Using Quick Filters

You can use the following quick filters to filter threat protection rules in the Grid Rules panel. When you select a filter, Grid Manager displays only the specified rules. Using filters makes it easier to locate specific rules for editing, enabling, and disabling.

- **All Auto Generated Rules**: This option shows all auto-generated rules defined in the Infoblox Advanced DNS Protection solution.
- **All Custom Rules**: This option shows all whitelisting and blacklisting custom rules defined by NIOS users.
- **All System Rules**: All protocol-specific rules associated with particular attack phenomena.
- **All Disabled Rules**: This option shows all disabled rules.
- **All Enabled Rules**: This option shows all enabled rules.

For more information about filters, see *Finding and Restoring Data*.

Monitoring Threat Protection Events

You can monitor threat protection events through the following:

- Syslog, as described in *Monitoring through Syslog*.
- Status Dashboard, as described in *Threat Protection Statistics Widget*.
- Threat protection report, as described in *Threat Protection Reports*.

Threat Protection Reports

NIOS provides a series of reports to monitor and analyze DNS threat protection events. When you integrate a reporting member in your Grid, you can get the threat protection both hardware and Software ADP related reports so you can monitor event counts by severity, member, rule, and rule category. Note that all reporting traffic goes over the MGMT port on the reporting member by default. If for any reasons you need to configure a different interface for the reporting traffic, you can do so through the reporting *Member Properties* editor. For detailed information about these reports and how to configure the interface for reporting traffic, see *Security Dashboards*.

Threat Protection Statistics Widget

You can also get a high-level view of the threat protection events through the Status Dashboard. The Advance Appliances provide the *Threat Protection Statistics* widget so you can monitor the trend and counts of the various events. For more information about the Dashboard and the *Threat Protection Statistics* widget, see *Status Dashboard*.

Monitoring through Syslog

To receive threat protection events in the syslog, you must enable the Security option in the DNS logging category of the Grid DNS Properties editor. For information about configuring the logging category as described in Setting DNS Logging Categories, see *Using a Syslog Server*. Once the Security option is enabled, hardware-based appliances log each threat protection related event in the syslog in CEF (Common Even Format). You can get detailed information about the events by reviewing the syslog periodically. For information about how to configure the syslog server, see *Using a Syslog Server*.
When a DNS attack is detected against an enabled rule, the appliance generates a log message. Note that only threat protection messages in CEF are displayed in the syslog. The log messages for rate limiting alert events also include the FQDNs extracted from DNS queries whose standard query and question count is greater than zero so you can quickly identify the offending clients. Note that the FQDN field displays “NA” for invalid DNS queries. This feature is enabled by default. You can disable this only in Maintenance Mode using the CLI command `set smartnic-debug-adp-log-fqdn off.`

Example:

When the appliance detects ICMP ping attacks that exceed the pint size against an existing auto rule that has the following configuration:

Log Severity = Critical
Rule ID = 120600925
Rule Name = Potential DDoS related domain
Rule Action = Drop
Rule Category = Potential DDoS related Domains

It generates the following threat detection event log message:

```
2018-04-20T09:43:21+00:00 daemon infoblox . localdomain named[14792]: info CEF:0|Infoblox|NIOS|8.3.0-369415|RPZ-QNAME|Local-Data|7|app=DNS dst=10.34.173.11 src=10.120.20.28 spt=52240 view=_default qtype=A msg="rpz QNAME Local-Data rewrite a_rec [A] via a_rec.local.com" IPSD=N/A Acct-Session-Id=8333332d-11111111 Parental-Control-Policy=010000000033 Calling-Station-Id=1101202041 NAS-PORT=1813 Subscriber-Secure-Policy=00000fff Guest=1 LocalID=000C2987FEEE CAT=RPZ
```

The number of log messages generated is based upon your Event per Second per Rule setting. For example, if the setting is 5, the appliance generates five log messages of the same event per second when the attack continues within the time duration. Each log message contains the following information:

- The timestamp when the event happened in yyyy-mm-ddThh:mm:ss+00:00 format.
- **Infoblox|NIOS|x.x.x**: Indicates the Infoblox product, and x.x.x represents the NIOS version.
- The string following the NIOS version is a hard-coded constant. In this example, it is RPZ QNAME.
- The number following the rule ID is the log severity. The following numbers indicate the severity levels:
  - **8** = **Critical**
  - **7** = **Major**
  - **6** = **Warning**
  - **4** = **Informational**
- **app**: DNS.

- **dst**: Destination IP address.
- **src**: Source IP address.
- **spt**: Source port.
- **view**: DNS view.
- **qtype**: Query type.
- **msg**: RPZ rule.
- **IPSD**: IP space discriminator.
- **Acct-Session-Id**: Session ID.
- **Parental-Control-Policy**: Parental Control Policy.
- **Calling-Station-Id**: Subscriber ID.
- **NAS-PORT**: NAS Port.
- **Subscriber-Secure-Policy**: Subscriber Secure Policy.
- **Guest**: Guest indicator. For fixed line or home router deployments, a guest indicator value '1' indicates guest device and '0' indicates subscriber device.
- **LocalID**: MAC address of the subscriber device. For fixed line or home router deployments, if the guest indicator value in the **Guest** field displays '1' then the **Local ID** field displays the MAC address of the guest device.
- **CAT**: The category to which the rule belongs. In this example, the category is "**RPZ**."

To view DNS threat protection related log messages:

1. From the **Administration** tab, select the **Logs** tab -> **Syslog** tab.
2. From the drop-down list at the upper right corner, select the Grid member on which you want to view the syslog.
3. From the Quick Filter drop-down list, select **Threat Rule Update Events** or **Threat Detection Event Logs** to view rule update events or threat detection events respectively. To narrow down the system messages you want to view, click Show Filter and then select the filters you want to use. For information about how to use filters, see *Using Filters*.

DNS and Network-Flood Threats

DNS is a tempting target for attacks given that it is a core Internet service. Attackers can send malformed DNS queries or DNS responses to the targeted server, hoping to exploit bugs in its DNS implementation. Other variants include code insertion, buffer overflows, memory corruption, NULL pointer dereferencing, and specific vulnerability exploits.
DNS attacks tend to follow specific patterns but can be difficult to deal with using only rate-limiting techniques, because of the sheer scale of many recent attacks. DNS threat protection is designed to grow and expand over time, through threat protection rule updates, to deal with both outside-in and inside-out attacks on network infrastructure and Internet services.
Following are some of the network-flood attacks that can target your DNS caching and authoritative servers:

- *Internet Control Message Protocol (ICMP) Flood*
- *SYN Flood*
- *UDP DNS Flood*
- *Inside-Out Attacks*
- *DNS Cache Poisoning*
- *DNS Reflection and Amplification Attacks*
- *DNS Malware*
- *DNS Domain Hijacking*

DNS Domain Hijacking

Domain hijacking or domain theft is the act of changing the registration of a domain name without the permission of its original registrant. Domain hijacking is generally done by exploiting a vulnerability in the domain name registration system or through social engineering. In some cases however, domain hijackers alter the DNS data of a domain after gaining control of it. They consequently redirect users to a fraudulent site, instead of the legitimate site, on the Internet.
To protect your authoritative DNS server against DNS domain hijacking, you can configure the appliance to monitor NS records and glue records of top-level authoritative zones. Based on your configuration, the appliance periodically checks DNS data in the NS RRsets for these zones and compares the data with that in the appliance database. It then reports any data discrepancies through SNMP traps and logs related events in the syslog. You can also monitor the status of DNS data discrepancies, if any, through the DNS integrity check widget, see *Status Dashboard*. The severity in data

discrepancies can help identify possible domain hijacking. For more information about how to configure this feature, see *Configuring DNS Integrity Check for Authoritative Zones*.

DNS Malware

Sophisticated malware also has emerged as a serious threat to DNS infrastructure. They are classified as Advanced Persistent Threats, and use DNS to embed themselves in the target network and stealthily communicate with external command servers to obtain malware updates, instructions, and to conduct attacks for data theft, industrial espionage and other goals.

DNS Reflection and Amplification Attacks

As with UDP flood, DNS reflection attacks use a form of IP spoofing, changing the source address in their DNS queries to show the address of their intended target, such as a DNS root server or a top-level domain (TLD) name server operator. DNS reflection and amplification recognizes UDP as an asymmetrical protocol (small requests, large responses) and the existence of open DNS resolvers to the Internet cloud. The result is that small DNS queries reflect large UDP datagram responses to the target address in the original source datagrams. Some recent attacks have used this DDoS technique at a huge scale.
Because DNS runs over UDP and does not require a handshake, it is possible to use the protocol as a means to lock down a host or a network. Designed a specific way, sending a small query to any open DNS resolver can result in a single response containing several kilobytes or more, that are sent to the unwitting spoofed victim. (This type of response typically is sent via TCP, as UDP does not allow for more than 512 bytes in a response datagram. The resulting packet usually exceeds the MTU of the recipient's interfaces, resulting in further packet fragmentation and processing.) Open DNS resolvers may allow for launching DDoS attacks containing hundreds of gigabytes of data. Attackers may also use the EDNS0 DNS protocol extension as a means to enable larger DNS responses. Many network operators, particularly overseas, allow open DNS resolvers to run on their networks, unwittingly allowing attackers to abuse them. Many network operators do provide intelligent rate-limiting to prevent abuse, even while supporting open recursive DNS servers. Hence, issues of this type usually result from mistakes in configuration.

DNS Cache Poisoning

With cache poisoning, attackers attempt to insert a spoofed DNS response to a DNS resolver, which then stores the response in its cache, where it lives until the TTL expires. The cache is poisoned and subsequent requests for the domain address to recursive name servers are answered with the address of a different server, presumably controlled by the attacker. So long as the fake entry resides in the DNS server cache (persistence of a cache entry is usually governed by time to live) it can result in hundreds of thousands of dangerous redirects. In such cases the URL is legitimate, but the destination servers are not. This process is often called a "pharming" attack. Web servers and mail servers are frequent targets. Other redirection attacks include DNS Changer and DNS Replay. Man-in-the-middle is another descriptive term for many redirection attacks.

DNS Fluxing

the use of a system called a Domain Generation Algorithm botnet to perform one of the following attacks:

- **Fast Fluxing**: Forcing rapid swapping in and out of IP addresses, with extremely high frequency through changing DNS records with brief TTLs
- **Domain Fluxing**: Forcing constant changing of and allocation of multiple fully-qualified domain names (FQDNs) to a single IP address on the recursive or authoritative DNS server.

Inside-Out Attacks

A sophisticated form of "phishing" in which an attacker is able to inject a worm or other piece of attack software onto a host machine, which thereupon captures sensitive information such as logins, and adds that data to DNS queries that can be sent from the trusted machine to an untrusted entity for collection. DDoS Security detects data leaks of this type, logs the incident, and funnels the suspect packets to a quarantine location. In a similar vein, **DNS Tunneling** uses DNS as a covert channel to avoid firewall and IPS security mechanisms. Tunneling encapsulates Inbound and outbound packets inside DNS requests and DNS responses.

UDP DNS Flood

UDP Flood is a denial-of-service attack that uses the connectionless UDP transport protocol and attempts to send large numbers of packets to random UDP protocol ports on a remote system, or to a specific protocol. UDP flood is a reflection attack that is often used for attacking DNS servers operating on UDP port 53. UDP flooding typically uses IP spoofing, in which the sender address is faked. The purpose is to occupy so many resources on the target that it can no longer provide its services on the network.

SYN Flood

A host sends a long stream of TCP SYN packets, frequently using a forged sender address. Because TCP regards a SYN packet as part of a legitimate connection request, the requested server starts a half-open connection by responding with a SYN ACK packet. Since the sender address is faked, the final ACK response from the sender never comes, and the half-open TCP socket closes only after a time out interval. A massive wave of SYN requests with fake senders can wipe out the connection resources of a network device, effectively locking it away from legitimate users.

Internet Control Message Protocol (ICMP) Flood

An ICMP flood attack is also known as a ping attack in which attackers send a large number of ICMP ping packets to a DNS server repeatedly in order to hinder the server's ability to respond to other requests. It can also be an attempt to send a large number of ping packets to the broadcast IP of a subnetwork, otherwise known as a Smurf attack, as a basic means of amplifying an attack across more hosts than a normal ping would typically permit. These types of attacks can be dealt with by setting a policy to disallow pings to the broadcast IP on the network.

> **Note**
>
> When threat protection is enabled, ICMP ping size (for IPv4 and IPv6) is limited to 16,000 bytes.

Infoblox DNS Firewall

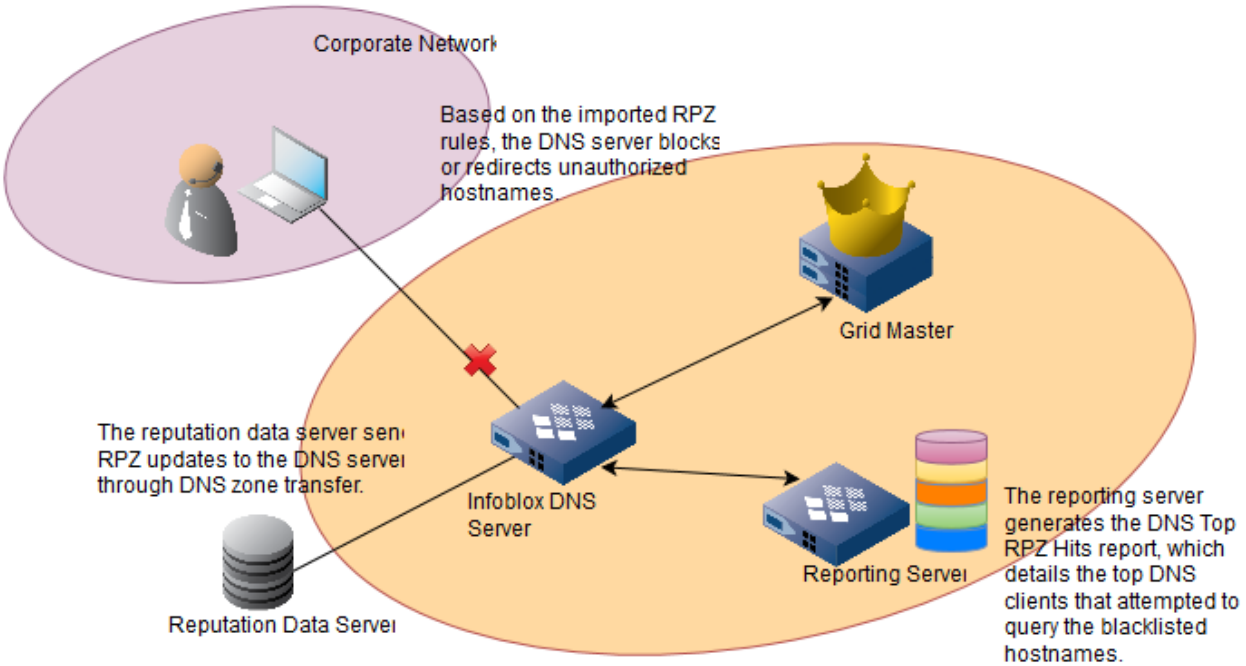
This section provides information about the Infoblox DNS Firewall feature that you can configure and manage on the Infoblox appliance. It includes the following topics:

About Infoblox DNS Firewall

Infoblox DNS Firewall employs DNS RPZs (Response Policy Zones), a technology developed by ISC (Internet System Consortium) for allowing reputable sources to dynamically communicate domain name reputation so you can implement policy controls for DNS lookups.

On an Infoblox appliance, you can configure RPZs and define RPZ rules to block DNS resolution for malicious or unauthorized hostnames, or redirect clients to a walled garden by substituting responses. You can assign actions to RPZ rules. For example, abc.com can have an action of pass thru or substitute (domain) with the domain xyz.com. You can also configure a Grid member to act as a lead secondary that receives RPZ updates from external reputation sources and redistributes the updates to other Grid members. Infoblox DNS Firewall supports both IPv4 and IPv6 networks. It also facilitates the detection of malware and APTs (Advanced Persistent Threats) by integrating the NIOS appliance with a FireEye appliance. You can employ APT mitigation strategy using FireEye as an external threat detection source.
An Infoblox Grid performs RPZ actions for queries that originate from external sources. The name server recursive cache on an RPZ enabled Grid member uses the address of the client from which the query originates to identify if the query is generated from an external source or an internal Grid. If the query originates from a Grid Master or a Grid member that has RPZ license installed, RPZ actions are automatically bypassed for those queries. For RPZ, Infoblox uses the ACL *infoblox-deny-rpz*, which contains a list of addresses for bypassing RPZ actions. The *infoblox-deny-rpz* list excludes Grid members that do not have an RPZ license. Note that RPZ action is performed only once for a single recursion.
As illustrated in the below figure, the Infoblox DNS server receives RPZ updates, which include blacklisted hostnames and responses, from a reputation data server through a DNS zone transfer. The appliance then blocks or redirects queries and responses based on the imported RPZ rules. The reporting server can then generate the *DNS Top RPZ Hits* report that details the top DNS clients that have received redirected responses through RPZs.

Infoblox DNS Firewall



There are three types of RPZs:

- Local RPZ – A local RPZ is a zone that allows administrators to define multiple response policies locally. Responses sent are based on the defined rules. For information about how to configure local RPZs, see *Configuring Local RPZs*.

- RPZ Feed – An RPZ feed receives response policies from external sources. DNS clients receive responses based on the imported rules from a reputable source, such as a commercial RPZ provider. For information about RPZ feed, see *Configuring Infoblox Threat Intelligence Feed*.
- FireEye integrated RPZ – By integrating the NIOS appliance with the FireEye appliance, you can detect malware and APTs and take necessary actions to mitigate those threats. For information about FireEye integrated RPZ, see *About FireEye Integrated RPZs*.

> ⚠ Note
>
> You can configure up to a total of 32 RPZs, including local and FireEye integrated RPZs.

For more information on configuring RPZ feeds using On-Prem Firewall Service, see *On-Prem DNS Firewall Service*.

Setting Up Infoblox DNS Firewall

For a successful Infoblox DNS Firewall deployment to protect your endpoint devices and servers from stealthy malware and malicious hostnames, consider the guidelines described in *Best Practices for Configuring RPZs*. To configure Infoblox DNS Firewall , complete the following tasks:

1. Install a valid RPZ license on the appliance, as described in *License Requirements and Admin Permissions for RPZ*.
   Note to ensure that you have installed a valid DNS license on the same appliance.
2. Enable recursive queries for a DNS view, member, or Grid, as described in *Enabling Recursion for RPZs*.
   Note to ensure that you enable recursive queries for RPZ rules to take effect.
3. Configure RPZ logging to ensure that all matching and disabled rules for all queries are logged in the syslog. You can view the syslog to ensure that the rules are set up correctly before they take effect. Ensure that you enable **rpz** in the **Logging Category** of *Grid DNS Properties* editor to log these events. For information about how to set logging categories, see *Using a Syslog Server*.
4. You can configure a local RPZ, an RPZ feed, or a FireEye RPZ on the NIOS appliance. Complete one of the following depending on your selection:
   - On a DNS member, complete the following to create local RPZ rules:
     i. Create an RPZ, as described in *Configuring Local RPZs*.
     ii. Configure rules for the local RPZ you have created, as described in *Configuring Rules for RPZs*.
   - Optionally, complete the following to receive RPZ updates from an RPZ feed:
     i. Configure an RPZ feed, as described in *Configuring Rules for RPZs*.. You can also configure the Infoblox DNS feed, as described in *Configuring Infoblox Threat Intelligence Feed*. The Infoblox DNS feed is a reputable data server validated by Infoblox to provide reputation RPZ updates.
     ii. Download rules from the RPZ feed, as described in *Downloading Rules for an RPZ Feed*.
   - Optionally, complete the following to receive alerts from a FireEye appliance:
     i. Create a FireEye integrated RPZ, as described in configuring fireeye RPZs, see *About FireEye Integrated RPZs*.
     ii. Define rules for FireEye RPZs,as described in configuring fireeye RPZs, see *About FireEye Integrated RPZs*.
     iii. Create FireEye admin users, as described in for fireeye integrated RPZs, see *About FireEye Integrated RPZs*.
     iv. Add URLs and user credentials on the FireEye appliance, as described in configuring fireeye RPZs, see *About FireEye Integrated RPZs*.

> **Note**
>
> To apply the configured RPZ policies regardless of whether a DNS query requests DNSSEC data, configure the appliance accordingly. For more information about how to configure this, see *Applying Policies and Rules to DNS Queries that Request DNSSEC Data*.

5. Test your RPZ configuration and verify that RPZ is functioning properly by viewing the syslog and the **Last Updated** column in the **Response Policy Zones** tab. For more information, see *Testing RPZ Feed Rules*.

After you have set up your RPZs, RPZ feeds, and RPZ rules. You can do the following:

- Manage local RPZs such as viewing a list of RPZs, modifying, reordering, and deleting RPZs. You can also lock or unlock RPZs. For more information, see *Managing RPZs*.
- Verify RPZs are functioning properly by viewing the syslog and the last updated RPZ. For more information, see *Managing RPZs*.
- Manage Local RPZ rules such as viewing, modifying, and deleting RPZ rules. You can also copy and import RPZ rules. For more information, see *Managing RPZs*.
- Generate the *DNS Top RPZ Hits* report, if you have a reporting server set up in the Grid. For more information DNS Top RPZ Hits, see *About Dashboards*.
- Define thresholds for RPZ hit rate and configure the appliance send alerts when the RPZ hit rate exceeds the thresholds. For information, see *Configuring Thresholds for RPZ Hit Rate*.

License Requirements and Admin Permissions for RPZ

You must install required licenses before you can use the RPZ feature. An RPZ license is required to configure local RPZs and RPZ feeds.

This section includes the following topics:

For more information, see For Local RPZs and RPZ Feeds below. For FireEye integrated RPZs, you must first install an RPZ license, and then a Security Ecosystem license. For more information, see For FireEye Integrated RPZs below. For all RPZ related licenses, you can install either a temporary or a permanent license on the NIOS appliance. The temporary license provides a 60-day free trial, which can be upgraded to a permanent license. After the license expires, the RPZs will remain intact, but you cannot delete existing or add new entries to it. Infoblox provides RPZ licenses that are compatible with each product model.

For Local RPZs and RPZ Feeds

Before you install an RPZ license, ensure that the following are completed:

- The entire Grid is running NIOS 6.6 or later.
- Grid members are properly configured and DNS is enabled on the members.

> **Note**
>
> Install RPZ licenses only on Infoblox members that have DNS recursion enabled.

Superusers can configure RPZs and RPZ rules by default. You can also assign global permissions for all RPZs and RPZ rules to specific admin groups and roles. For more information about administrative permissions for zones, see *Administrative Permissions for DNS Resources*.

Grid-wide licenses for RPZ

Infoblox offers a Grid-wide **BloxOneThreat Defense Business On-Premises, BloxOneThreat Defense Business Cloud, and BloxOneThreat Defense Advanced** additional services for DNS Firewall feature. These are subscription licenses that you may have to purchase from Infoblox. When you purchase these services, you can use the BloxOne threat subscription data on any appliance that can run DNS Firewall across the Infoblox Grid which you have configured. You can buy these additional services if you do want to use Infoblox threat data and instead use your own or an external threat feed. With these additional services, you get to use a separate license key for each Grid that you use.

When you configure Grid-wide RPZ license for each Grid, RPZ rules are not applied for queries that originate from the other RPZ member(s) of the Grid. When you use multiple Infoblox Grids, you can use the same TSIG key to configure feed zones across all Grids to synchronize feed subscriptions. Note that these services are valid for NIOS versions 8.0 and above. For more information about managing Grid-wide licenses, see *Managing Licenses*.

For a thorough understanding of the RPZ process using various NIOS versions, consider a scenario where you have configured four members on the Grid: GM(RPZ license), M1(RPZ license), M2(DNS license), M3(RPZ license), and RM1 (Reporting Member).

- In NIOS version 7.3, all members with RPZ licenses are added to the ACL list:

```
infoblox-deny-rpz { localhost; GM_IP, Member1_IP; Member3_IP; }
```

- In NIOS version 8.x:
  - When you install a Grid Wide RPZ license, all members with DNS licenses are added to the ACL list:

    ```
    infoblox-deny-rpz { localhost; GM_IP, Member1_IP; Member2_IP;
    Member3_IP; }
    ```

  - When you install a Grid Wide RPZ license, but not a member level RPZ license, NIOS adds all the members with DNS licenses to the ACL list:

    ```
    infoblox-deny-rpz { localhost; GM_IP, Member1_IP; Member2_IP;
    Member3_IP; }
    ```

  - When you do not install a Grid-wide RPZ license but install member-level RPZ licenses, NIOS adds all members that have RPZ licenses to the ACL list and enables the **Apply RPZ rules only on this member if possible** check box for that member. You can clear the check box.

    ```
    infoblox-deny-rpz { localhost; GM_IP, Member1_IP; Member2_IP;
    Member3_IP; }
    ```

> **Note**
>
> Infoblox suggests that when you upgrade to NIOS 8.0 and later versions, select the check box **ApplyRPZrulesonlyonthismemberifpossible** only if there is an existing RPZ license for the Grid member to ensure that there is no change in behavior due to an upgrade.

Note the following about Grid-wide licenses for RPZ:

- NIOS displays **rpz** in the Grid-wide and Member tabs when RPZ license is installed.
- When you enable a temporary license for RPZ, it is enabled at the Grid level and listed under the **Grid Wide** tab. You do not have to set the license at the member level.
- NIOS performs a pre-provision check for an RPZ member who joins the Grid to verify if a Grid-wide license is installed for the RPZ member. If the Grid-wide license is found, NIOS allows the member to join the Grid.
- If an RPZ license expires, Feed Zone stops receiving feed updates after the grace period. However, the RPZ feature remains until it expires. This grace period TTL is configured in BloxOne Plus/Advanced services.

- After you remove the Grid-wide license for RPZ, this feature still keeps functioning for members that do not have a Grid-wide license until you restart the service. When you remove the RPZ license that is associated with a specific member, NIOS restarts the service automatically and disables RPZ for the respective member.
- NIOS checks for a Grid-wide license of a pre-provisioned type when a member first joins the Grid. For example, if a member is pre-provisioned for RPZ and a Grid-wide RPZ license is installed, then NIOS allows the member to join the Grid, even though the member does not have a valid RPZ license.

Customizing Threat Feeds on an RPZ Member

To configure an RPZ member to use your own or external threat feeds instead of RPZ feeds, complete the following:

1. From the **Data Management** tab, select **DNS**, and then click **Members**.
2. Select a member and click **Edit** from the Toolbar.
3. In the *Member DNS Properties* editor, click **General** tab -> **Advanced** tab.
    - **Apply RPZ rules only on this member if possible**: Select this check box if the forwarders must not apply RPZ rules to the responses that is returned to the other member, when this RPZ member queries other Grid member details.
4. Save the configuration.

For FireEye Integrated RPZs

You can enable FireEye integrated RPZs on the appliances that have both the RPZ and Security Ecosystem licenses installed. Note that you must install an RPZ license prior to installing the Security Ecosystem license.

NIOS appliance creates a new group, **fireeye-group**, when you add the first FireEye zone. The FireEye admin group is read-only and you cannot assign permissions to it. It will not have any superuser privileges and you cannot modify or delete this group. You can add users to the **fireeye-group** admin group, and FireEye users can only send alerts to the NIOS appliance. They cannot access the Infoblox GUI, CLI, API, or RESTful API. These users are authenticated based on the usernames and passwords you configure in the FireEye admin group. Only admin users who belong to the FireEye admin group can publish FireEye alerts. Other admin users cannot do so. For information about how to configure the FireEye appliance, see *Configuring the FireEye Appliance*.

> **Note**
>
> The **fireeye-group** is created automatically. Infoblox recommends that you do not add a group with the same name. In addition, The "force password change at next login" feature does not apply to admin users in the **fireeye-group**. These users will not be prompted to change their passwords at the next login. Their original passwords continue to work. For more information managing passwords, see *Creating Local Admins*.

To add users to the **fireeye-group**, complete the following:

1. From the **Administration** tab, select **Administrators**, and then click **Admins**.
2. Click **Add** and enter the usernames and passwords. For more information on how to add users to an admin group, see *Creating Local Admins*. Select **fireeye-group** for the admin group and add users to this group.

> **Note**
>
> Ensure that you save the usernames and passwords. You must use these credentials when configuring FireEye alerts to enable the alerts to be received by NIOS.

Uninstalling the Security Ecosystem License

When you uninstall the Security Ecosystem license, new FireEye alerts will not be processed. However, the FireEye integrated RPZs and the rules in those zones will not be deleted. Note the following when you uninstall the Security Ecosystem license:

- New FireEye alerts will not be processed

- FireEye RPZ zones that were created before uninstalling the license will remain
- You cannot create new FireEye RPZ zones
- RPZ rules created from the alert will remain
- Note that if the RPZ and Security Ecosystem licenses are installed, then you must first remove the Security Ecosystem license to remove the RPZ license.
- The fireeye-group and the FireEye zones will remain even after you delete the Security Ecosystem license.

Enabling Recursion for RPZs

For RPZ rules to function properly, you must enable DNS recursion. You can enable DNS recursion at the Grid, member, or DNS view level. To enable recursion:

- For the Grid or member, see *Enabling Recursive Queries*.
- For a DNS view, see *Managing Recursive DNS Views.*

Configuring RPZs for All Recursive Servers

When you configure a local or FireEye integrated RPZ, you must define an internal primary name server. The primary name server can be either recursive or non-recursive, depending on its usage. When you configure an RPZ feed, you must define an external primary name server. You can associate a name server or a name server group with the local RPZ, RPZ feed, or FireEye RPZ. You can also configure RPZs and RPZ feeds for all recursive servers in the Grid.
A local RPZ can have one or more secondary name servers associated with it. For an RPZ feed, you must create an external primary name server.
To configure a local RPZ, or RPZ feed, or FireEye RPZ for all recursive servers, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then click the *Add* icon.
2. Enter the *Response Policy Zone* details and click **Next** to associate an RPZ with at least one name server. For information about creating a local RPZ, and creating an RPZ feed, see *Configuring Local RPZs*. For information about creating a FireEye integrated RPZ, see *Configuring FireEye RPZs*.
3. Select **All Recursive Name Servers** from the list to add all the recursive name servers in the Grid as the secondary name servers for the corresponding zone.
    - Save the configuration and click **Next** to define extensible attributes. Click **Restart** if it appears at the top of the screen. For information about extensible attributes, see *Managing Extensible Attributes*.

Enabling and Disabling RPZ Query Name Recursion

In previous NIOS releases, RPZ query name recursion was enabled by default. The DNS recursive name server performed RPZ recursive lookups for the fully qualified domain name that was part of an RPZ. Starting with NIOS 7.1.0, RPZ query name recursion is disabled by default. When RPZ query name recursion is disabled, the DNS recursive name server sends responses for the domains being queried, without forwarding queries to the authoritative name servers. This can speed up recursive RPZ lookups by eliminating unnecessary recursions for domains that are known to be malicious, possibly caused by internal DDoS attacks on the recursive server.
You can enable RPZ query name recursion by selecting the **Enable RPZ query name recursion (qname-wait-recurse)** checkbox. When you select this checkbox, the appliance performs RPZ query name recursions. You can configure this at the Grid, member, and DNS view levels.

> **Note**
>
> RPZ query name recursion is disabled by default. The **EnableRPZquerynamerecursion(qname-wait-recurse)** checkbox is deselected for all new installations and upgrades. You can select this checkbox to enable RPZ query name recursion.

To enable or disable RPZ query name recursion:

1. From the **Data Management** tab, select the **DNS** tab, and then click **Grid DNS Properties** from the Toolbar.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *Grid_member* checkbox, and then click the Edit icon.

or
From the **Data Management** tab, select the **DNS** tab -> **Zones** tab -> *dns_view* checkbox, and then click the Edit icon.

2. In the *Grid DNS Properties*, *Member DNS Properties,* or *DNS View* editor, click the **General** tab -> **Advanced** tab and complete the following.
    - **Enable RPZ query name recursion (qname-wait-recurse)**: This checkbox is deselected by default, meaning RPZ query name recursion is disabled. When RPZ query name recursion is disabled, the DNS recursive name server sends responses for the domains being queried, without forwarding queries to the authoritative name servers. When you select this checkbox, the DNS recursive name server performs recursive lookups for the fully qualified domain names that are part of an RPZ. To override the value inherited from the Grid, click **Override**. To retain the same value as the Grid, click **Inherit**.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Following are sample configuration details in the named.conf file when the **Enable RPZ query name recursion (qname-wait-recurse)** checkbox is deselected:

```
response-policy {
   zone "local.com" policy Given;# priority 0
   zone "rpz.net" policy Given;# priority 1
   zone "example.com" policy Given;# priority 2
     } qname-wait-recurse no ;
     dnssec-enable yes;
     dnssec-validation yes;
     dnssec-accept-expired no;
    filter-aaaa-on-v4 no;
     zone "." in {
         type hint;
         file "named.cache._default";
   };
```

Configuring Local RPZs

You can define local RPZs to match responses for recursive queries. Each RPZ can have various rules associated with it. The response of a recursive query is modified if it matches any of the RPZ rules. The responses are first matched with the RPZ rules, and if there is a match, the rule defined at the RPZ level override is used. When creating a new RPZ zone, you can associate this zone with a threat severity level. The RPZ syslog messages provide information about threat severity level of an RPZ zone associated with the matched RPZ rule. To view threat details, you can drill down to the syslog messages. For more information about viewing RPZ in the syslog, *Verifying RPZ Configuration*. You can create multiple local RPZs and define multiple rules for a local RPZ. Note that override depends on the order of the zones. The zones on top will override the zones below. You can change the order of the RPZs. For more information reordering RPZs, see *Managing RPZs*. You can also configure FireEye integrated RPZs on the NIOS appliance to detect persistent threats and malwares. The NIOS appliance considers the FireEye integrated RPZ as a local RPZ. For more information, see *About FireEye Integrated RPZs*.

> **Note**
>
> When using IDN (Internationalized Domain Name) in a local RPZ or RPZ feed, you must manually convert the IDN to punycode. For information about IDN, see *Support for Internationalized Domain Names*.

To configure local RPZs:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then click the *Add* icon.
2. When you click the *Add* icon, either the *Add Response Policy Zone Wizard* or the *Add DNS View* wizard is displayed based on the following:
    - When you click the *Add* icon, the *Add Response Policy Zone Wizard* is displayed if you have not created additional DNS views and only have the default view.
3. If you have configured multiple DNS views, you must drill-down to the corresponding view to assign a local RPZ. Click the *Add* icon and the *Add Response Policy Zone Wizard* is displayed. To create a new DNS view for your local RPZ, click the *Add* icon and complete the details in the *Add DNS View* wizard. For information about adding a DNS view, see *Adding a DNS View*.
    - In the *Add Response Policy Zone Wizard*, select **Add Local Response Policy Zone**, click **Next** and specify the following:
        - **Name:** Enter the name of the local RPZ. It can be a combination of alphanumeric characters. You can enter up to 256 characters.
        - **DNS View:** The name of the view that you have selected is displayed by default. You can select a view from the drop-down list to associate it with the local RPZ.

          Note that the local RPZ must have a primary Grid name server before you can configure it.
    - **Policy Override**: Select a value from the drop-down list. You can override the policy actions that are specified in the rule level.
        - **Log Only (Disabled)** – Select this if you want to disable an RPZ rewrite using rules in the RPZ. If the response to the recursive query matches any RPZ rule, then the rule is logged, but the response will not be altered. Note that this option will not override RPZ rules in other RPZ zones, if they take precedence. Select this option to preview the rules in the syslog before they take effect.
        - **None (Given)** – Select this if you want to use the policy from the rule level.
        - **Block (No Data)** – Select this to send a response that contains no data in it.
        - **Block (No Such Domain)** – Select this if you want the user to receive a DNS response that indicates there is no domain. All the policy actions in an RPZ are replaced with a NXDOMAIN block.
        - **Pass thru** – Select this if you want to send an actual response without modification. All the policy actions in an RPZ are replaced with the passthru action.
        - **Substitute (Domain Name)** – Select this if you want to replace all the policy actions in an RPZ with the specified substitution action.
        - **Domain Name**: This appears only when you select **Substitute (Domain Name)** from the **Policy Override** list. Enter the domain name that you want the client to receive instead of the actual domain name, which is malicious or unauthorized.
    - **Severity**: Select the threat severity level for the RPZ zone. The threat severity you select here determines the severity for the RPZ zone. Select Critical, Major, Warning, or Informational. The default threat severity level is Major. Note that each of these levels is represented by a number in the syslog (8 being Critical and 4 being Informational). When you upgrade to NIOS 7.0.0, the appliance automatically updates the threat severity level to Informational (displayed as 4 in the syslog) for existing RPZ zones. For information about viewing RPZ in the syslog RPZ and severity levels, see *Verifying RPZ Configuration*.
    - **Comment**: Optionally, enter additional information about the local RPZ.
    - **Disable:** Select the checkbox to disable a local RPZ without deleting its configuration. Clear the checkbox to enable the local RPZ. For information, see *Enabling and Disabling Zones*. Note that disabling a local RPZ may take a longer time to complete depending on the size of the data.
    - **Lock:** Select the checkbox to lock the zone so that you can make changes to it and prevent others from making conflicting changes. As described in locking and unlocking RPZs, see *Managing RPZs*.
4. Click **Next** to associate the local RPZ with at least one primary name server:
    - Define the name servers for the local RPZ. A Grid name server must be recursive when primary Grid name server is used as an RPZ source. A local RPZ may or may not have a recursive server. For

example, there could be a Grid that has only primary Grid name server for a local RPZ to act as an RPZ source for an external set of name servers. A local RPZ must have only one primary Grid name server and it can have one or more secondary Grid name servers. When you select **All Recursive Name Servers** from the list, all the recursivename servers in the Grid are added as secondary servers for the zone. For information on specifying primary or secondary name servers, see *Assigning Zone Authority to Name Servers*. For information on specifying name server groups, see *Using Name Server Groups*. For information about configuring RPZs for all recursive servers, see *Enabling Recursion for RPZs*.

5. Save the configuration and click **Next** to define extensible attributes. Click **Restart** if it appears at the top of the screen. For information, see *Managing Extensible Attributes*.

> ⚠ Note
>
> You cannot convert a local RPZ to an RPZ feed or vice versa.

Configuring Rules for RPZs

You can define different RPZ rules to block DNS resolution for malicious or unauthorized hostnames or redirect clients to a walled garden by substituting responses. Depending on the nature of the rule and its usage, each rule is designed to match a hostname, domain name, or IP address, specification or pattern, and an associated action.
These rules are applicable to local RPZs, including FireEye integrated RPZs, except for the RPZ client IP address or network rules which are not applicable for FireEye integrated RPZs. For RPZ feeds, rules are imported from external servers. You cannot change the content of an RPZ feed, but you can override the actions in an RPZ feed.
The RPZ rules are triggered based on the order of the RPZ zones that you have configured. When you configure one or more RPZ rules with the same FQDNs or IP addresses in different RPZ zones, then the RPZ rules in the top-level RPZ zone are triggered first.

This section includes the following topics:

- *Managing Passthru Rules*
- *Managing Block (No Such Domain) Rules*
- *Managing Block (No Data) Rules*
- *Managing Substitute (Domain Name) Rules*
- *Managing Substitute (Record) Rules*

To configure RPZ rules:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, click *DNS_View -> Zone* and then click **Add** -> select a **Rule**.
2. The rules are classified as follows:
   - **Passthru Rule**
   - **Block (No Such Domain) Rule**
   - **Block (No Data) Rule**
   - **Substitute (Domain Name) Rule**
   - **Substitute (Record) Rule**
3. Complete the details in the corresponding editor.
4. Save the configuration and click **Next** to define extensible attributes.

You cannot define the above rules for an RPZ feed. An RPZ feed uses rules defined by external servers. When you click on an RPZ feed, the appliance displays a dialog box that provides various options to export the rules of the configured external servers in .CSV format.

Managing Passthru Rules

You can define passthru rules if you do not want to modify the actual responses of the recursive queries. The response received for a query is not modified, if there is a matching passthru rule and the actual response is forwarded to the user.

Adding Passthru Rules for Domain Names

To define passthru rules for domains:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Rule** -> select **Passthru Rule** -> **Passthru Domain Name Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Rule** -> select **Passthru Rule** -> **Passthru Domain Name Rule**.
2. The following fields are displayed in the *Add a Passthru Domain Name Rule* wizard:
   - **Name**: Enter the domain name for which you want to define the passthru rule. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Policy**: Displays the selected policy.
   - **Comment**: Optionally, enter additional information.
   - **Disable**: Clear the checkbox to enable the passthru rule. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Adding Passthru Rules for IP Addresses or Networks

To define passthru rules for IP addresses or networks:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Rule** -> select **Passthru Rule** -> **Passthru IP Address Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Rule** -> select **Passthru Rule** -> **Passthru IP Address Rule**.
2. The following fields are displayed in the *Add a Passthru IP Address Rule* wizard:
   - **IP Address or Network**: Enter the IP address or specify the address in CIDR format for which you want to define the passthru rule. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Policy**: Displays the selected policy.
   - **Comment**: Optionally, enter additional information.
   - **Disable**: Clear the checkbox to enable the passthru rule. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Adding Passthru Rules for Client IP Addresses or Networks

You can define a passthru rule for a client IP address or network, if you do not want to modify the response to a query from a specific client IP address or network and forward the actual response to the client.
To define passthru rules for the client IP addresses or networks:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Rule** -> Select **Passthru Rule** -> **Passthru Client IP Address Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Rule** -> select **Passthru Rule** -> **Passthru Client IP Address Rule**.
2. The following fields are displayed in the *Add a Passthru Client IP Address Rule* wizard:
   - **Client IP Address or Network**: Enter the client IP address or specify the client address in CIDR format for which you want to define the passthru rule. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Policy**: Displays the selected policy.
   - **Comment**: Optionally, enter additional information.
   - **Disable**: Clear the checkbox to enable the passthru rule. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Managing Block (No Such Domain) Rules

You can define rules to block certain domain names, IP addresses or networks, or client IP addresses or networks. When you choose this option to block a domain name, the query name is matched with the RPZ rule. If the query name matches the RPZ rule, the DNS client receives a DNS response that indicates the domain does not exist.
When you block an IP address or network using this option, the A and AAAA records are matched with the RPZ rule. If the records match an RPZ rule, the DNS client receives a DNS response that indicates the domain does not exist.
When you choose this option to block a specific client IP address or network, the IP address or network of a client querying the DNS server is matched with the RPZ rule. If the IP address or the network of the client matches the RPZ rule, the DNS client receives a DNS response that indicates the domain does not exist.

Defining Block (No Such Domain) Rules for Domain Names

To define block rules for domains:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Block (No Such Domain) Rule** -> **Block Domain Name (No Such Domain) Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Block (No Such Domain) Rule** -> **Block Domain Name (No Such Domain) Rule**.
2. The following fields are displayed in the *Add a Block Domain Name (No Such Domain) Rule* wizard:
   - **Name**: Enter the domain name which you want to be blocked from being resolved by the DNS. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Policy**: Displays the selected policy.
   - **Comment**: Optionally, enter additional information.
   - **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Defining Block (No Such Domain) Rules for IP Addresses or Networks

To define block rules for IP addresses or networks:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Block (No Such Domain) Rule** -> **Block IP Address (No Such Domain) Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Block (No Such Domain) Rule** -> **Block IP Address (No Such Domain) Rule**.
2. The following fields are displayed in the *Add a Block IP Address (No Such Domain) Rule* wizard:
   - **IP Address or Network**: Enter the IP address or specify the address in CIDR format which you want to block. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Policy**: Displays the selected policy.
   - **Comment**: Optionally, enter additional information.
   - **Disable**: Clear the checkbox to enable the block rule. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.\
4. Save the configuration.

Defining Block (No Such Domain) Rules for Client IP Addresses or Networks

To define block rules for client IP addresses or networks:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Block (No Such Domain) Rule** -> **Block Client IP Address (No Such Domain) Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone.

Expand the Toolbar, click **Add** -> select **Block (No Such Domain) Rule** -> **Block Client IP Address (No Such Domain) Rule**.

2. The following fields are displayed in the *Add a Block Client IP Address (No Such Domain) Rule* wizard:
    - **Client IP Address or Network**: Enter the client IP address or specify the client address in CIDR format which you want to block. Click **Select Zone** to select a different zone.
    - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
    - **Policy**: Displays the selected policy.
    - **Comment**: Optionally, enter additional information.
    - **Disable**: Clear the checkbox to enable the block rule. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Managing Block (No Data) Rules

You can define rules to block certain domain names, IP addresses or networks, or client IP addresses or networks. When you choose this option to block a domain name, the query name is matched with the RPZ rule. If the query name matches the RPZ rule, the DNS client receives a DNS response that indicates there is no data for the requested record type.
When you block an IP address or network using this option, the A and AAAA records are matched with the RPZ rules. If the records match an RPZ rule, the DNS client receives a DNS response that indicates there is no data for the requested record type.
When you choose this option to block a specific client IP address or network, the IP address or network of a client querying the DNS server is matched with the RPZ rule. If the IP address or the network of the client matches the RPZ rule, the DNS client receives a DNS response that indicates there is no data for the requested record type.

Defining Block (No Data) Rules for Domain Names

To define block rules for domains:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Block (No Data) Rule** -> **Block Domain Name (No Data) Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Block (No Data) Rule** -> **Block Domain Name (No Data) Rule**.
2. The following fields are displayed in the *Add a Block Domain Name (No Data) Rule* wizard:
    - **Name**: Enter the domain name which you want to block. Click **Select Zone** to select a different zone.
    - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
    - **Policy**: Displays the selected policy.
    - **Comment**: Optionally, enter additional information.
    - **Disable**: Clear the checkbox to enable the block rule. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Defining Block (No Data) Rules for IP Addresses or Networks

To define block rules for IP addresses or networks:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Block (No Data) Rule** -> **Block IP address (No Data) Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Block (No Data) Rule** -> **Block IP address (No Data) Rule**.
2. The following fields are displayed in the *Add a Block IP Address (No Data) Rule* wizard:
    - **IP Address or Network**: Enter the IP address or specify the address in CIDR format which you want to block. Click **Select Zone** to select a different zone.
    - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
    - **Policy**: Displays the selected policy.
    - **Comment**: Optionally, enter additional information.

- **Disable**: Clear the checkbox to enable the block rule. Select the checkbox to disable it.

3. Click **Next** to define extensible attributes.
4. Save the configuration.

Defining Block (No Data) Rules for Client IP Addresses or Networks

To define block rules for client IP addresses or networks:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Block (No Data) Rule** -> **Block Client IP address (No Data) Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Block (No Data) Rule** -> **Block Client IP address (No Data) Rule**.
2. The following fields are displayed in the *Add a Block Client IP Address (No Data) Rule* wizard:
   - **Client IP Address or Network**: Enter the client IP address or specify the client address in CIDR format which you want to block. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Policy**: Displays the selected policy.
   - **Comment**: Optionally, enter additional information.
   - **Disable**: Clear the checkbox to enable the block rule. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Managing Substitute (Domain Name) Rules

You can define an alternate IP address or a domain name to redirect a domain name or an IP address, which is malicious or unauthorized. When the response to the client query matches an RPZ rule, the actual domain name or IP address is substituted with the alternative domain name or IP address. The client will receive the substituted value instead of the actual response.

> **Note**
>
> The domain name and substitute name for which you want to define a substitute rule are not case-sensitive. For example, if a domain name is "*corpxyz.com*" and you want to substitute it with "*corpxyz.com*" or "*corpxyz.com*," the substitute rule you define becomes a passthru rule because no substitution will occur since "*corpxyz.com*" is the same as "*corpxyz.com*" and "*corpxyz.com*." Grid Manager displays such substitute rule as a passthru rule.

Defining Substitute Domain Name (Based on Domain Name) Rules

To define substitutes for domain names:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Domain Name) Rule** -> **Substitute Domain Name (Domain Name) Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Domain Name) Rule** -> **Substitute Domain Name (Domain Name) Rule**.
2. The following fields are displayed in the *Add a Substitute (Domain Name) Rule* wizard:
   - **Name:** Enter the domain name for which you want to define a substitute. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Policy**: Displays the selected policy.
   - **Substituted Name:** Enter an alternative domain name that has to be substituted with the actual domain name. Click **Select Zone** to select a different zone.
   - **Comment**: Optionally, enter additional information.
   - **Disable**: Clear the checkbox to enable the substitute rule. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.

4. Save the configuration.

Defining Substitute Domain Name (Based on IP address) Rules

To define substitutes for IP addresses:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Domain Name) Rule** -> **Substitute Domain Name (IP Address) Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Domain Name) Rule** -> **Substitute Domain Name (IP Address) Rule**.
2. The following fields are displayed in the *Add a Substitute Domain Name (IP Address) Rule* wizard:
   - **IP address or Network:** Enter the IP address or network for which you want to define a substitute. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Policy**: Displays the selected policy.
   - **Substituted Name:** Enter an alternative domain name or IP address that has to be substituted with the actual IP address. Click **Select Zone** to select a different zone.
   - **Comment**: Optionally, enter additional information.
   - **Disable**: Clear the checkbox to enable the substitute rule. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Defining Substitute Domain Name (Based on Client IP address) Rules

You can define a substitute domain name rule for a client IP address if you want to substitute the actual response to a query from the DNS client with an alternate domain name or IP address. When the IP address of the client querying a DNS server matches the RPZ rule, the actual response is substituted with the alternative domain name or IP address specified in the RPZ rule.
To define substitute domain name rule for client IP addresses:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Domain Name) Rule** -> **Substitute Domain Name (Client IP Address) Rule**.
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Domain Name) Rule** -> **Substitute Domain Name (Client IP Address) Rule**.
2. The following fields are displayed in the *Add a Substitute Domain Name (Client IP Address) Rule* wizard:
   - **Client IP address or Network:** Enter the client IP address or client network for which you want to define a substitute domain name (client IP address) rule. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Policy**: Displays the selected policy.
   - **Substituted Name:** Enter an alternative domain name or IP address that replaces the actual DNS response. Click **Select Zone** to select a different zone.
   - **Comment**: Optionally, enter additional information.
   - **Disable**: Clear the checkbox to enable the substitute rule. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Managing Substitute (Record) Rules

You can define a substitute record for a domain name, which is considered malicious. You can define substitutes for the following in a zone:

- **A records:** For information about defining substitutes for A records, see the following section Defining Substitutes Rules for A Records.

- **AAAA records:** For information about defining substitutes for AAAA records, see Defining Substitute Rules for AAAA Records below.
- **MX records:** For information about defining substitutes for MX records, see Defining Substitute Rules for MX Records below.
- **NAPTR records:** For information about defining substitutes for NAPTR records, see Defining Substitute Rules for NAPTR Records below.
- **PTR records:** For information about defining substitutes for PTR records, see Defining Substitute Rules for PTR Records below.
- **SRV records:** For information about defining substitutes for SRV records, see Defining Substitute Rules for SRV Records below.
- **TXT records:** For information about defining substitutes for TXT records, see Defining Substitute Rules for TXT Records below.
- **IPv4 address:** For information about defining substitutes for IPv4 addresses, see Defining Substitute Rules for IPv4 Addresses or Networks below.
- **IPv6 address:** For information about defining substitutes for IPv6 addresses, see Defining Substitute Rules for IPv6 Addresses or Networks below.

You can define a substitute for a certain owner name and record type. When you substitute a record for a certain owner name and record type, then responses to queries for that owner name and type are modified to contain the substituted value(s).

Defining Substitutes Rules for A Records

An RPZ A (address) record maps a domain name to a substitute IPv4 address. To define a specific name-to-address mapping, add an A record to a previously defined RPZ.
To define substitute rules for A records:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Record) Rule** -> **Substitute (A Record) Rule.**
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Record) Rule** -> **Substitute (A Record) Rule**.
2. The following fields are displayed in the *Add a Substitute (A Record) Rule* wizard:
   - **Name:** Enter the domain name that you want to map to an IP address. The name that you specify, irrespective of the RPZ name, is used to determine a match for the RPZ rule. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **IP Address:** Enter the IPv4 address to which you want the domain name to map.
   - **Comment**: Optionally, enter additional information about the A record.
   - **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Defining Substitute Rules for AAAA Records

An RPZ AAAA (address) record maps a domain name to a substitute IPv6 address. To define a specific name-to-address mapping, add an RPZ AAAA record to a previously defined RPZ.
To define substitute rules for AAAA records:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Record) Rule** -> **Substitute (AAAA Record) Rule.**
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Record) Rule** -> **Substitute (AAAA Record) Rule**.
2. The following fields are displayed in the *Add a Substitute (AAAA Record) Rule* wizard:
   - **Name:** Enter the domain name that you want to map to an IP address. The name that you specify, irrespective of the RPZ name, is used to determine a match with the RPZ rule. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.

- **IP Address:** Enter the IPv6 address to which you want the domain name to map.
- **Comment**: Optionally, enter additional information about the AAAA record.
- **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.

3. Click **Next** to define extensible attributes.
4. Save the configuration.

Defining Substitute Rules for MX Records

An RPZ MX (mail exchanger) record maps a domain name to a mail exchanger. A mail exchanger is a server that either delivers or forwards mail. A wildcard MX record applies to an RPZ and all its subdomains of the owner name.
To define substitute rules for MX records:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Record) Rule** -> **Substitute (MX Record) Rule.**
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Record) Rule** -> **Substitute (MX Record) Rule**.
2. The following fields are displayed in the *Add a Substitute (MX Record) Rule* wizard:
   - **Mail Destination**: Enter the owner name of the MX record you want to substitute.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Host Name Policy:** Displays the hostname policy of the selected zone. Ensure that the hostname you enter complies with the hostname restriction policy defined for the zone.
   - **Mail Exchanger:** Enter the fully qualified domain name of the mail exchanger.
   - **Preference:** Select an integer from 10 to 100. The preference determines the order in which a client attempts to contact the target mail exchanger.
   - **Comment**: Optionally, enter additional information about the MX record.
   - **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Defining Substitute Rules for NAPTR Records

A DNS NAPTR object represents a Naming Authority Pointer (NAPTR) resource record. This resource record specifies a regular expression-based rewrite rule that, when applied to an existing string, produces a new RPZ name or URI.
To define substitute rules for NAPTR records:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Record) Rule** -> **Substitute (NAPTR Record) Rule.**
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Record) Rule** -> **Substitute (NAPTR Record) Rule**.
2. The following fields are displayed in the *Add a Substitute (NAPTR Record) Rule* wizard:
   - **Domain:** Enter the domain name to which this resource record refers. Make sure that you enter a valid FQDN. Example: test.com, foo.com, etc. The name that you specify, irrespective of the RPZ name, is used to determine a match with the RPZ rule. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Service:** Select a service from the drop-down list. This field specifies the service and protocol that are used to communicate with the host at the domain name.
   - **Flags:** The Flag field indicates whether the current lookup is terminal; that is, the current NAPTR record is the last NAPTR record for the lookup. It also provides information about the next step in the lookup process. The flags that are currently used are:
     - **U**: Indicates that the output maps to a URI (Uniform Record Identifier).
     - **S:** Indicates that the output is a domain name that has at least one SRV record. The DNS client must then send a query for the SRV record of the resulting domain name.
     - **A:** Indicates that the output is a domain name that has at least one A or AAAA record. The DNS client must then send a query for the A or AAAA record of the resulting domain name.
     - **P:** Indicates that the protocol specified in the Service field defines the next step or phase.
   - **Order:** Select an Integer from 10 to 100, or enter a value from 0 to 65535. This value indicates the order in which the NAPTR records must be processed. It processes the record with the lowest value first.

- **Preference:** Select an Integer from 10 to 100, or enter a value from 0 to 65535. Similar to the Preference field in MX records, this value indicates which NAPTR record the DNS client should process first when the records have the same Order values. It processes the record with the lowest value first.
- **REGEX**: The regular expression that is used to rewrite the original string from the client into a domain name. RFC 2915 specifies the syntax of the regular expression. Note that the appliance validates the regular expression syntax between the first and second delimiter against the Python re module, which is not 100% compatible with POSIX Extended Regular Expression as specified in the RFC. For information about the Python re module, refer to *http://docs.python.org/release/2.5.1/lib/module-re.html.*
- **Replacement:** This specifies the domain name for the next lookup. The default is a dot (.), which indicates that the regular expression in the REGEX field provides the replacement value. Alternatively, you can enter the replacement value in FQDN format.
- **Comment**: Optionally, enter additional information about the NAPTR record.
- **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.

3. Click **Next** to define extensible attributes.
4. Save the configuration.

Defining Substitute Rules for PTR Records

In a forward-mapping zone, a PTR (pointer) record maps a domain name to another domain name. In an RPZ, a PTR (pointer) record maps an address to a domain name. To define a specific address-to-name mapping, add an RPZ PTR record to a previously defined RPZ.
To define substitute rules for PTR records:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Record) Rule** -> **Substitute (PTR Record) Rule.**
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Record) Rule** -> **Substitute (PTR Record) Rule**.
2. The following fields are displayed in the *Add a Substitute (PTR Record) Rule* wizard: You can select either **Name** or **IP address** from the drop-down list.
   - **Name:** Enter a domain name for which you want to create a pointer to another domain. The name that you specify, irrespective of the RPZ name, is used to determine a match with the RPZ rule. Click **Select Zone** to select a different zone. The name should be in the following format for RPZ:

     ipaddress.in-addr.arpa.

     Note that the IP address should be in the reverse format. For example, if the IP address is 10.2.1.4, then the name format for RPZ is 4.1.2.10.in-addr.arpa. The following fields are displayed when you select **Name** from the drop-down list:
     - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
     - **Domain Name:** Enter the domain name to which you want the PTR record to point. Make sure that you enter a valid FQDN. Example: test.com, foo.com, etc.
   - **IP Address:** Enter an IP address for which you want to create a pointer to a domain. The following fields are displayed when you select **IP Address** from the drop-down list:
     - **Zone:** Displays the RPZ you have selected. Click **Select Zone** to select a different zone.
     - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
     - **Domain Name:** Enter the domain name to which you want the PTR record to point. Make sure that you enter a valid FQDN. Example: test.com, foo.com, etc.
   - **Comment**: Optionally, enter additional information about the PTR record.
   - **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Defining Substitute Rules for SRV Records

A DNS RPZ SRV object represents an SRV resource record, which is also known as a service record. You can define a substitute for an SRV record. When the response to a user's query matches with an RPZ rule, then the combination of actual service, protocol, domain name and the zone is substituted with a combination of priority, weight, port and target

details that you specify.
To define substitute rules for SRV records:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Record) Rule** -> **Substitute (SRV Record) Rule.**
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Record) Rule** -> **Substitute (SRV Record) Rule**.
2. The following fields are displayed in the *Add a Substitute (SRV Record) Rule* wizard:
   - **Display input as:** Select the format in which you want the SRV record to be displayed. When you select RFC 2782 format, the appliance follows the *_service._protocol.name* format as defined in RFC 2782. When you select Free format, enter the entire name in the Domain field.
   - **Service**: Specify the service that the host provides. You can either select a service from the list or type in a service, if it is not on the list. For example, if you are creating a record for a host that provides FTP service, select _ftp. To distinguish the service name labels from the domain name, the service name is prefixed with an underscore. If the name of the service is defined in RFC 1700, Assigned Numbers, use that name. Otherwise, you can use a locally-defined name. This field is disabled when you select **Free Format** as the display input.
   - **Protocol**: Specify the protocol that the host uses. You can either select a protocol from the list or type in a protocol, if it is not on the list. For example, if it uses TCP, select _tcp. To distinguish the protocol name labels from the domain name, the protocol name is prefixed with an underscore. This field is disabled when you select **Free Format** as the display input.
   - **Domain:** If Grid Manager displays a zone name, enter the name here to define an SRV record for a host or subdomain. The displayed zone name can either be the last selected zone or the zone from which you are adding the SRV record. If no zone name is displayed or if you want to specify a different zone, click **Select Zone**. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box. Click a zone name in the dialog box, and then enter the name to define the SRV record. The SRV record name is used to determine the substitute.
   - **Preview**: After you enter all the information, this field displays the FQDN.
   - **DNSView:** Displays the DNS view to which the selected RPZ belongs.
   - **Priority**: Select or enter an integer from 0 to 65535. The priority determines the order in which a client attempts to contact the target host; the domain name host with the lowest number has the highest priority and is queried first. Target hosts with the same priority are attempted in the order defined in the **Weight** field.
   - **Weight**: Select or enter an integer from 0 to 65535. The weight allows you to distribute the load between target hosts. The higher the number, the more that host handles the load (compared to other target hosts). Larger weights give a target host a proportionately higher probability of being selected.
   - **Port**: Specify the appropriate port number for the service running on the target host. You can use standard or nonstandard port numbers, depending on the requirements of your network. You can select a port number from the list or enter an integer from 0 to 65535.
   - **Target**: Enter the canonical domain name of the host (not an alias); for example, www2.corpxyz.com.
   - **Comment**: Optionally, enter additional information about the SRV record.
   - **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.
4. Save the configuration.

Defining Substitute Rules for TXT Records

A TXT (text) record contains supplemental information for a host. SPF (Sender Policy Framework) records are specialized RPZ TXT records that identify the servers that send mail from a domain.
To define substitute rules for TXT records:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Record) Rule** -> **Substitute (TXT Record) Rule.**
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Record) Rule** -> **Substitute (TXT Record) Rule**.
2. The following fields are displayed in the *Add a Substitute (TXT Record) Rule* wizard:

- **Name**: Enter the name to define a TXT record for a host or subdomain. The name that you specify, irrespective of the RPZ name, is used to determine a match with the RPZ rule. Click **Select Zone** to select a different zone.
- **DNS View:** Displays the DNS view to which the selected RPZ belongs.
- **Text**: Enter the text that you want to associate with the record. It can contain substrings of up to 255 bytes, up to a total of 512 bytes. Additionally, if you enter leading, trailing, or embedded spaces in the text, add quotes around the text to preserve the spaces. For example: " v=spf1 include:corp200.com -all ".
- **Comment**: Optionally, enter additional information about the TXT record.
- **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.

3. Click **Next** to define extensible attributes.
4. Save the configuration.

Defining Substitute Rules for IPv4 Addresses or Networks

You can define a substitute for an IPv4 address or a network address. When a client queries for A records of a domain name, if the IP address in A records in the response match the specified address or network, then the response is modified to instead contain the substituted address.
To define substitute rules for IPv4 addresses or networks:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Record) Rule** -> **Substitute (IPv4 Address) Rule.**
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Record) Rule** -> **Substitute (IPv4 Address) Rule**.
2. The following fields are displayed in the *Add a Substitute (IPv4 Address) Rule* wizard:
   - **IP Address or Network**: Enter the IPv4 address which you want to substitute with another IPv4 address. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Policy**: Displays the selected policy.
   - **Substituted IP Address:** Enter the IPv4 address that must be returned to the user when the response matches the A records.
   - **Comment**: Optionally, enter additional information about the IPv4 address.
   - **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.
3. Click **Next** to define extensible attributes.4. Save the configuration.

> ⚠ You cannot define a substitute rule for the same IP address or a network address for which you have already defined a passthru rule.

Defining Substitute Rules for IPv6 Addresses or Networks

You can restrict access to specific IPv6 addresses or networks by providing a substitute IP address. When a client queries for AAAA records of a domain name if the IP addresses in AAAA records in the response match the specified address or network, then the response is modified to instead contain the substituted address.
To define substitute rules for IPv6 addresses or networks:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select *DNS_View -> Zone,* and then click **Add** -> select **Substitute (Record) Rule** -> **Substitute (IPv6 Address) Rule.**
   or
   From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then select a zone. Expand the Toolbar, click **Add** -> select **Substitute (Record) Rule** -> **Substitute (IPv6 Address) Rule**.
2. The following fields are displayed in the *Add a Substitute (IPv6 Address) Rule* wizard:
   - **IP Address or Network**: Enter the IPv6 address or the network address which you want to substitute with another IP address. Click **Select Zone** to select a different zone.
   - **DNS View:** Displays the DNS view to which the selected RPZ belongs.
   - **Policy**: Displays the selected policy.

- **Substituted IP Address**: Enter the IPv6 address that must be returned to the user when the response matches the AAAA records.
- **Comment**: Optionally, enter additional information about the IPv6 address.
- **Disable**: Clear the checkbox to enable the record. Select the checkbox to disable it.

3. Click **Next** to define extensible attributes.
4. Save the configuration.

Configuring Infoblox Threat Intelligence Feed

Starting with NIOS 7.3.200, Infoblox introduces the Infoblox Threat Intelligence Feed, a threat feed subscription for RPZ updates that offer protection against malicious hostnames. Contact your Infoblox representative for pricing and availability information.
When you upgrade from a previous NIOS release to NIOS 7.3.200 and later releases, the Infoblox RPZ feeds you configured in the previous NIOS release are migrated to the upgraded release. For information about the old RPZ feeds, refer to the NIOS 7.3.4 and earlier *NIOS Administrator Guides*.
You can configure the Threat Intelligence Feed and receive reputation RPZ updates on a regular basis. An RPZ feed receives response policies from the Infoblox in-house threat intelligence team, which produces reputation RPZ data and transfers the data to Grid name servers through zone transfers with or without a TSIG key. To ensure proper authentication and integrity of the RPZ feed zone transfers, using a TSIG key is recommended.

> **Note**
>
> TSIG Key is used for authentication when downloading information about threat protection feeds. If you have a complex configuration, such as using standalone appliances or Grids that receive threat protection feeds from other standalone appliances or Grids and not directly from the Infoblox distribution servers, ensure that you use the same TSIG key for the RPZ feed zone transfers.

Note that the RPZ feed must have an external primary name server before you can configure it. To propagate RPZs as quickly as possible, the secondary DNS server needs an address to which the RPZ source feed can send NOTIFY messages. For example, if the secondary DNS server is configured behind a NAT, you may want to establish a one-to-one NAT for the lead secondary DNS server so it can receive NOTIFY messages from the RPZ source feed. Otherwise, the lead secondary DNS server will need to periodically poll the RPZ source feed, which could take longer than expected.

> **Note**
>
> To enter IDNs (Internationalized Domain Name) in an RPZ feed, you can use the punycode representation of the IDN.

To configure the Threat Intelligence Feed:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then click the *Add* icon.
2. When you click the *Add* icon, either the *Add Response Policy Zone Wizard* or the *Add DNS View* wizard is displayed based on the following:
   - When you click the *Add* icon, the *Add Response Policy Zone Wizard* is displayed, if you have not created additional *DNS views* and only have the *default view.*
   - If you have configured multiple DNS views, you must drill-down to the corresponding *DNS_View* to assign an RPZ feed. Click the *Add* icon and the *Add Response Policy Zone Wizard* is displayed. To create a new DNS view for your RPZ feed, click the *Add* icon and complete the details in the *Add DNS View* wizard. For information about adding and modifying a DNS View, see *Configuration Example: Configuring a DNS View.*
3. In the *Add Response Policy Zone Wizard*, select **Add Response Policy Zone Feed**, click **Next** and specify the following:
   - **Name:** Enter the name of the Infoblox RPZ feed. It can be a combination of alphanumeric characters. You can enter up to 256 characters. For more information, see Infoblox Threat Intelligence Feeds below.
   - **DNS View:** The name of the view that you have selected is displayed by default. You can select a view from the drop-down list to associate it with the RPZ feed.

- **Policy Override:** Select a value from the drop-down list. You can override the policy actions that are specified in the rule level.
- **Log Only (Disabled)** – Select this if you want to disable an RPZ rewrite using rules in the RPZ zone. If the response to the recursive query matches any RPZ rule, the rule is logged, but the response will not be altered. You cannot overwrite the response to the user. Note that this option will not override RPZ rules in other RPZ zones, if they take precedence.

  Note that when you select the **Log Only** option, the RPZ related reports are not updated even though the information is logged to the syslog.

  - **None (Given)** – Select this if you want to use the policy from the rule level.
  - **Block (No Data)** – Select this if you want the user to receive a response that indicates that there is no data.
  - **Block (No Such Domain)** – Select this if you want the user to receive a NXDOMAIN as the DNS response. All the policy actions in an RPZ are replaced with a NXDOMAIN block.
  - **Passthru** – Select this if you want the user to see the actual response without modification. All the policy actions in an RPZ are replaced with the passthru action.
  - **Substitute (Domain Name)** – Select this if you want to replace all the policy actions in an RPZ with the substitution action that is specified.
    - **Domain Name**: This appears only when you select **Substitute (Domain Name)** from the **Policy Override** list. Enter the domain name that you want the client to receive instead of the actual domain name, which is malicious or unauthorized.
- **Severity**: Select the threat severity level for the RPZ zone. The threat severity you select here determines the severity for the RPZ rule. Select **Critical**, **Major**, **Warning**, or **Informational**. The default threat severity level is Major. Note that each of these levels is represented by a number in the syslog (8 being Critical and 4 being Informational). When you upgrade to NIOS 7.0.0, the appliance automatically updates the threat severity level to Informational (displayed as 4 in the syslog) for existing RPZ zones. For information about viewing RPZ in the syslog
  and severity levels, see *Verifying RPZ Configuration*.
- **Comment**: Optionally, enter additional information about the Infoblox RPZ feed.
- **Disable:** Select the checkbox to disable the RPZ feed without deleting its configuration. Clear the checkbox to enable the RPZ feed. For information, see *Enabling and Disabling Zones*. Note that disabling an RPZ feed may take a longer time to complete depending on the size of the data.
- **Lock:** Select the checkbox to lock the RPZ feed so that you can make changes to it and prevent others from making conflicting changes. For information about Locking and Unlocking RPZ*s*, see *Managing RPZs*.

4. Click **Next** to associate the RPZ feed with at least one external primary name server and a secondary name server:
   - Define name servers for the RPZ feed. An RPZ feed must have at least one RPZ source as an external primary name server and at least one Grid secondary name server. For external primary servers, specify the following:
     - **Name:** Enter the zone name of the primary name server.
     - **Address**: Enter the name server IP address provided by Infoblox for the RPZ feed.
     - **Use TSIG:** Select the checkbox to specify TSIG settings.
     - **Key Name:** Enter the TSIG Key Name provided by Infoblox.
     - **Key Algorithm:** Select **hmac-md5**.
     - **Key Data:** Enter the TSIG string provided by Infoblox.
       Note that either the Grid name server or the DNS view must be recursive for the RPZ feed. You can associate a lead secondary with an RPZ feed. For information on specifying primary and secondary, see *Assigning Zone Authority to Name Servers*. When you select **All Recursive Name Servers** from the list, all the recursive name servers in the Grid are added as secondary servers for the zone. For information about how to configure a local RPZ, or RPZ feed, or FireEye RPZ for all recursive servers, see *Configuring RPZs for All Recursive Servers*. For information on specifying name server groups, see *Using Name Server Groups*.
5. Save the configuration and click **Next** to define extensible attributes. Click **Restart** if it appears at the top of the screen. For information, see *Managing Extensible Attributes*.

Infoblox Threat Intelligence Feeds

Infoblox RPZ feeds are categorized into pure malicious feeds and combination feeds. All the feeds listed below are set to return NXDOMAIN for items in the feed. Threat data changes are pushed every 20 minutes from the DNS servers and significant changes are typically made every two hours.
The following table list the Infoblox Threat Intelligence feeds:

Pure Malicious Feeds

Name	Description
Base (base.rpz.infoblox.local)	Enables protection against known hostnames that are dangerous as destinations, such as APT, Bot, Compromised Host/Domains, Exploit Kits, Malicious Name Servers, and Sinkholes along with bogon IP addresses.
AntiMalware (antimalware.rpz.infoblox.local)	Enables protection against known malicious threats that can take action on or control of your system, such as Malware Command & Control, Malware Download, and active Phishing sites.
Ransomware (ransomware.rpz.infoblox.local)	Enables protection against ransomeware that restricts access to the computer system that it infects, and demands a ransom paid to the creator of the malware in order for the restriction to be removed. Some forms of ransomware encrypt files on the system's hard drive, while some may simply lock the system and display messages intended to coax the user into paying. Examples include Locky, CryptoLocker, Dircrypt, and CryptoWall.
Bogon (bogon.rpz.infoblox.local)	Enables protection against bogons, which are commonly found as the source addresses of DDoS attacks. A bogon is an informal name for an IP packet on the public Internet that claims to be from an area of the IP address space reserved, but not yet allocated or delegated by the Internet Assigned Numbers Authority (IANA) or a delegated Regional Internet Registry (RIR). The areas of unallocated address space are called bogon space. Many ISPs and end-user firewalls filter and block bogons, because they have no legitimate use, and usually are the result of accidental or malicious misconfiguration.
AntiMalware_IP (antimalware-ip.rpz.infoblox.local)	Enables protection against known malicious or compromised IP addresses. These are known to host threats that can take action on or control of your system, such as Malware Command & Control, Malware Download, and active Phishing sites.
Bot_IP (bot-ip.rpz.infoblox.local)	Enables protection against self-propagating malware designed to infect a host and connect back to a central server or servers that act as a command and control (C&C) center for an entire network of compromised devices, or "botnet." With a botnet, attackers can launch broad-based, "remote-control," flood-type attacks against their target(s). Bots can also log keystrokes, gather passwords, capture and analyze packets, gather financial information, launch DoS attacks, relay spam, and open back doors on the infected host.
ExploitKit_IP (exploitkit-ip.rpz.infoblox.local)	Enables protection against distributable packs that contains malicious programs that are used to execute "drive-by download" attacks in order to infect users with malware. These exploit kits target vulnerabilities in the users' machines (usually due to unpatched versions of Java, Adobe Reader, Adobe Flash, Internet Explorer, …) to load malware onto the victim's computer.
Malware_DGA (malware-dga.rpz.infoblox.local)	Domain generation algorithm (DGA) are algorithms seen in various families of malware that are used to periodically generate a large number of domain names that can be used as rendezvous points with their command and control servers. Examples include Ramnit, Conficker, and Banjori.

Name	Description
TOR_Exit_Node_IP (tor-exit-node-ip.rpz.infoblox.local)	Tor Exit Nodes are the gateways where encrypted Tor traffic hits the Internet. This means an exit node can be used to monitor Tor traffic (after it leaves the onion network). It is in the design of the Tor network that locating the source of that traffic through the network should be difficult to determine
SURBL_Multi (multi-domain.surbl.rpz.infoblox.loc al)	Blacklist of Malicious Domains including up-to-date intel on active malware, phishing, botnet, and spam domains. Based on data provided by our partner SURBL.
SURBL_Fresh (fresh-domain.surbl.rpz.infoblox.loca l)	Newly Observed Domains. SURBL Fresh feed provides critical, accurate, information on the time new domains are placed into service. Security policy can be easily applied (block, quarantine, walled garden, etc.) to prevent resolution of new domains, based on the user's defined policies. Based on data provided by our partner SURBL.

Downloading Rules for an RPZ Feed

You can perform a zone transfer to transfer the rules from an external primary name server to the RPZ feed. You cannot modify these rules, but you can override the entire ruleset or an individual rule. However, if you import a zone to a local zone, you can edit the rules within a local zone. The feed zone supports NSIP and NSDNAME rules; however local RPZs do not support these rules. To download rules from an external primary name server:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then click the corresponding *RPZ Feed*.
2. In the **Export** dialog box, complete the following:
    - **Separator**: Select the separator used in the data file. The default value is **Comma**.
    - Click **Export**.

All the rules are transferred. You can download rules only if the lead secondary has completed at least one zone transfer from the external primary. You can either open the data file or save it to your computer. The rules are displayed for the selected RPZ feed in the *Rule* wizard.
After you have downloaded rules from an RPZ feed, you can test RPZ feed policies, as described in *Testing RPZ Feed Rules*.

Testing RPZ Feed Rules

After you have downloaded rules from an RPZ feed, you can test the downloaded policies by using the dig command and observing log messages that contain redirect or rewrite responses in the syslog. The NIOS appliance supports generation of RPZ log messages in CEF (Common Event Format). Note that non-RPZ messages cannot be generated in CEF.
You must enable the **rpz** option in the **Logging Category** of the *Grid DNS Properties* editor to receive RPZ related messages in the syslog. For information about setting DNS logging categories, see *Using a Syslog Server*.
To view RPZ log messages in the syslog, you can use the system filter **RPZ Logs** from the **Quick Filter** to filter the messages. Note that only messages in CEF are displayed.
To view RPZ log messages:

1. From the **Administration** tab, select the **Logs** tab -> **Syslog** tab.
2. From the drop-down list at the upper right corner, select the Grid member on which you want to view the syslog.
3. Click **Show Filters** to enable the filters. Select **RPZ Logs** from the **Quick Filter** drop-down list to narrow down the system messages you want to view.

The name server recursive cache makes a syslog entry when an RPZ functionality fails. The syslog message log format is as follows:

```
rpz <TYPE> rewrite <QUERY> via <RPZ_RECORD><ERROR_MESSAGE>
```

where: `<TYPE>` is one of following RPZ action types: QNAME, IP, NSIP, NSDNAME, CLIENT-IP;
`<QUERY>` is a query record to process;
`<RPZ_RECORD>` is an RPZ record that is used to perform an action to the query;
`<ERROR_MESSAGE>` is a message with error details. Example: `NS address rewrite rrset failed:, concatentate() failed:, NS db_find() failed:, stop on qresult in rpz_rewrite() failed:, stop on unrecognized qresult in rpz_rewrite() failed:,` etc.

To test RPZ feed policies:

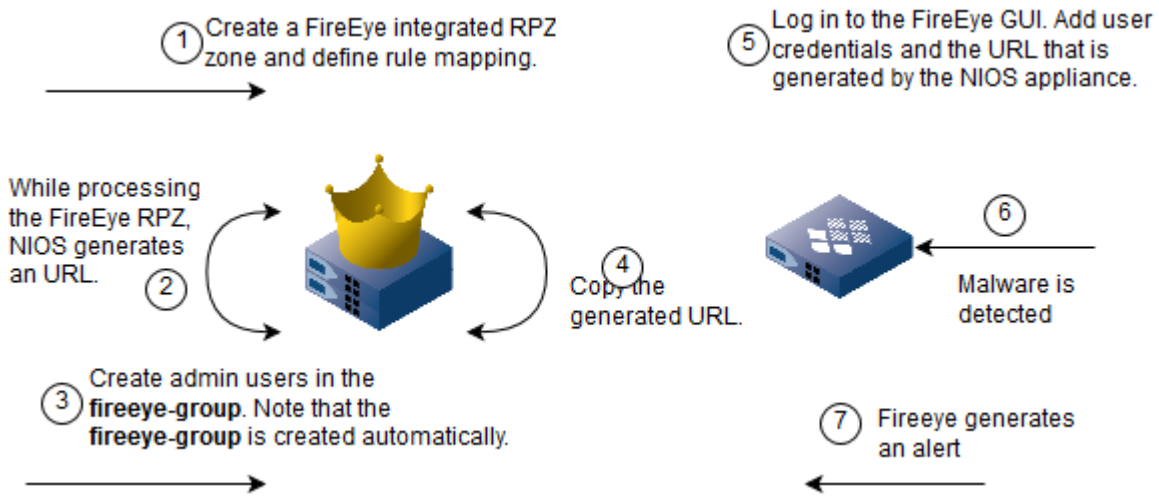
1. Open a terminal console on your computer.
2. Type the command **dig @*<your DNS server IP>* *<queried domain>***.
3. Go to the **Administration** tab -> **Logs** tab -> **Syslog** tab to view CEF log messages.

About FireEye Integrated RPZs

Infoblox DNS Firewall provides a mechanism to further protect your network from malware and APTs (Advanced Persistent Threats) through the integration of FireEye appliances. When your NIOS appliance is properly integrated with a FireEye appliance, it receives periodic alerts and APTs from the FireEye appliance when it identifies such threats. Based on your configuration, the NIOS appliance translates these alerts into RPZ rules that not only further protect your network from malicious attacks, but also aid in identifying clients that have been compromised.

As illustrated in the below figure, after installing the required RPZ and Security Ecosystem licenses on the NIOS appliance, you can configure a FireEye integrated RPZ in which you map RPZ rules to FireEye alert types. While creating the FireEye RPZ, the appliance generates a URL to which the FireEye appliance sends alerts. Ensure that you enter this URL when configuring the FireEye appliance. The NIOS appliance also creates the **fireeye-group** admin group after you define the first FireEye RPZ. You can add multiple admin users to this admin group. Note that users in the **fireeye-group** can only send alerts to the NIOS appliance; they cannot access the Infoblox GUI, CLI, API and RESTful API. They also do not have permissions to perform other tasks on the appliance. Ensure that you record the usernames and passwords for all user accounts so you can enter them correctly when you configure the FireEye appliance. You can map a single or multiple FireEye appliances to a NIOS appliance where multiple users or zones exist.

FireEye Integrated RPZ



To configure a FireEye integrated RPZ, complete the following:

1. Create a new FireEye integrated RPZ, as described in Configuring FireEye RPZs below.
2. Create FireEye admin users, as described in For FireEye Integrated RPZs below.

3. Add URL and user credentials on the FireEye appliance, as described in Configuring the FireEye appliance below.
4. When a malware or threat is detected, the FireEye appliance sends an alert message to the NIOS appliance, which is stored in the syslog. For more information, see Handling Alerts from the FireEye appliance below.

Configuring FireEye RPZs

You must create an RPZ zone and map the FireEye alerts with an RPZ rule to receive alerts from FireEye. These alerts will then be translated into appropriate RPZ rules that are added to the FireEye RPZ. You can also define a time limit for a specific alert type or set the alert type to live forever. When you define a lifetime, the alert type will be active for the specified number of days or weeks in the NIOS appliance, and will then expire after the specified time. After you configure the FireEye integrated RPZ, the NIOS Grid receives alerts from the FireEye appliance and creates RPZ rules for some of the alerts received. FireEye appliance sends alert messages with basic authentication. You must configure a username and password on the NIOS appliance prior to receiving any alerts from the FireEye appliance.

> **Note**
>
> The NIOS appliance treats the FireEye integrated RPZ as a local RPZ. Thus, you cannot assign an external primary name server to the zone.

An alert contains the malware URL along with a valid FQDN. The NIOS appliance can only map an alert to a RPZ rule if the FQDN is present. If an alert doesn't contain the FQDN, then the alert is ignored by the NIOS appliance. Once the alert is processed and properly mapped to an RPZ rule, it remains in the database until you delete it manually. You can get more information about the alerts, which are sent by the FireEye appliance, from the syslog.

> **Note**
>
> You can configure feeds from multiple FireEye appliances. To enable or disable FireEye integration module feeds from individual appliances, you must enable or disable user access of the particular FireEye appliance. Note that the FireEye feeds will not be in the RPZ format, but when you configure a FireEye integrated RPZ, the NIOS appliance creates a new URL through which the FireEye appliance sends alerts.

To configure a FireEye integrated RPZ:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, and then click the *Add* icon.
2. When you click the *Add* icon, either the *Add Response Policy Zone Wizard* or the *Add DNS View* wizard is displayed based on the following:
    - When you click the *Add* icon, the *Add Response Policy Zone Wizard* is displayed if you have not created additional DNS views and only have the default view.
3. If you have configured multiple DNS views, you must drill-down to the corresponding view to assign a FireEye Integrated RPZ. Click the *Add* icon and the *Add Response Policy Zone Wizard* is displayed. To create a new DNS view for your FireEye integrated RPZ, click the *Add* icon and complete the details in the *Add DNS View* wizard. For information adding and modifying a DNS view, see *Adding a DNS view.*
4. In the *Add Response Policy Zone Wizard*, select **Add FireEye-Integrated Response Policy Zone**, click **Next** and specify the following:
    - **Name:** Enter the name of the FireEye integrated RPZ. It can be a combination of alphanumeric characters. You can enter up to 256 characters.
    - **DNS View:** The name of the view that you have selected is displayed by default. You can select a view from the drop-down list to associate it with the FireEye integrated RPZ.
    - **Policy Override**: Select a value from the drop-down list. You can override the policy actions that are specified in the rule level.
        - **Log Only (Disabled)** – Select this if you want to disable an RPZ rewrite using rules in the RPZ. If the response to the recursive query matches any RPZ rule, then the rule is logged, but the response will not be altered. Note that this option will not override RPZ rules in other RPZ zones, if they take precedence. Select this option to preview the rules in the syslog before they take effect.
        - **None (Given)** – Select this if you want to use the policy from the rule level.

- **Block (No Data)** – Select this to send a response that contains no data in it.
- **Block (No Such Domain)** – Select this if you want the user to receive a DNS response that indicates there is no domain. All the policy actions in an RPZ are replaced with a NXDOMAIN block.
- **Passthru** – Select this if you want to send an actual response without modification. All the policy actions in an RPZ are replaced with the passthru action.
- **Substitute (Domain Name)** – Select this if you want to replace all the policy actions in an FireEye integrated RPZ with the specified substitution action.
    - **Domain Name**: This appears only when you select **Substitute (Domain Name)** from the **Policy Override** list. Enter the domain name that you want the client to receive instead of the actual domain name, which is malicious or unauthorized.

- **Comment**: Optionally, enter additional information about the FireEye integrated RPZ.
- **Disable:** Select the checkbox to disable the FireEye integrated RPZ without deleting its configuration. Clear the checkbox to enable the FireEye integrated RPZ. For information, see *Enabling and Disabling Zones*. Note that disabling the FireEye integrated RPZ may take a longer time to complete depending on the size of the data.

5. Click **Next** to define rule mapping:
    - **Server URL**: The appliance displays the URL that you use when configuring the FireEye appliance. This URL is used to handle alerts, which is sent by the FireEye appliance. It handles alerts based on the standard authentication. The URL generated by the NIOS appliance consists of the Grid Manager IP address, network view, and DNS view of the FireEye zone. If you change the IP address, network view, zone or DNS view after you have configured a FireEye RPZ, the URL will change accordingly. Thus FireEye will not be able to send alerts to the updated URL. You must update the URL in the FireEye appliance to send alerts to the NIOS appliance. The **Server URL** is generated in this format:

      https://<host address>/alert/feye/<network view>/<dns view>/<zone>
    - **Rule Mapping**: You can map a **FireEye alert type** with an RPZ policy. Select an **RPZ policy type** from the drop-down list. Note that the **FireEye alert type** is read-only. The NIOS appliance applies corresponding RPZ policy type when the FireEye appliance sends an alert to the NIOS appliance. You can also specify a time limit for each FireEye RPZ rule depending on the FireEye alert type. NIOS displays default lifetime value for each alert type. You can change the default lifetime of the alert type. When you define a value, the value must be greater than zero. When you select **Live Forever** from the drop-down list, the alert type will never expire and will be stored in the database until further notice. The NIOS appliance will use the default time if you do not specify a value. You can specify the expiration time in days or weeks only. The following table lists the FireEye alerts, RPZ policy types, and the time limit for a specific FireEye alert:

FireEye Rule Mapping

FireEye Alert Type	RPZ Policy Type	Lifetime
Domain Match Infection Events Callback Events Malware Object Web Infection	Select a value from the drop-down list for a FireEye alert when a malware object is detected: **None**, **Passthru**, **Block (No Such Domain)**, **Block (No Data)**, and **Substitute (Domain Name)**. The drop-down list displays **Passthru**, by default. For more information about the **RPZ Policy Types**, see *Configuring Rules for RPZs*.	Specify a lifetime for each FireEye alert in **Days**, **Weeks**, or select **Live Forever** from the drop-down list. The following are the default values for different alert types: • Domain Match - 1 week • Infection Events - 1 day • Callback Events - 1 week • Malware Object - 1 day • Web Infection - 1 day Click on the default value to change the lifetime value.

When you edit the lifetime of an existing alert type, NIOS deletes the alert type based on the new lifetime setting. It also updates the expiration time for the corresponding alert type. Note that there might be an impact on the performance when you delete expired FireEye RPZ rules.

- **Override rule mapping for APT events:** Select a value from the drop-down list to override rule mapping for Advanced Persistent Threats. Events that are marked as APT events by FireEye override rules that are set for other event types. The values in the drop-down list are:

- **NoOverride** – Select this if you want to use the policy from the rule level and do not want to override the rule mapping settings. This value is displayed in the drop-down list, by default.
- **Passthru** – Select this if you want the user to see the actual response without modification. All the policy actions in an RPZ are replaced with the passthru action.
- **Block (No Such Domain)** – Select this if you want the user to receive a NXDOMAIN as the DNS response. All the policy actions in an RPZ are replaced with a NXDOMAIN block.
- **Block (No Data)** – Select this if you want the user to receive a response that indicates that there is no data.
    - **Substitute (Domain Name)** – Select this if you want to replace all the policy actions in an RPZ with the substitution action that is specified.
- **Substituted Domain Name**: This appears only when you select **Substitute (Domain Name)** from the **Policy Override** list either for APT events or for FireEye alerts. Enter the domain name that you want the client to receive instead of the actual domain name, which is malicious or unauthorized.

6. Click **Next** to associate the FireEye integrated RPZ with at least one primary name server:

- Define the name servers for the FireEye integrated RPZ. A Grid name server must be recursive when primary Grid name server is used as an RPZ source. A FireEye integrated RPZ may or may not have a recursive server. For example, there could be a Grid that has only primary Grid name server for a FireEye integrated RPZ to act as an RPZ source for an external set of name servers. When you select **All Recursive Name Servers** from the list, all the recursive name servers in the Grid are added as secondary servers for the zone. For information on specifying primary or secondary name servers, see *Assigning Zone Authority to Name Servers*. For information on specifying name server groups, see *Using Name Server Groups*. For information about all recursive name servers, see *Configuring RPZs for All Recursive Servers*.

7. Save the configuration and click **Next** to define extensible attributes.
8. Click **Restart** if it appears at the top of the screen.

Configuring Rules for FireEye RPZs

You can define a list of rules based on how the DNS server determines its response to recursive queries. Based on the rules defined, responses to clients are either manipulated or forwarded without any changes. To configure rules for FireEye RPZs:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, click *DNS_View* -> *Zone* and then click **Add** -> select a **Rule**.
2. The rules are classified as follows, for more information about these rules see, *Configuring Rules for RPZs*:
    - **Passthru Rule**
    - **Block (No Such Domain) Rule**
    - **Block (No Data) Rule**
    - **Substitute (Domain Name) Rule**
    - **Substitute (Record) Rule**
3. Complete the details in the corresponding editor.
4. Save the configuration and click **Next** to define extensible attributes.

Configuring the FireEye appliance

You must configure the FireEye appliance to send alerts to the NIOS appliance. Ensure that the following are complete before you configure the FireEye appliance:

1. Install required license on the NIOS appliance. For more information about license, see *License Requirements and Admin Permissions*.
2. Create a new FireEye RPZ zone.
3. Create FireEye admin users. For more information, see *For FireEye Integrated RPZs*.
4. Get the URL from the NIOS appliance and record it. You need this to configure the FireEye appliance. For more information about the Server URL, see Configuring FireEye RPZs above. If you have already configured a FireEye integrated RPZ, then you can retrieve the URL through the **FireEye** tab of the corresponding FireEye RPZ zone. For more information about managing and retrieving the URL, see *Modifying RPZs*.

5. Record the usernames and passwords on the NIOS appliance. You must use these credentials when configuring FireEye alerts to enable the alerts to be received by NIOS. For more information, see Configuring the FireEye appliance to send alerts to NIOS below.

Configuring the FireEye appliance to send alerts to NIOS

You must configure the NIOS generated URL, usernames and passwords on the FireEye appliance. FireEye appliance embeds the configured usernames and passwords in the alerts for authentication. When an alert is received, the NIOS appliance verifies the FireEye username prior to processing the alert. Note that the NIOS appliance accepts alerts sent by the FireEye appliance in **JSON Normal** format only.

To configure a FireEye appliance:

1. Login to the FireEye appliance with your username and password.
2. In the FireEye GUI, click **Settings** tab and then click the **Notifications** tab on the left panel.
3. In the **Notification Settings** page, click the **http** link and then enter the name of the HTTP server you want to add. Click **Add HTTP Server** and complete the following:
    - **Name**: When you click add, the HTTP server name that you specified is listed in this column.
    - **Enabled**: Select the checkbox to enable alerts and notifications for the HTTP server.
    - **Server Url**: Enter the URL you received on the NIOS appliance. The alerts and notifications are sent using this URL by the FireEye appliance.
    - **Auth**: Select this checkbox if authentication is required for the server.
    - **Username and Password**: Enter the Username and Password of the user that you have configured for the **fireeye-group** on the NIOS appliance. For more information, see *For FireEye Integrated RPZs*.
    - **Notification**: Select a notification from the drop-down list. You can choose to include notifications for all events or only events of a selected type. The FireEye appliance will send an alert to the NIOS appliance only when selected event is encountered. When you select **All Events**, alerts are sent when each event is encountered by the FireEye appliance.
    - **Delivery**: Select **Per Event** from the drop-down list. Note that the NIOS appliance supports only **Per Event** selection. The FireEye appliance sends an alert each time it encounters an event.
    - **Account**: You can specify a user account name for this notification.
    - **SSL Enable**: Select this checkbox to enable SSL for secure transmission of alerts from the FireEye appliance to NIOS.
    - **Default Provider**: Select a default provider from the list.
    - **Message Format**: Select **JSON Normal** from the drop-down list. Note that the NIOS appliance supports only this message format.
4. Click **Update** at the bottom of the page.

> ⚠ **Note**
>
> You can also click **Test-Fire** to test the configuration. If the configuration is successful, FireEye sends a confirmation message to the NIOS appliance and the NIOS appliance logs this message in the syslog. It generally takes a few seconds for the NIOS appliance to receive alerts. You must verify the configuration, if there is no entry in the syslog.

Handling Alerts from the FireEye appliance

The NIOS appliance processes each alert that it receives from the FireEye appliance. The alert contains the malware URL along with a valid FQDN. NIOS appliance can only map an alert to a RPZ rule if the FQDN is present. Once the alert is processed and properly mapped to an RPZ rule, it remains in the database until you delete it manually. When the RPZ rule is different from the existing rules, the new RPZ rule gains precedence over the existing RPZ rule in the FireEye integrated RPZ. Note that you cannot retrieve alerts that are ignored. You can get more information about the alerts, which are sent by the FireEye appliance, from the syslog. An alert will not be processed and will be ignored:

- when there are changes to the URL or if the alert does not have the malware URL or FQDN in them.
- if the zone is not found.
- if the alert is sent without any username in it or if the username does not belong to the fireeye-group.

- if a FireEye admin user is deleted. NIOS will neither authenticate the deleted user credentials nor process any future alerts with deleted user credentials.
- if the search mapping fields contain IP addresses other than FQDNs.
- if alerts contain domain names in an IPv4 or IPv6 address format.

Logging FireEye Integrated RPZ messages

The NIOS appliance logs FireEye events and alerts in the syslog and audit log. Each FireEye feed event is logged every time an alert is sent to NIOS by the FireEye appliance. When you create a new rule or update an existing rule, then those are also logged in the syslog. You can use messages logged in syslog to verify events that are related to communication between the FireEye and NIOS appliances. It also enables the admin to monitor alerts and verify how the alerts are processed. Details about alerts that are received and processed are also logged. Syslog messages are logged when:

- an alert is received from the FireEye appliance.
- syslog messages contain required information for reporting.
- an alert is successfully mapped to an RPZ rule. The message format is as follows:
    - <FireEye: Found an APT alert>
- the NIOS appliance cannot process alerts. For example, alert structure mismatch, unrecognizable data, etc. The messages will have the following format:
    - <FireEye: Cannot parse FQDN due to missing field"cnc-services">
    - <FireEye: Cannot determine if it is an APT alert..>
    - <FireEye: Invalid Alert Type ....>
    - <FireEye: Couldn't find the required field...>
    - <FireEye: No mapping rule has been set for alert type.....>
- a duplicate alert is sent by the FireEye appliance for which the same RPZ rule already exists.

> **Note**
>
> For debugging purposes, alert messages will be displayed in the infoblox.log file.

NIOS periodically scans the syslog of a member that has RPZ license installed to generate recent hits data for the *RPZ Recent Hits* tab. This might cause a performance impact as CPU cycles will be used on the member. For more information about *RPZ Recent Hits* tab, see *RPZ Recent Hits*.

Configuration Examples

This section illustrates some of the examples of local and FireEye integrated RPZs.

Local RPZ Examples

`Following is an example of an IP related rule. For example, execute the following command:`

`dig @10.35.104.19 abc.net`

If the above command returns `18.58.20.1`, then define an IPv4 substitute rule `18.0.0.0/8, Substitute (IPv4) 8.8.8.89.`

Execute the command `dig @10.35.104.19 abc.net` again. You will receive the substituted address instead of the actual domain name.

Following is an example of values in CEF for the above substitution example:

```
2012-11-06T19:04:02+00:00 daemon (none) named[25193]: info
```

```
CEF:0|Infoblox|NIOS|6.6.0-185622|RPZ-IP|records|4|app=DNS dst=10.35.104.19
src=10.32.0.242 spt=50035 view=_default qtype=A msg="rpz IP records rewrite
abc.net [A]
via 8.0.0.0.18.rpz-ip.localrpz"
```

Following is an example of values in the CEF for Block (No Data) rules:

```
2012-11-06T19:00:01+00:00 daemon (none) named[25193]: info
CEF:0|Infoblox|NIOS|6.6.0-185622|RPZ-QNAME|NODATA|4|app=DNS dst=10.35.104.19

src=10.32.0.242 spt=50035 view=_default qtype=A msg="rpz QNAME NODATA
rewrite nodata.net [A]
via nodata.net.localrpz"
```

You can view the NIOS version, name of the view, source, and destination.

FireEye Integrated RPZ Examples

Following is an example of a syslog message when an alert gets converted to an RPZ rule:

```
013-09-11T10:59:55-07:00 user (none) httpd[]: info fireeye-rpt:
'79167','infection-match','minr''eng-lab-249.inca.infoblox.com'
2013-09-11T10:59:55-07:00 user (none) httpd[]: info FireEye: Create an RPZ
rule for
'd.bnksw.com' with 'SUBSTITUTE' rule in RPZ zone 'com.lock'
```

Note that the domain name lock.com is displayed in the reverse format.
Following is an example of a syslog message when an alert is ignored by the NIOS appliance:

```
2013-09-11T11:04:01-07:00 user (none) httpd[]: info fireeye-rpt:
'114488','malware-object','majr''eng-lab-249.inca.infoblox.com'
2013-09-11T11:04:01-07:00 user (none) httpd[]: info FireEye: Cannot parse
FQDN due to
missing field''cnc-services''
```

Example of a basic RPZ Workflow

Following is an example of a basic RPZ workflow:

1. Install the RPZ license. For more information, see *License Requirements and Admin Permissions*.
2. Enable recursive queries for a DNS view, member, or Grid, as described in *Enabling Recursion for RPZs*.
3. Enable RPZ logging in the *Grid DNS Properties* editor to view syslog entries for RPZ queries. For more information about setting DNS logging categories, see *Using a Syslog Server*.

4. Create a local RPZ. For more information, see *Configuring Local RPZs*.
5. Define a **Substitute (PTR Record) Rule** for domain name 3.3.3.5.in-addr.arpa, which is substituted with the domain name ptr1.com. For more information, see *Defining Substitute Rules for PTR Records*.
6. Execute the dig command to view output. The output contains the substituted domain name ptr1.com. Following is the output of an RPZ query for **Substitute (PTR Record) Rule**:

```
$ dig @10.36.2.73 3.3.3.5.in-addr.arpa in ptr
 ; <<>> DiG 9.6.2-P2-RedHat-9.6.2-5.P2.fc12 <<>> @10.36.2.73 3.3.3.5.in-
addr.arpa in ptr
 ; (1 server found)
 ;; global options: +cmd
 ;; Got answer:
 ;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 7351
 ;; flags: qr rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 0, ADDITIONAL: 0

 ;; QUESTION SECTION:
 ;3.3.3.5.in-addr.arpa.          IN         PTR

 ;; ANSWER SECTION:
 3.3.3.5.in-addr.arpa. 7200      IN         PTR       ptr1.com.

 ;; Query time: 3 msec
 ;; SERVER: 10.36.2.73#53(10.36.2.73)
 ;; WHEN: Thu Sep 26 23:27:10 2013
 ;; MSG SIZE rcvd: 60
```

7. Following is the syslog entry for the query mentioned above:

```
2013-09-27T02:26:46-04:00 daemon (none) named[21737]: info
CEF:0|Infoblox|NIOS|6.9.0-218052|RPZ-QNAME|Local-Data|4|app=DNS
dst=10.36.2.73
src=10.120.20.194 spt=40518 view=2 qtype=PTR msg="rpz QNAME Local-Data
rewrite
3.3.3.5.in-addr.arpa [PTR] via 3.3.3.5.in-addr.arpa.local1.com"
```

For more information about syslog, see *Viewing RPZ in the Syslog*.

Mitigating Cyber Threats using TAXII

To mitigate the increasingly complex cyber attacks, you can enable the appliance to run a TAXII (Trusted Automated eXchange of Indicator Information) service to receive information on real-time threat incidents. The information in each threat incident is represented using the STIX (Structured Threat Information eXpression) language format. STIX is a standard language used to describe structured cyber threat information, which is shared between different TAXII clients. When you run the TAXII service on a Grid member, the appliance acts as a TAXII server that receives TAXII messages

(for one or more specified STIX collection) from TAXII clients. The TAXII message typically contains a list of IP addresses (both IPv4 and IPv6) and domains. The member then communicates with the Grid Master and sends a request to create an RPZ rule on the specified RPZ based on the TAXII messages it receives. The RPZ rule created on NIOS is available in the **Response Policy Zones** tab, as shown in the RPZ Rules created for the Mapped RPZ and Collection figure below.

> **Note**
>
> Once you start the TAXII server, the inbox for the configured collections is available at https://<member address>/services/inbox and the TAXII discovery service is available at https://<member address>/services/discovery, where <member address> is the MGMT or LAN IP address (IPv4 or IPv6 address of the port that is configured).

For more information about TAXII and STIX, refer to the following:

https://taxii.mitre.org/

http://taxiiproject.github.io/

Supported Appliances for TAXII Service

You can run the TAXII service on the following Infoblox appliance models: IB-1410, IB-1415, IB-1420, IB-1425, IB-VM-1410, IB-VM-1415, IB-VM-1420, IB-VM-1425, TE-815, TE-2215, TE-2225, IB-VM-4010, IB-4030-10GE, IB-VM-2220, IB-VM-2225, PT-1405, PT-2205 and PT-2205-10GE.

Licensing Requirements and Permissions

To enable the TAXII service, you must install the **Security Ecosystem** license on any Grid member. You must also install an **RPZ** license on any Grid member in the Grid in order to create RPZ rules based on the TAXII messages. To allow a group to access the TAXII service, you can enable the group to authenticate with the TAXII server.
To enable a group to access the TAXII server:

1. From the **Administration** tab, select the **Administrators** tab -> **Groups** tab, and then click the Add icon.
2. In the *Add Admin Group* wizard, click the **Roles** tab and then complete the following in the **Allowed Interfaces** section:
    - **TAXII**: Select this checkbox to enable a group to authenticate with the TAXII server.
3. Save the configuration.

Mapping RPZs with TAXII Collections

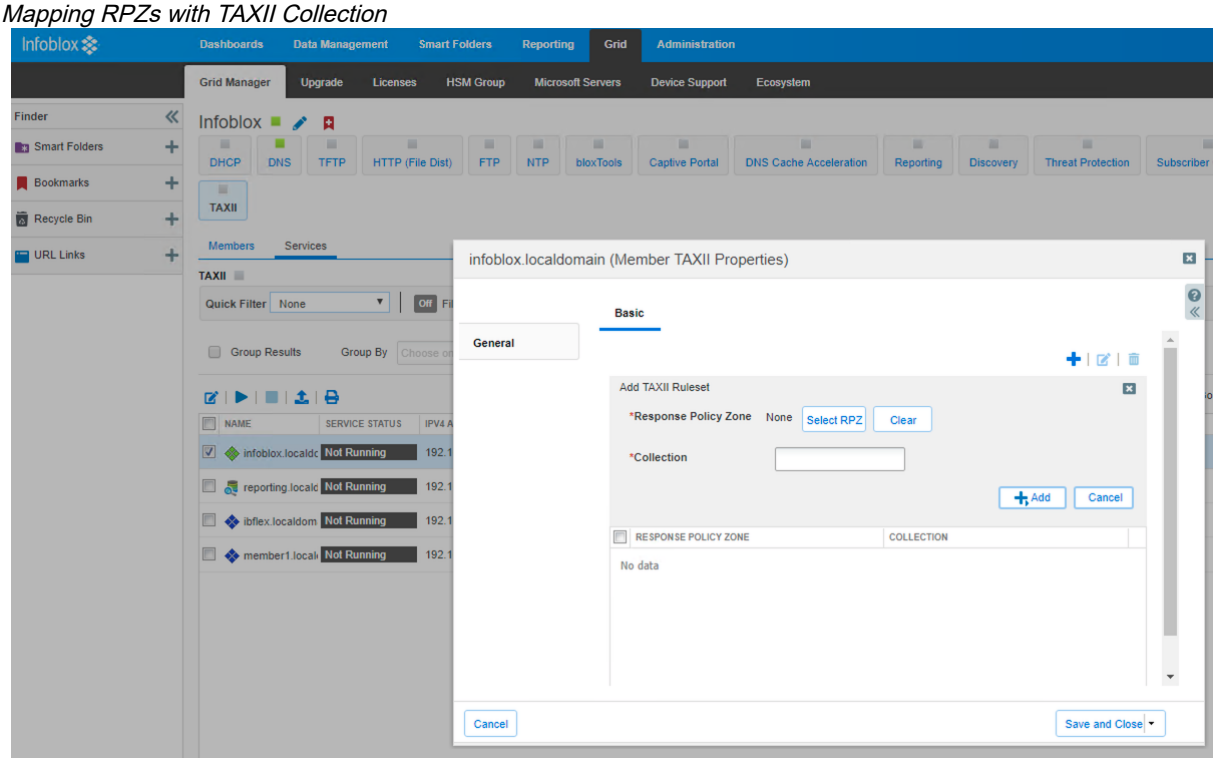
NIOS supports arbitrary set of RPZ rules mapped to the corresponding TAXII collection. To map an RPZ with a TAXII collection:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Services** tab.
2. In the **Services** tab, select the *TAXII_member* checkbox, and then click **Edit** -> **Member TAXII Properties** from the Toolbar.
3. In the *Member TAXII Properties* editor, complete the following:
    - **Response Policy Zone**: Click the Add icon and click **Select RPZ** to select an RPZ. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box from which you can select one.
    - **Collection**: Enter the name of the TAXII collection that will be mapped to the RPZ. Note that you can only use valid URI characters as collection names. You cannot use special characters or spaces.
    - **Add**: Click the Add icon to add the RPZ and collection name to the table.
    - **Save and Close**: Click this to save the configuration and close the editor.

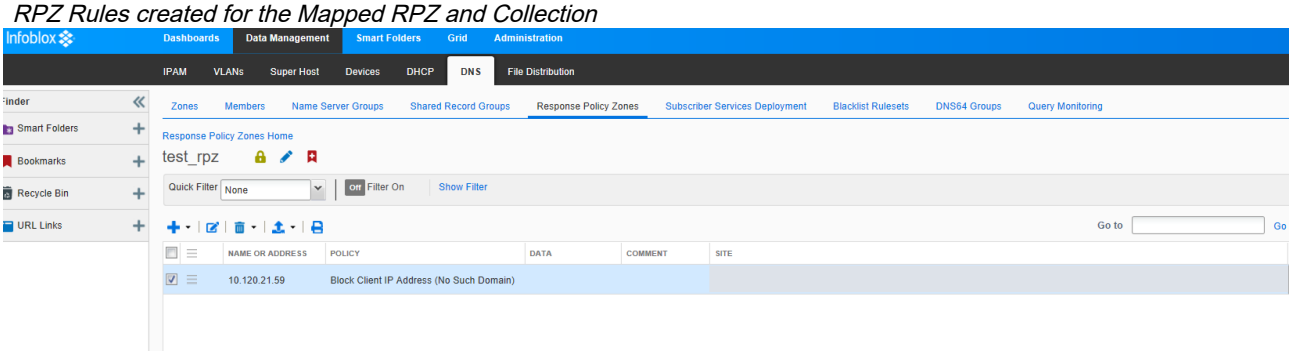
You can do the following in this tab:

- To edit an entry in the list, click the checkbox beside an RPZ, and then click the Edit icon.
- To delete an entry in the list, select the checkbox beside an RPZ, and then click the Delete icon.

Mapping RPZs with TAXII Collection



RPZ Rules created for the Mapped RPZ and Collection



Starting and Stopping the TAXII Service

To start the TAXII service:
1. From the **Grid** tab, select the **Services** tab -> *TAXII_member* checkbox and then click the Start icon from the vertical Toolbar.
To stop the TAXII service:
1. From the **Grid** tab, select the **Services** tab -> *TAXII_member* checkbox and then click the Stop icon from the vertical Toolbar.

Extensible Attributes for TAXII Service

You can define extensible attributes that are specific to the TAXII service. When you define TAXII specific extensible attributes, the RPZ rules created will have these attributes and their corresponding values (received in the TAXII messages) added automatically.
For information about how to configure extensible attributes, see *Managing Extensible Attributes*.

Extensible attributes for TAXII service

Attribute Name	Attribute Type	Description
TAXII_collection	String	The name of the TAXII collection the TAXII client delivered the message to.
TAXII_source	String	The IP address of the TAXII client that sent the TAXII message.
TAXII_member	String	The TAXII Grid member that receives TAXII message resulting in the creation of the RPZ rule.
TAXII_timestamp	Date/Integer	The timestamp when the TAXII message was received.
TAXII_user	String	The login name of the user the TAXII client connected as to the TAXII server on the member that received the message.

Monitoring TAXII Server

You can monitor the status of the TAXII server, as described in *Monitoring Grid Services*. If there are any invalid TAXII messages, the appliance makes a syslog entry. For information, see *Verifying RPZ in the Syslog*. The appliance also sends an SNMP trap and an email notification, if configured. For information about setting SNMP and email notification, see *Configuring SNMP*.

Managing RPZs

You can manage RPZs that you defined earlier and modify their information. You can perform the following:

- *Viewing RPZs*
- *Modifying RPZs*
- *Reordering RPZs*
- *Locking and Unlocking RPZs*
- *Deleting RPZs*

Viewing RPZs

You can view the list of RPZs, local, feed, or FireEye integrated RPZs, which are currently listed in the Grid. To view RPZs, complete the following:

1. From the **Data Management** tab -> **DNS** tab -> **Response Policy Zones** tab.
2. Grid Manager displays the following:
    - **Order**: Displays the order of RPZs. The order value is empty if you do not assign a primary name server when configuring a local RPZ, or if the local RPZ or the service is disabled.
    - **Name**: Displays the name of the RPZs. Click the RPZ link to view the following details:
        - **Name or Address:** Displays the domain name or the IP address.
        - **Policy**: Defines the policy defined for the corresponding domain name or IP address.
        - **Data**: Displays the target data of the rule.
        - **Comment**: Displays the comment specified when an RPZ is defined.
        - **Disabled**: Displays **Yes** if the RPZ rule is disabled.
        - **Site**: Displays extensible attributes that are associated with the domain name or IP address.
    - **Type**: Displays the type of RPZs, that is, **Local**, **Feed**, or **FireEye**.
    - **Primary Name Server**: Displays the primary name server that is associated with an RPZ.

- **Last Updated:** Displays the last updated time. For RPZ feed, it indicates if the RPZ feed has stalled and when the last zone transfer happened. For a local and FireEye integrated RPZ, it indicates the last time the zone or data was modified.
- The last updated time is empty, if:
    - A local RPZ is not associated with a primary Grid name server.
    - A zone, either a local RPZ or an RPZ feed, is not enabled.
    - An inbound zone transfer has not occurred for an RPZ feed.
    - Member's DNS service is disabled.
- **Comment**: Displays the comment recorded when creating the zone. You can double-click on a row to edit the comment. Click **Save** after modification.

  For FireEye integrated RPZs, this column displays the comment recorded when creating the FireEye integrated RPZ. The rules that are created from the FireEye alerts will have alert information in this column. This differentiates between FireEye alert created rules and user created rules. You can double-click on a row to edit the comment. Click **Save** after modification. Infoblox recommends that you do not modify any internal objects. For example, the **Comment** column has alert related information, if you modify the data, then the actual alert data will be compromised.
- **Disabled**: Displays **Yes** if the RPZ is disabled. Otherwise, this field displays **No**.
- **Locked**: Displays **Yes** when a zone is locked by an admin, and displays **No** when the zone is unlocked.
- **Site**: Displays the values that were entered for this pre-defined attribute. You can double-click on a row to edit the Site. Click **Save** after modification.

  You can also perform the following:
- Use **Quick Filter** and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches. Select a value from the drop-down list to filter the RPZs.
    - **None:** Select this to display all the RPZs that you have configured.
    - **All Local Response Policy Zones:** Select this to list only the local RPZs.
    - **All Feed Response Policy Zones:** Select this to list only the RPZ feeds.
    - **All Fire Eye Response Policy Zones**: Select this to list only the FireEye RPZs.
- Create a quick filter to save frequently used filter criteria. For more information, see *Using Quick Filters*.
- You can create a bookmark for the RPZs. For more information, see *Using Bookmarks*.
- You can modify some of the data in the table. Double-click a row of data, and either edit the data in the field or select an item from a drop-down list. Note that some fields are read-only. For more information, see *Modifying Data in Tables*.
- To export the list of RPZs to a .csv file, click the *Export* icon. For more information, see *Importing and Exporting Data using CSV Import*.
- Click the *Print* icon to print the list of RPZs. For more information, see *Printing from Grid Manager*.

Modifying RPZs

You can modify the name servers or name server groups, update policy override details and permissions, or edit extensible attributes that are associated with an RPZ.

To modify RPZs, complete the following:

1. From the **Data Management** tab -> **DNS** tab -> **Response Policy Zones** tab -> *Response Policy Zone* checkbox and then click the *Edit* icon.
2. The RPZ editor provides the following tabs from which you can modify data:
    - **General:** In this tab, you can change the information you previously entered through the wizard, as described in *Configuring Local RPZs*. For FireEye integrated RPZs, you can update the policy type, comments, enable or disable, or lock the zone. For more information, see *Configuring FireEye RPZs*.
    - For a FireEye integrated RPZ, the **FireEye** tab is displayed. This tab is displayed only after you install the Security Ecosystem license. You can modify or override the rule mapping for FireEye alerts or APT events. For more information, see *Configuring FireEye RPZs*.

- You can also enter or edit information in the **Name Servers**, **Extensible Attributes**, **Settings**, and **Permissions** tabs. For more information, see *Modifying, Disabling, and Deleting Host and Resource Records*.
- **Logging:** In this tab, you can enable or disable logging at the zone level for RPZ zones. You can **Override the RPZ logging** option only if the **RPZ/Security log** is enabled at the Grid or member level. The values are inherited from the Grid or member by default. To view RPZ logs at the Grid level, see *Setting DNS Logging Categories*. Selecting the **Override** option allows you to disable RPZ logging for the particular zone. However, if the **RPZ logging** is not enabled at the Grid or member level, you cannot **Override** or **Inherit** logging at the zone level.

3. Save the configuration and click **Restart** if it appears at the top of the screen.

Reordering RPZs

You can change the order of RPZs, local feeds, or FireEye integrated RPZs, in each view. When you add a new local RPZ, it is added to the top of the zone list and an RPZ feed is automatically added to the bottom of the zone list. You can change the order of each through the re-ordering process.

The policy override works based on zone ordering. The zone at the top has the highest priority and it overrides the lower priority zone. To override an RPZ feed with a local RPZ, place the local feed at the top before an RPZ feed. You cannot reorder zones if they are disabled or do not have any primary name server assigned.

To reorder RPZs, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, click **Order Response Policy Zones** from the **Toolbar**.
2. The following are displayed in the *Order Response Policy Zones* wizard:
   - **Ordering**: Use the up and down arrows to move the RPZ to the desired order.
   - **Response Policy Zone:** Displays all the RPZs.
   - **Priority**: Displays the order of RPZs.
3. Click **OK** to save the changes.

Locking and Unlocking RPZs

You can lock an RPZ so only you can make changes to it, which prevents others from making conflicting changes. When you lock an RPZ, the Grid Manager displays LOCKED beside the RPZ. When other administrators try to make changes to a locked RPZ, the system displays a warning message that the RPZ is locked and the name of the admin who locked the RPZ.

Only a superuser or the administrator who locked the RPZ can unlock it. RPZ locks do not expire and you must manually unlock a locked RPZ.

To lock or unlock RPZs, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, select the *Response Policy Zone -> Ruleset.*
2. You can do the following:
   - **To Lock:** Click the *Lock* icon to lock the zone.
   - **To Unlock:** Click the *Unlock* icon to unlock the zone.

Deleting RPZs

You can delete RPZs or schedule them for deletion at a later date. The NIOS appliance moves the deleted RPZs to the Recycle Bin if enabled. When you restore the zone from the Recycle Bin, it will be restored to the bottom of the zone list.

To delete RPZs, complete the following:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab -> *Response Policy Zone* checkbox.

2. To delete an RPZ immediately, click the *Delete* icon, and then click **Yes** to confirm the delete request.
3. To schedule the deletion, click **Schedule Deletion** and in the *Schedule Change* panel, enter a date, time, and time zone. For more information, see *Scheduling Deletions*.

The Grid Manager moves the RPZ to the Recycle Bin, from which you can restore it or permanently delete it.

Managing RPZ Rules

You can manage local RPZ, including FireEye integrated RPZ rules that you defined earlier and modify their information. You can do the following:

- *Viewing RPZ Rules*
- *Modifying RPZ Rules*
- *Deleting RPZ Rules*
- *Copying RPZ Rules*
- *Importing RPZ Rules*
- *Disabling NSDNAME and NSIP rules for RPZ zones*

> **Note**
>
> You cannot modify the rules of an RPZ feed. However, you can override the entire ruleset or each rule using local RPZs.

Viewing RPZ Rules

You can view and edit the rules that are defined for each local RPZ, including FireEye integrated RPZs. To view RPZ rules:

1. From the **Data Management** tab -> **DNS** tab -> **Response Policy Zones** tab -> click the RPZ link.
2. You can view the following:
   - **Name or Address:** Displays the domain name or the IP address on which the rule is defined.
   - **Policy**: Displays the rule applied on the domain name or the IP address.
   - **Data**: Displays the target data of the rule.
   - **Comment**: Displays the comment specified when the rule is defined.
   - **Disabled**: Displays **Yes** if the RPZ rule is disabled. Otherwise, this field displays **No**.
   - **Site**: Displays an extensible attribute, **Site**.
   - **Expiration**: Displays the expiration time for the corresponding FireEye integrated RPZ rule. Note that NIOS updates the expiration time when you change the lifetime of the FireEye integrated RPZ rule, or if the last updated time of the rule changes, or if the alert type that generates the rule changes. This time is estimated based on the following:
     Expiration Time = Lifetime of an alert type + Last updated time of the rule
     NIOS runs a scheduler every 10 minutes to identify FireEye integrated RPZ rules whose expiration time is less than the current time. If there are rules whose expiration time is less than the current time, then such rules will be deleted. NIOS logs all deletion activities in the syslog. You can view the syslog to verify expired rules. For more information, see *Viewing RPZ in the Syslog*.
   - **Fire Eye Alert Type**: Displays the type of FireEye alert.
   - **Last Updated**: Displays the time when the RPZ rule was last updated.

> **Note**
>
> The columns, **Expiration**, **FireEyeAlertType**, and **LastUpdated**, are displayed only for FireEye integrated RPZ rules. These columns are not displayed for non-FireEye RPZ rules.

You can also do the following:

- Use **Quick Filter** and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria. For information, see *Using Quick Filters*.
- Modify some of the data in the table. Double click a row of data, and either edit the data in the field or select an item from a drop-down list. You can edit **Comments** and **Extensible Attributes**. Note that some fields are read-only. For more information about this feature, see *Modifying Data in Tables*.
- To export the list of RPZ rules to a .csv file, click the *Export* icon. For information on the export options, see *Importing and Exporting Data using CSV Import*.
- Click the *Print* icon to print the list of RPZ rules. For more information, see *Printing from Grid Manager*.

Modifying RPZ Rules

You can modify the name of a local or FireEye integrated RPZ rule, IP address, network address, substituted name, and the comment recorded for the corresponding rule. You can also update the TTL settings or the extensible attributes that are associated with an RPZ rule.
To modify RPZ rules:

1. From the **Data Management** tab -> **DNS** tab -> **Response Policy Zones** tab -> click the RPZ link -> *Name or Address* checkbox, and then click the *Edit* icon.
2. The RPZ rules editor provides the following tabs from which you can modify data:
    - In the **General** tab, you can change the information you previously entered through the wizard. For more information, see *Configuring Rules for RPZs*.
    - You can also enter or edit information in the **TTL and Extensible Attributes** tabs. For information about TTL settings, see *Specifying Time To Live Settings*. For information about extensible attributes, see *Managing Extensible Attributes*.
3. Save the configuration.

Deleting RPZ Rules

You can delete local RPZ rules, including FireEye integrated RPZ rules, or schedule them for deletion for a later date. When you remove an RPZ rule, the NIOS appliance moves it to the Recycle Bin, if enabled.
To delete RPZ rules:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab -> *Response Policy Zone* -> *Ruleset*.
2. To delete an RPZ rule immediately, click the *Delete* icon, and then click **Yes** to confirm the delete request. To schedule the deletion, click **Schedule Deletion** and in the **Schedule Change** panel, enter a date, time, and time zone. For information, see *Scheduling Deletions*.

Grid Manager moves the RPZ rule to the Recycle Bin, from which you can restore or permanently delete it.

Copying RPZ Rules

You can copy rules from one local RPZ to another local RPZ or from one FireEye integrated RPZ to another FireEye RPZ. You can also copy rules from a local RPZ to a FireEye integrated RPZ or vice-versa. Different views of the same RPZ may have a number of rules in common. If this is the case, you can copy rules between views and zones.
To copy RPZs between DNS zones and views:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab, click **Copy Rules** from the **Toolbar**.
2. In the *Copy Rules* dialog box, Grid Manager displays the last selected zone or the zone from which you are copying rules in the **Source** field. The following fields are displayed:
    - **Source**: Grid Manager displays the last selected zone or the zone from which you are copying rules. It also displays the associated DNS view.
    - **Destination**: Click **Select Zone** to select the destination zone. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box from which you can select one. After you select the zone, Grid Manager displays the associated DNS view.
    - **Copy All Rules**: Select this option to copy all the rules.

- **Copy Specific Rules**: Select this option to copy specific rules only. Select a rule from the **Available** column and click the right arrow to move it to the **Selected** column.
- **Copy Options:** Select one of the following:
  - **Delete all rules in the destination before copying the rules:** Select to delete all rules in the destination zone before the records are copied.
  - **Overwrite existing rules:** Select to overwrite existing rules that have the same domain name owners as the rules being copied.

3. Click **Copy & Close**.

Importing RPZ Rules

You can import rules from an RPZ zone to a local zone. To import, you must enable zone transfer on the external server. The rules of the existing zone are overwritten when you import rules from an external server.
To import RPZ rules:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab -> click the RPZ link in the **Name** column -> *Rules*, click **Import Zone** from the **Toolbar**.
2. In the *Import Zone* dialog box, the following fields are displayed:
   - **Zone**: The RPZ that you have selected is displayed.
   - **DNS View**: The DNS view that you have selected is displayed.
   - **Address**: Enter the address of the external server from where you want to import rules.
3. Click **Import.**

Disabling NSDNAME and NSIP rules for RPZ zones

NSDNAME and NSIP rules are enabled for RPZ zones by default. You can disable or enable NSDNAME and NSIP rules to control the validation of NS records and glue records received by upstream DNS servers. When you enable RPZ on internal DNS servers and if there are forward-mapping zones that are not reachable from external networks, NSDNAME and NSIP validation is not necessary. In this case, you can disable NSDNAME and NSIP rules to reduce delays in responses. When you disable these rules for RPZ zones, the appliance bypasses NSDNAME and NSIP validation for the queries and it significantly improves the performance. Note that this setting disables both NSDNAME and NSIP rules at the same time for both internal and external RPZ zones. This setting only affects the lookup process but the zone data remains unchanged. NSDNAME and NSIP records will still be available in RPZ zones during zone transfers (AXFR and IXFR). If you disable NSDNAME and NSIP rules for RPZ zones at the Grid level, all members inherit this setting. You can override this setting for each member.

> ⚠ **Note**
>
> Disabling NSDNAME and NSIP rules for RPZ zones on members which may send recursive queries to external servers, results in reduced security. Accordingly, it is not recommended to disable these rules for RPZ zones on members that respond with data from external servers.

To disable NSDNAME and NSIP rules for RPZ zones:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, expand the Toolbar and click **Grid DNS Properties**.
   Member: From the **Data Management** tab, select the **DNS** tab, click the **Members** tab -> *member* checkbox -> Edit icon.
2. In the *Grid DNS Properties* or *Member DNS Properties* editor, click the **General** tab -> **Advanced** tab and complete the following.
   - **Disable NSDNAME and NSIP rules for RPZ zones**: This checkbox is deselected and NSDNAME and NSIP rules are enabled for RPZ zones by default. Select this checkbox to disable NSDNAME and NSIP rules for all RPZ zones. To override the value inherited from the Grid, click **Override**. To retain the same value as the Grid, click **Inherit**.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring Prefix Length Limit for RPZ-IP Triggers

To avoid the possibility of DNS outage resulting from errors in the RPZ rules received from external sources by the RPZ feed or due to errors in the RPZ rules added to local RPZ, Infoblox provides an option to set the prefix length limit for RPZ-IP triggers. This enables the appliance to ignore RPZ-IP rules with prefix lengths that are less than the configured minimum prefix length, and to enforce only those RPZ-IP rules whose prefix lengths are equal to or greater than the configured minimum prefix length, thus accepting legitimate queries instead of dropping all queries. For example, if you configure 24 as the minimum IPv4 prefix length, the Grid enforces only those RPZ-IP rules with prefix length equal to or greater than 24 and the RPZ-IP rules with prefix lengths less than 24 are not enforced on queries that originate from external sources.

You can configure the prefix length limit for IPv4 and IPv6 prefixes at the Grid level and override it for a member, DNS view, or RPZ zone. The appliance logs a warning message in the syslog when RPZ-IP rules with prefix length less than the configured minimum prefix length are added to the local RPZ and, when an RPZ feed receives RPZ-IP rules with prefix length less than the configured prefix length from external sources.

To configure the prefix length limit for RPZ-IP triggers:

1. **Grid**: From the **Data Management** tab, select the **DNS** tab, and then select **Grid DNS Properties** from the Toolbar.
   Member: From the **Data Management** tab, select the **DNS** tab -> **Members** tab -> *member* checkbox -> Edit icon.
   DNS View: From the **Data Management** tab, select the **DNS** tab and click the **Zones** tab -> *dns_view* checkbox -> Edit icon.
   RPZ Zone: From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab -> *Response policy zone* checkbox -> Edit icon.
2. In the editor, click **Toggle Advanced Mode,** and then select the **Security** tab.
3. Complete the following in the Response Policy Zones section of the **Security** tab:
   To override the Grid settings, click **Override**. To retain the same settings as the Grid, click **Inherit**.
   - **Ignore RPZ-IP triggers with too small prefix lengths**: Select this checkbox to set the prefix length limit for RPZ-IP triggers and enable the appliance to ignore the RPZ-IP rules with prefix lengths that are less than the specified prefix length limit. This checkbox is deselected by default.
     - **Minimum IPv4 Prefix Length**: Enter the minimum prefix length for IPv4 prefixes. You can specify a value between 1 to 31. The default value is 29.
     - **Minimum IPv6 Prefix Length**: Enter the minimum prefix length for IPv6 prefixes. You can specify a value between 1 to 127. The default value is 112.
4. Save the configuration and click **Restart** if it appears at the top of the screen.

Configuring Thresholds for RPZ Hit Rate

When the RPZ hit rate, which is the ratio of the number of queries that result in modifying the genuine response due to RPZ rules to the total number of incoming queries is high, it is unexpected and might warrant your attention. Note that the queries that hit passthru RPZ rules are not considered for the RPZ hit rate. You can configure thresholds for RPZ hit rate, above which the appliance makes a syslog entry and sends alerts as SNMP traps and email notifications. Note that you must enable notifications in order for the appliance to send SNMP traps and email notifications. For information about setting the SNMP trap and email notifications, see *Setting SNMP and Email Notifications*.

Note that the appliance calculates the RPZ hit rate globally for all DNS views and sometimes the RPZ hit rate might be misleading. For example, if there are multiple DNS views with or without RPZ rules, there is a possibility that some DNS views might receive a substantial number of normal queries, obscuring the possible high RPZ hit rate in the other DNS views. Also, when the DNS server is configured for both authoritative and recursive queries, it is possible that the authoritative zones receive a substantial number of queries for which RPZ rules are not considered. It might make the resulting RPZ hit rate normal even if there is an excessive number of hit for recursive queries.

To configure the thresholds for RPZ hit rate:

1. **Grid**: From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar.
   Member: From the **Grid** tab, select the **Grid Manager** -> **Members** tab -> *member*, and then click the **Edit** icon.
2. In the *Grid Properties* or *Grid Member Properties* editor, click **Toggle Advanced Mode,** and then select the **SNMP Threshold** tab.
3. Complete the following in the Response Policy Zones Hit Rate Configuration section of the **SNMP Threshold** tab.

- **RPZ Hit Rate**: Click **Override** to override the inherited settings, and specify the following:
  - **Trigger %**: Enter the Trigger value between 0 and 100. If the RPZ hit rate equals the Trigger value, the appliance logs a syslog entry and — if configured to do so — sends an SNMP trap and an email notification. The default Trigger value is 10%.
  - **Reset %**: Enter the Reset value between 0 and 100. If the RPZ hit rate equals the Reset value, the appliance logs a syslog entry and — if configured to do so — sends an SNMP trap and an email notification, to notify that the RPZ hit rate has gone back to an acceptable level. The default Reset value is 2%.
- **Interval**: Enter the time interval that determines when the appliance starts calculating the RPZ hit rate. You can enter a value between 1 and 86400. The default value is 10 seconds. At the end of each interval, if the number of incoming queries equals or exceeds the **Minimum query** value, the appliance calculates the RPZ hit rate and if the RPZ hit rate exceeds the **Trigger** value, the appliance sends notifications and continues to send notifications at the end of subsequent intervals, until the RPZ hit rate equals the **Reset** value.
  Note that the appliance calculates the RPZ hit rate at the end of each **Interval** or when the number of incoming queries reach the **Maximum query** value, whichever comes sooner.
- **Minimum query**: Specify the minimum number of queries received between the RPZ hit rate checks. The default value is 1000. The appliance calculates the RPZ hit rate when the number of incoming queries equals or exceeds the **Minimum query** value at the end of the **Interval**. If the total number of incoming queries is less than the **Minimum query** value, the appliance skips the RPZ hit rate check and the query count continues to cumulate into subsequent intervals until the **Minimum query** is met.
- **Maximum query**: Specify the maximum number of queries received between the RPZ hit rate checks. The default value is 100000. When the number of incoming queries equals or exceeds this value, the appliance calculates the RPZ hit rate and does not wait for the expiration of the **Interval**.

4. Save the configuration and click **Restart** if it appears at the top of the screen.

Verifying RPZ Configuration

After you have set up and configured RPZs and RPZ rules, you can verify whether the RPZ zone transfers are functioning properly by doing the following:

- *Viewing RPZ in the Syslog*
- *Viewing the Last Updated RPZs*

The appliance also makes a syslog entry, when an RPZ zone refresh succeeds or fails and also sends an SNMP trap and an email notification, if configured. For information about setting SNMP and email notification, see *Setting SNMP and Email Notifications*.

Viewing RPZ in the Syslog

To receive RPZ information in the syslog, make sure that you enable the RPZ option in the Logging tab of the Grid DNS Properties editor. Once the RPZ option is enabled, the appliance logs RPZ threats in CEF (Common Event Format) in the syslog. You can click the Action icon to view the RPZ threat details in the RPZ Threat Details viewer. For information about how to configure the syslog server, see *Using a Syslog Server*.

Following is a sample RPZ threat message:

```
2014-09-15T07:14:47-07:00 daemon info rpz:
CEF:0|Infoblox|NIOS|6.12.0-252689|RPZ-QNAME |PASSTHRU|7|app=DNS
dst=172.31.1.156
src=10.120.20.69 spt=39503 view=_default qtype=A msg="rpz QNAME PASSTHRU
rewrite
passthru.com [ANY] via passthru.com.rpz_1.com
```

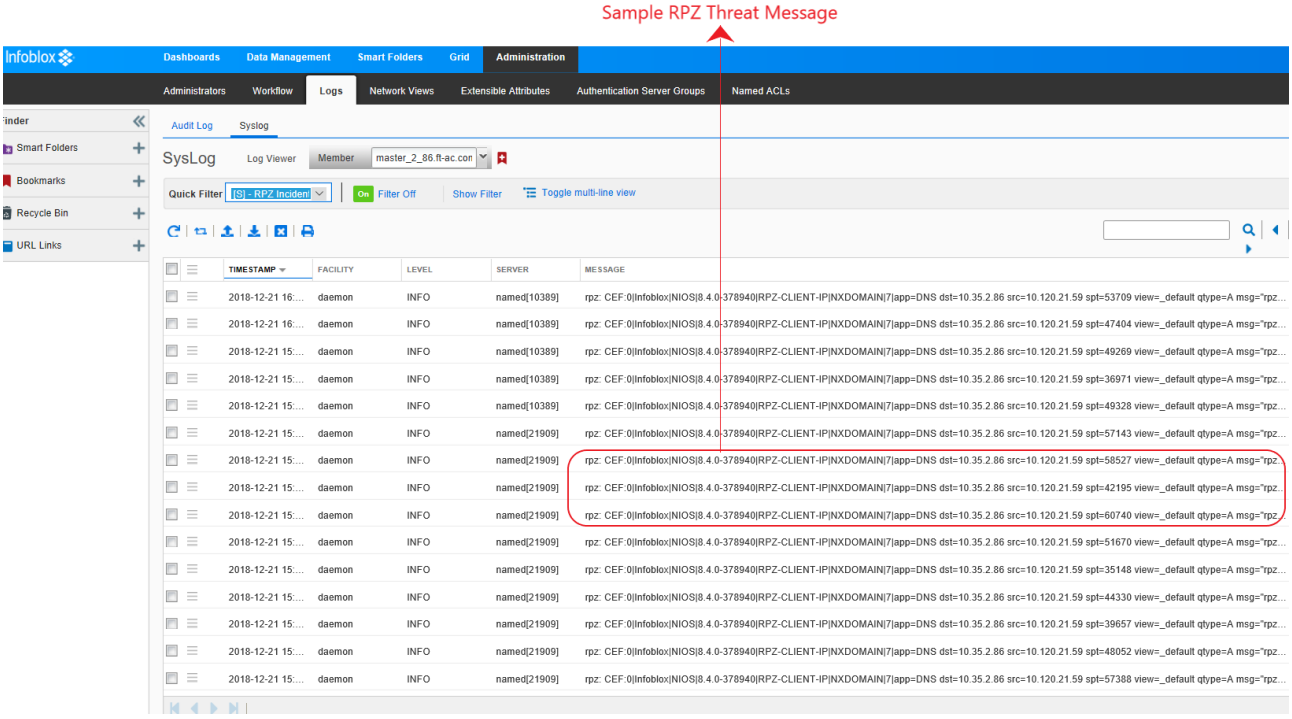
Each log message contains the following information:

- The timestamp when the event happened in yyyy-mm-ddThh:mm:ss-00:00 format.
- **Infoblox|NIOS |x.x.x**: Indicates the Infoblox product, and x.x.x represents the NIOS version.
- The string following the NIOS version is a hard-coded constant. In this example, it is RPZ QNAME.
- The hard-coded constant is followed by mitigation action. In this example, it is PASSTHRU.
- The number following the mitigation action is the threat severity level. The following numbers indicate the severity levels:
    - **8** = **Critical**
    - **7** = **Major**
    - **6** = **Warning**
    - **4** = **Informational**
- **dst**: Destination IP address.
- **src**: Source IP address.
- **spt**: Source port.
- **view**: DNS view.
- **qtype**: Query type.
- **msg**: RPZ rule.

The syslog messages are optionally tagged according to the logging category configured in the external syslog servers. For more information, see *Syslog Message Prefixes*.
To verify RPZ zone transfers:

1. Go to the **Administration** tab -> **Logs** tab -> **Syslog** tab.
2. Select **RPZ Incident Logs** from the **Quick Filter** drop-down list.
3. Review the syslog for zone transfer confirmation, as shown in the below figure.

The Syslog Viewer



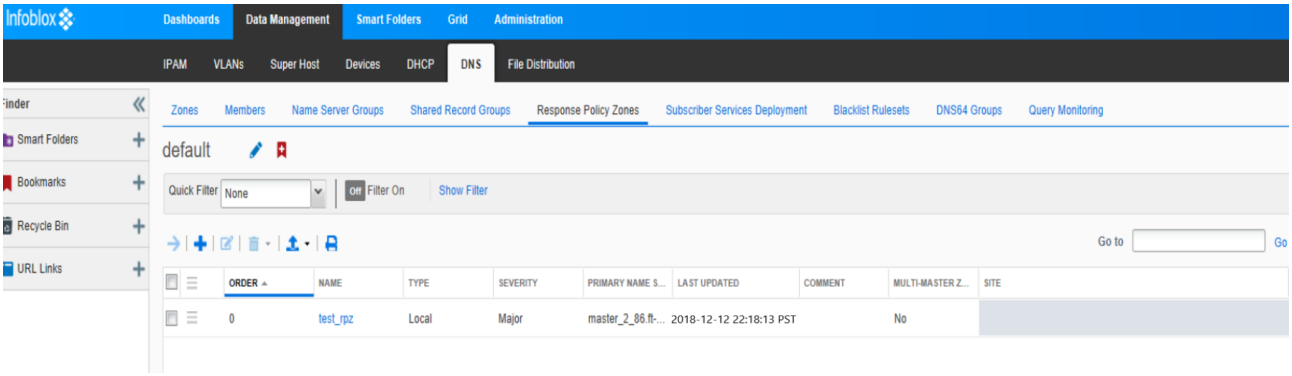
Viewing the Last Updated RPZs

To view the last updated RPZs:

1. Go to the **Data Management** tab -> **DNS** tab -> **Response Policy Zones** tab.
2. Review the **Last Updated** column and confirm the time when an RPZ was last updated, as shown in the following figure.

> ⚠ It may take up to 10 minutes before the updated information is displayed.

Last Updated RPZ



Best Practices for Configuring RPZs

Before configuring RPZs, observe the following best practices to ensure a successful configuration:

General RPZ Best Practices

- When you enable Infoblox DNS Firewall , DNS performance for all queries, recursive or authoritative, will be affected.
- For performance reasons, Infoblox recommends that you maintain a reasonable number of zones.
- Do not enable RPZ on multiple layers, such as on DNS client facing servers and forwarders.
- If you have multiple DNS servers in a Grid, ensure that you configure RPZs on the recursive server that is closest to your DNS clients. If you configure RPZs on second level DNS caching servers, you will not be able to identify the DNS clients because only the IP addresses of the forwarding name servers can be identified.
- Infoblox recommends that you preview your RPZ rules to ensure ruleset integrity and to avoid unexpected results. You can preview your rules by selecting **Log Only (Disabled)** when you configure **Policy Override** for an RPZ, RPZ feed, or FireEye integrated RPZ. For information about how to configure this, see *Configuring Local RPZs* and *About FireEye Integrated RPZs*.
- The appliance logs all matching and disabled rules for all queries in the syslog. You can view the syslog to ensure that the rules are set up correctly before they take effect. Ensure that you enable **rpz** in the **Logging Category** of *Grid DNS Properties* editor to log these events. For information about how to set logging categories as described in setting DNS logging categories, see *Using a Syslog Server*.
- You can use the standard TSIG mechanism to ensure that feed zones come from the correct servers. Grid members can function either as a primary or secondary servers for the RPZ. As with hosting any zone as a secondary, please ensure that the appliance is sized properly to hold the zone contents in memory.
- You can only export or import the RPZ local zones using the CSV export or import feature, but you cannot import or export FireEye zones using this feature.
- Note that the NIOS blacklist and NXDOMAIN features take precedence over RPZs.
- In order to leverage DNS notify messages to trigger zone transfer of the feed zone, port 53 of the lead secondary must be open to receive such messages. If not, the zone will refresh based on the refresh setting in the SOA.
- The name of the zone, which is assigned to an RPZ member, must not exceed 241 characters. When the name exceeds this limit, respective zone fails to load.

- For RPZs that contain IP addresses, RPZ query name recursion continues to take place irrespective of other settings (such as the **Enable RPZ query name recursion (qname-wait-recurse)** checkbox). Recursion takes place for the first RPZ that contains the IP rules. Because of this, if data exfiltration through DNS is to be blocked, then RPZs associated with disrupting the blockage must be placed before RPZs containing the IP rules. That is, RPZs that use IP rules must be placed last in the RPZ order.

Best Practices For FireEye Integrated RPZs

Before you configure a FireEye integrated RPZ, consider the following:

- FireEye integrated RPZs inherit default values from local RPZs. You can create, edit and delete rules using the Infoblox GUI, API, and RESTful API.
- To avoid false positives, Infoblox recommends that you create a whitelist of allowed zones using a local RPZ that is sorted above the FireEye RPZ and add your own domain to the whitelist RPZ. For example, you can add your company domain name, such as corpxyz.com. This list must contain popular domains, such as Alexa 250, and other desired domains.
- Note that there will be an impact on the storage capacity when you create a new FireEye alert and map it with an RPZ rule. The processing of alerts will consume a few CPU cycles, which will have some impact on the system.
- You must properly configure the settings on a FireEye appliance. NIOS supports only **Per Event** delivery mechanism and **JSON Normal** message format. To ensure that the NIOS appliance process alerts properly, configure the FireEye appliance accordingly. For more information about alerts as described in handling alerts from the fireeye appliance, see *About FireEye Integrated RPZs*.
- You cannot add a FireEye integrated RPZ during a scheduled full upgrade. However, updates to the CNAME record are processed during a full upgrade. NIOS updates CNAME records in the database to store information that is specific to FireEye alerts.
- The rules created due to insertion of alerts will be visible through the FireEye RPZ viewer. Infoblox recommends that you do not modify any internal objects. For more information about viewing RPZs, see *Managing RPZs*.
- Note that SSL certificate validation is not supported.
- You must verify the following after you configure the FireEye and NIOS appliances:
    - The URL configured on the FireEye appliance matches the URL in the FireEye integrated RPZ on NIOS.
    - Verify the username and password for FireEye admin on the FireEye appliance.
    - Ensure that the settings are properly configured on the FireEye appliance.
    - Verify the state of the FireEye appliance.

  For more information about configuring the FireEye appliance to send alerts to the NIOS appliance, see *About FireEye Integrated RPZs..*
- Note that the frequency of alerts received from FireEye can be minimal. A very small number of alerts are generated on a weekly basis. For example, the FireEye appliance may generate only tens of alerts per day.

Configuring Combination Threat Feeds

Infoblox has a large and robust offering of threat intelligence feeds that allow you to tailor your security to your needs. In an effort to simplify the process, Infoblox has created “combination feeds” to group sets of threat intelligence feeds in order to reduce the number of choices and make the process more intuitive. As no two users have the same requirements, threat intelligence feeds have been narrowed to a small number of “sets”. The set you choose depends on the sensitivity your environment has to protection of potential threats as compared to the sensitivity your environment has to blocking potentially benign sites.

Aside from simplifying the choice from more than twenty individual feeds to a single set, there are other benefits to these feeds as well. These feeds will continue to be curated over time. As new feeds that qualify for inclusion are introduced, new classes of indicators will be added automatically and do not require a major change to your policy rules. Similarly, as some feeds are deprecated, they can be removed from the combination feed automatically, thus not requiring maintenance of your policy rules. As these feeds are enhanced and maintained, you will be updated about any substantive changes to their contents.

Infoblox provides four sets of combination feeds:

- **Low**: Blocks the fewest number of threats but also minimizes the potential of blocking benign sites. Examples of these environments may be universities, service providers, and public wifi access points.

- **Medium**: An ideal balance between detection while minimizing the potential for positives. The “Medium” set has been designed to be appropriate for most enterprise organizations. If you are unsure of which set to use, “Medium” is probably the best fit for your organization
- **High**: Designed for environments where security is the most important factor. These feeds are most appropriate for environments where communication is well understood and security of the devices is critical. Examples of environments where “High” is most appropriate include server farms, networks with IoT devices or Point-of-Sale terminals. It is not recommended for networks in which users typically surf the web or check their email.
- **Extreme**: Created to provide the greatest degree of security, but these sets are not recommended for most users as the potential for positives is much higher than normal. Use this feed at your own risk.

Each set includes two separate feeds that must be deployed together and without any other set:

- **Block**: Deploy this file with the policy action of “Block”. This should be one of the first actions in the policy list, possibly following a global allow list.
- **Log**: Deploy this file with the policy action of “Allow” (preferably with log). This should be one of the last actions in the policy list.

For example, this is what a minimal policy should look like if the “Medium” set best describes your organization.

Order	Object	Action
1	Local RPZ: Allowlist	Passthru
2	RPZ: ib-med-block	Block
3	RPZ: ib-med-log	Log Only (Disabled)

Contents of Combination Feeds

Combination feeds are combinations of existing feeds. If you deploy either the Low, Medium, High, or Extreme combination feed set, these feeds are already combinations of one or more of the following existing feeds:

- AntiMalware
- AntiMalware_IP
- Base Hostnames
- Bogon
- Cryptocurrency hostnames and domains
- DoH Public Hostnames
- DoH Public IPs
- Exploit Kit IPs
- Extended Base & anti-malware Hostnames
- Extended Exploit Kits IPs
- Extended malware IPs
- Extended Ransomware IPs
- Extended TOR Exit Node IPs
- Malware DGA hostnames
- Malware IPs
- Ransomware
- SURBL Fresh domains
- SURBL Multi domains
- SURBL Multi Lite domains
- TOR Exit Node IPs

This means that if you use one of the combination feed sets, you must not:

- Use it in combination with any other set. That is, do not deploy Low, Medium, and High together. Each is completely self-contained, and deploying them together will almost certainly not provide the results you are looking for.

- Use it in combination with any of the other above feeds, as these feeds are already reselected in the contents of the combination feed. Therefore, deploying them together will at minimum cause your NIOS appliance to expend more resources than necessary, and may also result in undesired actions if there are conflicting policies.

Current Contents of Each of the Combination Threat Feeds

Feeds	Extreme Block	Extreme Log	High Block	High Log	Med Block	Med Log	Low Block	Low Log
AntiMalware	✓		✓			✓		✓
AntiMalware_IP	✓		✓			✓		
Base Hostnames	✓		✓		✓		✓	
Bogon	✓		✓		✓			✓
Cryptocurrency hostnames and domains	✓		✓			✓		✓
DoH Public Hostnames	✓		✓			✓		✓
DoH Public IPs		✓		✓		✓	✓	✓
Extended Base & anti-malware Hostnames	✓		✓		✓		✓	
Extended malware IPs	✓			✓		✓		✓
Extended Ransomware IPs	✓			✓		✓		✓
Extended TOR Exit Node IPs	✓		✓			✓		✓
Malware DGA hostnames	✓		✓		✓		✓	
Malware IPs	✓			✓		✓		✓
Ransomware	✓		✓		✓		✓	

Best Practices for Deploying Combination Threat Feeds

Before deploying combination threat feeds, observe the following best practices to ensure a successful deployment:

1. Choose the set of feeds that best describes your organization: Low, Medium or High. If in doubt, most organizations are best served with Medium.
2. Deploy the set of feeds together. For example, if “Medium” best describes your organization, deploy both *ib-med-block* and *ib-med-log* together.
3. Do not deploy one set of threat intelligence with any other set. That is, do not deploy Medium together with High. Choose one set and deploy it together and without any other set.

4. Do not deploy a set with any feeds listed in *Contents of Combination Feeds*. These feeds are already reflected in the combination feeds, so using them together may cause duplication, redundancy, or potential of conflict.
5. Deploy blocking feeds as close to the first policy action as possible (potentially after a global allow list).
6. Deploy logging feeds after all blocking feeds so as to not accidentally allow an indicator that another feed wanted to block.

What to do if you have already deployed a combination threat feed?

If you have already deployed a combination threat feed, review the best practice recommendations above and make sure that you have followed the guidelines described above. Specifically:

- If you have deployed two or more sets of combination feeds, **remove the lower sets** as these are already reflected in the higher sets. For example, if you have deployed all three (Low, Medium, and High), remove Low and Medium because the indicators in these sets are already reflected in High.
- If you have deployed one of the sets along with any of the feeds reflected in the Contents of Combination Feeds table at *Configuring Combination Threat Feeds* , **remove those feeds** from the policy actions list as they are already reflected in your selected policy group.

Infoblox Threat Insight

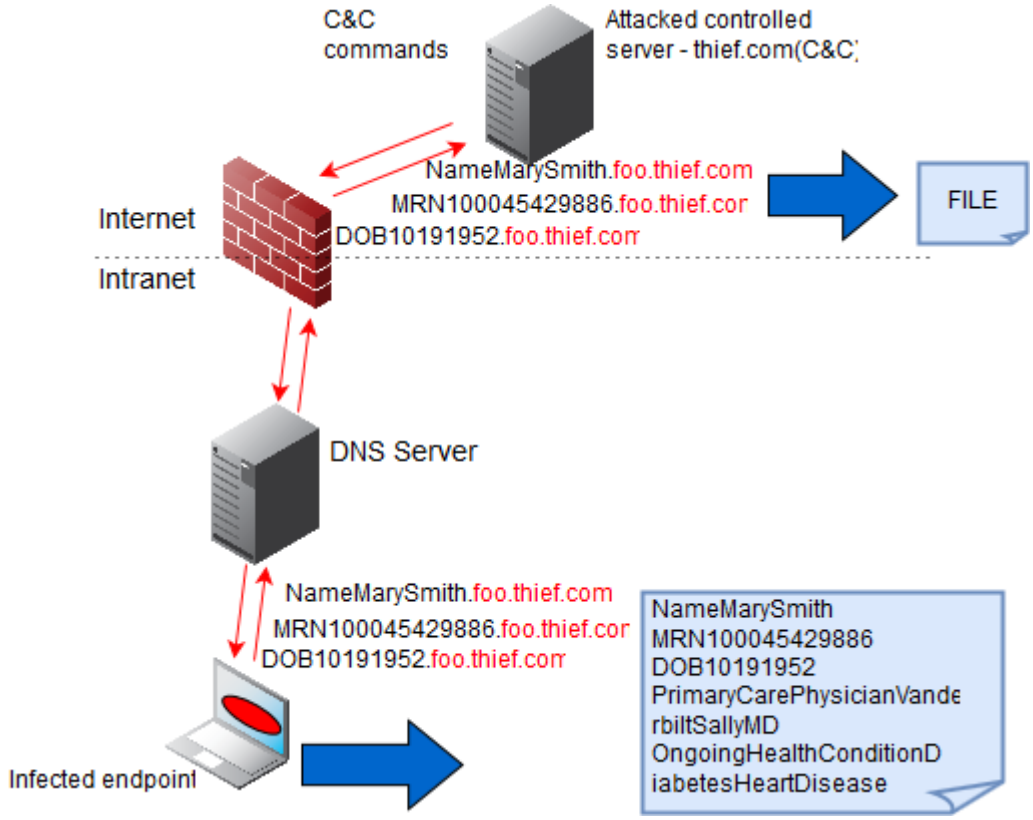
This section provides information about the Infoblox Threat Insight (also referred to as Threat Analytics in Grid Manager), which protects mission-critical DNS infrastructure from data exfiltration through DNS tunneling. This section includes the following topics:

About Data Exfiltration

The DNS protocol is increasingly used as a pathway for data exfiltration through DNS tunneling attacks. DNS tunneling involves tunneling another protocol through port 53 — often not inspected by firewalls (even the next-generation firewalls) — by malware-infected devices or malicious insiders. There are a number of tools available for tunneling over DNS for a common motivation of bypassing captive portals for paid Wi-Fi access. A free tunneling application released under the ISC license for forwarding IPv4 traffic through DNS servers is one example of the software used in this kind of attack.

As illustrated in the below figure, sensitive information such as credit card numbers and company financial can be stolen either by establishing a DNS tunnel from within the network or by encrypting and embedding chunks of that data in DNS queries. Data is decrypted at the other end and put back together so valuable information can be stolen and misused by malicious attackers.

Data Exfiltration



You can use the following features to specifically target DNS tunneling traffic and minimize the risk of DNS data exfiltration:

- Anti-DNS tunneling threat protection rules: These rules detect signature-based payload encoding techniques, such as Base32, Base64 and suspicious label lengths, commonly used by tunneling products such as OzymanDNS, Iodine, DNS2TCP, and SplitBrain. For more information about the threat protection rules, refer to the Threat Protection Rules document available on the Infoblox Support site.
- Infoblox Threat Insight: Infoblox employs streaming analytics to study DNS statistics and create algorithms to identify DNS tunneling traffic. o further defend your system against DNS data exfiltration, Infoblox Threat Insight detects and mitigates DNS tunneling traffic by analyzing DNS queries and responses. Infoblox Threat Insight constantly evaluates incoming DNS traffic and develops a systematic pattern in defending against illegitimate DNS tunneling traffic and constantly updating blacklists of known malicious destinations. For information about how to configure Infoblox Threat Insight, see *About Infoblox Threat Insight*.

About Infoblox Threat Insight

To mitigate DNS data exfiltration, Infoblox Threat Insight (also referred to as Threat Analytics in the Infoblox GUI or Grid Manager) employs analytics algorithms to detect DNS tunneling traffic by analyzing incoming DNS queries and responses. These algorithms are developed through an extensive study and analysis of sample DNS statistics within which DNS tunneling data is identified by algorithms that cannot be detected by normal rules and signatures. For more information about DNS data exfiltration, see *About Data Exfiltration*.

Infoblox Threat Insight identifies data exfiltration tunnels that bypass typical firewall systems. Some popular tunneling tools are OyzmanDNS, SplitBrain, Iodine, DNS2TCP, TCP-Over-DNS, and others. These types of DNS threats are identified as having high activities by using the TXT records in DNS queries. Infoblox Threat Insight also identifies tunnels that are used for C&C. These threats typically do not exhibit high activities or payloads. In general, NXDOMAIN responses fall into this category of threats.

You must have at least one **RPZ** license installed in your Grid (it can be installed on any Grid member) and the **Threat**

Analytics license installed on the Grid member on which you want to start the threat analytics service. To download updates for threat analytics module and whitelist sets, you must have at least one **Threat Analytics** license installed in the Grid. When you enable the threat analytics service, NIOS starts analyzing incoming DNS data and applying these algorithms to detect security threats that have the same or similar behavior as the known data. Once security threats are detected, NIOS blacklists the domains and transfers them to the designated mitigation RPZ (Response Policy Zone), and traffic from the offending domains is blocked and no DNS lookups are allowed for these domains from NIOS members on which RPZ are assigned to them. The appliance also sends an SNMP trap each time it detects a new blacklisted domain.

Infoblox Threat Insight also includes a whitelist that contains trusted domains on which NIOS allows DNS traffic. These are known good domains that carry legitimate DNS tunneling traffic such as Avast, Sophos, McAfee, Boingo, Barracuda, and others. The whitelist is extensible so new whitelisted domains can be added and rolled out accordingly. For Threat Insight running on an On-Prem Infoblox DDI appliances, internal governance and vetting applied by Infoblox ensures all whitelist entries are accurate and curated, and contain only valid entries.

You can also add custom whitelisted domains or move blacklisted domains to the whitelist. For more information about how to configure Infoblox Threat Insight, see Configuring Infoblox Threat Insight below. Before you utilize Infoblox Threat Insight, there are a few guidelines you might need to consider. For more information about Guidelines for Using Infoblox Threat Insight, see below.

Infoblox Threat Insight came installed with a module set and a whitelist set. To receive subsequent module set and whitelist set updates, you can configure the appliance to automatically download and apply the updates for you, or you can manually upload the updates when the appliance displays a banner message notifying about available updates. For information about how to configure the update policy, see Defining the Threat Analytics Update Policy below.

Licensing Requirements and Admin Permissions

You must obtain and install valid licenses on your appliance before using Infoblox Threat Insight. Contact your Infoblox representative to obtain these licenses. For more information, see *Managing Licenses*.

Infoblox Threat Insight

To start the threat analytics service, you must have at least one **RPZ** license installed in your Grid (it can be installed on any Grid member) and the **Threat Analytics** license installed on the Grid member on which you want to start the threat analytics service. To download updates for threat analytics module and whitelist sets, you must have at least one **Threat Analytics** license installed in the Grid.

Note that running the threat analytics service might affect your system performance if the appliance has a small capacity and is taking on heavy traffic. Evaluate your Grid and Grid members to ensure that you select an appliance that is appropriate for running the threat analytics service. For more information about supported appliances, see Supported Appliances for Infoblox Threat Insight below.

Admin Permissions

Superusers can configure all threat protection and analytics related tasks. You can assign **Security Permissions** to specific admin groups and roles so these users can configure security related tasks. You can also add a global permission for managing Grid security properties or add an object permission for managing member security properties.

To manage the analytics related tasks, you must assign appropriate read-only or read/write **Analytics Permissions** to the specified admin groups and roles. You can also add the **Global Analytics Permission** as a global permission or add **Member Analytics Permission** to specific Grid members as an object permission. For more information about how to assign admin permissions, see *Managing Permissions*.

Guidelines for Using Infoblox Threat Insight

Following are some guidelines to take into consideration when using Infoblox Threat Insight:

- To start the threat analytics service, you must have at least one **RPZ** license installed in your Grid (it can be installed on any Grid member) and the **Threat Analytics** license installed on the Grid member on which you want to start the threat analytics service. To download updates for threat analytics module and whitelist sets, you must have at least one Threat Analytics license installed in the Grid.

- Infoblox recommends that you run the threat analytics service for a limited time to monitor and preview what has been detected before actually blocking blacklisted domains. You can carefully review the list of detected domains and decide which domains you want to continue blocking and which domains you want to add to the analytics whitelist. You should review the blacklisted domains on a regular basis to make sure that no legitimate use of DNS tunneling is blocked. Note that you can update the analytics whitelist by adding new whitelisted domains, moving legitimate domains from the blacklisted domain list, or using CVS import and export. For more information about Configuring a Local RPZ as the Mitigation Blacklist Feed, see below.
- Analytics whitelisted domains and supported DNS tunneling tools are updated periodically and are bundled with future NIOS releases. To ensure that your appliance is using the most up-to-date whitelist, upgrade to the next NIOS release or configure the appliance to download threat analytics updates. For information about upgrades, see *Upgrading NIOS Software*. Note that this process may change in future NIOS releases.
- There are no configurable parameters for Infoblox Threat Insight. Infoblox uses the build-in algorithms to analyze DNS statistics and blocks offending domains based on the analyzed data.
- DNS tunneling detection is not instantaneous. It may take a few seconds to a few minutes for the analytics to determine positive DNS tunneling activities.
- During an HA failover, analytics data that is in progress on the active node might be lost. Only new DNS queries on the new active node after a successful failover are being analyzed. It may take a few minutes for the analytics to reach its normal state. If there is no connection between the Grid Master and Grid member, blacklisted domains detected by the analytics cannot be transferred to the Grid Master as RPZ records for a pre-configured RPZ zone — this is not applicable to standalone appliances with RPZ license installed. In addition, ensure that the passive node must also have the RPZ license installed and that its hardware model is capable of running the threat analytics service. For information about supported appliance models, see Supported Appliances for Infoblox Threat Insight below.
- The threat analytics service only works on recursive DNS servers and forwarding servers that use BIND as the DNS resolver. It does not support Unbound as the DNS resolver.
- The analytics whitelist only applies to Infoblox Threat Insight; it does not apply to signature-based tunneling detection. Anti-DNS tunneling threat protection rules are implemented to address signature-based tunneling analysis. For detailed information about threat protection rules, refer to the *Infoblox Threat Protection Rules* available on the Support web site.
- Infoblox Threat Insight does not support RESTful APIs.

Supported Appliances for Infoblox Threat Insight

Due to memory and capacity required to perform analytics, ensure that you install the Threat Analytics and RPZ licenses, and enable the threat analytics service on an appliance that has a big enough capacity. Following are the supported Infoblox appliance models on which you can run the threat analytics service:

- PT-1405, and PT-2205.
- IB-4015, and IB-4030-10GE.
- TE-1415, TE-1425, TE-2215, and TE-2225.
- TE-V1415, TE-V1425, TE-V2215, TE-V2225, TE-V4010, and TE-V4015.

> **Note**
>
> Using unsupported appliance models for Infoblox Threat Insight might cause performance issues.

Configuring Infoblox Threat Insight

You must have at least one RPZ license installed in your Grid (it can be installed on any Grid member) and the Threat Analytics license installed on the Grid member on which you want to start the threat analytics service. You must also create a new RPZ and use it as the designated mitigation blacklist feed so the appliance can transfer all blacklisted domains to this feed.

NIOS continuously collects and analyzes statistics of incoming queries and responses, detects possible DNS tunneling activities, blocks offending domains that match the known data, and updates the mitigation blacklist feed (a designated local RPZ) of any known malicious domains. For supported appliance models for Infoblox Threat Insight, see Supported Appliances for Infoblox Threat Insight.

To configure Infoblox Threat Insight, complete the following:

1. Obtain and install valid **RPZ** and **Threat Analytics** licenses on the appliance that is used to support analytics. Note that you must have the threat analytics service running on the member serving recursive DNS queries or have recursive DNS queries forwarded to another DNS server. To generate reports that contain statistics about DNS tunneling, you must also configure a reporting appliance in the Grid.
2. Create and add a new local RPZ and use it as the designated mitigation blacklist feed so the appliance can transfer all blacklisted domains to this feed. Ensure that you configure an appropriate policy for this RPZ. To monitor the threat analytics service before actually blocking domains, set **Policy Override** to **Log Only (Disabled).** When you are ready to block offending domains, set **Policy Override** to **None (Given)**.
3. Configure admin permissions so admin users can manage the threat analytics service and analytics related tasks. For information about how to configure admin permission, see *About Administrative Permissions*.
4. Start the threat analytics service on the appliance that has the **Threat Analytics** license installed, as described in Starting and Stopping the Threat Analytics Service.

Note

The analytics functionality only works on recursive servers and forwarding servers that use BIND as the DNS resolver; it does not function on authoritative servers or servers that use Unbound as the DNS resolver.

After you set up Infoblox Threat Insight to mitigate DNS data exfiltration, you can do the following to manage it:

- View supported whitelisted domains for analytics, as described in Viewing the Analytics Whitelist below. Note that these domains are specific to analytics only. They are not used in the anti-DNS tunneling threat protection rules.
- Manually add a custom domain to the analytics whitelist, as described in Adding Custom Whitelisted Domains below.
- Review the blacklisted domains and make decisions about whether to move them to the analytics whitelist so future DNS activities will not be blocked. For more information, see Viewing Blacklisted Domains below.
- Move a blacklisted domain to the analytics whitelist, as described in Moving Blacklisted Domains to the Whitelist.
- Monitor DNS tunneling activities and events using pre-defined reports and the syslog, as described in Monitoring DNS Tunneling Activities below.

Starting and Stopping the Threat Analytics Service

To start the threat analytics service, you must have at least one RPZ license installed in your Grid (it can be installed on any Grid member) and the Threat Analytics license installed on the Grid member on which you want to start the threat analytics service. You can also stop the service when necessary.

To start or stop the threat analytics service:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Services** tab, click the **Threat Analytics** service link. Grid Manager displays only the member or members with the RPZ license installed. Select the member checkbox.
2. From the Toolbar, click **Start** to start the service or **Stop** to stop the service.

When you stop the threat analytics service, the appliance does not detect or protect against non-signature-based DNS tunneling. In addition, reports that you generate might not include statistics related to DNS tunneling.

Note

After you enable the threat analytics service, you must restart DNS service for the analytics to start working.

Viewing the Analytics Whitelist

The **DataManagement** tab -> **ThreatAnalytics** tab -> **Whitelist** tab of Grid Manager lists the trusted domains on which NIOS allows DNS traffic by default. These are known good domains that carry legitimate DNS tunneling traffic such as Avast, Sophos, McAfee, Boingo, Barracuda, and others. They are marked as **System** domains, and you cannot delete them; but you can disable them so NIOS does not treat them as trusted domains. You can also add custom domains or

move blacklisted domains to the analytics whitelist. For more information, see Adding Custom Whitelisted Domains and Moving Blacklisted Domains to the Whitelist below.

To view a complete list of trusted domains in the analytics whitelist:

1. From the **Data Management** tab, select the **Threat Analytics** tab -> **Whitelist** tab.
2. The appliance displays the following for each trusted domain:
    - **Actions**: Click the Action icon  next to a domain and select one of the following:
        - **Disable**: Click this to disable the domain. When you disable a domain, the appliance does not treat this domain as trusted domain until you enable it.
        - **Edit**: Click this to open the *Whitelist* editor. For system domains, the only property you can modify is to disable or enable them. For custom domains however, you can also add information to the **Comment** field.
        - **Delete**: This is only applicable to custom domains. You cannot delete system domains. Select this to delete the custom domain.
    - **Domain Name**: The name of the trusted domain.
    - **Type**: Displays the domain type. This can be **System** or **Custom**. A system domain is a trusted domain that carries legitimate DNS tunneling traffic such as Avast, Sophos, McAfee, Boingo, Barracuda, and others. A custom domain is one that you have added to the whitelist or moved from the mitigation blacklist RPZ.
    - **Disabled**: Indicates whether this domain is disabled or not. The appliance does not treat disabled domains as trusted domains. You can disable both system and custom domains.
    - **Comment**: Additional information about the domain.

Note

When you upgrade to a future NIOS release or update the analytics whitelist, all changes made to the whitelist will be preserved.

You can also do the following in this panel:

- Click **Go to Mitigation Response Policy Zone** to access the blacklisted domains that are identified as offenders for DNS tunneling. Blacklisted domains are detected through Infoblox Threat Insight and automatically transferred to the blacklist RPZ feed. For information about these domains, see Viewing Blacklisted Domains below.
- Export or import whitelisted domain names using the CSV import and export functionality.
- Navigate to the next or last page of the whitelist using the paging buttons at the bottom of the panel.
- Refresh the analytics whitelist by clicking the Refresh button.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Select a quick filter to search for **System** or **Custom** whitelist entries, or both.
- Print the whitelist or export it in CSV format.

Adding Custom Whitelisted Domains

The analytics whitelist is populated with trusted domains that carry legitimate DNS tunneling traffic such as Avast, Sophos, McAfee, Boingo, Barracuda, and others.You can add domains that you deem trustworthy to this list. When you add a custom domain, it is marked as **Custom** in the whitelist.

To add a custom whitelisted domain, complete the following:

1. From the **Data Management** tab, select the **Threat Analytics** tab -> **Whitelist** tab, click the Add icon or click **Add Custom Whitelist** from the Toolbar.
2. In the *Add Custom Whitelist* wizard, complete the following:
    - **Domain Name**: Enter the name of the domain that you want to add to the analytics whitelist.
    - **Comment**: Enter additional information about this domain.
    - **Disable**: When you select this, the appliance does not treat this domain as a trusted domain. When you enable the domain again, it is considered as a whitelisted domain.
3. Save the configuration. You do not need to restart DNS service to update the analytics whitelist.

Configuring a Local RPZ as the Mitigation Blacklist Feed

For the threat analytics service to function properly and for NIOS to properly report detected backlisted domains, you must create and designate local RPZs as the mitigation for the Grid. You can add any Response Policy Zones to the list of RPZs from different Network and DNS Views. When a domain is detected as malicious, NIOS will update all RPZs in the list. If you assign an existing RPZ that is used for other purposes as the mitigation blacklist feed, you may experience the following:

- Existing RPZ hits are reported as hits detected by the analytics after an upgrade.
- If you manually add rules to the RPZ, all RPZ hits are reported as hits detected by the analytics, regardless of whether they match the manually created rules or are detected through the threat analytics service.

Infoblox recommends that you run the threat analytics service for a limited time to monitor and preview what has been detected before actually blocking domains. To do so, set **Policy Override** to **Log Only (Disabled)** when you create the RPZ so you can monitor blacklisted domains without actually blocking them.

> ⚠ Note
>
> You can designate only one local RPZ as the Grid-wide mitigation blacklist feed.

To create and designate a local RPZ as the blacklist feed:

1. Create a local RPZ by completing the procedure described in *Configuring Local RPZs*.

   Note to monitor the threat analytics service without blocking domains, set **Policy Override** to **Log Only (Disabled).** When you are ready to block blacklisted domains, set **Policy Override** to **None (Given)**.
2. From the **Data Management** tab, select the **Threat Analytics** tab -> **Whitelist** tab, click the **Grid Threat Analytics Properties** from the Toolbar.
3. In the *Grid Threat Analytics Properties* editor, click the DNS Threat Analytics tab, and complete the following:
   - Click the Add icon to open the *Zone Selector* dialog box and select the RPZs. You must configure at least one local RPZ. To remove an RPZ, select it from the table and click **Delete**.
   - Save the configuration.

> ⚠ Note
>
> You cannot delete an RPZ that is used as the mitigation blacklist feed until you remove or clear it from the *Grid Threat Analytics Properties* editor.

Enabling Integration with BloxOne Threat Defense Cloud for Threat Insight

If your network configuration includes BloxOne Threat Defense Business On-premises, BloxOne Threat Defense Business Cloud, or BloxOne Threat Defense Advanced, you can configure a cloud integration client to collect malicious domains detected by Threat Insight in the BloxOne Threat Defense cloud. NIOS then applies the detected domains to RPZs that were configured for the on-premises Grid. This feature ensures that all malicious domains detected in BloxOne Threat Defense Cloud are also applied on Grid members on-prem.

You can use this feature when you have BloxOne Threat Defense Business On-premises, BloxOne Threat Defense Business Cloud, or BloxOne Threat Defense Advanced license. Note that you can configure only one cloud client per on-premises Grid. Ensure that you configure the email address and password in the *Grid Properties Editor* before you enable the integration with BloxOne Threat Defense Cloud Client. For more information about Configuring Integration with BloxOne Threat Defense Cloud, see *Configuring Integration with BloxOne Threat Defense Cloud*.

To enable the integration with BloxOne Threat Defense Cloud, complete the following steps:

1. From the **Data Management** tab, select the **DNS** tab -> **Response Policy Zones** tab. Expand the Toolbar and click **BloxOne Threat Defense Cloud Client**.
2. In the *BloxOne Threat Defense Cloud Integration Client* editor, complete the following:
   - **Enable Cloud Client**: Select this checkbox to enable NIOS to get Threat Insight results in BloxOne Threat Defense Cloud.
     The results are periodically synchronized based on the interval you set. NIOS requests only subsequent data since the last data timestamp.
   - **Interval**: You can specify how often to request Threat Insight results detected in BloxOne Threat Defense Cloud in seconds or minutes. The default is 10 minutes.
   - **The list of Response Policy Zones to use for blacklisted domains**: Click the Add icon to add an RPZ to the list. When there are multiple zones, Grid Manager displays the *Zone Selector* dialog box from which you can select one. You can add RPZs from different network and DNS views.
3. Click **Save & Close**.

> ⚠ Note
> Whenever a new RPZ is added and NIOS requests Threat Insight results, Grid Manager displays a *Warning* dialog box to confirm that you wish to request all detected domains by Threat Insight in BloxOne Threat Defense Cloud. If you click **No** in the *Warning* dialog box, you can use the set `cloud_services_portal_force_refresh` CLI command in maintenance mode and set the flag to request all domains detected in BloxOne Threat Defense Cloud.

Viewing Blacklisted Domains

To review the list of blacklisted domains, complete the following:

1. From the **Data Management** tab, select the **Data Management** tab -> **DNS** tab -> **Response Policy Zones** tab, click the mitigation blacklist RPZ name.
2. Grid Manager displays the following for each blacklisted domain:
   - **Name or Address**: Displays the name or IP address of the blacklisted domain.
   - **Policy**: Displays the policy used to handle the responses when NIOS detected the blacklisted domain.
   - **Data**: Displays the target data about this domain.
   - **Comment:** Displays additional information about this domain.
   - **Site**: This is a pre-defined extensible attribute (if configured) that is used to indicate the location of the domain.
   - **Disable**: Indicates whether this domain is disabled or not. When the domain is disabled, the appliance does not block activities on this domain, and configuration for this domain does not change. When the domain is enabled, it is considered as a blacklisted domain and all DNS activities are blocked.

You can also do the following in the blacklisted domain panel:

- Click **Go to Analytics Whitelist View** to view the analytics whitelist. In the Whitelist panel, you can see all the trusted domains for Infoblox Threat Insight, and DNS activities are allowed on these domains.
- If you want to move a blacklisted domain to the analytics whitelist so it becomes a trusted domain, select the domain checkbox and click the Action icon next to the domain, and then select **Move to Whitelist**.
- Navigate to the next or last page of the whitelist using the paging buttons at the bottom of the panel.
- Refresh the blacklist feed by clicking the Refresh button.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Select a quick filter to search for specific entries.
- Print the blacklist or export it in CSV format.

Moving Blacklisted Domains to the Whitelist

When the appliance detects an offending domain for possible DNS tunneling, it responds according to the policy defined in the mitigation blacklist RPZ and adds the domain to the blacklist RPZ feed. You can view all blacklisted domains and turn those you deem trustworthy into trusted domains by moving them to the analytics whitelist. Note that once you move a blacklisted domain to the whitelist, you cannot reverse the action.

To move a blacklisted domain to the analytics whitelist:

1. From the **Data Management** tab, select the **Data Management** tab -> **DNS** tab -> **Response Policy Zones** tab.
2. Select a blacklisted domain and click the Action icon next to a domain and select **Move to Whitelist**.

The appliance removes the selected domain from the blacklist and adds it to the analytics whitelist. You can click **Go to Analytics Whitelist View** to verify that the domain has been successfully moved.

Updating Threat Analytics Module and Whitelist Sets

Infoblox periodically releases threat analytics module and whitelist sets. To ensure that you can import threat analytics updates, you must have at least one Threat Analytics license installed in the Grid. The threat analytics module set consists of the analytics application .jar file, which delivers changes and updates for DNS tunneling detection; and the whitelist set consists of updated trusted domains that carry legitimate DNS tunneling traffic. You can download updates for the module set and whitelist set independently depending on how often Infoblox rolls them out. The appliance displays the version numbers of the module set and whitelist set that your Grid is currently using. To view this information before downloading updates, see Viewing Module and Whitelist Versions below.

You can configure the appliance to automatically receive and apply the latest module set and/or whitelist set. When you define an automatic update policy, the appliance checks both the analytics module and whitelist files and automatically downloads the files that have changed. You can also configure a manual update policy in which the appliance notifies you through the message banner when there are updates available. You can then decide whether you want to apply the updates to your Grid or not. For information about how to define the update policy, see Defining the Threat Analytics Update Policy below. For information about how to perform manual updates, see Manually Uploadin*g* Threat Analytics Updates below.

> **Note**
>
> Only the Grid Master receives module set and whitelist set updates. Grid member receives these updates through standard Grid replication from the Grid Master. Module and whitelist data is only replicated to Grid members that have the threat analytics service enabled (an RPZ license is required to start this service on the members). The appliance uses the port 443 (HTTPS) for downloading the module set and whitelist data updates.

Infoblox recommends that you configure the appliance to automatically receive module and whitelist updates, so your appliance receives the latest information periodically. If you prefer to manually upload updates to your Grid, ensure that you apply them frequently to receive the most updated information.

Viewing Module and Whitelist Versions

1. On the **Data Management** tab ->**Threat Analytics** tab -> **Whitelist** tab, expand the Toolbar, and then click **Grid Threat Analytics Properties**.
2. In the *Grid Threat Analytics Properties* editor, click the **Updates** tab. This tab displays the following information:
   - **Active Whitelist Version**: Displays the version number of the threat analytics whitelist set that is currently running on the Grid.
   - **Active Module Set Version**: Displays the version number of the threat analytics module set that is currently active on the Grid.

Defining the Threat Analytics Update Policy

You can configure the settings to obtain policy updates independently for Whitelist or module set, or for both. To configure how you want to obtain the latest threat analytics updates, complete the following:

1. On the **Data Management** tab -> **Threat Analytics** tab -> **Whitelist** tab, expand the Toolbar, and then click **Grid Threat Analytics Properties**.
2. In the *Grid Threat Analytics Properties* editor, click the **Updates** tab,
3. In the *Whitelist Updates* section, complete the following:
   - **Latest Available Whitelist**: Displays the latest whitelist that is available for download.

- **Last Checked For Updates**: Displays the timestamp when the Grid last checked for updates.
- **Whitelist Update Policy**: When you select **Automatic**, the appliance automatically downloads the latest whitelist updates based on the default or custom schedule. The appliance checks whitelist files and automatically downloads only the files that have changed. When you select an automatic policy, latest updates are activated automatically. If you select **Manual** as the update policy, the appliance displays a banner message in Grid Manager to notify you when new updates are available. You must then decide whether to apply the updates to the Grid or not. For information about how to manually apply the updates, see Manually Uploading Threat Analytics Updates below.
- **Enable Automatic Whitelist Updates**: Select this checkbox to enable the automatic upload feature. When necessary, you can click **Download Whitelist Now** to override the automatic update policy.
  In the *Schedule* section, set up a recurring schedule for automatic updates as described in step 5.

4. In the *Module Set Updates* section, complete the following:
   - **Latest Available Module Set**: Displays the latest module set that is available for download.
   - **Last Checked For Updates**: Displays the timestamp when the Grid last checked for updates.
   - **Module Set Update Policy**: When you select **Automatic**, the appliance automatically downloads the latest module set and/or whitelist set based on the default or custom schedule. The appliance checks both the module and whitelist files and automatically downloads only the files that have changed. When you select an automatic policy, the threat analytics service on the Grid members is restarted automatically to activate the latest updates. If you select **Manual** as the update policy, the appliance displays a banner message in Grid Manager to notify you when new updates are available. You must then decide whether to apply the updates to the Grid or not. For information about how to manually apply the updates, see Manually Uploading Threat Analytics Updates below.
   - **Enable Automatic Module Set Updates**: Select this checkbox to enable the automatic upload feature. When necessary, you can click **Download Module Set Now** to override the automatic update policy.
     set up a recurring schedule for automatic updates as described in step 5.
5. In the *Schedule* section, select one of the following to set up a recurring schedule for automatic downloads:
   - **Default**: When you select this, the appliance downloads the updates between 12:00 a.m. and 6:00 a.m. local time based on the time zone configured on your appliance. The appliance automatically selects a time between this time window the first time it performs an automatic update. All subsequent updates then follow the same schedule based on the selected time.
   - **Custom**: Select this and click the calendar icon to configure a custom schedule. Based on the policy you are configuring, in the *Automatic Whitelist Updates Scheduler* or *Automatic Module Set Updates Scheduler*, you can select **Hourly**, **Daily**, **Weekly**, or **Monthly** based on how often you want to update the module set and whitelist set.

     Note that the scheduled time does not indicate the exact time for the download. Downloads occur during the mid-point during of a 30-minute time frame. Therefore, the actual download can happen 15 minutes before or after the scheduled time.
     - When you select **Hourly**, complete the following:
       - **Schedule every hour(s) at**: Enter the number of hours between each update instance. You can enter a value from 1 to 24.
       - **Minutes past the hour**: Enter the number of minutes past the hour. For example, enter 5 if you want to schedule the rule update five minutes after the hour.
       - **Time Zone**: Select the time zone for the scheduled time from the drop-down list.
     - When you select **Daily**, you can select either **Every day** or **Every Weekday**, and then complete the following:
       - **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
       - **Time Zone**: Select the time zone for the scheduled time from the drop-down list.
     - When you select **Weekly**, complete the following:
       - **Schedule every week on**: Select any day of the week.
       - **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
       - **Time Zone**: Select the time zone for the scheduled time from the drop-down list.
     - When you select **Monthly**, complete the following:
       - **Schedule the day of the month**: Enter the day of the month and the monthly interval. For example, to schedule the rule update on the first day after every 2 months, you can enter Day 1 every 2 month(s).

- **Time**: Enter a time in hh:mm:ss AM/PM (hours:minutes:seconds AM or PM) format. You can also select a time from the drop-down list by clicking the time icon.
- **Time Zone**: Select the time zone for the scheduled time from the drop-down list.

6. Save the configuration.

Manually Uploading Threat Analytics Updates

When you configure a manual update policy, the appliance notifies you about newly available module set and/or whitelist set updates. You can manually upload the updated files and apply them to the Grid.

To manually upload threat analytics updates:

1. From the **Data Management** tab, select the **Threat Analytics** tab -> **Whitelist** tab, click **Updates** -> **Manual Update** from the Toolbar.
2. The *Threat Analytics Upload* dialog displays the following:
   - **Current Whitelist Version**: Displays the version of the whitelist set that is currently running on the Grid.
   - **Last Applied On**: Displays the timestamp and time zone when the last whitelist set was applied to the Grid. This field changes each time when a whitelist set is applied.
   - **Latest Available Module Set**: Displays the version string of the latest available module set. This field changes each time when the module set is updated.
   - **Last Applied On**: Displays the timestamp and time zone when the last module set was applied to the Grid. This field changes each time when a module is applied.

     To upload the module set or whitelist set:
   - **File**: Click **Select** to navigate to the file location, and then upload the file. The appliance displays the file name in this field. You can upload either a module set or a whitelist set. Check the current version numbers of the whitelist and module sets to verify if they have changed before uploading new files.

> ⚠ Note
> You can only update to a newer whitelist set even though you can switch back to an older version of module set, if any. However, if you have configured an **Automatic** update policy, the appliance overwrites the older file version with the new one. To avoid this, you can change the update policy to **Manual** or disable automatic downloads.

Click **Test** to check the changes that will occur during the update, without actually applying the update. You can view update details in the Syslog Viewer. The appliance preserves the uploaded file if you do not click **Update** to update the module set or whitelist set. When you manually upload next time, this file name is displayed in the dialog. You can then choose to apply the update from this file or upload a new file before performing the update. Uploading a new file will remove the file that has not been applied.

3. Click **Update** to update the module set or whitelist set. You can also click **View Update Results** to view the update results.

Monitoring DNS Tunneling Activities

You can monitor DNS tunneling activities through the following:

- **Pre-defined Reports**: If you have a reporting appliance configured in the Grid, you can generate the following reports that include DNS tunneling data.
  For more information about the following topics, see *Security Dashboards*:
  - DNS Top Tunneling Activity.
  - DNS Tunneling Traffic by Category.
  - Top Malware and DNS Tunneling Events by Client.
- **Syslog**: All DNS tunneling activities are logged to the syslog. You can view this log to identify specific activities related to DNS tunneling. For more information, see *Using a Syslog Server*.

Cisco ISE Integration

This section describes how to integrate Cisco ISE (Identity Services Engine) into the NIOS appliance to enhance identity management across devices and applications that are connected to your network routers and switches. It provides guidelines about how to subscribe and publish contextual data, and add notification rules. By integrating Cisco ISE, you can gain greater visibility in user and device information, thereby enhances security across your network resources. It includes the following topics:

Integrating Cisco ISE into NIOS

With the rapid growth of BYOD (Bring Your Own Device) trend, the complexity of securing network resources has become more challenging. To ensure data privacy and security of all network resources against threats, Infoblox introduces the **Ecosystem** feature that allows you to expand the visibility of networks, users, and devices. Using this feature improves overall IT operations by sharing information between network and security teams.
Integrating Cisco ISE server into NIOS enables NIOS and Cisco ISE to exchange valuable network, user, device, and security-event information, enriching both Infoblox DDI and Cisco ISE data. Cisco ISE is a centralized security solution (Network Access Control) that automates and enforces context-aware security access to network resources. This feature ensures that only the authorized users from legitimate devices get access to the services they need.

Note

- Cisco ISE does not support IPv6 addresses.
- Cisco ISE version 3.0 is only supported in NIOS version 8.6.2.
- If you want to use Cisco ISE version 3.1 (pxGrid 2.0), Infoblox recommends that you integrate using the Outbound endpoint. For more information about outbound endpoints, see *Configuring Outbound Endpoints*.

When you configure a Cisco ISE, you can do the following:

- **Subscribe to contextual data**: NIOS acts as a client to the Cisco ISE and collects information about the subscribed data types. You can configure extensible attributes without restricting them to specific object types, and then map these extensible attributes to Cisco ISE data to collect additional information. You can view subscribed information collected from the Cisco ISE in the appropriate tabs (**IPAM**, **IP Map** panel, and **Network Users**) of the Infoblox GUI. For information about how to subscribe to contextual data, see *Configuring Cisco ISE on NIOS.* You can also monitor subscription data using the **Subscription** report. For information, see *Subscription Data*.
- **Publish contextual data** - You can publish contextual data from NIOS to specific Cisco ISE based on the conditions and criteria specified in the notification rules. To publish RPZ and threat protection notifications, you must first set up an external syslog server, as described in *Specifying Syslog Server for Notifications*, .For more information about configuring notification rules, see *Configuring Notification Rules*. You can monitor published data using the **Publish Data** report through the Reporting and Analytics feature. For information, see *Publish data*.

Supported Integrations

NIOS supports the integration of Cisco ISE versions 2.6 and 2.7, and 3.0.

Infoblox recommends that you use the Outbound endpoint for Cisco ISE integrations using Cisco pxGrid 2.0. For more information about outbound endpoints, see *Configuring Outbound Endpoints*.

Administrative Permissions

By default, only superusers can add, edit, and delete Cisco ISEs. Limited-access admin groups can access Cisco ISEs only if their administrative permissions are defined. For information about administrative permissions, see *About Administrative Permissions*.

Prerequisites to Integrate Cisco ISE with NIOS

Do the following before you begin using this feature on NIOS:

- You must install the **Security Ecosystem** license to configure Cisco ISE. You might need the following licenses to configure notification rules for RPZ and threat protection event types:

License	Event Types
RPZ	DNS RPZ
Threat Protection	Security ADP
DNS, DHCP, and MSMGMT	IPAM
DNS and DHCP	DHCP Lease

  For information about how to install licenses, see *Managing Licenses*.
- Cisco ISE uses SSL certificates as the method of authentication. You must upload the client certificate and client key when configuring the Cisco ISE server. You can include both client certificate and key in a single file and then upload. For information, see *Generating Certificates*.

  Note to make sure to use the host name of the Grid member that is selected as the subscribing member. The host name of the subscribing member must match with the Common Name that you mention while generating the certificate.
- For the bulk download certificate, download the server certificate from the monitoring node. If the admin node and monitoring node are on one node, then download the certificate from the admin node.
  Log into Cisco ISE and download the default self-signed server certificate (**Administration** -> **System** -> **Certificates** -> **Export**).
- For the CA certificate, download the CA certificate from the admin node or the self-signed certificate (**Administration** -> **System** -> **Certificates** -> **Export**).
- Register NIOS as a client on the Cisco ISE. You must enable the **Auto-Registration** option on the Cisco ISE: From the **Administration** menu -> click **pxGrid Services**, and then click **Enable Auto-Registration**. For more information, refer to Cisco ISE documentation. When you register NIOS successfully, you can view infoblox_client_subscribe_xxxx and infoblox_client_publish_xxxx, where xxxx is a number generated based on the IP of the subscribing member on the Cisco ISE. If auto-registration is not enabled, approve the pxGrid client after registration. If you change the certificates, Cisco ISE may not register the client successfully. In this case, delete the related pxGrid client from the Cisco ISE server, which is automatically created again.
- Enable the Identity Mapping feature on the NIOS appliance:
  a. From the **Grid** tab, select the **Grid Manager** tab -> **Grid Properties** -> **Edit** from the Toolbar.
  b. In the *Grid Properties Editor*, select the **General** tab -> **Advanced** tab, select the **Enable network users feature** checkbox.
- To publish data:
  - To publish dynamic data, such as DHCP lease and IPAM information, make sure that you approve **Infoblox_DHCP** and **Infoblox_IPAM** on the Cisco ISE, and then configure notification rules as described in *Configuring Notification Rules*.
  - To publish RPZ and threat protection notifications to the Cisco ISE server, you must first set up an external syslog server and then configure notification rules, as follows:

i. Configure an external syslog server that listens on port 2000, as described in *Specifying Syslog Server for Notifications*.
ii. Set up notification rules, as described in *Configuring Notification Rules*.
.

> **Note**
>
> Refer to Cisco ISE documentation for information about how to perform auto-registration, creating authorized groups, and approving dynamic topics.

Limitations of Integrating Cisco ISE with NIOS

Integrating Cisco ISE with NIOS has the following limitations:

- You can publish IPAM data only from the Grid Master that is a subscribing member. A subscribing member is a Grid member that you want to subscribe as the client on the Cisco ISE. For more information, see *Publishing Data*.
- Only the subscribing member can publish its data to Cisco pxGrid.
- If the Grid Master is the subscribing member and you promote a Grid Master candidate to the Grid Master, then you have to create a client certificate for the promoted Grid Master.

Generating Certificates

To generate a self-signed key and certificate:

1. openssl genrsa -out self1.key 4096
2. openssl req -new -key self1.key -out self1.csr
3. openssl req -x509 -days 365 -key self1.key -in self1.csr -out self1.cer

```
For CSR request:
```

```
Country Name (2 letter code) [XX]: <Country Name>, for example: US
```

```
State or Province Name (full name) []: <State Name>, for example: CA
```

```
Locality Name (eg, city) [Default City]:<City Name>, for example: SC
```

```
Organization Name (eg, company) [Default Company Ltd]:<Company Name>, for example Infoblox
```

```
Organizational Unit Name (eg, section) []:<Organization Name>, for example: QA
```

```
Common Name (eg, your name or your server's hostname) []:<host name of the subscribing member>
```

```
Email Address []:
```

Enter the following 'extra' attributes to be sent with your certificate request:

```
A challenge password []:
```

Import the certificate generated in step 3 to Cisco ISE's trusted store. Select the **Trust for authentication within ISE** checkbox.

Export the self-signed ISE certificate of the ISE server (under System -> Certificates). Make sure to select the **pxGrid: Use certificate for the pxGrid Controller** checkbox before exporting it.

You can call this as isemnt.cert

Wait for ISE services to restart. It may take a few minutes.

Configuring Cisco ISE on NIOS

You can configure the supported versions of Cisco ISE servers on the NIOS appliance. You can subscribe for identity information that you wish to collect from the Cisco ISE, such as user name, domain name, VLAN, session state, SSID, endpoint profile, and security group. You can also add extensible attributes without restricting it to specific object types, and map these extensible attributes with the Cisco ISE field types to collect additional information. Note that you can subscribe to only one Cisco ISE per member and each member can subscribe to only one Cisco ISE. You can publish ADP and RPZ notifications, DHCP and IPAM information from NIOS to Cisco ISEs based on the notification rules that you have configured. You can view the subscribed information from the IPAM tab and the IP Map panel. Make sure that you synchronize time between the managing member and Cisco ISE.

⚠ The procedures in the sections below is for configuring Cisco pxGrid 1.0. For instructions on configuring Cisco pxGrid 2.0, see *Configuring Outbound Endpoints*. Infoblox recommends that you integrate Cisco ISE through the outbound endpoint.

Configuring Cisco ISE Servers

You can configure a Cisco server either by using the **Ecosystem** -> **Cisco ISE Endpoint** tab or by using the **Ecosystem** -> **Outbound Endpoint** -> **Add** -> **Add Cisco ISE Endpoint** option. This section describes how to configure a Cisco server using the **Ecosystem** -> **Cisco ISE Endpoint** tab. For information about using the **Add Cisco ISE Endpoint** option, see *Configuring Outbound Endpoints*.

To configure a Cisco ISE server:

1. From the **Grid** tab, select the **Ecosystem** tab -> **Cisco ISE Endpoint** tab, and then click the Add icon.
   or
   From the **Grid** tab, select the **Ecosystem** tab, and click **Add Cisco ISE** from the Toolbar.
2. In the *Add Cisco ISE* wizard, complete the following.
   - **Server Address**: Enter the IP address of the Cisco ISE.
   - **Version**: Select the version of the Cisco ISE.
   - **Subscribing Member**: Click **Select** to select a Grid member that you want to subscribe as the client on the Cisco ISE. In the *Member Selector* dialog box, select a Grid member from the list. This member interacts with the Cisco ISE to obtain contextual information for the subscribed data types.
   - **Network View**: This appears only when you have multiple network views. From the drop-down list, select the network view in which you want to create the network.
   - **Client Certificate**: Click **Select** to upload the client certificate. In the *Upload* dialog box, click Select to navigate to the certificate, and then click **Upload**.
   - **Bulk Download Certificate**: Click **Select** to download the server certificate from the monitoring node or self-signed certificate.
   - **Manage Certificates**: Click **CA Certificates** to upload the self-signed certificate or CA certificate. In the *CA Certificates* dialog box, click the Add icon, and then navigate to the certificate to upload it.
   - **Test Credentials**: Click this to validate the Cisco ISE configuration before proceeding. When you click Test Credentials, the appliance validates the certificates.
   - **Comment**: Enter additional information about the configuration.
   - **Disabled**: Select this if you want to save the configuration but do not want to use it yet. You can clear this checkbox when you are ready to use this Cisco ISE.
3. Click **Next** to specify the data types that you are interested to obtain from the Cisco ISE. The Cisco ISE shares information only for the subscribed data types. Complete the following to specify data types you want to collect from the Cisco ISE:
   - **Subscription Settings**: There are predefined data types in the **Available Data Type** table you can subscribe. Use the arrows to move data types from the **Available Data Type** table to the **Selected Data**

Type table and vice versa. The appliance receives information for all data types in the **Selected Data Type** table.

- **Map other data types to Extensible Attributes**: You can create extensible attributes and map these extensible attributes to receive additional Cisco ISE data values, such as IP address, MAC, NAS IP Address, NAS Port ID, EPS Status, Posture Status, Posture Timestamp, Endpoint Profile Name, Account Session ID, and Audit Session ID. Click the Add icon and map a Cisco ISE data type to an extensible attribute. You can also select a row and click the Delete icon to delete it.

4. Click Next to add extensible attributes to the Cisco ISE. For information, see *Managing Extensible Attributes*.
5. Save the configuration.

Modifying Cisco ISE Configurations

You can select data types that need to be published from NIOS to Cisco ISE after you have configured the Cisco ISE. You can modify the Cisco ISE configurations, as follows:

1. From the **Grid** tab, select the **Ecosystem** tab -> **Cisco** tab, click the **Action** icon next to the server name and select **Edit** from the menu.
2. The *Cisco ISE Server* editor provides the following tabs from which you can modify data:
   - **General**: You can modify data in this tab as described in *Configuring Cisco ISE on NIOS*.
   - **Subscription**: You can edit data types that you have subscribed. You can use the arrows to move data types from the **Available Data Type** table to the **Selected Data Type** table and vice versa. The appliance receives information for all data types in the **Selected Data Type** table and extensible attributes that are configured.
   - **Publication**: To publish dynamic data from NIOS, you must first configure notification rules, as described in *Configuring Notification Rules*. You can add data types that you want to publish to Cisco ISE server by using the arrows to move data types from the **Available** table to the **Selected** table and vice versa. The appliance publishes information only for the data types that are added in the **Selected** table.
   - **Extensible Attributes**: You can add, modify, and delete extensible attributes that are associated with the Cisco ISE server. For information, see *Managing Extensible Attributes*.
3. Save the changes.

Overriding Subscription Settings

You can override subscription settings and mapped extensible attributes at the network container, network, and DHCP range levels. By default, networks inherit subscription settings from those configured while adding the Cisco server. You can override these settings and subscribe new values at the DHCP range, network container, or network level. A network inherits subscription settings from its parent object. If you override the values at the network container level, then the network inherits the network container values. Otherwise, the network continues to inherit the values configured from the Cisco ISE. A shared network without a parent network container continues to inherit settings from the Cisco ISE.
To override an inherited value, click **Override** next to it and complete the appropriate fields. When you click **Override**, the appliance displays the value inherited from its parent object (if any).
To override subscription settings and mapped extensible attributes:

1. **Network Level**: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* checkbox, and then click the Edit icon.
   Network Container: From the **Data Management** tab, select the **IPAM** tab -> *network_container* checkbox, and then click the Edit icon.
   DHCP Range Level: From the **Data Management** tab, select the **DHCP** tab -> **Networks** tab -> **Networks** -> *network* -> *addr_range* checkbox, and then click the Edit icon.
2. In the *Network or Range* editor, click **Toggle Advanced Mode** if the editor is in basic mode, and then click the Cisco ISE tab.
3. Save the configuration and click **Restart** if it appears at the top of the screen.

Viewing Identity Mapping Information

To view user information, you must first enable identity mapping feature at the Grid level. For information about enabling Identity Mapping feature, see *Enabling Identity Mapping*.

> **Note**
>
> You do not need an **MSManagement** license to enable the identity mapping feature.

You can view user information in the **Network Users** tab. For more information, see *Viewing Identity Mapping Information*.

Deleting Cisco ISE Servers

When you delete a Cisco ISE, the appliance moves it to the Recycle Bin, if enabled. You can later restore it if needed. To delete a Cisco ISE server:

1. From the **Grid** tab, select the **Ecosystem** tab > **Cisco** tab -> *Cisco ISE server* checkbox, and then click the Delete icon.
2. In the *Delete Confirmation* dialog box, click **Yes** to delete the Cisco ISE server.

Publishing Data

To publish dynamic data, such as DHCP lease and IPAM information, make sure that you approve **Infoblox_DHCP** and **Infoblox_IPAM** on the Cisco ISE, and then configure notification rules as described in Configuring Notification Rules below.
To publish RPZ and threat protection notifications to the Cisco ISE server, you must first set up an external syslog server and then configure notification rules, as follows:

1. Configure an external syslog server that listens on port 2000, as described in Specifying Syslog Server for Notifications below.
2. Set up notification rules, as described in Configuring Notification Rules below.

Specifying Syslog Server for Notifications

Before you can publish RPZ and threat protection notifications to the Cisco ISE, you must first configure the syslog server to which the appliance logs RPZ and threat protection events. The appliance generate notifications about these events and analyze the data before sending it to the Cisco ISE. When setting up the syslog server, ensure that you select **DNS RPZ** and **Threat Protection** logging categories so all events related to RPZ and threat protection hits are logged to the syslog.

> Note
>
> For Cisco ISE to take appropriate action to quarantine malicious IP addresses, ensure that the **EPSStatus** (Endpoint Protection Status) in the Authorization Policy is set to "**Quarantine**." This is set by default.

To specify an external syslog server in NIOS, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab -> **Members** tab, and then click **Grid Properties** -> **Edit** from the Toolbar.
2. In the *Grid Properties* editor, select the **Monitoring** tab, and then follow the procedures described in *Specifying Syslog Servers* using the following settings:
   - **Address:** Enter the loopback address **127.0.0.1** so that the appliance sends notifications to itself.
   - **Transport:** Select **UDP**.
   - **Interface:** Select **LAN**. The appliance uses the LAN1 port to send syslog messages.
   - **Source:** Select **Any.** The appliance sends both internal and external syslog messages.
   - **Port:** Enter **2000** as the port number.
   - **Logging Category**: Select **DNS RPZ** and **Threat Protection**.
3. Save the configuration.

Configuring Notification Rules

You can configure notification rules after you have configured Cisco ISE on the NIOS appliance. For information, see *Configuring Cisco ISE on NIOS*. To publish data and notifications from NIOS to Cisco ISE, you must configure notification rules. You can create notification rules for the following event types: **DNS RPZ**, **Security ADP**, **IPAM**, and **DHCP Lease**. Note that the DNS RPZ and Security ADP event types are available only if you have installed **RPZ** and **Threat Protection** licenses in the Grid. Each notification rule specifies the target Cisco ISE, the Grid member on which you wish to run this rule, notification rule criteria, and the action to be taken for the matching events. NIOS publishes information, such as DHCP lease information, IPAM data, and quarantine events, when the triggered events matches the notification rule criteria. Note that the **DHCP Lease** and **IPAM** event types are available only for the Cisco ISE 2.0 and 2.2 target servers.

> ⚠ Note
>
> Quarantine events are published to the Cisco ISE whenever the first rule matches the trigger criteria and it ignores all other rules.

To add notification rules:

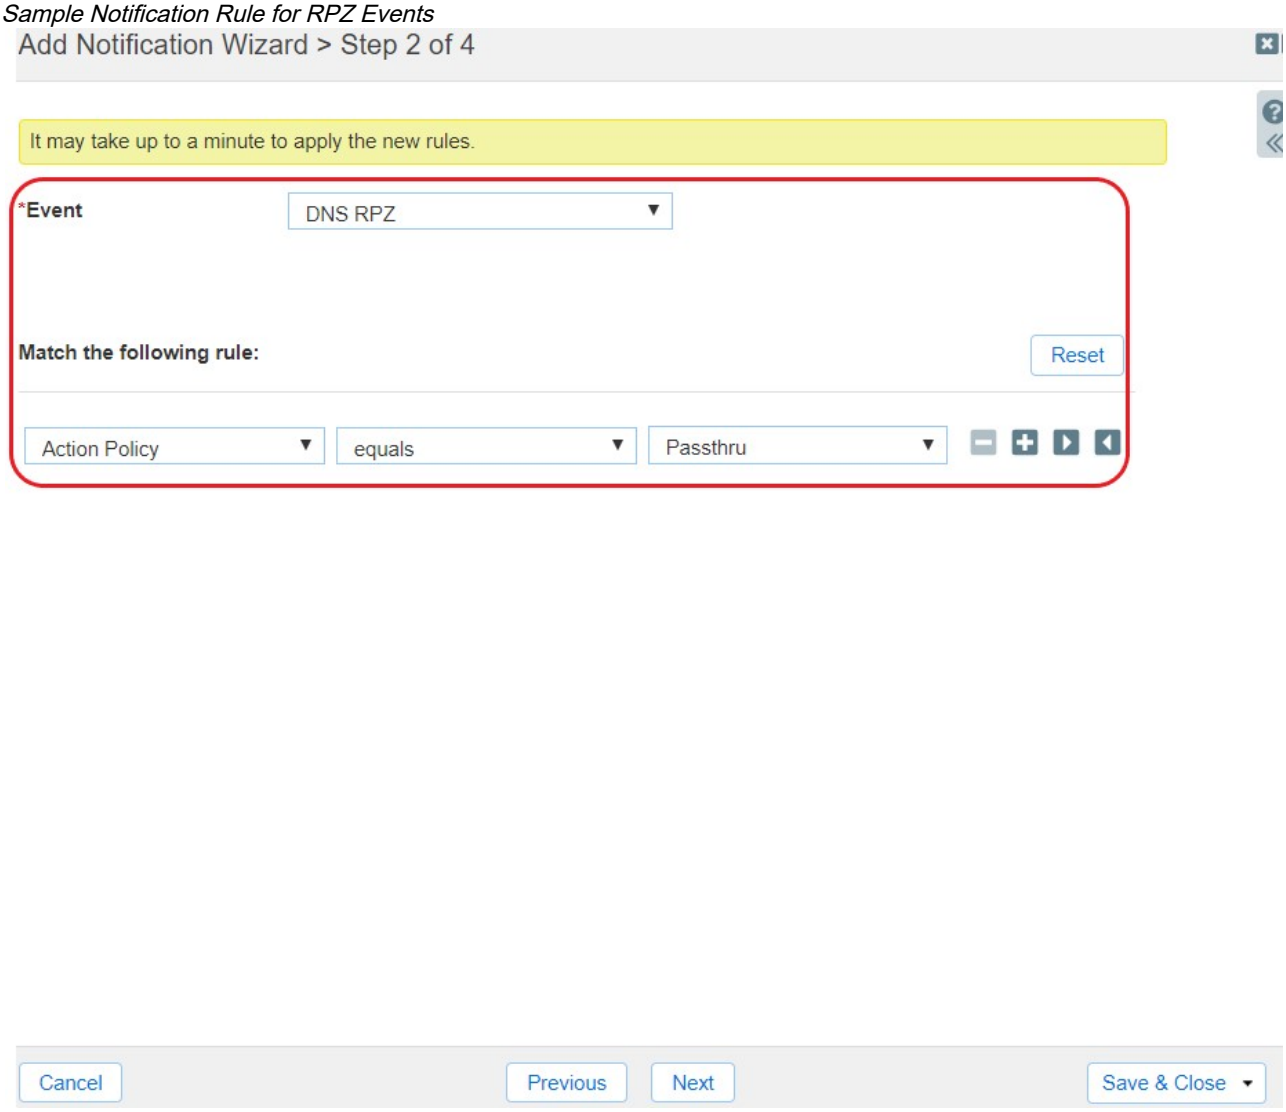
1. From the **Grid** tab, select the **Ecosystem** tab -> **Notification** tab, and then click the Add icon.
   Or
   From the **Grid** tab, select the **Ecosystem** tab, and click **Add Notification Rule** from the Toolbar.
2. In the *Add Notification* wizard, complete the following.
   - **Name**: Enter the name of the rule.
   - **Target**: Select the IP address of the target server on which you want to publish from NIOS. This field displays all the IP addresses of the Infoblox servers and the PT servers that you added.
   - **Comment**: Enter useful information about the notification rule.
   - **Disable**: Select this option to disable the notification rule.
3. Click **Next** and complete the following:
   - **Event**: The appliance displays the list of event types based on the licenses installed. The values in the drop-down list are:
     - **DNS RPZ**: Select this to create notification rules for the DNS RPZ events.
     - **Security ADP**: Select this to create notification rules for Security ADP threat events.
     - **IPAM Type**: Select this to send IPAM data. No notification rule is required for this event type.
     - **DHCP Leases**: Select this to create notification rules for DHCP Lease events. This is available for Cisco ISE 2.0 and 2.2 servers.
   - In the **Match the following rule** section, select filters, operators and values from the drop-down lists for the selected event type. You can use the + icon to construct nested expressions within an event category. See the table detail at the end of this procedure.
   - For **IPAM** and **DHCP Lease** events: In the *Notify the target* section, there are predefined data types in the **Available** table you can publish. Click **Override** and use the arrows to move data types from the **Available** table to the **Selected** table and vice versa. The appliance sends information for all data types that are added to the **Selected** table. If you do not override, the publication settings is inherited from those configured while adding the Cisco ISE server. Note that you can configure only one IPAM rule per Cisco ISE server.
   - **Action**: The action to be taken for various events. Displays **Quarantine the end host** for **DNS RPZ** and **Security ADP** events. The Quarantine the end host action and Notify target data action are published through the subscribing member. Only the subscribing member can publish data to the Cisco pxGrid node.
4. Click **Next** to select Grid members. You can apply this notification rule on specific Grid members or apply this notification rule on all the Grid members.
   - **Apply rule to relevant members**: Select this option to apply notification rule to all relevant Grid members.
   - **Select Member(s)**: Select this option to select a Grid member for applying the notification rule. If there are multiple members, the *Member Selector* dialog box is displayed, from which you can select a member. Click the required member name in the dialog box. You can also click **Clear** to clear the displayed member and select a new one.
5. Click **Save** to save the Cisco ISE configuration.

Event Type	Filters	Operators	Value
DNS RPZ	Query Name	equals, begins with, and ends with	Enter the value that you want your rule to match
	Rule Name	equals, begins with, and ends with	Enter the value that you want your rule to match
	Action Policy	equals	Log Only, None, Block No Data, Block No Such Domain, Passthru, Substitute Domain Name
	Source IP	equals, matches CIDR, matches range	Enter the value that you want your rule to match
Security ADP	Rule Severity	equals, equal to or more severe, equal to or less severe	Information, Major, Critical, Warning
	SID	contains, equals, begins with and ends with	Enter the value that you want your rule to match
	Rule Message	contains, equals, begins with and ends with	Enter the value that you want your rule to match
	Source IP	equals, matches CIDR, matches range	Enter the value that you want your rule to match
DHCP Leases	Lease State	equals	Started, Renewed, and Expired
	You can override your Publish settings configured for the Cisco ISE server.		

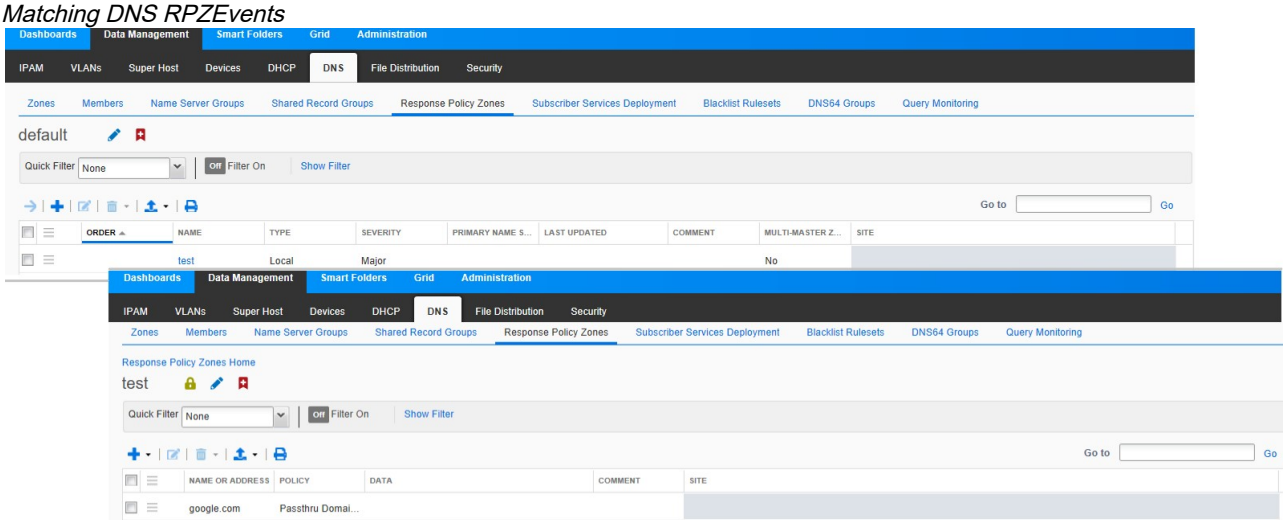
Examples

The following illustrations show sample notification rules and how the information is displayed in Grid Manager and the Cisco ISE:

Sample Notification Rule for RPZ Events



Matching DNS RPZEvents



Ecosystem - Outbound Notifications

This section describes how you can use outbound templates to convert NIOS specific events into outbound notifications and send the notifications to REST (REpresentational State Transfer) enabled and DXL (Data Exchange Layer) endpoints. These endpoints use the REST APIs to send user and event data to external servers or to update other outbound settings. It also explains how to create and add RESTful API and DXL endpoints that use NIOS specific data to construct outbound notifications, and how to configure notification rules to trigger outbound notifications based on the parameters defined in the templates. It also includes sample templates for supported servers.

It includes the following topics:

Outbound Notification Overview

The Infoblox outbound API is a framework that is used to exchange both IPAM data (such as networks, network containers, hosts, leases) and DNS threat data with external interfaces. It sends object information and conversations to other REST APIs when an event triggers in NIOS. It is important that you receive notifications about the updates to the system. On the other hand, you may sometimes also need to identify and manage low-risk or accidental threats so the endpoint performance is not negatively affected. For example, if a user inadvertently browses to a faulty web site and you have configured RPZ rules to block this site, you may want to receive notifications and take certain actions so the user is not being blocked or quarantined. In addition, when the Infoblox appliance detects a new host or network, the detection might trigger a vulnerability scan by services such as Qualys and a scan for RPZ events configured in NIOS. In this scenario, you might want to configure conditions to capture these events so you can receive outbound notifications and perform appropriate actions to handle the situation.

For example, you can first configure RPZ rules to mitigate a malicious IP address, and then configure RESTful API and DXL endpoints to which you want to send the outbound notifications. When configuring your notification rules, you can match RPZ events that are initiated by the RPZ rules and apply the outbound template containing actions to mitigate the threat. The configuration rules then trigger outbound notifications, and the appliance sends the notifications to the configured endpoints and applies the configured actions to combat the offensive IP address.
Before you configure the appliance to send outbound notifications, there are a few limitations you might want to consider, as described in Best Practices for Outbound Notifications, below. For detailed information about how to use the outbound notification feature, see *Configuring Outbound Notifications*.

To enable, configure, and test outbound notifications you must first install the **Security Ecosystem** license in your Grid and do the following in the below mentioned order:

1. Ensure that the necessary services and features are configured. These include DHCP, RPZ, Threat Insight, ADP, Network Insight, and BloxOne Threat Defense Cloud.
2. Create necessary extensible attributes, if required. For more information, see *Managing Extensible Attributes*.
3. Create or download login and logout templates from the Infoblox Community Site at *https://community.infoblox.com*. Next, add or upload the login and logout templates followed by the session template. Note that you can add a session template or download it from the Infoblox Community Site.
4. Download or create notification templates from the Infoblox Community Site at *https://community.infoblox.com*. Next, add or upload the notification templates.

5. Add an endpoint. You can either add REST API or DXL endpoints. For DXL endpoints, you must generate a NIOS client certificate, import DXL certificates and import or add list of DXL brokers. For more information, see *Configuring Outbound Endpoints*.
6. Define notification rules. For more information, see *Configuring Notification Rules*.

The outbound notification feature employs the following mechanism to enable and deliver event-driven messages to configured endpoints:

1. Accepts the configuration of events that you want to monitor (such as RPZ hits) and the configuration of endpoints to which you want to send outbound notifications.
2. Filters events for specific data sets or thresholds, such as RPZ hits for a specific domain within a specific time interval.
3. Matches the selected events and conditions defined in the templates to create outbound messages.
4. Sends outbound notifications to the configured endpoints.

Depending on the notification rules for RPZ and threat protection event types you want to configure on NIOS, you may need to install the applicable licenses. For information about other licensing requirements, see Licensing Requirements below.

> **Note**
>
> To access online resources about this feature, including training videos and sample outbound templates for supported ecosystem partners, ensure that you visit the Infoblox Community Site at *https://community.infoblox.com*.

For debugging purposes, you can look at the syslog to see if the Outbound service has been started or stopped on specific members. You can also set the logging level to **Debug** to view all events in the log files, including deduplicated events. However, leaving the logging level at the **Debug** level could negatively affect your system performance. Therefore, Infoblox does not recommend leaving the logging level at **Debug**. For information about how to configure the severity level and deduplication, see *Configuring Outbound Endpoints*.

Licensing Requirements

You must install the **Security Ecosystem** license to enable outbound API notifications. After you install the Security Ecosystem license, you can configure REST and DXL endpoints. If you do not have this license installed, the outbound notification feature is disabled. You might also need the following licenses to configure notification rules for certain event types:
Licenses required for certain event types

License	Event Types
RPZ	DNS RPZ
DNS and DHCP	DHCP Lease
Threat Analytics	DNS Tunneling
Advanced DNS Protection	Security ADP
RPZ and Security Ecosystem	BloxOne Threat Defense Cloud
Network Discovery	Object Change Discovery Data

For information about how to install licenses, see *Managing Licenses*.

Administrative Permissions

Only superusers can add, edit, and delete REST endpoints and notification rules by default. Limited-access admin groups can perform these tasks only if their administrative permissions are defined. For information about administrative permissions, see *About Administrative Permissions*.

Best Practices for Outbound Notifications

The following are some best practices and limitations you might want to consider while configuring outbound notifications:

- You can configure REST and DXL endpoints only on the Grid Master and Grid Master Candidate, but not on Grid members.
- During a scheduled full upgrade in the Grid, you cannot modify any configuration related to the outbound feature until all Grid members are upgraded.
- Outbound notification is not supported during an HA failover. Any events that are in transit during a failover might be lost.
- When you remove or disable a notification rule, no new events will be triggered. However, the appliance continues to process events that are already in queue.
- The buffer to hold events temporarily are limited and not configurable in this release. In very unlikely conditions, events may be dropped due to a full buffer. If events are dropped, summary information is logged to the syslog to indicate the type of events and the number that have been dropped. If this issue occurs continuously, contact Infoblox Technical Support.
- Events generated due to changes made by admin users do not support the Microsoft Management feature. The appliance does not generate events when there are changes done from the Microsoft servers. However, if you make changes that need to be synchronized to the Microsoft servers, the object change event is generated before the changes are synchronized with the Microsoft servers.
- The Grid Master Candidate will continue to perform event enrichments and outbound API calls during and after a Grid Master promotion.
- If you disable the outbound notification feature or make changes to stop future notifications sent to an endpoint, all notifications that are currently in queue for this endpoint will stop immediately.
- The appliance uses rate limiting to control both data collection from Grid members and outbound notifications to external endpoints. It is possible for the appliance to drop events if its buffer is full or if there is a loss of connection between the Grid Master and the Grid members. Logs for these events are consolidated and logged to the syslog.
- The number of outbound notifications sent to external endpoints can be limited, depending on the requirements configured for the external servers. For example, some REST enabled servers only take 10 API calls per second. Some servers might put a user in suspended mode if the number of API calls sent to the user exceeds the limit. If necessary, you can adjust the rate limit criteria for API calls on the external servers.

Configuring Outbound Notifications

A notification is an association between an event type, a template, and an endpoint. You must define the event type that triggers the notification, choose the template you want to use and an API endpoint with which the Grid must establish a connection.

Note the following before you configure outbound notifications:

- You must define an endpoint and create or upload outbound templates to the Grid before adding a notification.
- To send outbound notifications to an endpoint, you must configure notification rules first. A notification rule contains the target endpoint to which you want to send outbound notifications and the event type upon which you want to take action.
- The event type you select in a notification rule must match the event type defined in the template you want to use for that rule. Otherwise, the appliance returns an error.

To configure outbound notifications, complete the following:

1. Prepare outbound templates that you want to use for notification rules. For more information about API templates, see *About Outbound Templates*. You can also reference sample API templates for supported ecosystem partners and modify them accordingly.

2. Upload outbound templates to the Grid so you can use them for corresponding notification rules. For more information, see in *Adding Outbound templates*.

3. Configure endpoints to which you want to send outbound notifications. Infoblox supports the following endpoints: RESTful API and DXL. For more information, see *Configuring Outbound Endpoints*.

4. Select event types and configure criteria for notification rules. For more information, see *Configuring Notification Rules*.

> **Note**
>
> To access online resources about this feature, including training videos and sample API templates for supported ecosystem partners, visit the Infoblox Community Site at *https://community.infoblox.com*.

About Outbound Templates

The appliance uses outbound templates to convert NIOS events into REST API, DXL, and Syslog messages. Outbound API templates control the integration and contains necessary steps to execute outbound notifications. Infoblox supports session management and action templates that are available in the Infoblox Community Site at *https://community.infoblox.com*. You can either modify these existing templates or create new ones through Grid Manager using the existing templates. You use supported variables in these templates to get respective events and define actions you want to take for those events. You can also define additional extensible attributes that are necessary for certain templates. The appliance uses the scripts in these templates to process and send outbound notifications to the endpoints.

The following are the outbound templates that you can create:

- **Session Management Template**: A session management template contains specific variables about an endpoint, such as the timeout value and rate limiting information. For more information, see *Creating Session Management Templates*.
- **Action Template**: An action template defines the action(s) to be taken on the selected endpoint for the matching event type(s). It contains scripts the appliance uses to query respective event data from NIOS and to perform actions you want to take in response to the events. For more information, see *Creating Action Templates*.

> **Note**
>
> When you add an outbound template or make changes to an existing one, it may take a few seconds to a few minutes until the changes are propagated to all the members.

You can also export the schema from the appliance and use it to create the outbound templates. For information about how to export template schema, see Exporting Template Schema below. Note that the exported schema is in the IETF JSON Schema format. For information about this schema format, see *https://tools.ietf.org/html/draft-zyp-json-schema-04.*

> **Note**
>
> To access online resources about this feature, including training videos and sample outbound templates for supported ecosystem partners, visit the Infoblox Community Site at *https://community.infoblox.com*.

Adding Outbound Templates

You can use the supported templates that are available in the Infoblox Community Site at *https://community.infoblox.com*. You can download these templates make necessary changes and upload them to the Infoblox Grid.

Complete the following to add or upload an outbound template to the Infoblox Grid:

1. **Grid**: From the **Grid** tab, select the **Ecosystem** tab -> **Templates** tab, and then click the Add icon.
   or
   From the **Grid** tab, select the **Ecosystem** tab, and click **Add Template** from the Toolbar.
   System: From the **System** tab, select the **Ecosystem** tab -> **Templates** tab, and then click the Add icon.
   or
   From the **System** tab, select the **Ecosystem** tab, and click **Add Template** from the Toolbar.
2. In the *Add Template* wizard, complete the following:
   - Click **Select** to upload an outbound template. In the **Upload** dialog box, click **Select** and navigate to the template, and then click **Upload**. Select the **Overwrite the existing template** checkbox to overwrite an existing template.
3. Click **Add** to add an outbound template. To add a session management template, see *Creating Session Management Templates* or *Creating Action Templates* to create an action template.
4. Optionally, click **View Results** to open the *Syslog Preview* dialog and view all the syslog messages. For more information, see *Previewing Syslog Events*.

Modifying Outbound Templates

To modify an outbound template:

1. **Grid**: From the **Grid** tab, select the **Ecosystem** tab -> **Templates** tab -> *template* checkbox, and then click the Edit icon.
   or
   From the **Grid** tab, select the **Ecosystem** tab, select the template that you want to modify, click the Action icon  and select **Edit**.
   System: From the **System** tab, select the **Ecosystem** tab -> **Templates** tab -> *template* checkbox, and then click the Edit icon.
   or
   From the **System** tab, select the **Ecosystem** tab, select the template that you want to modify, click the Action icon and select **Edit**.
2. The *<Template Name>Template* editor contains the following tabs from which you can modify information:
   - **General**: You can modify the **Name** and **Comment** fields. All other fields are automatically propagated with available information, such as the template type, vendor type, event type, and action type. The **Name** field is optional for NIOS 8.3.0 and later releases, but note that it is mandatory for jump operations. When you do not specify a name for the template, an auto-generated value is set for this field. Example: `templatestep#N` or `functionstep#N` where N represents the step number. When you import a template, ensure that the goto functions are sent to named steps and not to automatically named steps.
   - **Contents**: This tab displays the content of the uploaded template file. You can modify the template contents and the appliance validates the content for proper JSON format when you save the configuration. For more information about the format of the templates, see *Creating Session Management Templates* and *Creating Action Templates*.
3. Save the configuration.

Viewing All Outbound Templates

To view the list of outbound templates:

1. **Grid**: From the **Grid** tab, select the **Ecosystem** tab, and then click the **Templates** tab.
   System: From the **System** tab, select the **Ecosystem** tab, and then click the **Templates** tab.
2. Grid/System Manager displays the following information:

- **Name**: The outbound template name.
- **Vendor Type**: The vendor type.
- **Event Type**: The event type specified in the template.
- **Template Type**: Displays the template type such as **Session Management** or **Event**.
- **Outbound Type**: The endpoint type. This can be REST, DXL, or Syslog.
- **Comment**: Comments that were entered for the outbound template.
- **Added On**: Displays the timestamp when the template was uploaded to the Grid Master in this format: YYYY-MM-DD HH:MM:SS, plus time zone.

You can do the following in this tab:

- You can select the Action icon  and do the following:
  - **Edit**: Select this to modify the outbound template information.
  - **Delete**: Select this to delete a template.
  - **Export**: Select this to export a template.
- Edit the outbound template information.
  - Select the outbound template, and then click the Edit icon.
- Delete an outbound template.
  - Select the template, and then click the Delete icon.
- Export the list of outbound templates.
  - Click the Export icon.
- Print the list of outbound templates.
  - Click the Print icon.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria:
  a. In the filter section, click **Show Filter** and define filter criteria for the quick filter.
  b. Click **Save** and complete the configuration In the Save Quick Filter dialog box.
  The appliance adds the quick filter to the quick filter drop-down list in the panel. Note that global filters are prefixed with [G], local filters with [L], and system filters with [S].
- Sort the outbound templates in ascending or descending order by column.

Deleting Outbound Templates

You can delete a template any time after you have created it.

> **Note**
>
> Before you delete a template, ensure that it is not in use by a notification or an endpoint.

To delete a template:

1. From the **Grid/System** tab, select the **Ecosystem** tab, and then click the **Templates** tab.
2. Select the template that you want to delete, and click the Delete icon.
3. Click **Yes** in the *Delete Confirmation* dialog.

Exporting Template Schema

The Export Template Schema feature allows you to export the session management and action template schema. You can use the exported schema to validate the templates before uploading them. The exported schema is in IETF JSON Schema format. It is a JSON file that is used to define and validate outbound templates that you want to upload to the appliance. If you want to create your own templates, you must follow this schema format. For information about this format, see *https://tools.ietf.org/html/draft-zyp-json-schema-04*.
Complete the following to export the outbound template schema:

1. From the **Grid/System** tab, select the **Ecosystem** tab -> select the **Templates** tab.
2. Expand the Toolbar, click **Export Template Schema** -> select **Action Template Schema** to export the action template schema or select **Session Template Schema** to export the session management template schema.

3. If there is only one template version, the appliance downloads the schema to your local system. If there are multiple template versions, the appliance displays the *Export Action Template Schema* or *Export Session Template Schema* dialog. In the dialog, select the outbound template and the template version that you want to export. The template schema is downloaded to your local system.

Creating Session Management Templates

You can use a session management template to specify settings that will be applied to an endpoint. You can define settings such as the timeout value after which the outbound requests are aborted. This template can also contain additional child templates that can be referenced by the configuration. However, you cannot reference other templates in the system from the session management template.
Once you upload a session management template to the Grid, the configuration in the template automatically applies to the specified endpoint, if the connection to the endpoint has been established and if the template is assigned to the endpoint.

The table below lists the supported variables you can use in a session management template.

> **Note**
>
> Changes made to the variables of the template through Grid Manager override the variables in the template. Although the latest template version is 3.0, template versions 2.0 and 1.0 continue to work with their respective syntax. Session management templates do not support instance variables. To access online resources about this feature, including training videos and sample outbound templates for supported ecosystem partners, visit the Infoblox Community Site at *https://community.infoblox.com*.

The following are the session management templates that you can create:

Session Management Template Variables

Session Management Template Variables

Variable	Type	Mandatory	Description
version	Must be 5.0	Yes	The version number of the template. Note that 5.0 is the latest version. The appliance still fully supports the previous schema version.
type	Must be REST_ENDPOINT for REST API endpoints Must be DXL_ENDPOINT for DXL endpoints Must be SYSLOG_EVENT for Syslog endpoints	Yes	The template type.
name	String	Yes	The template name.
vendor_identifier	String	Yes	The vendor identifier for an endpoint.
comment	String	No	Additional information.

Variable	Type	Mandatory	Description
path	String	No	Path string to append to what the user enters in the GUI.
override_path	Boolean	No	If present, the path above replaces the path the user enters in the GUI.
timeout	Integer	No	The timeout value in seconds. The minimum is 1 and the maximum is 3600. The default is 30.
keepalive	Boolean	No	The value can be **True** or **False**. The default is **False**.
keepalive_timeout	Integer	No	The keepalive timeout value in seconds. The connection is closed after this timeout. The minimum is 1 and the maximum is 300. The default is 5.
dxl_keepalive_timeout	Integer	No	The keepalive timeout value in seconds with a connected DXL broker. This controls the rate at which the client will send ping messages to the broker if there is no exchange of other messages. The minimum is 1 and the maximum is 3600. The default is 30. **Note**: This field is applicable only for the DXL templates.
dxl_topic	String	No	The DXL topic that is used to send data by DXL. **Note**: This variable is applicable only for the DXL templates
retry	Integer	No	The number of attempts to try to connect to the endpoint before considering the connection a failure (this covers only timeout/network errors). The default value is 2.
retry_template	Integer	No	The number of attempts the appliance retries the full template if it returns a failure (this covers a template returning anything but 200). The default value is 0 (no retry).
rate_limit	Float	No	The maximum number of messages (per second) that are sent to an endpoint. The default value is 0 (no rate limiting). You can enter a value less than 1.0 to have lower rate limits. For example, if you set the value to 0.5, the appliance sends less than 1 message in every 2 seconds.
rate_limit_requests	Integer	No	Use this along with `rate_limit_interval` to define the absolute number of requests for rate limiting. For example, if you set this to 10 and `rate_limit_interval` to 5000 milliseconds, no further requests are sent until the number of requests falls below 10 in 5000 milliseconds. So if 3 requests are sent at 0 second and 7 requests are sent at the 3rd second, no requests will be sent until the 5th second, where 3 requests are allowed for another 3 seconds. The default is 0 = no rate limiting. You can set this to an integer between 0 and 267840000000.
rate_limit_interval	Integer (in milliseconds)	No	Use this along with `rate_limit_requests` to define the rate limiting interval . The default is 0 = no rate limiting. You can set this to an integer between 0 and 2678400000 milliseconds.

Variable	Type	Mandatory	Description
rate_limit_reset	Integer (in epoch time)	No	Use this together with rate_limit_requests and rate_limit_interval to reset the epoch time for rate limiting. The default is 0 = not resetting the epoch time for rate limiting. You can set this to an integer between 0 and 4102437600 milliseconds. Example: If `rate_limit_requests = 10, rate_limit_interval = 5` seconds, and `rate_limit_reset = 3 p.m. on 10 January 2017` (set in epoch time), 10 requests can be sent within 5 seconds after the reset time. For instance, 3 messages are sent at the 1st second and 7 messages sent at the 3rd second and no more messages can be sent in the next 2 seconds, which is within 5 seconds after 3 p.m. on 10 January 2017.
endpoint_variables	List of VARIABLE structs	No	If specified these will be accessible via the S: namespace in templates.
inactivity_interval	Integer (in milliseconds)	No	A logout request is sent after this time interval, provided no other requests have occurred during this time period. The default is 0 = “disable.” You can set this to an integer between 0 and 2^63-1 milliseconds.
login_template	String	No	The template that requires user login if there is no active session currently running for the endpoint. Only templates with `event_type` set to SESSION are supported for this. You must include the template name in the string. Ensure that you upload the login template if you plan to use this variable in the session management template.
logout_any_condition	Boolean	No	Specifies whether a logout request is sent, depending on whether `logout_status_code` or `logout_regexp` are set. The value can be **True** or **False**. The default is **False**. If this is set to **True**, a logout request is triggered if either `logout_status_code` or `logout_regexp` is set. If this is set to **False**, both `logout_status_code` and `logout_regexp` must be set.
logout_regexp	String	No	Any response returned by the endpoint that matches the regular expression in this field will trigger a logout request.
logout_status_code	Integer	No	The HTTPS response status code used for the provisional response will trigger a logout request. The default is 0 = “disable.” Valid values are between 0 and 599.
logout_template	String	No	The template that is being executed after steps are executed or after various session duration constraints are met. You must include the template name in the string. Only templates with `event_type` set to SESSION are supported for this. Ensure that you upload the logout template if you plan to use this variable in the session management template.
requests_per_session	Integer	No	The number of requests that are sent before a logout request is sent. The default is 0 = “disable.” You can set this to an integer between 0 and 2^63-1.

Variable	Type	Mandatory	Description
logout_only_at_template_end	Boolean	No	The value can be **True** or **False**. The default is **False**. If this is set to **True**, a logout request is sent only after the execution of the template has been completed to ensure that all template requests pertaining to a session are executed if that is required by the API. Therefore, it is possible to set `requests_per_session` to 1 and have each template call executed in its own session regardless of the number of requests it contains.
session_cooldown	Integer (in milliseconds)	No	When this is set, a login request will be sent only after the amount of time set for this has been elapsed after a logout. The default is 0 = “disable.” You can set this to an integer between 0 and 2^63-1 milliseconds.
session_duration	Integer (in milliseconds)	No	The time interval after which a logout request is sent unconditionally after a login. For example, if you sent this to 150 milliseconds, after a login, a logout will be sent after 150 milliseconds whether there is current traffic or not. The default is 0 = “disable.” You can set this to an integer between 0 and 2^63-1 milliseconds.
wapi_rate_limit	Float	No	Independent of the endpoint rate limiting, use this for persistent WAPI requests only. The maximum number of messages (per second) that are sent to an endpoint. The default value is 0 (no rate limiting). You can enter a value less than 1.0 to have lower rate limits. For example, if you set the value to 0.5, the appliance sends less than 1 message in every 2 seconds. The default is 0 = “disable.” You can set this to an integer between 0 and 100000.
wapi_rate_limit_requests	Integer	No	Independent of the endpoint rate limiting, use this for persistent WAPI requests only. Use this along with the `wapi_rate_limit_interval` field to define the absolute number of requests for rate limiting . For example, if you set this to 10 and `rate_limit_interval` to 5000 milliseconds, no further requests are sent until the number of requests falls below 10 in 5000 milliseconds. So if 3 requests were sent at 0 second and 7 requests were sent at the 3rd second, no requests will be sent until the 5th second, where 3 requests are allowed for another 3 seconds. The default is 0 = “disable.” You can set this to an integer between 0 and 267840000000.
wapi_rate_limit_interval	Integer (in milliseconds)	No	Independent of the endpoint rate limiting, use this for persistent WAPI requests only. Use this along with the `wapi_rate_limit_requests` field to define the rate limiting interval . The default is 0 = no rate limiting. The default is 0 = “disable.” You can set this to an integer between 0 and 2678400000 milliseconds.
wapi_rate_limit_reset	Integer (epoch time)	No	Independent of the endpoint rate limiting, use this for persistent WAPI requests only. Use this to reset the epoch time for rate limiting. The default is 0 = not reseting the epoch time for rate limiting. You can set this to an integer between 0 and 4102437600 milliseconds.

Creating Action Templates

The purpose of an action template is to convert an event into one or more RESTful API, DXL, and Syslog messages that are sent from the NIOS appliance to the endpoint configured in the notification rule. An action template consists of a series of statements that are interpreted into specific actions. When creating an action template, ensure that it consists of an initial section with some general template settings, followed by one or more steps that are executed in sequence.

Steps are constructed for sending messages to the endpoint and for receiving responses. It can also perform specific operations on template variables.

> **Note**
>
> The steps in an action template are executed sequentially. Some constructs enable steps to be skipped by jumping forward in the list of steps; jumping backwards is not supported.

Consider the following guidelines while composing action templates:

- Template error handling is active only if the severity level for logging is set to **Debug**, otherwise error handling is disabled and the server continues to execute a template even if the template tries to access nonexistent variables or perform invalid operations such as trying to increment a STRING variable. For information about setting the severity level for logging, see *Configuring Outbound Notifications*. If you have disabled template error handling, then accessing any nonexistent variables will return an empty string and invalid operations are not executed.
- Matching a regular expression is performed un-anchored. If anchoring is required, you must add the characters ^ and/or $ to the respective regular expression.
- For outbound notifications, only template instances are considered. Template instances are constructed from action templates as well as template instance variables in the template. You may configure these variables through Grid Manager when a specific template is associated to an event.
- You can use functions that contain the list of steps to be executed. The **FUNCTION** operation executes the steps in the function.
- Note that the function steps use step execution limit. Step counters for functions are removed when you return to template steps from function steps.
- You must specify the list of functions in the event template and these functions can be used only by the event template.
- Jumping between functions and template steps is not supported.
- Infoblox supports unused functions and allows execution of a function that is located within a function, including itself.
- You cannot upload or update a template if the function does not exist.

An action template consists of the variables and elements listed in the Action template Variables table blow.

> **Note**
>
> When "yes" is indicated in the "Sub" column for a variable, it means that variable substitution (where it is possible to have ${...} variables as part of the value, and have them substituted when the template is executed) is supported for that variable, a * means that the substitution is supported for some of the fields of the struct.

Action Template Variables

Action template Variables

Variable	Type	Mandatory	Sub	Description
version	Must be 5.0	No	No	The version number of the template. Note that 5.0 is the latest version. The appliance still fully supports the previous schema version.
name	String	No	No	The template name.

Variable	Type	Mandatory	Sub	Description
type	Must be REST_EVENT for REST API endpoints Must be DXL_EVENT for DXL endpoints Must be SYSLOG_EVENT for Syslog endpoints	No	No	The template type.
vendor_identifier	String	No	No	The vendor identifier for an endpoint.
event_type	List of ENUM (except for SESSION)	Yes	No	Available event types: RPZ, LEASE, TUNNEL, ADP, DXL, NETWORK_IPV4, NETWORK_IPV6, RANGE_IPV4, RANGE_IPV6, FIXED_ADDRESS_IPV4, FIXED_ADDRESS_IPV6, HOST_ADDRESS_IPV4,HOST_ADDRESS_IPV6, DISCOVERY_DATA, SCHEDULE, DNS_RECORD, DNS_ZONE, SESSION, SYSLOG_SEND_EVENT, DXL_SEND_REQUEST Note that SESSION is used for the login and logout events for the session management templates. For information about supported variables for the session management template, see *Session Management Template Variables*.
action_type	String	No	No	The action type.
comment	String	No	No	Additional information.
content_type	String	No	No	The content type for the whole template. If not specified, it is set as “application/json”. It can be specified either in the template, inside the transport, or both. If both are specified, then the content type specified in the template takes precedence.
quoting	ENUM	No	No	Sets the default serialization for template variables. The valid value is one of the following: JSON, XML, XMLA, ASIS, or URL. If not specified, this is set to JSON. To use XMLA for serialization, you must specify a valid quoting for variables. Infoblox strongly recommends that you use XMLA as the quoting option (as opposed to XML) when you create new action templates. New operations such as PUSH, POP, SHIFT and others are not officially supported for XML parsed data.
headers	Dictionary of key/value pairs	No	Yes	If specified, it is sent for every request of the template, in addition to any other H: namespace variables.
instance_variables	List of VARIABLE structs	No	No	It must be specified in the GUI to create a template instance.
template_variables	List of VARIABLE structs	No	No	template_variables is used when there are common settings in various steps. They are specified for maintainability and they are also available in L: namespace. Note that the template variables are evaluated immediately so that they can be used as reference values in other areas of the template.
transport	TRANSPORT struct	No	No	It is the default for steps.

Variable	Type	Mandatory	Sub	Description
				Steps are executed in sequence. You cannot execute them
steps	List of STEP structs	Yes		Steps are executed in sequence. You cannot execute them in a backward manner.
step_execution_limit	Integer			The maximum number of times a step can be executed. Steps can be executed more than once if using certain template constructs. To avoid possible endless loops, you can limit an individual step to be executed up to a certain number of times. If a step is executed again after the limit is reached, the execution will be interrupted and a failure is logged. The default is 10. The maximum number is 1000.

STEP Struct

Each step can perform a different operation, such as **SLEEP**, **CONDITION**, **NOP**, **GET**, **POST**, **PATCH**, **DELETE**, **DXL_EVENT_SEND**, or **PUT**. The STEP Structs table below, lists the step variables.

> **Note**
>
> The name for each step must be unique.

- **SLEEP**: Steps with a SLEEP operation will pause the execution for the number of seconds specified in the timeout parameter.
- **NOP**: Steps with a NOP operation will only parse the text specified in body/body_list without sending it to the endpoint. This can be useful for executing operations on variables to prepare data for subsequent steps.
- **CONDITION**: Steps with a CONDITION operation will cause a condition specified in statements to be matched. See CONDITION Structs table below, for information about condition variables and STATEMENT Structs table below, for statement variables.

  If the condition matches, the execution of the template will do the following:

  - Stop without errors If the stop field is present,
  - Stop with an errors if the error field is present,
  - Jump forward to the specified step if the next field is present,
  - and/or evaluate the text in eval if the field is present.

If the condition does not match, the text in the else_eval field will be evaluated instead, if the field is present.

- **GET, POST, PATCH**, **DELETE**, and **PUT**: These steps will result in an endpoint communication. The request will be sent to an URI composed by the URI configured in the endpoint, plus the path configured in the session management template if present (or replaced by it, depending on its override setting), plus the path configured in the event template if present (same override considerations), plus the path configured in the individual step if present (same override considerations).
  After variable substitution, any data present in the H: namespace will be sent as headers, any parameters listed will be sent as URI parameters, and any data in body/body_list will be sent as the body of the request. Note also that each step can override the endpoint timeout. This is useful when a certain operation is known to require a longer execution time.
  If the result variable is set in the step, the reply from the server will be evaluated and compared against the specified codes and/or REGEX, and the operation specified in the result step will be executed.
  If parse is set in the step, the result from the server will also be parsed and be made available in the P: namespace as described above.

> **Note**

Set the "wapi" field to send WAPI requests to the Grid Master using available event data. For example, you can add or modify extensible attributes of a NIOS object at the time when the object is being synchronized. If you include the "wapi" field in a step, you must enable WAPI integration by entering the WAPI login username and password while configuring the endpoint. Otherwise, the WAPI step will fail due to an authorization error. For information about how to configure endpoints, see *Configuring Outbound Notifications*.

STEP Structs

Variable	Type	Mandatory	Sub	Description
name	String	Yes	No	Used to refer to the steps used in the execution of the template.
operation	ENUM	Yes	No	The valid value can be one of the following: GET, POST, DELETE, PATCH, PUT, SLEEP, CONDITION, NOP, VARIABLEOP, DXL_EVENT_SEND, SERIALIZE, or FUNCTION. If you specify SLEEP, only timeout is supported, where timeout is the sleep length in seconds. If you specify NOP, only variable operations are performed, and only body/body_list is supported. If you specify VARIABLEOP, you must use the VARIABLE struct within your steps that are executed in sequence. See VARIABLE Struct below, for the supported fields. If you specify **SERIALIZE**, see SERIALIZE Struct below, for the supported variables.
function_name	String	Yes		Function name. Applicable only if the operation is set to **FUNCTION**.
condition	CONDITION Struct	No		Applicable only if the operation is set to **CONDITION**.
timeout	String	No	Yes	If specified, overrides the endpoint configuration value (it is useful if the template is slow during execution). Note that the timeout value is invalid for NOP. Since the timeout variable is a string, you can substitute the variable in individual steps.
transport	TRANSPORT Struct	No	Path only	
result	List of RESULT Structs	No	No	If not present, you can assume 200, everything else is a failure. If not specified, the steps are executed sequentially. This is not valid for SLEEP, NOP, or CONDITION variables.
parse	ENUM	No	No	If specified, the output of the server will be parsed. The valid value is one of the following: JSON, REGEXLINE, REGEXMULTILINE, REGEX, REGEXSPLIT, XMLA, or XML. Infoblox recommends that you use **XMLA** instead of **XML** for parsing. Ensure that you see Result Parsing below for details.
parse_regex	String	No	No	You can set one of the following: REGEX, REGEXSPLIT, REGEXLINE, or REGEXMULTILINE

Variable	Type	Mandatory	Sub	Description
parameters	List of PARAMETERS	No	Value only	These are URI parameters.
headers	Dictionary of name/value pairs	No	Yes	This is sent as HTTP headers. The name space substitution is supported only for value. Note that assigning to the H: name space also sends headers.
override_headers	Boolean	No	No	If specified, only these headers and H: name space headers are sent instead of template headers.
body	String	No	Yes	This is applicable only for POST, PATCH, DXL_EVENT_SEND, and PUT requests as well as NOP and FUNCTION operations. It will be sent as the body of the request. Note that name space substitution is supported.
body_list	List of strings	No	Yes	This is an alternative to the body. If specified, the strings in the list will be joined before sending it. Any leading or trailing whitespace is removed. This is applicable to FUNCTION operation.
no_connection_debug	Boolean	No	No	The valid value is True or False. If this is set to True even if the endpoint is set to a Debug level logging, only the body, headers, and cookies for the corresponding step will NOT be output to the debug log. Only explicit DEBUG calls will be displayed. This is generally used in login templates to avoid usernames and passwords from being logged to the log files in plain text.
variable_ops	List of VARIABLEOP structs	No	No	For more information, see VARIABLEOP Struct below.
serializations	List of SERIALIZE structs	No	No	For more information, see SERIALIZE Struct below.
comment	String	No	No	Adds information about the steps.
wapi	String	No	No	The WAPI version. When this is set, the username and password (auth username and auth password) specified for the endpoint are ignored for WAPI related steps only. Other steps still use the configured auth username and auth password. All WAPI requests are sent to the Grid Master IP. The path of the requests is */wapi/[version]/* with the appended path as specified in the step. The override path option as well as any path configured in the session management template will have no effect.
wapi_quoting	ENUM	No	No	The valid value is one of the following: JSON or XML. If this is not specified, it is set to JSON. The default is JSON. JSON and XML parsing performs as usual for WAPI.
dxl_topic	String	No	Path only	The DXL topic that is used to send data by DXL. **Note**: This variable is applicable only for the DXL templates.

VARIABLEOP Struct

Note that all fields are optional, except operation and typeNo schema validation is made for variable combinations. Validation of the schema is performed when you add or modify the action template., no specific JSON schema validation is made for variable combinations as it would be too complex, the validation will be done at template conversion time (which is still done when users upload / edit templates).

> **Note**
>
> All variables listed in the following table are applicable only for the VARIALBEOP operation in the STEP struct. The VARIABLEOP struct converts specified keys/values in a complex variable (such as LIST, DICTIONARY, or XML values with attributes) or performs operations on an existing complex variable. No schema validation is made for variable combinations. Validation of the schema is performed when you add or modify the action template.

VARIABLEOP Struct

Variable	Type	Mandatory	Sub	Description
source	String	No	Yes	You must specify the variable name, including the namespace. You can include nested variables. Example: L:DICT{key}{list})
destination	String	No	Yes	You must specify the variable name, including the namespace. You can include nested variables. Example: L:DICT{key}{list})
operation	ENUM	Yes	Yes	Specifies the operation being performed for the value defined or created in type. The valid value is one of the following: PUSH, POP, SHIFT, UNSHIFT, or ASSIGN. Note that both `operation` and `type` are mandatory for the struct. For examples, see Using OPERATION in the VARIABLE Struct below.

Variable	Type	Mandatory	Sub	Description
type	ENUM	Yes	Yes	Specifies the type of variables for the operation. Valid value is one of the following: LIST, DICTIONARY, COMPOSITE, or SINGLE. This field defines how the values in `keys`, `values`, and `composite_value` are combined to create a variable while `operation` defines how the variable is being used. The appliance handles `keys`, `values` and `composite_value` differently based on the type you select, as follows: • LIST: `keys` will be ignored; `values` will contain the required values and be serialized in a simple list of strings. • DICTIONARY: The list of `key/value` pairs in `keys` and `values` will be put in a simple dictionary. • COMPOSITE: The list of `key/value` pairs in `keys` and `values` will be put in an XMLA dictionary with a name set to `name` and a value set to either the value in `composite_value` OR the value in the variable set in `source`. See Using the COMPOSITE Type below for details about how to use COMPOSITE. • SINGLE: `keys` will be ignored; the value will be the first element in the `values` list.
name	String	No	Yes	This is applicable only if you select COMPOSITE as the variabletype. Enter the name value for this type.
keys	List of strings	No	Yes	This can contain arbitrary serializable constructs.
values	List of strings	No	Yes	This can contain arbitrary serializable constructs. When you specify this field inside any variable operation for the VARIABLEOP step type, it is possible to use the constant of a specific type, instead of using string. For details about how to specific type, instead of using string. For details about how to use constant, see Constant Specification for values below.
composite_value	String	No	Yes	This can contain arbitrary serializable constructs.
destination_key	String	No	Yes	This can contain arbitrary serializable constructs.
if_exists	ENUM	No	Yes	The action taken if the variable exists. The valid value is one of the following: SKIP, ERROR, or NEXT.

Variable	Type	Mandatory	Sub	Description
if_exists_next	String	No	Yes	Enter the name for the next step.
condition	CONDITION Struct	No		This can be specified for POP and UNSHIFT operations.

Using the COMPOSITE Type

When you use COMPOSITE as the type in the VARIABLE struct, the list of key/value pairs in `keys` and `values` is put in an XMLA dictionary with a name set to `name` and a value set to either the value in `composite_value` OR to the value in the variable set in `source`.

Here is an example of using COMPOSITE as the type when you use the following variables and values:

Field	Value
type	COMPOSITE
name	varname
keys	["a1", "a2"]
values	["value is ${L::SOMEVAR}", "2"]
composite_value	"123"

It results in the following:

```
{
   "<xmla>": true,
   "attrs": {
      "a1": "value is 123",
      "a2": "2",
   },
   "index": {},
   "value": ["123"],
   "name": "varname"
}
```

Note

If source is set, the value in source is used as is (this can be seen especially for PUSH operations).

Using OPERATION in the VARIABLE Struct

operation ASSIGN

If operation is set to ASSIGN, the value in type will be simply put in the variable identified by `destination`, overwriting any value it might already have.

The following are several examples of the ASSIGN operation having namespace E as follows:

```
{
  'some_field': 'some_value',
  'some_list': ['item1', 'item2']
}
```

(1) When assigning a single value:

```
{
  'operation': 'ASSIGN',
  'type': 'SINGLE',
  'destination': 'L:var',
  'values': ['value']
}
```

It returns name space L as follows:

```
{'var': 'value'}
```

(2) When assigning a list:

```
{
  'operation': 'ASSIGN',
  'type': 'LIST',
  'destination': 'L:list',
  'values': ['value', '${E:A:some_field}']
}
```

It returns the following:

```
{'list': ['value', 'some_value']}
```

(3) When assigning a dictionary:

```
{
  'operation': 'ASSIGN',
  'type': 'DICTIONARY',
  'destination': 'L:dict',
  'keys': ['${E:A:some_field}_1', '${E:A:some_field}_2'],
  'values': ['${E:A:some_list[0]}', '${E:A:some_list[1]}']
}
```

It returns the following:

```
{'dict': {'some_value_2': 'item2', 'some_value_1': 'item1'}}
```

(4) When assigning a composite value, as follows:

```
{
  'operation': 'ASSIGN',
  'type': 'COMPOSITE',
  'destination': 'L:composite',
  'name': 'tag_name',
  'keys': ['attr_1', 'attr_2'],
  'values': ['${E:A:some_field}', 'another_value'],
  'composite_value': 'tag_content'
}
```

It gives the following:

```
{'composite': {
  'index': {}, '<xmla>': True,
  'attrs': {
    'attr_2': 'another_value',
    'attr_1': 'some_value'
```

```
  },
  'value': ['tag_content'],
  'name': 'tag_name'
}}
```

This composite value can be serialized to the following XML:

```
<tag_name attr_1="some_value" attr_2="another_value">tag_content</tagname>
```

operation PUSH and SHIFT without setting if_exists

If `destination_key` is set, the assumption is to push or shift to a dictionary; otherwise, it is to push or shift to a list.

For pushing to a list, if the `destination` variable exists and is a list, the list of values in `values` will be added to the existing list. With PUSH, it means that the values will be added to the right side of the list (at the end) of the list. With SHIFT however, the values will be added to the left side (at the beginning) of th list.

If the `destination` variable is a dictionary, it will be converted to a list that contains only one element with the value appended to it. This means that for XML deserializing and JSON values, it is possible to create a list by pushing it on to an existing scalar value.

For pushing to a dictionary, it means that with `destination_key` set, if the `destination` variable exists and is anything but a dictionary, it is considered as an error. If it is a dictionary however, the value above will be added with its key set to `destination_key` overwriting any existing value.

If the variable denoted by `destination` has a composite value, the COMPOSITE type can be pushed or shifted to it only. If the destination composite value contains text, the text will be replaced with the composite value. In other cases, the PUSH operation using the new value will be added to the right side of the children list. For the SHIFT operation, the new value will be added to the left side of the children list.

The following are several examples of the ASSIGN operation having namespace E:

```
{'some_field': 'some_value'}
```

and namespace L as follows:

```
{
   'some_list': ['item1', 'item2'],
   'some_dict': {'key': 'val'},
   'comp1': {
     'index': {}, '<xmla>': True,
     'attrs': {
        'attr1_b': 'another_value',
        'attr1_a': 'some_value'
```

```
        },
        'value': ['tag_1_content'],
        'name': 'tag_1'
    },
    'comp2': {
        'index': {}, '<xmla>': True,
        'attrs': {},
        'value': ['tag_2_content'],
        'name': 'tag_2'
    }
}
```

(1) When PUSH or SHIFT to a list:

```
{
    'operation': 'PUSH',
    'type': 'SINGLE',
    'destination': 'L:some_list',
    'values': ['${E:A:some_field}_right'],
},
{
    'operation': 'SHIFT',
    'type': 'LIST',
    'destination': 'L:some_list',
    'values': ['left_${E:A:some_field}']
},
```

It returns namespace L as the following:

```
{'some_list': [['left_some_value'], 'item1', 'item2', 'some_value_right']}
```

(2) When PUSH or SHIFT to a dictionary, it returns the following:

```
{'some_dict': {
  'push1': 'item',
  'push2': ['item_1', 'item_2'],
  'key': 'val'
}}
```

Note: There is no difference between PUSH and SHIFT when destination is DICTIONARY.

---

(3) When PUSH or SHIFT to a composite value:

```
{
   'operation': 'PUSH',
   'type': 'COMPOSITE',
   'destination': 'L:comp1',
   'name': 'pushed',
   'composite_value': ''
},
{
   'operation': 'SHIFT',
   'type': 'COMPOSITE',
   'destination': 'L:comp1',
   'source': 'L:comp2'
},
```

It returns the following:

```
{
   'comp1': {
   'index': {u'pushed': 1, 'tag_2': 0},
   '<xmla>': True,
```

```
   'attrs': {'attr1_a': 'some_value', 'attr1_b': 'another_value'},
   'value': [
     {'index': {}, '<xmla>': True, 'attrs': {}, 'value': ['tag_2_content'],
'name': 'tag_2'},
     {'index': {}, '<xmla>': True, 'attrs': {'attr': 'val'}, 'value': [],
'name': 'pushed'}
   ],
   'name': 'tag_1'
  }
}
```

Note that the first operation (PUSH) overwrites existing value and the second operation (SHIFT) shifts the value to the existing list. This composite value can be serialized to the following XML:

```
<tag_1 attr1_a="some_value" attr1_b="another_value">
  <tag_2>tag_2_content</tag_2>
  <pushed attr="val"/>
</tag_1>
```

operation PUSH and SHIFT with if_exist set

If `destination_key` is set, the assumption is to push or shift to a dictionary. Otherwise it is to push or shift to a list.

If you are pushing to a list, and the variable already exists, the operation specified there will be executed as follows: SKIP will not modify the original value, NEXT will not modify and jump to the step specified in `if_exists_next`, and ERROR will instead return an error.

If you are pushing to a dictionary, and the variable matches, there is no need to modify the values because they would already be the same. Therefore, SKIP will be a no-operation, NEXT will not modify and jump to the step specified in `if_exists_next`, and ERROR will instead return an error.

The decision for whether a new value exists or not is a simple comparison with the value/attributes of the existing variables in the list or dictionary in `destination_key`. They all have to match for `if_exists` for the operation to be triggered.

If variable denoted by `destination` has a composite value, the semantics is as above, with additional checks. The check is complete before the value is added to the list of children. During the check, the new composite value is compared one by one with the existing values. If the values are the same, the “if_exists” logic is triggered as above.

The following are a few examples using namespace L as follows:

```
{
   'some_list': ['item1', 'item2'],
```

```
   'some_dict': {'key1': 'val1', 'key2': 'val2'},
   'list_of_lists': [['a', 'b'], ['a', '2'], ['1', '2']],
   'composite': {
     '<xmla>': True,
     'index': {'inner_1': 0, 'inner_2': 1},
     'name': 'outer',
     'attrs': {'outer_attr': 'outer_val'},
     'value': [
       {
         '<xmla>': True,
         'index': {},
         'name': 'inner_1',
         'attrs': {},
         'value': ['inner_1_content']
       },
       {
         '<xmla>': True,
         'index': {},
         'name': 'inner_2',
         'attrs': {'inner_attr': 'inner_val'},
         'value': []
       }
     ]
   }
}
```

(1) When PUSH to a list with the item exists:

```
{
```

```
    'operation': 'PUSH',
    'type': 'SINGLE',
    'destination': 'L:some_list',
    'values': ['item2'],
    'if_exists': 'ERROR'
}
```

It triggers the `'if_exits` login. `ERROR` means stopping the template execution with error, `SKIP` means 'do nothing for this operation' and `NEXT` will jump to the step with name specified in `'if_exists_next`.

(2) When PUSH to a dictionary with the item exists:

```
{
    'operation': 'PUSH',
    'type': 'SINGLE',
    'destination': 'L:some_dict',
    'destination_key': 'key2',
    'values': ['val2'],
    'if_exists': 'ERROR'
}
```

It triggers an error. Note that both `key` and `value` should be the same in order to trigger the `if_exists'` logic. If `key` is the same but `value` differs, `value` will be overwritten. If `key` is different, the new `key` with `value` will be added.

(3) When PUSH to a list of list with the item exists:

```
{
    'operation': 'PUSH',
    'type': 'LIST',
    'destination': 'L:list_of_lists',
    'values': ['a', '2'],
    'if_exists': 'ERROR'
}
```

It triggers an error.

(4a) When PUSH to a composite value with the item exists, as follows:

```
{
   'operation': 'PUSH',
   'type': 'COMPOSITE',
   'destination': 'L:composite',
   'name': 'inner_1',
   'composite_value': 'inner_1_content',
   'if_exists': 'ERROR'
}
```

It triggers an error.

(4b) When PUSH to a composite value with the item exists, as follows:

```
{
   'operation': 'PUSH',
   'type': 'COMPOSITE',
   'destination': 'L:composite',
   'name': 'inner_2',
   'keys': ['inner_attr'],
   'values': ['inner_val'],
   'composite_value': '',
   'if_exists': 'ERROR'
}
```

It triggers an error.

operation POP and UNSHIFT

If the `source` variable is anything but a dictionary, a list, or a composite value, an error is returned. If keys is set, the `source` value is assumed to be a dictionary. Otherwise, an error is returned.

If the `source` variable is a list, a single value is removed from the list. If the operation is POP, it is removed from the right side (from the end). If the operation is UNSHIFT, it is removed from the left (at the beginning). The removed value is put in the `destination` variable.

If the `source` variable is a composite value, the operation is on the children list of the composite value. Note that it is not possible to POP or UNSHIFT from a composite value, if it has text only.

If the `source` variable is a dictionary, the specified `keys` and/or key/value pairs will be removed from the variable in `source`. If only `keys` are passed, those keys will be unconditionally removed. If `keys` and `values` are passed, the key will be removed from the `source` variable only if its value matches what is passed in `values` here. If only one key or key/value pair is passed, the removed value will be put in `destination`. Otherwise, it will simply be dropped.

For the `values` match, the value in the list or dictionary will be serialized with quoting specified in the template before being compared to the string value passed in `values`. This also means that using comparison on large lists would potentially be a slow operation.

In the POP or UNSHIFT case, `type` is validated to be the same as the type of the popped or unshifted variable (you can validate if they were planning to pop a simple scalar if there is one). If it is not, an error will be raised if debug is turned on.

The following are a few examples using namespace L as follows:

```
{
   'some_list': ['item1', 'item2'],
   'some_dict': {'key1': 'val1', 'key2': 'val2'},
   'list_of_lists': [['a', 'b'], ['1', '2']],
   'list_of_dicts': [{'a': '1'}, {'b': '2'}],
   'composite': {
     '<xmla>': True,
     'index': {'inner_1': 0, 'inner_2': 1},
     'name': 'outer',
     'attrs': {'outer_attr': 'outer_val'},
     'value': [
          {
              '<xmla>': True,
             'index': {},
             'name': 'inner_1',
```

```
            'attrs': {},
            'value': ['inner_1_content']
        },
        {
            '<xmla>': True,
            'index': {},
            'name': 'inner_2',
            'attrs': {'inner_attr': 'inner_val'},
            'value': []
        }
    ]
  }
}
```

(1) When POP from a list:

```
{
   "operation": "POP",
   "type": "SINGLE",
   "source": "L:some_list",
},
```

It gives the variable as follows:

```
{"some_list": ["item1"]}
```

(2) When UNSHIFT from a list:

```
{
   "operation": "UNSHIFT",
   "type": "SINGLE",
   "source": "L:some_list",
}
```

It returns the following:

```
{"some_list": ["item2"]}
```

(3) When UNSHIFT from a dict by key:

```
{
   "operation": "UNSHIFT",
   "type": "SINGLE",
   "source": "L:some_dict",
   "keys": ["key1"]
}
```

It returns the following:

```
{"some_dict": {"key2": "val2"}} There is no difference between POP/UNSHIFT
fro dictionarries
```

(4) When POP from a dict by multiple keys:

```
{
   "operation": "POP",
   "type": "SINGLE",
   "source": "L:some_dict",
   "keys": ["key1", "key2"]
}
```

It returns the following:

```
{"some_dict": {}}
```

(5) When POP from a dict when a key is absent:

```
{
   "operation": "POP",
   "type": "SINGLE",
   "source": "L:some_dict",
   "keys": ["key1", "absent_key"]
}
```

It returns an error in the DEBUG mode. For non-DEBUG mode, all existing keys are POPed. Note that items are popped one by one, so key1 item is popped before the error is returned.

```
{"some_dict": {"key2": "val2"}}
```

(6) When POP from composite value:

```
{
   "operation": "POP",
   "type": "SINGLE",
   "source": "L:composite",
}
```

It returns the following:

```
{
   "composite": {
      "index": {"inner_1": 0},
      "<xmla>": True,
      "name": "outer",
      "value": [{
         "index": {},
         "<xmla>": True,
         "name": "inner_1",
         "value": ["inner_1_content"],
         "attrs": {}
     }],
     "attrs": {"outer_attr": "outer_val"}
   }
}
```

This can be serialized to the following:

```
<outer outer_attr="outer_val">
   <inner_1>inner_1_content<inner_1>
```

```
</outer>
```

(7) When conditional POP/UNSHIFT from a list:

```
{
   "operation": "POP",
   "type": "SINGLE",
   "source": "L:some_list",
   "values": ["item1"]
}
```

It returns the following:

```
{"some_list": ["item2"]}
```

There is no difference between POP and UNSHIFT when ‘ `values` ’ is specified. When source is either **LIST** or **COMPOSITE**, all occurrences of a value are deleted.

(8) When conditional POP/UNSHIFT from a dictionary:

```
{
   "operation": "UNSHIFT",
   "type": "SINGLE",
   "source": "L:some_dict",
   "keys": ["key2"],
   "values": ["val2"]
}
```

It returns the following:

```
{"some_dict": {"key1": "val1"}}
```

(9) When conditional POP/UNSHIFT of multiple values:

```
{
   "operation": "UNSHIFT",
   "type": "SINGLE",
   "source": "L:some_dict",
   "keys": ["key2", "key2"],
```

```
    "values": ["abc", "val2"]
}
```

It returns the following:

```
{"some_dict": {"key1": "val1"}}
```

(10) When conditional POP/UNSHIFT with list values:

```
{
    "operation": "POP",
    "type": "SINGLE",
    "source": "L:list_of_lists",
    "values": ["\"['1', '2']\""]
}
```

It returns the following:

```
{"list_of_lists": [["a", "b"]]}
```

For conditional POP/UNSHIFT, non-string values are serialized with the template's `quoting`. For JSON, `quoting` is added to `value`.

(11) When conditional POP/UNSHIFT with dictionary value:

```
{
    "operation": "POP",
    "type": "DICTIONARY",
    "source": "L:list_of_dicts",
    "values": ["\"{'b': '2'}\""]
}
```

It returns the following:

```
{"list_of_dicts": [{"a": "1"}]}
```

(12a) When conditional POP/UNSHIFT with the following composite values:

```
{
    "operation": "POP",
    "type": "COMPOSITE",
```

```
   "source": "L:composite",
   "values": ["\"{'index': {}, '<xmla>': True, 'name': 'inner_2', 'value': [],
   'attrs': {'inner_attr': 'inner_val'}}\""]
}
```

It returns the following:

```
{
   "composite": {
     "index": {"inner_1": 0},
     "<xmla>": True,
     "name": "outer",
     "value": [{
       "index": {},
       "<xmla>": True,
       "name": "inner_1",
       "value": ["inner_1_content"],
       "attrs": {}
     }],
    "attrs": {"outer_attr": "outer_val"}
  }
}
```

(12b) When conditional POP/UNSHIFT with the following composite values, and with the template quoting set to XMLA:

The example in (12a) can be specified as follows:

```
{
   "operation": "POP",
   "type": "COMPOSITE",
   "source": "L:composite",
   "values": ["<inner_2 inner_attr=\"inner_val\"/>"]
```

```
}
```

Type check after POP/UNSHIFT:

```
{
   "operation": "POP",
   "type": "LIST",
   "source": "L:some_dict",
   "keys": ["key2"]
}
```

It returns an error in the DEBUG mode. Since the type of POPed value is not **LIST**, the possible values for type are '**SINGLE**', '**LIST**', '**DICTIONARY**', and '**COMPOSITE**', where '**SINGLE**' means 'no check'. Note that type check is done after the item is retrieved from `source`. In the **DICTIONARY** case, when several keys are specified, there is no type check. Type check is done after value comparison.

(13) When putting the item to 'destination':

```
{
   "operation": "POP",
   "type": "COMPOSITE",
   "source": "L:composite",
   "destination": "L:sub_item"
}
```

It returns the following:

```
{
   "composite": {
      "index": {"inner_1": 0},
      "<xmla>": True,
      "name": "outer",
      "value": [
        {"index": {}, "<xmla>": True, "name": "inner_1", "value":
["inner_1_content"],
   "attrs": {}}
```

```
      ],
      "attrs": {"outer_attr": "outer_val"}
      },
    "sub_item": {
      "index": {},
      "<xmla>": True,
      "name": "inner_2",
      "value": [],
      "attrs": {"inner_attr": "inner_val"}
   }
}
```

If the value popped/unshifted from source and destination is specified, the value is written to the destination. The value is written after the type check.

The L:sub_item can be serialized as the following:

```
<inner_2 inner_attr="inner_val"/>
```

Constant Specification for values

When you specify the `values` field inside any variable operation for the VARIABLEOP step type, it is possible to use the constant of a specific type, instead of string.

For example, the following describes three string values:

```
‘values’: [‘True’, ‘42’, ‘${L::some_var}’]
```

If you specify `values` as ‘ `{X:something}’, ‘` something `’` is represented as a constant of type X. Note that this is the only allowed syntax. For example, ‘ `text{X:something}` ’ is treated as a string, instead of a constant specification.

The following types are supported in constant specification:

- **Bool type (B)**: Both '{B:1}' and '{B:true}' are evaluated as bool true, while '{B:0}' and '{B:false} are evaluated as bool false. Note that both 'true' and 'false' are not case-sensitive. Therefore, True, FALSE or even tRuE are all allowed. Other invalid values such as 'B:' and '{B:anythingelse}' are evaluated as bool=false (the 'default value') without further debugging; and an error is logged in the debug mode.
- **Integer type (I)**: '{I:}' is evaluated to its corresponding integer value. For example, {I:-42} is evaluated as integer -42. The default value is 0.
- **Empty type (E)**: ‘{E:}’ is evaluated as None. ‘{E:[]}’ is evaluated as an empty list. ‘{E:{}}’ is evaluated as an empty dictionary. The default value is None.
- **Float type (F)**: The float type is similar to the integer type. Float numbers can be specified as '{F:0.0}', '{F:-4.2}', '{F:-4E+2}' or '{F:+1.23e-45}. The default value is 0.0.
- **String type (S)**: '{S:}' is evaluated as string ''. For example, '{S:{I:42}}' is string '{I:42}'. There is no default value for string. For the unknown type (e.g. '{U:%^&}'), the default value is an empty string.

The following example illustrates how to use constant specification to define ipv4addr with a DHCP option:

```
{
   “ipv4addr”: “1.2.3.4”,
   “options”: [
     {
       “name”: 'dhcp-lease-time”,
       “num”: 51,
       “use_option”: true,
       “value': '43200”,
       'vendor_class': “DHCP”
     }
   ]
}
```

Note that `num` is an integer (in this string: “num”: “51”) and `use_option` is bool (in this string: “use_option”: “true”).

In the action template, you can do the following:

```
{
   “steps”: [
   {
     “operation': 'VARIABLEOP”,
     “variable_ops”: [
       {
         “operation”: “ASSIGN”,
         “type”: “DICTIONARY”,
         “destination”: “L:addr”,
         “keys”: [“ipv4addr”, “options”],
         “values': [“1.2.3.4”, “{E:[]}”]
      },
```

```
      {
        “operation”: “PUSH”,
        “type”: “DICTIONARY”,
        “destination”: “L:addr{options}”,
       “keys”: [ “name”, ”num”, “use_option”, “value”, “vendor_class”],
        “values': [“dhcp-lease-time”, ”{I:51}”, ”{B:true}”, “43200”,
“DHCP”]
      }
    ]
  },
  {
  “operation”: “PUT”,
  “transport”: {“path”: “record:host_ipv4addr”},
  “body”: “${L:J:addr}”
  }
 ]
}
```

SERIALIZE Struct

SERIALIZE Struct

Note: All variables listed in the following table are applicable only for the SERIALIZE operation in the STEP struct. The SERIALIZE structs inside the step are executed in sequence.

Field	Type	Mandatory	Sub	Description
content	String	Yes	Yes	Defines what to serialize. This can contain arbitrary variables and text.
destination	String	Yes	Yes	Defines the destination for the serialization.

TRANSPORT Struct

TRANSPORT Structs

Variable	Type	Mandatory	Sub	Description
path	String	No	Yes, if specified in step.	If present, it is appended to the endpoint URI.
override_path	Boolean	No	No	If this is true, the specified path completely overrides the endpoint URI after the first /.
content_type	String	No	No	If specified, this overrides the endpoint content type.

RESULT Struct

Note the following:

- **codes** and **regex** are ignored if the operation is SLEEP or NOP.
- At least one of the following is required: **next**, **stop**, or **error**.

RESULT Structs

Variable	Type	Mandatory	Sub	Description
codes	string separated by commas	No	No	The http return code.
regex	REGEX	No	No	If specified, REGEX is matched against the returned body.
next	id	No	No	The step to execute the next template if the code (and REGEX, if specified) match. But if the next template is already executed once, the appliance displays an error.
stop	Boolean	No	No	If set, the execution of the script is stopped. Note that next, error, and stop are mutually exclusive.
error	Boolean	No	No	If set, the execution of the script is stopped and then rerun with an error status if the retry_template is not set to 0. Note that next, error, and stop are mutually exclusive.

PARAMETER Struct

PARAMETER Structs

Variable	Type	Mandatory	Sub	Description
name	String	Yes	No	Name of the parameter.
value	String	Yes	Yes	Value of the parameter. Note that this value is used as-is, so any strings that are not part of the variables must be URL encoded (%20 for spaces, and etc.)

CONDITION Struct

CONDITION Structs

Variable	Type	Mandatory	Sub	Description
condition_type	String	Yes	No	This can be one of the following: AND, OR, NAND, or NOR. NAND means not (st1, st2, etc.)
next	String	No	No	The name of the step to jump to if the condition is successful.
eval	String	No	Yes	This is executed if the condition is successful. Generally, it will be an XC: set of operations.
else_eval	String	No	Yes	This is executed if the condition is NOT successful. Generally, it will be an XC: set of operations.
else_next	String	No	Yes	The execution will jump to specified step if the condition is NOT successful.
else_stop	String	No	Yes	The template execution will be stopped if the condition is NOT successful.
else_error	String	No	Yes	Generates an error if the condition is NOT successful.
stop	Boolean	No	No	If the condition is successful the execution will be stopped without any error.
error	Boolean	No	No	If the condition is successful the execution will be stopped with an error.
statements	List of STATEMENT structs	Yes	Yes	The statements to evaluate.

STATEMENT Struct

STATEMENT Structs

Variable	Type	Mandatory	Sub	Description
left	String	Yes	Yes	The left operand. Note that it is acceptable to include variables that do not exist on the left side (to test if a variable is set in an event). Any error during evaluation of the `left` is ignored even if it is run under debug mode.
op	ENUM	Yes	No	The operation to execute. This can be one of the following: =, >, <, >=, <=, =~, and !~. Note that the >, <, >=, and <= operations try to convert the operands to numbers before executing the comparison, then = ~, and !~ are REGEX matches and the right side is considered the REGEX.
right	String	Yes	Yes	The right operand.

Action Template Variables and Name Spaces

Action templates can access variables in several different name spaces. The following are the available name spaces:

- **C**: http cookies. It supports only the DEL operation (primarily for logout purposes), but it can be used as a substitution origin.
- **Read-Only E**: Event data.
- **H**: http headers. Note that the assigned variables are sent in the next HTTP request and it survives the template execution.
- **Read-Only I**: Template instance variables. It is set in the GUI during the creation of the filter and it also includes the endpoint variables that are set in the GUI when creating an endpoint. Note that the instance variables can override endpoint variables, if needed.
- **L**: Local template variables. This name space is empty at name space startup and will not survive the template invocation.
- **Read-Only P**: Previous endpoint response values (if parsing is enabled for the response.)
- **Read-Only R**: Previous endpoint request http-specific return values. This includes RC, the http status code of the previous request (Example: 200), BODY, and the body of the response.
- **Read-Only RH**: Previous endpoint request that returned http headers.
- **S**: Endpoint session state variables. These variables survive the template invocation (it is used similar to L: name space which is not cleared at the end of the template execution.)
- **Read-Only UT**: Read-only utility variables. The UT: name space contains the following read-only variables:
  - **EPOCH**: EPOCH seconds since Jan 1st, 1970 (integer, 1 second resolution.)
  - **TIME**: UTC time in ISO-8601 format. Example: 2016-04-08T23:09:35Z (1 second resolution).
  - **UUID**: Random UUID of the form 00000000-0000-0000-0000-000000000000.
  - **PROTOCOL**: The protocol used for the request.
  - **URI**: Complete URI used for the request.
  - **HOST**: The endpoint address.
  - **PORT**: The port used for the request.
- **Read-Only XC**: Execute a command on the variable. This results no output.

Action Template Variable Format

The following sequences are substituted with dynamic data:

```
${<data namespace>:<output format>:<name of the data or operation dependent values>}
```

The sequences cannot contain the following characters as variable names: {, }, [, and]. Therefore, if names contain keys of dictionary/EA variables, they must be quoted with the \ character. Example: *${E::SOME_EA{name with \{ embedded \] braces or brackets}*. But if the \ character is desired, it must be quoted as \. Note that variable substitution happens only once, it is not nested (i.e. if the value contains ${...}, it will not be recursively substituted). Also, the dynamic data is not supported for instance and template variables which are assumed to be immediate values.
The following types of variables allow further qualifiers after the variable name. The qualifiers are always mandatory. Therefore, if a variable is a list or a dictionary, then you must specify [ ] or { }.

- EA (Extensible Attribute) variables or dictionaries. In general, you must specify {EAname} for EA variables or dictionaries. For example, if you specify ${E::NETWORK_EA{City}}, it means the city EA from the network EAs. Note that data specific portion is mandatory for EA variables.
- List variables. You can specify the list index using square brackets. For example, for a list of DNS names if you specify ${E::DNS_NAMES[0]}, this indicates the first DNS name in the list.

You can also use { } or [ ] to signify the full dictionary or list that is supported only in some encodings. Optionally, you can specify the output format. The following output formats are supported:

- **J**: The output is in the form of JSON formatted variable. It supports deserializing lists as well as dictionaries. Note that strings will have double quotes prepended/appended when serialized with J.
- **j**: The output is in the form of JSON formatted variable. It supports deserializing lists as well as dictionaries without the leading or trailing double quotes, if the variable is a string.
- **X**: The output is in the form of XML formatted variable. It supports only deserializing lists, such as < item >..</item > sequence.
- **U**: The output is in the form of url encoded variable. It supports deserializing lists and the output will be a string (comma separated value.)
- **A**: The output will be a variable, which is as-is.
- **S**: The output is in the form of a string. This is the default for JSON if you do not specify any output format. By default, even numbers will be serialized as JSON strings, meaning the output in a JSON quoted template for a numerical value of 1234 will be "1234".
- **N**: The output is in the form of numbers. For example, if the variable is a boolean, the output will be 0, 1, etc.
- B: The output will be a boolean, that is true/false.
- **L**: The length of the variable. This is supported only for lists (the length of the list) and dictionaries (the number of keys).
- **T**: The type of the variable. This can be one of the following characters: 'S' for strings, 'L' for lists, 'D' for dictionaries, 'B' for booleans, 'N' for numbers, and 'O' for otherwise.

The default is set by the template quoting option and by using a variable. If you have not set the template quoting, then JSON will be set, by default. If you have set the template quoting, the output format will be as specified, unless the variable is in the following fields:

- **Headers**: Any variable inside a headers block is serialized by default, as ASIS.
- **Parameters**: Any variable inside a parameters block is serialized by default, as URL.
- **Path**: Any variable inside a path block is serialized by default, as ASIS.

Command Execution

If you use XC: name space, then the value can be one of the following:

Note: The argument will be one or two nested variable specifications separated by ':' but without the '$' symbol.
The variables inside 'XC' do not have an output format, so you must use only one ':'.

- **ASSIGN**: Assigns the value to the specified variable. Note that the value assigned is in the format I/S/B:value for integer, string, and boolean values. Example: ASSIGN:variable:value.
- **DEBUG**: Outputs the specified variable to the debug file (if the log level is not set to DEBUG, this will be ignored), if only the name space is used, the whole name space will be printed.
- **INC**: Increments the variable value. If the value is not a number, NIOS displays an error.

- **DEC**: Decreases the variable value. If the value is not a number, NIOS displays an error.
- **COPY**: Copies one variable into another. Example: COPY:destination:source.
- **DEL**: Removes the variable. This supports only the C:, H:, L:, and S: name spaces.
- **FORMAT**: Formats the value according to what is specified after the second ':'. Currently, NIOS supports the following formats:
- **U**: Converts to uppercase value.
- **L**: Converts to lowercase value.
- **DATE_EPOCH**: Assuming that the value is a date expressed in UTC ISO 8601 date format. For example, 2016-03-13T04:50:31Z will be converted to EPOCH seconds.
- **DATE_ISO8601**: Assuming that the value contains EPOCH seconds. The value is converted to a date string expressed in UTC ISO 8601 date format. For example, 1467152565 will be converted to 2016-06-28T22:22:45Z. If the variable contains milliseconds, they will be preserved. For example 1467152565.57 will be converted to 2016-06-28T22:22:45.570Z.
- **DATE_STRFTIME**: Assuming that the variable contains EPOCH seconds. The value is converted to a date string with the specified format which is passed as the second parameter to the function.
- **PUNYCODE_TO_UTF-8**: Assuming that the variable contains a punycode encoded domain name. The domain name representation will be converted to UTF-8 characters. Note that there might be a failure if the domain name has non-UTF-8 characters in its wire format.
- **TRUNCATE**: Assuming that the variable is a string and it will be truncated as specified. The format is a number (positive or negative) followed by the letter 'l' or 'r'. The number is the starting character of the string (positive will be counted from the beginning, negative will be counted from the end) and f/t defines if the characters are from, after, or to that point. For example, if a string is 12345, then 1f will produce 2345, 1t will produce 1, -1f will produce 5 and -1t will produce 1234.

Format operations will function like other operations if an error occurs, but the variable is not modified. However, the error can be ignored if the log setting is not set to **Debug.** For information about how to set the logging level, see *Configuring Outbound Endpoints*.

The following are some examples of using XC operations to increment and decrement IP address strings, create a network range, or remove a specific IP address.

Incrementing or Decrementing IP addresses

Use the `XC:INC` and `XC:DEC` operations respectively to increment and decrement IP address strings.

Examples:

- For namespace {'L':{'ip_str': '1.2.3.4'}}, an evaluating variable "${XC:DEC:{L:ip_str}}" results in {'L':{'ip_str': '1.2.3.3'}}.
- The same goes for IPv6 addresses. For namespace {'L':{'ip_str': '2001:db8::2'}}, an evaluating variable "${XC:INC:{L:ip_str}}" results in {'L':{'ip_str': 2001:db8::3'}}, and an evaluating "${XC:DEC:{L:ip_str}}" results in {'L':{'ip_str': '2001:db8::1'}}.

The increment of the last address results in the first address. The decrement of the first address results in the last address.
Examples:

```
INC of ‘255.255.255.255’ results in ‘0.0.0.0’
INC of ‘ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff’ results in ‘::’
DEC of ‘0.0.0.0’ results in ‘255.255.255.255’
DEC of ‘::’ results in ‘fff:ffff:ffff:ffff:ffff:ffff:ffff:ffff’
```

Creating Network Ranges from Strings

Use the `XC:NETWORKTORANGE` operation to create a range from a network string. This operation should be specified as the following: `${XC:NETWORKTORANGE:{“var_with_network”}:{“var_for_range”}}` where network is a string such as ‘`1.2.3.4/16’` or `‘2001:db8:ce4::/48’`

The resulting range is an XMLA value such as the following:

```
{
   '<xmla>': True,
   'name': 'range',
   'attrs': {'from': '1.2.0.0', 'to': '1.2.255.255'},
   'value': [],
   'index': {}
}
```

or

```
{
   '<xmla>': True,
   'name': 'range',
   'attrs': {'from': '2001:db8:ce4::', 'to':
 '2001:db8:ce4:ffff:ffff:ffff:ffff:ffff'},
   'value': [],
   'index': {}
}
```

Note: “`var_with_network”` must be a top-level variable in a namespace such as `E:var,` but not `L:var{key}[42]`.

When namespace E is `{‘E’: {‘net’: ‘1.2.3.4/16’}}` and the response is as follows:

```
<SiteConfigResponse success="1">
  <Site id="42" name="this_site" description="testing site" riskfactor="1.0"
isDynamic="0">
   <Description>testing site</Description>
   <Hosts>
     <host>a.com</host>
   </Hosts>
```

```
   <Credentials></Credentials>
   <Alerting></Alerting>
   <ScanConfig configID="21" name="CIS" templateID="cis"
engineID="3"  configVersion="3">
   <Schedules></Schedules>
   </ScanConfig>
  </Site>
</SiteConfigResponse>
```

Then using the following steps:

```
{
     "name": "copy",
     "operation": "NOP",
     "body_list": [
       "${XC:COPY:{L:Site}:{P:PARSE{SiteConfigResponse}}}",
       "${XC:NETWORKTORANGE:{E:net}:{L:range}}"
     ]
},
{
     "name": "add",
     "operation": "VARIABLEOP",
     "variable_ops": [
        {
          "operation": "PUSH",
          "type": "COMPOSITE",
          "destination": "L:Site{Site}{Hosts}",
          "source": "L:range"
         }
     ]
},
{
     "name": "post",
     "operation": "POST",
     "body_list": [
        '<?xml version="1.0" encoding="UTF-8"?>',
        '<SiteSaveRequest session-id="some_sess_id">',
        '${L:x:Site}',
```

```
        '</SiteSaveRequest>'
    ]
}
```

returns the following XML results:

```
<?xml version="1.0" encoding="UTF-8"?>
<SiteSaveRequest session-id="some_sess_id">
  <Site name="this_site" isDynamic="0" description="testing site"
riskfactor="1.0" id="42">
    <Description>testing site</Description>
    <Hosts>
      <host>a.com</host>
      <range from="1.2.0.0" to="1.2.255.255"/>
    </Hosts>
    <Credentials/>
    <Alerting/>
    <ScanConfig configID="21" configVersion="3" name="CIS" templateID="cis"
engineID="3">
    <Schedules/>
    </ScanConfig>
  </Site>
</SiteSaveRequest>
```

Removing Specific IP Addresses from Hosts or Ranges

Use the `XC:REMOVEIP` operation to remove a specific IP address from a list of hosts or ranges. This operation should be specified as the following: `${XC:REMOVEIP:{“var_with_ip”}:{“var_with_list”}}` where IP address is a string such as `‘1.2.3.4’` or `‘2001:db8:ce4::42’`.

The list of hosts/ranges is as follows:

```
[
  {
    '<xmla>': True,
    'name': 'range',
    'attrs': {'from': '1.2.3.1', 'to': '1.2.3.7'},
    'value': [],
    'index': {}
  },
  {
```

```
    '<xmla>': True,
    'name': 'host',
    'attrs': {},
    'value': ['a.com'],
    'index': {}
  }
]
```

Note: `“var_with_IP”` must be a top-level variable in a namespace such as `E:var`, but not `L:var{key}[42]`.

Having namespace E as `{‘E’: {‘ip’: ‘1.2.3.4’}}` and Rapid7 response as follows:

```
<SiteConfigResponse success="1">
  <Site id="42" name="this_site" description="testing site" riskfactor="1.0" isDynamic="0">
  <Description>testing site</Description>
  <Hosts>
    <host>a.com</host>
    <range from="1.2.3.1" to="1.2.3.7"/>
    <host>b.com</host>
  </Hosts>
  <Credentials></Credentials>
  <Alerting></Alerting>
  <ScanConfig configID="21" name="CIS" templateID="cis" engineID="3"  configVersion="3">
  <Schedules></Schedules>
  </ScanConfig>
 </Site>
</SiteConfigResponse>
```

Use the following steps:

```
{
    "name": "copy",
    "operation": "NOP",
    "body_list": [
```

```
        "${XC:COPY:{L:Site}:{P:PARSE{SiteConfigResponse}}}",
        "${XC:REMOVEIP:{E:ip}:{L:Site{Hosts}}}"
      ]
},
{
     "name": "post",
     "operation": "POST",
     "body_list": [
        '<?xml version="1.0" encoding="UTF-8"?>',
        '<SiteSaveRequest session-id="some_sess_id">',
        '${L:x:Site}',
        '</SiteSaveRequest>'
      ]
}
```

It returns the following XML results:

```
<?xml version="1.0" encoding="UTF-8"?>
<SiteSaveRequest session-id="some_sess_id">
     <Site name="this_site" isDynamic="0" description="testing site"
riskfactor="1.0" id="42">
     <Description>testing site</Description>
     <Hosts>
        <host>a.com</host>
        <range from="1.2.3.1" to="1.2.3.3"/>
        <range from="1.2.3.5" to="1.2.3.7"/>
        <host>b.com</host>
     </Hosts>
     <Credentials/>
     <Alerting/>
     <ScanConfig configID="21" configVersion="3" name="CIS" templateID="cis"
engineID="3">
     <Schedules/>
     </ScanConfig>
  </Site>
</SiteSaveRequest>
```

XC:Remove* Operations

There are several XC:REMOVE* operations that can be used to remove one or more IP specified addresses from a list of hosts and ranges. Such list is the deserialized representation of the 'Hosts' element of the Rapid7 response or request.

For example,

```
[
{
'<xmla>': True,
'name': 'host',
'attrs': {},
'value': ['a.com'],
'index': {}
},
{
'<xmla>': True,
'name': 'range',
'attrs': {'from': '1.2.3.1', 'to': '1.2.3.7'},
'value': [],
'index': {}
},
{
'<xmla>': True,
'name': 'host',
'attrs': {},
'value': ['b.com'],
'index': {}
}
]
```

Represents the following `Hosts` element:

```
<Hosts>
<host>a.com</host>
<range from="1.2.3.1" to="1.2.3.7"/>
<host>b.com</host>
</Hosts>
```

Items in the list are iterated one by one upon execution of any REMOVE command. The first argument of the REMOVE* command is the variable specification that contains an IP address. The second argument is the variable with the list of

ranges or hosts. If the item is ‘range’, then the specified IP address is deleted from the range. Execution of any REMOVE command may result in no range, one range or two ranges that do not contain any specified IP addresses. The IP addresses specified in non-range items and ranges with different IP addresses are ignored.

- The `XC:REMOVEIP` command specifies the single IP address as string (for example, ‘1.2.3.4’ or ‘2001:db8:ce4::42’).
- The `XC:RMEOVERANGE` command specifies the set of IP addresses as Rapid7 range.
- The `XC:REMOVENET` command specifies the set of IP addresses as network string.

If the first argument denotes an incorrect IP address (range or network respectively), the template execution is stopped and an error is generated for DEBUG mode, and nothing happens for non-DEBUG mode.

XC:Parse* Operations

The XC:PARSE command parses variable data based on the configuration. Some endpoints may return mixed outputs that cannot be parsed using a single parse statement. Hence, Infoblox provides you the flexibility to parse a response or a variable multiple times.

Using the XC:PARSE command to evaluate a string

You can use the `${XC:PARSE:{L:config}:{L:data}}` command to parse a variable data based on the configuration. Infoblox supports parsing methods such as REGEX, REGEXSPLIT, XML, and so on. The REGEXSPLIT parsing method can be used to split a string to array of items.

The second argument `(L:data)` is updated to the result of parsing operation.

Having the L namespace as:

```
{
"config": {
"parse": "REGEXSPLIT",
"regex": "/"
},
"data": "infoblox.com/contacts"
}
```

The `${XC:PARSE:{L:config}:{L:data}}` variable will update `L:data` to `list ["infoblox.com", "contacts"].`

Using the XC:IS_IP_IN command to evaluate a string

You can use the `XC:IS_IP_IN` command to evaluate if a string is within a range or a network. The `${XC:IS_IP_IN:{L:address}:{L:range}}` variable evaluates the string to `true`. You can specify the second argument as a plain string that contains a mixed list of ranges, or networks or addresses that are separated by a comma. Example: " `10.0.0.1-10.1.0.0,10.1.1.0/24,10.2.2.2` ".

Having the L namespace as:

```
{
"address": "1.2.3.4",
```

```
"range": "1.2.0.0-1.2.255.255"
}
```

Using the XC:REMOVEIP command to remove a string

You can remove an IP address from a range as a plain string using the `XC:REMOVEIP` command. Example: "`10.0.0.1-10.0.0.4`". In this case, the result format is a plain string with ranges that are separated by a comma. You can specify the second argument as a plain string that contains a mixed list of ranges, or networks, or addresses separated by a comma. Example: `"10.0.0.1-10.1.0.0,10.1.1.0/24,10.2.2.2`".

Having the L namespace as:

```
{
"address": "1.2.3.4",
"range": "1.2.3.1-1.2.3.3,1.2.3.5-1.2.3.20"
}
```

The `${XC:REMOVEIP:{L:address}:{L:range}}` variable updates `L:range` to `string "1.2.3.1-1.2.3.3,1.2.3.5-1.2.3.20"`.

Using the XC:REMOVENET command to remove a string

You can use the `XC:REMOVENET` command to remove all the IP addresses of a specified network from the list of ranges. Example: "`10.0.0.1-10.0.0.4`". In this case, the result format is a plain string with ranges that are separated by a comma. You can specify the second argument as a plain string that contains a mixed list of ranges, or networks, or addresses separated by a comma. Example: "`10.0.0.1-10.1.0.0,10.1.1.0/24,10.2.2.2`".

Having the L namespace as:

```
{
"network": "1.2.3.0/28",
"range": "1.2.3.1-1.2.3.20"
}
```

The `${XC:REMOVENET:{L:network}:{L:range}}` variable updates `L:range` to `string "1.2.3.15-1.2.3.20"`.

Using the XC:REMOVERANGE command to remove a string

You can use the `XC:REMOVERANGE` command to remove all the IP addresses of a specified range from the list of ranges. Example: `"10.0.0.1-10.0.0.4"`. In this case, the result format is a plain string with ranges that are separated by a comma. You can specify the second argument as a plain string that contains a mixed list of ranges, or networks, or addresses separated by a comma. Example: `"10.0.0.1-10.1.0.0,10.1.1.0/24,10.2.2.2`".

Having the L namespace as:

```
{
"range1": "1.2.3.2-1.2.3.10",
"range2": "1.2.3.1-1.2.3.20"
}
```

The `${XC:REMOVERANGE:{L:range1}:{L:range2}}` variable updates `L:range2` to `string "1.2.3.1,1.2.3.11-1.2.3.20"`.

Evaluating IP Address in a Range or Network

Use the XC:IS_IP_IN operation to validate if an IP address is in the range and network. This operation should be specified as follows: ${XC:IS_IP_IN:{“var_with_IP”}:{“var_with_net_or_range”}} where IP address is a string such as ‘1.2.3.4’ or ‘2001:db8:ce4::42’.
Having the L namespace as:

```
{
'ip1': '1.2.3.4',
'ip2': '2001:db8:ce5::42'
'range': {
'<xmla>': True,
'name': 'range',
'attrs': {'from': '1.2.0.0', 'to': '1.2.255.255'},
'value': [],
'index': {}
},
'net': '2001:db8:ce4::/48'
}
```

`The ${XC:IS_IP_IN:{L:ip1}:{L:range}} variable will be evaluated to string as "true".`

`The ${XC:IS_IP_IN:{L:ip2}:{L:net}} variable will be evaluated to string as "false".`

Creating Keys

Use the XC:KEYS operation to create keys. This operation should be specified as follows: ${XC:KEYS:{“var_with_dict”}:{“var_for_key_list”}}. It creates a list from the keys of the `var_with_dict` variable and includes it in the `var_for_key_list` variable.
Having L namespace as

```
{
```

```
'some_dict': {
'key1': 'value',
'key2': 42,
'key3': ['item1', 'item2']
}
}
After evaluating the ${XC:KEYS:{L:some_dict}:{L:key_list}} variable, the
L namespace will contain new variable key_list with the following
values:
[
'key1,
'key2,
'key3'
]
```

Variable Examples

The following are variable examples.

Note: The XC: examples refer to the operations discussed in the Command Execution section.

Variables and Results
Variable: ${E::FQDN} Result: Substitute the FQDN value from the event.
Variable: ${I::QUARANTINE} Result: Substitute the quarantine value from the template instance.
Variable: ${XC:COPY:{L:epoch_timestamp}:{E:timestamp}}${XC:FORMAT:DATE_EPOCH:{L:epoch_timestamp}} Result: Copy the event timestamp value into a local epoch_timestamp variable.
Variable: ${XC:COPY:{L:custom_timestamp}:{E:timestamp}}${XC:FORMAT:DATE_STRFTIME:{L:custom_timestamp}:{%a, %d %b %Y %H:%M:%S}} Result: Copy the event timestamp value to a local custom_timestamp variable and format it. In this example, the result might be Wed, 18 Jun 2015 16:13:11.
Variable: ${XC:INC:{S:SERIAL}}${S::SERIAL} Result: Increment the state 'SERIAL' value and substitute its value

Variables and Results
Variable: ${XC:COPY:{S:SERIAL}:{H:X-customheader}} Result: Copy the state SERIAL value to a custom HTTP header for future requests
Variable: ${XC:DEL:{H:X-loginvalue}} Result: Removes the specified HTTP header.
Variable: ${XC:DEL:{C:logincookie}} Result: Removes the specified cookie.
Variable: ${XC:ASSIGN:{L:INT}:{I:123}} Result: Assign the integer 123 to the value INT in the L name space.
Variable: ${XC:ASSIGN:{L:BOOL}:{B:true}} Result: Assign true to the value BOOL in the L name space.
Variable: ${XC:ASSIGN:{L:STR}:{S:some } random string}} Result: Assign the string some } random string to the value STR in the L name space.
Variable: ${XC:DEBUG:{L:INT}} Result: Output the value of the L name space INT variable to the debug file.
Variable: ${XC:DEBUG:{L:}} Result: Output the values in the whole L name space to the debug file.
Variable: ${XC:FORMAT:TRUNCATE:{L:VAR}:{-1f}} Result: Truncate L:VAR to the last character.

Event Variables

The E: event name space is populated with variables from the event. For performance reasons, only the variables referred in the template will be available in the name space. This means that if the template is changed and if a new variable is added, it might take some time for the changes to be propagated to all the Grid members and the new variable to be available in future template executions.

You can use `event_type` in an action template to specify the following supported event types: RPZ, LEASE, TUNNEL, NETWORK_IPV4, NETWORK_IPV6, RANGE_IPV4, RANGE_IPV6, FIXED_ADDRESS_IPV4, FIXED_ADDRESS_IPV6, HOST_ADDRESS_IPV4, HOST_ADDRESS_IPV6, and SESSION. Note that SESSION is used only for the login and logout events for the session management templates. For information about action templates, see *Creating Action Templates*; and for information about session management templates, see *Creating Session Management Templates*.

The following tables list the supported variables by event type:

Variables for RPZ Events

45.12 Variables for RPZ Events

NIOS Field Name	Template Variable Name	Supported Filter(s)	Enriched Data	Comment
Timestamp	timestamp (ISO 8601 format)			The timestamp when the event occurred.
Infoblox Member IP	member_ip			Infoblox Member IP (VIP or LAN1) that generated this event.
Infoblox Member Name	member_name			
Action Policy	rpz_policy	equals		(PASSTHRU DROP TCP-ONLY NXDOMAIN NODATA Local-Data CNAME MISS)
RPZ Type	rpz_type	equals		Possible values: BAD, CLIENT-IP, QNAME, IP, NSDNAME, NSIP
Query Name or Query FQDN	query_name	contains, equals, begins with, ends with		
Rule Name	rule_name	contains, equals, begins with, ends with		
Source IP	source_ip	equals, matches range, matches CIDR	Parent range, Associated objects' DNS Names and EAs, Parent Network, Parent Network EA, Discovered data	
Source Port	source_port			
Destination IP	destination_ip			The name server that responded to the RPZ rule.
Query Type	query_type			DNS query type: A, AAAA, CNAME, DNAME, TXT, and other.
Query View Name	query_view_name			Query DNS view name.

NIOS Field Name	Template Variable Name	Supported Filter(s)	Enriched Data	Comment
Event Type	event_type	equals	RPZ LEASE TUNNEL NETWORK_IPV4 NETWORK_IPV6 RANGE_IPV4 RANGE_IPV6 FIXED_ADDRESS_IPV4 FIXED_ADDRESS_IPV6 HOST_ADDRESS_IPV4 HOST_ADDRESS_IPV6 SESSION	SESSION is used for the login and logout events for the session management templates.
Enriched from IPv4 or IPv6 Addresses				
Source IP User Name	ip.username		From IPv4Address and IPv6Address	This field can be empty.
Source IP Associated EA	ip.extattrs		From IPv4Address and IPv6Address pyabs class	Can be empty, EA needs to be stored as "name-value" pair.
Source IP Associated DNS Names	ip.names		From IPv4Address or IPv6Address	List of FQDN
Enriched from Discovered Data				
Source IP Attached Device Model	ip.discovered_data.device_model		From discovered data	
Source IP Attached Device Name	ip.discovered_data.device_port_name		From discovered data	
Source IP Attached Device Port	ip.discovered_data.device_port_type		From discovered data	
Source IP Attached Device Type	ip.discovered_data.device_type		From discovered data	
Source IP Attached Device Vendor	ip.discovered_data.device_vendor		From discovered data	
Source IP Discovered Name	ip.discovered_data.discovered_name		From discovered data	

NIOS Field Name	Template Variable Name	Supported Filter(s)	Enriched Data	Comment
Source IP First Discovered	ip.discovered_data.first_discovered (ISO 8601 format)		From discovered data	
Source IP Discovered MAC	ip.discovered_data.mac_address		From discovered data	
Source IP NetBIOS Name	ip.discovered_data.netbios_name		From discovered data	
Source IP Port Link	ip.discovered_data.port_link_status		From discovered data	
Source IP Port Speed	ip.discovered_data.port_speed		From discovered data	
Source IP Port Status	ip.discovered_data.port_status		From discovered data	
Source IP VLAN Description	ip.discovered_data.port_vlan_description		From discovered data	
Source IP VLAN Name	ip.discovered_data.port_vlan_name		From discovered data	
Enriched from Parent Range				
Source IP Range Start Address	range.start_addr		From parent range	
Source IP Range End Address	range.end_addr		From parent range	
Enriched from Parent Network				
Source IP Network View Name	network.network_view		From parent network	The network view name in string format.
Source IP Network	network.network		From parent network	ip_addr/cidr Example: 1.2.3.4/24
Source IP Network Address	network.ipv4addr		From parent network	ip_addr
Source IP Network Cidr	network.netmask		From parent network	cidr

NIOS Field Name	Template Variable Name	Supported Filter(s)	Enriched Data	Comment
Source IP Network EA	network.extattrs		From parent network	EA name can be any UTF8 characters.
Enriched from Lease Data				
Source IP Lease Start Time	lease.starts (ISO 8601 format)		From lease data	
Source IP Lease End Time	lease.ends (ISO 8601 format)		From lease data	
Source IP Lease State	lease.binding_state		From lease data	Possible values: UNKNOWN, ABANDONED, ACTIVE, BACKUP, DECLINED, EXPIRED, FREE, OFFERED, RELEASED, RESET, STATIC
Source IP Lease Client Host Name	lease.client_hostname		From lease data	
Source IP Lease MAC Address	lease.hardware		From lease data	
Source IP Lease DUID	lease.ipv6_duid		From lease data	
Source IP Fingerprint	lease.fingerprint		From lease data	

Variables for DHCP Lease Events

When searching for DHCP lease events with associated discovered data, both the "address" and "hardware" or "duid" must match the discovered data. If there is no hardware or DUID, the lease event cannot be associated with any discovered data.
For leases, same IP addresses may be used by multiple systems, so the IP address must match the MAC address or DUID to ensure that the discovered data has the most likely correct value.

Variables for DHCP Lease Events

NIOS Field Name	Template Variable Name	Supported Filter	Enriched Data	Comment
Timestamp	timestamp (ISO 8601 format)			The timestamp when the event occurs.
Infoblox Member IP	member_ip		.	Infoblox member IP (VIP or LAN1) that has generated the event
Infoblox Member Name	member_name			

NIOS Field Name	Template Variable Name	Supported Filter	Enriched Data	Comment
Lease Binding State	binding_state	equals		This can be either UNKNOWN, ABANDONED, ACTIVE, BACKUP, DECLINED, EXPIRED, FREE, OFFERED, RELEASED, RESET, or STATIC.
Lease IP address	address	equals, matches range, matches CIDR	Parent Network EA, Parent Range, DNS Names and EA of associated objects	Some information from parent network is already in the DHCP lease data.
Lease Protocol	protocol			Possible values are IPv4 or IPv6.
Lease Start Time	starts			
Lease End Time	ends			
Client MAC address	hardware			
Client IPv6 DUID	ipv6_duid			
Client Host Name	client_hostname			
Fingerprint		contains, equals, begins with, ends with		
Lease Network View Name	network_view	contains, equals, begins with, ends with		
Lease Network	network			ip_addr/cidr Example: 1.2.3.4/24
Lease Network Address	network_ipaddr			ip_addr
Lease Network CIDR	network_netmask			CIDR
Lease IP Range Start Address	range_start_addr			
Lease IP Range End Address	range_end_addr			

NIOS Field Name	Template Variable Name	Supported Filter	Enriched Data	Comment
Event Type	event_type	equals	RPZ LEASE TUNNEL NETWORK_IPV4 NETWORK_IPV6 RANGE_IPV4 RANGE_IPV6 FIXED_ADDRESS_IPV4 FIXED_ADDRESS_IPV6 HOST_ADDRESS_IPV4 HOST_ADDRESS_IPV6 SESSION	SESSION is used for the login and logout events for the session management templates.
Enriched from Network EA				
Lease Network EA	network.extattrs		From parent network EA	EA name can be any UTF-8 characters.
Enriched from IPv4 Address and IPv6 Address				
Lease IP Username	ip.username		From IPv4 Address and IPv6 Address	
Lease IP Associated EA	p.extattrs		From IPv4 Address and IPv6 Address pyabs class	EA must be stored as “<EA name>-<EA value>” pair.
Lease IP Associated DNS Names	ip.names		From IPv4 Address and IPv6 Address	List of FQDN
Enriched from Discovery Data				
Lease IP Attached Device Model	ip.discovered_data.device_model		From discovered data	
Lease IP Attached Device Name	ip.discovered_data.device_port_name		From discovered data	
Lease IP Attached Device Port	ip.discovered_data.device_port_type		From discovered data	
Lease IP Attached Device Type	ip.discovered_data.device_type		From discovered data	
Lease IP Attached Device Vendor	ip.discovered_data.device_vendor		From discovered data	

NIOS Field Name	Template Variable Name	Supported Filter	Enriched Data	Comment
Lease IP Discovered Name	ip.discovered_data.discovered_name		From discovered data	
Lease IP First Discovered	ip.discovered_data.first_discovered (ISO 8601 format)		From discovered data	
Lease IP Discovered MAC	ip.discovered_data.mac_address		From discovered data	
Lease IP NetBIOS Name	ip.discovered_data.netbios_name		From discovered data	
Lease IP Port Link	ip.discovered_data.port_link_status		From discovered data	
Lease IP Port Speed	ip.discovered_data.port_speed		From discovered data	
Lease IP Port Status	ip.discovered_data.port_status		From discovered data	
Lease IP VLAN Description	ip.discovered_data.port_vlan_description		From discovered data	
Lease IP VLAN Name	ip.discovered_data.port_vlan_name		From discovered data	

Variables for Object Change Discovery Data

Note: Infoblox supports insert and update operations from Network Insight and Cloud Discovery for object change discovery data in the NIOS 8.3.0 release version.

Variables for Object Change Discovery Data

NIOS Field Name	Template Variable Name	Supported Filter	Enriched Data	Comment
timestamp	timestamp			Timestamp when event occurs, will be used record_timestamp from incoming data
member_ip	member_ip			Infoblox Member IP

NIOS Field Name	Template Variable Name	Supported Filter	Enriched Data	Comment
member_name	member_name			Infoblox Member Name
object_type	object_type			Object Type, ENUM {DiscoveryData}
operation_type	operation_type	equals {INSERT, MODIFY, DELETE}		Operation Type, ENUM {INSERT, MODIFY, DELETE}
Values				
network	network		Yes	Network (from network ref)
is_ipv4	is_ipv4	equals {true, false}		This boolean flag will indicate whether structure is of type IPv4 or IPv6
ip_address	ip_address	equals, matches range, matches CIDR	Yes (default)	Discovered IP address
mac_address	mac_address		Yes	Discovered MAC address
duid	duid		Yes	DUID associated with IPv6 address
ap_ip_address	ap_ip_address			Discovered IP address of Wireless Access Point
ap_name	ap_name			Discovered name of Wireless Access Point
ap_ssid	ap_ssid			Service set identifier (SSID) associated with Wireless Access Point
bridge_domain	bridge_domain			Discovered bridge domain
cisco_ise_endpoint_profile	cisco_ise_endpoint_profile			Endpoint profile in Cisco ISE
cisco_ise_security_group	cisco_ise_security_group			Name of security group created in Cisco ISE
cisco_ise_session_state	cisco_ise_session_state			session state
cisco_ise_ssid	cisco_ise_ssid			service set identifier
cmp_type	cmp_type			if the IP is coming from a Cloud environment, the Cloud Management Platform type
device_contact	device_contact			Contact information from device on which the IP address was discovered

NIOS Field Name	Template Variable Name	Supported Filter	Enriched Data	Comment
device_location	device_location			Location of device on which the IP address was discovered
device_model	device_model			Model name of the device in the vendor terminology
device_port_name	device_port_name			System name of the interface the IP associates with
device_port_type	device_port_type			Hardware type of the interface the IP associates with
device_type	device_type			Type of the device in the vendor terminology
device_vendor	device_vendor			Vendor name of the device
discovered_name	discovered_name			Name of the ip as seen by the discovery station.
discoverer	discoverer	contains, equals, begins with, ends with	Yes (default)	Name of the discoverer
endpoint_groups	endpoint_groups			List of discovered endpoint groups represented as a single string containing comma-separated values
first_discovered_timestamp	first_discovered_timestamp			When was this ip first seen by the discovery station
iprg_id	iprg_id			iprg(port redundant group) ID of this device interface
iprg_no	iprg_no			Port redundant group no of this device interface
iprg_state	iprg_state			State of this IP address in the group
iprg_type	iprg_type			Type of this prg
is_end_host	is_end_host			Is this object an end host or an infrastructure device for the purpose of discovery
last_discovered_timestamp	last_discovered_timestamp			When was this data discovered
last_updated_timestamp	last_updated_timestamp			Used by NetMRI sync to store timestamp when was this data updated
method	method			What method was being used for network discovery
mgmt_ip_address	mgmt_ip_address			Management IP address of the device if the device has more than one IP

NIOS Field Name	Template Variable Name	Supported Filter	Enriched Data	Comment
netbios_name	netbios_name			Discovered NetBIOS name
network_component_contact	network_component_contact			Contact information from network component on which the IP address was discovered
network_component_description	network_component_description			A descriptive string for the network component
network_component_ip	network_component_ip			IP Address the network component
network_component_location	network_component_location			Location of network component on which the IP address was discovered
network_component_model	network_component_model			Model name of the network component the device is connected to in the vendor terminology
network_component_name	network_component_name			The name of network component
network_component_port_description	network_component_port_description			Description of the port on the network component
network_component_port_id	network_component_port_id			Interface ID of the connected switch/switch-router
network_component_port_name	network_component_port_name			Port name on the network component on which the ip was discovered
network_component_port_number	network_component_port_number			Port number on the network component on which the ip was discovered
network_component_type	network_component_type			The type of network component. Eg. Switch, Router etc.
network_component_vendor	network_component_vendor			Vendor name of the network component the device is connected to
open_ports	open_ports			List of opened ports on the IP address, represented as: "TCP: 21,22,23 UDP: 137,139". Limited to max total 1000 ports
os	os			Guess for OS by network discovery
port_duplex	port_duplex			Duplex settings on the port on the network component
port_link_status	port_link_status			Link Status of the port on the network component
port_speed	port_speed			Speed settings on the port on the network component

NIOS Field Name	Template Variable Name	Supported Filter	Enriched Data	Comment
port_status	port_status			Status of the port on the network component
port_type	port_type			Type of the interface on the network component the device is connected to
port_vlan_description	port_vlan_description			Description of the vlan on the port on the network component
port_vlan_name	port_vlan_name			Name of the vlan on the port on the network component
port_vlan_number	port_vlan_number			Number of the vlan on the port on the network component
task_name	task_name			Name of the task discovers this data
tenant	tenant			Discovered tenant
unmanaged	unmanaged	equals {true, false}		Flag to indicate if the discovered data is associated with a managed object or not
v_adapter	v_adapter			Vmware physical adapter in which entity was found
v_cluster	v_cluster			Vmware cluster in which entity was found
v_datacenter	v_datacenter			Vmware datacenter in which entity was found
v_entity_name	v_entity_name			Vmware entity name in which entity was found
v_entity_type	v_entity_type			Type of encryption to use
v_host	v_host			Vmware host system in which entity was found
v_os	v_os			Vmware OS system in which entity was found
v_switch	v_switch			Vmware virtual switch in which entity was found
vlan_port_group	vlan_port_group			Port group which the virtual machine belongs to
vmhost_ip_address	vmhost_ip_address			IP address of the physical node on which the virtual machine is hosted
vmhost_mac_address	vmhost_mac_address			MAC address of the physical node on which the virtual machine is hosted

NIOS Field Name	Template Variable Name	Supported Filter	Enriched Data	Comment
vmhost_name	vmhost_name			Name of the physical node on which the virtual machine is hosted
vmhost_nic_names	vmhost_nic_names			List of all physical port names used by the virtual switch on the physical node on which the virtual machine is hosted. Represented as: "eth1,eth2,eth3"
vmhost_subnet_cidr	vmhost_subnet_cidr			CIDR subnet of the physical node on which the virtual machine is hosted
vmi_id	vmi_id			ID of the virtual machine
vmi_ip_type	vmi_ip_type			Discovered IP address type
vmi_is_public_address	vmi_is_public_address			Indicates whether the IP address is a public address
vmi_name	vmi_name			Name of the virtual machine
vmi_private_address	vmi_private_address			Private IP address of the virtual machine
vmi_tenant_id	vmi_tenant_id			ID of the tenant which virtual machine belongs to
vport_conf_mode	vport_conf_mode			Configured mode of the network adapter on the virtual switch where the virtual machine connected to
vport_conf_speed	vport_conf_speed			Configured speed of the network adapter on the virtual switch where the virtual machine connected to. Unit is kb
vport_link_status	vport_link_status			Link status of the network adapter on the virtual switch where the virtual machine connected to
vport_mac_address	vport_mac_address			MAC address of the network adapter on the virtual switch where the virtual machine connected to
vport_mode	vport_mode			Actual mode of the network adapter on the virtual switch where the virtual machine connected to
vport_name	vport_name			Name of the network adapter on the virtual switch connected with the virtual machine
vport_speed	vport_speed			Actual speed of the network adapter on the virtual switch where the virtual machine connected to. Unit is kb

NIOS Field Name	Template Variable Name	Supported Filter	Enriched Data	Comment
vswitch_available_ports_count	vswitch_available_ports_count			Numer of available ports reported by the virtual switch on which the virtual machine/vport connected to
vswitch_id	vswitch_id			ID of the virtual switch
vswitch_ipv6_enabled	vswitch_ipv6_enabled			Indicates the virtual switch has IPV6 enabled
vswitch_name	vswitch_name			Name of the virtual switch
vswitch_segment_id	vswitch_segment_id			ID of the network segment on which the current virtual machine/vport connected to
vswitch_segment_name	vswitch_segment_name			Name of the network segment on which the current virtual machine/vport connected to
vswitch_segment_port_group	vswitch_segment_port_group			Port group of the network segment on which the current virtual machine/vport connected to
vswitch_segment_type	vswitch_segment_type			Type of the network segment on which the current virtual machine/vport connected to
vswitch_tep_dhcp_server	vswitch_tep_dhcp_server			DHCP server of the virtual tunnel endpoint (VTEP) in the virtual switch
vswitch_tep_ip	vswitch_tep_ip			IP address of the virtual tunnel endpoint (VTEP) in the virtual switch
vswitch_tep_multicast	vswitch_tep_multicast			Muticast address of the virtual tunnel endpoint (VTEP) in the virtual swtich
vswitch_tep_port_group	vswitch_tep_port_group			Port group of the virtual tunnel endpoint (VTEP) in the virtual switch
vswitch_tep_type	vswitch_tep_type			Type of virtual tunnel endpoint (VTEP) in the virtual switch
vswitch_tep_vlan	vswitch_tep_vlan			VLAN of the virtual tunnel endpoint (VTEP) in the virtual switch
vswitch_type	vswitch_type			Type of the virtual switch: standard or distributed

Variables for Security ADP Events

Result Parsing

Besides the R: name space, which is always initialized, if a template step includes the parse setting, then the result returned by the server is interpreted and will be available in the P: name space. Result parsing is extremely naive and supports only the following:

- **JSON**: In this case, the returned JSON will be available in the P name space if it is a dictionary, otherwise it will be as-is in the P:PARSE variable. If JSON is malformed, an error will be logged and P:PARSE will be set to an empty dictionary.
- **REGEX**: The supplied REGEX is applied to the whole body and it will be available in P:PARSE[0] to P:PARSE[N], if you have specified more than one groupings. In this case, P:PARSE[0] contains the full match, and P:PARSE[1..N] contains each individual grouping match. If no groupings are parsed, then P:PARSE will be a string with the matched expression. If one grouping is parsed, then P:PARSE will be a string with the matched grouping result. Note that ^ and $ anchors are the anchors for the whole output to be parsed.
- **REGEXLINE**: The supplied REGEX is applied to every line returned by the server, and each match is assigned to P:PARSE[0] to P:PARSE[N] depending on how many lines match. The REGEX must contain only one grouping. If there are many groupings then the last matched grouping is put in the PARSE value, but if there are no groupings provided then the full match is put in each line. Note that ^ and $ anchors in this case are the anchors for each line.
- **REGEXMULTILINE**: REGEXMULTILINE can be used when multiple groupings are required to be matched in multiple lines. Each match will be in P:PARSE[0..n] and each individual match is a list where the first value is the full REGEX match, and each subsequent value is a grouping match. The first grouping match of the first match can be accessed via ${P:PARSE[0][1]}. Note that ^ and $ anchors in this case are the anchors for each line.

For all REGEX cases, if there are no matches, P:PARSE is set to an empty string.

- **CONDITION**: In some cases, when a condition on a REGEX match is required, it is recommended to use a CONDITION step with the :L (length) format specifier applied to PARSE. So when ${P:L:PARSE} is matched with = 0, it would create a condition evaluating to true if there was a regular expression match.
- **XML**: For XML, the XML data is converted into a dictionary of dictionaries/lists depending on the XML present. Similar to JSON, this will be available in the P name space if it is a dictionary, otherwise it will be as-is in the P:PARSE variable. If the XML is malformed or not parsable, then an error is logged and P:PARSE is set to an empty dictionary.

Parsing does not support DTDs, schemas, or XML attributes. It simply converts the XML document as-is. This also means that if the schema defines a particular element to be a list, it might not be deserialized as a list depending on how many members are present (if there is only one, then the parent is not considered a list.) When serializing XML, any variable composed of a dictionary with an '`<xmla>`' member set to True will be serialized as an XML element with attributes.

If an XMLA element is serialized under JSON/XML, the attributes will be ignored and the appliance returns a meaningful result (a list of XMLA variables will be serialized in JSON as a list of the values of these elements, assuming the values are simple strings/numbers).

For example, consider the following XML:

```
<?xml version="1.0" encoding="UTF-8" ?>
<!DOCTYPE APPLIANCE_LIST_OUTPUT SYSTEM
"https://qualysapi.qualys.com/api/2.0/fo/appliance/appliance_list_
output.dtd">
<APPLIANCE_LIST_OUTPUT>
   <RESPONSE>
     <DATETIME>2014-01-02T09:26:01Z</DATETIME>
     <APPLIANCE_LIST>
       <APPLIANCE>
```

```
            <ID>777</ID>
            <NAME>scanner1</NAME>
            <SOFTWARE_VERSION>2.6</SOFTWARE_VERSION>
            <RUNNING_SCAN_COUNT>0</RUNNING_SCAN_COUNT>
            <STATUS>Online</STATUS><S2>Online</S2>
        </APPLIANCE>
        <APPLIANCE>
            <ID>1127</ID>
            <NAME>scanner2</NAME>
            <SOFTWARE_VERSION>2.6</SOFTWARE_VERSION>
            <RUNNING_SCAN_COUNT>0</RUNNING_SCAN_COUNT>
            <STATUS>Online</STATUS><S2>Online</S2>
        </APPLIANCE>
        <APPLIANCE>
            <ID>1131</ID>
            <NAME>scanner3</NAME>
            <SOFTWARE_VERSION>2.6</SOFTWARE_VERSION>
            <RUNNING_SCAN_COUNT>0</RUNNING_SCAN_COUNT>
            <STATUS>Offline</STATUS><S2>Online</S2>
        </APPLIANCE>
    </APPLIANCE_LIST>
    <LICENSE_INFO>
        <QVSA_LICENSES_COUNT>10</QVSA_LICENSES_COUNT>
        <QVSA_LICENSES_USED>3</QVSA_LICENSES_USED>
    </LICENSE_INFO>
  </RESPONSE>
</APPLIANCE_LIST_OUTPUT>
```

The XML will be deserialized as follows:

```
{
    "APPLIANCE_LIST_OUTPUT":
    {
        "RESPONSE": {
            "APPLIANCE_LIST": [
                {
```

```
                    "ID": "777",
                    "NAME": "scanner1",
                    "RUNNING_SCAN_COUNT": "0",
                    "S2": "Online",
                    "SOFTWARE_VERSION": "2.6",
                    "STATUS": "Online"
                },
                {
                    "ID": "1127",
                    "NAME": "scanner2",
                    "RUNNING_SCAN_COUNT": "0",
                    "S2": "Online",
                    "SOFTWARE_VERSION": "2.6",
                    "STATUS": "Online"
                },
                {
                    "ID": "1131",
                    "NAME": "scanner3",
                    "RUNNING_SCAN_COUNT": "0",
                    "S2": "Online",
                    "SOFTWARE_VERSION": "2.6",
                    "STATUS": "Offline"
                },
        ],
        "DATETIME": "2014-01-02T09:26:01Z",
        "LICENSE_INFO": {
            "QVSA_LICENSES_COUNT": "10",
            "QVSA_LICENSES_USED": "3"
        }
```

```
      },
   }
}
```

But the following will be deserialized differently:

```
<?xml version="1.0" encoding="UTF-8" ?>
<!DOCTYPE APPLIANCE_LIST_OUTPUT SYSTEM
"https://qualysapi.qualys.com/api/2.0/fo/appliance/
appliance_list_  output.dtd">
<APPLIANCE_LIST_OUTPUT>
      <RESPONSE>
         <DATETIME>2014-01-02T09:26:01Z</DATETIME>
         <APPLIANCE_LIST>
            <APPLIANCE>
               <ID>777</ID>
               <NAME>scanner1</NAME>
               <SOFTWARE_VERSION>2.6</SOFTWARE_VERSION>
               <RUNNING_SCAN_COUNT>0</RUNNING_SCAN_COUNT>
               <STATUS>Online</STATUS><S2>Online</S2>
            </APPLIANCE>
         </APPLIANCE_LIST>
         <LICENSE_INFO>
            <QVSA_LICENSES_COUNT>10</QVSA_LICENSES_COUNT>
            <QVSA_LICENSES_USED>3</QVSA_LICENSES_USED>
         </LICENSE_INFO>
    </RESPONSE>
</APPLIANCE_LIST_OUTPUT>
```

The XML will be deserialized as follows (note the difference in the appliance_list):

```
{
       "APPLIANCE_LIST_OUTPUT":
```

```
      {
          "RESPONSE": {
              "APPLIANCE_LIST": {
                  "APPLIANCE": {
                  {
                      "ID": "777",
                      "NAME": "scanner1",
                      "RUNNING_SCAN_COUNT": "0",
                      "S2": "Online",
                      "SOFTWARE_VERSION": "2.6",
                      "STATUS": "Online"
                  }
        },
        "DATETIME": "2014-01-02T09:26:01Z",
        "LICENSE_INFO": {
            "QVSA_LICENSES_COUNT": "10",
            "QVSA_LICENSES_USED": "3"
        }
    },
  }
}
```

- **XMLA**: Infoblox strongly recommends that you use XMLA as the quoting option (as opposed to XML) when you create new action templates. New operations such as PUSH, POP, SHIFT and others are not officially supported for XML parsed data.
  XMLA parsing strips all white spaces (horizontal tab, line feed, vertical tab, form feed, carriage return, and space). To keep all white spaces, XMLA_WHITESPACE enum is added. The parsing is the same as XMLA except that there is no white space stripping.
  If you set parse to XMLA, the XML parsing supports XML attributes, and the XML document is put in the P:PARSE namespace variable, as illustrated in the following example. This example contains a mixed-attribute XML message with some values that contain attributes and some do not.

```
<?xml version="1.0" encoding="utf-8"?>
<SiteConfigResponse success="1">
   <Site id="27" name="SOAPUI13006925d-7dac-428d-
```

```

                    },
                    "name": "Alerting",
                    "value": [
                        {
                            "<xmla>": true,
                            "attrs": {
                                "enabled": "1",
                                "maxAlerts": "2",
                                "name": "test"
                            },
                            "index": {
                               "scanFilter": 0,
                               "smtpAlert": 2,
                               "vulnFilter": 1
                            },
                            "name": "Alert",
```

```
                "value": [
                    {
                        "<xmla>": true,
                        "attrs": {
                            "scanFailed": "1",
                            "scanPaused": "1",
                            "scanResumed": "1",
                            "scanStart": "1",
                            "scanStop": "1"
                        },
                        "index": {},
                        "name": "scanFilter",
                        "value": []
                    },
                    {
                        "<xmla>": true,
                        "attrs": {
                            "confirmed": "1",
                            "potential": "1",
                            "severityThreshold": "1",
                            "unconfirmed": "1"
                        },
                        "index": {},
                        "name": "vulnFilter",
                        "value": []
                    },
                    {
                        "<xmla>": true,
                        "attrs": {
                            "limitText": "0",
                            "sender": "user1@example.com",
                            "server": "server6.example.com"
                        },
```

```
                                        "index": {
                                            "recipient": 0
                                        },
                                        "name": "smtpAlert",
                                        "value": [
                                            {
                                                "<xmla>": true,
                                                "attrs": {},
                                                "index": {},
                                                "name": "recipient",
                                                "value":
["user2@example.com"]
                                            }
                                        ]
                                    }
                                ]
                            }
                        ]
                    },
                    {
                        "<xmla>": true,
                        "attrs": {
                            "configID": "28",
                            "configVersion": "3",
                            "engineID": "3",
                            "name": "Full audit",
                            "templateID": "full-audit"
                        },
                        "index": {
                            "Schedules": 0
                        },
                        "name": "ScanConfig",
                        "value": [
                            {
                                "<xmla>": true,
                                "attrs": {},
                                "index": {},
```

```
                                        "name": "Schedules",
                                        "value": []
                                    }
                                ]
                            }
                        ]
                    }
                ]
            }
]
```

As shown in the example above, any XML value will become an internal dictionary that contains separate '`attrs`' and '`value`' members representing the XML attributes (if exist) and the XML values (if exist) of the element respectively, as well as the single "" boolean (set to `True`) to qualify this particular field as an XML attribute field (this is used when serializing, as well as for user-created XMLA values, see below).

You typically address the XMLA variable by using `VAR{tag}{subtag}`, which uses the VALUES of the tag (its value or its subtag(s)). To access the attributes of a tag, you use `VAR{tag}{{attributename}}`.
Example: `P::PARSE{SiteConfigResponse}{{success}}`

If you need to access the name of a tag instead (for example if the remote server can return different tags depending on the status), use the `[[name]]` syntax. For example, you can use `P::PARSE[[name]].`

Repeating a Parse Operation

You can use the `XC:PARSE` operation to parse the body once again using another method. `R:BODY` contains the body of the response.

Example:
Having the L namespace as:

```
{
"config": {
"parse": "JSON"
},
}
```

`L:data` contains the result of the parsing operation after the following step:

```
{
"version": "4.0",
...
"steps": [
...
{
"name": "repeat_parse",
"operation": "NOP",
"body_list": [
"${XC:COPY:{L:data}:{R:BODY}}",
"${XC:PARSE:{L:config}:{L:data}}"
]
},
...
],
...
}
```

Configuring Outbound Endpoints

An endpoint sends outbound notifications based on the notification rule and the outbound template that you have configured. With NIOS, you can configure REST API, DXL, Syslog, Cisco ISE endpoints to send outbound notifications. You can use the RESTful API and DXL fabric to obtain core network service information from the Infoblox Grid to assist with profiling the source or destination of network devices or use the RESTful API and WAPI in DXL endpoint to change configurations in the Infoblox Grid to help mitigate security threats. In addition to querying inbound data and changing system configurations and query interfaces, you can use the RESTful API and DXL messages to send outbound notifications so you can prioritize your security needs by detecting new hosts or networks or managing network access control.

The REST API endpoint you configure must be REST enabled so that they can handle RESTful API calls. The DXL endpoints must be connected to DXL brokers and listen on specific DXL topics as configured in the DXL action template. You must upload session management and action templates before you configure endpoints.

Note

Infoblox recommends that you send notifications from a Grid Master Candidate, when it is available, instead of the Grid Master.

Configuring REST API Endpoints

You can configure REST API endpoints and define rules to send outbound notifications to the REST enabled target system.

To configure a REST API endpoint, complete the following:

1. From the **Grid/System** tab, select the **Ecosystem** tab -> **Outbound Endpoint** tab and then click **Add** -> **Add REST API Endpoint** from the Toolbar.
2. In the **Add REST API Endpoint** wizard, complete the following:
    - **URI**: Specify the URI for the endpoint to which you are sending the outbound notifications. Example: https://10.36.101.14/offices.
    - **Test Connection**: Click this to validate the endpoint settings and test the connectivity between the Grid Master and the endpoint. It also tests the connection between the Grid Master Candidate that is assigned as the outbound member and the endpoint. Grid Manager displays a message indicating whether the connection is successful. Note that the test does not validate username, password, or certificate for the endpoint. It only tests the basic connection between the Grid Master and the endpoint.
    - **Name**: Specify the name used to identify the endpoint.
    - **Vendor Type**: The REST API vendor type associated with the endpoint. This is optional.
    - **Network View**: This appears only when you have multiple network views. From the drop-down list, select the network view in which you want to create the network.
    - **Auth Username**: Enter the username of the target endpoint. The appliance ignores the **Auth Username** for WAPI related steps in any action templates if WAPI integration is configured. It still uses this username for other non-WAPI related steps.
    - **Auth Password**: Enter the user account password for the target endpoint. You can click **Clear Password** to clear the password and set a new one. The appliance ignores the **Auth Username** for WAPI related steps in any action templates if WAPI integration is configured. It still uses this password for other non-WAPI related steps.
    - **Client Certificate**: Click **Select** to upload the endpoint certificate. In the *Upload* dialog box, click **Select** to navigate to the certificate, and then click **Upload**.
    - **WAPI Integration Username**: If you have included at least one "wapi" related field in your action template, you must configure WAPI integration; otherwise the WAPI step will fail due to an authorization error. Enter the username of the admin user you want to designate for RESTful API outbound notifications. The appliance ignores the **Auth Username** and **Auth Passwor**d for WAPI related steps in any action templates if WAPI integration is configured.
    - **WAPI Integration Password**: Enter the password of the admin user you have designated for RESTful API outbound notifications.
    - **Server Certificate Validation**: Select one of the following for server certificate validation:
        - **Use CA Certificate Validation (Recommended)**: Select this to validate the CA certificate for the endpoint. The certificate is used to establish a secure connection to the endpoint before data transmission. Click **CA Certificates** to upload the trusted CA certificate of the endpoint. In the *CA Certificates* dialog box, click the Add icon, and then navigate to the certificate to upload it. This is the default.
            - **Enable Host Validation**: Select this to enable the validation of the hostname for the endpoint, in addition to the CA certificate. If you do not select this, the appliance validates only the CA certificate.
            - **Do not use validation (Not recommended)**: Infoblox does not recommend using this for your production system. Use this for testing purposes only.
    - **Member Source outbound API requests from**: Select the one of the following to process and send outbound API notifications:
        - **Selected Grid Master Candidate (Recommended)**: Select this to use the Grid Master Candidate to process and send outbound notifications to the endpoint. If there are multiple Grid Master candidates, select a Grid Master Candidate from the drop-down list. This is the recommended choice and is selected by default because the CPU and memory required for processing and sending outbound events from the Grid Master Candidate can be offloaded or manually load balanced across multiple Grid Master Candidates if required.
        - **Current Grid Master**: Click this to use the Grid Master to send outbound notifications to the endpoint. When you use the Grid Master as the outbound member, ensure that it has enough CPU and memory to process all the workloads and processes, in addition to being an outbound

member. Infoblox recommends that you use the Grid Master as an outbound member only for testing purposes to avoid overloading the Grid Master and to maintain optimal performance for the Grid.

- **Comment**: Enter additional information about the REST API endpoint.
- **Disable**: Select this if you want to save the configuration but do not want to use it yet. You can clear this checkbox when you are ready to use this configuration.

3. Click **Next** to set the duration of time that the endpoint waits for a response from the outbound member. Complete the following to specify session timeout value:
   - **Timeout**: Specify the session timeout value for the endpoint. The default value is 30 seconds.
   - **Log Level**: From the drop-down list, select the severity level for the events. The severity level you select here determines the type of events that are being logged. This can be **Debug**, **Info**, **Warning**, or **Error**. When you select **Debug**, all fields or variables used in the events that were sent to the endpoint are logged, including deduplicated events for RPZ hits. For information about deduplication, see *Deduplicating Events*. Note that setting this to **Debug** might slightly affect the performance of your production system.
   - **Template**: Click **Select Template** to select a session management template. For information, see *Creating Session Management Templates*.
   - **Vendor Type**: Displays the vendor information for the endpoint.
   - **Template Type**: Displays the Session Management template.
   - **Parameters**: Displays the parameters of the template you select. You can access these values in the notification rules.
4. Click **Next** to add extensible attributes for the endpoint. For information, see *Managing Extensible Attributes*.
5. Save the configuration.

> ⚠ Note
> If your outbound member is a Grid Master Candidate and in case the Grid Master Candidate is promoted to the Grid Master, make sure that you modify the outbound member to the Grid Master on the endpoint configuration to avoid any outbound notification failures.

Configuring DXL Endpoints

When adding a DXL endpoint, you must configure the DXL client and the broker. DXL brokers that are installed on managed systems route messages between connected clients. The network of brokers tracks active consumers and dynamically adjusts the message routing as needed. As shown in the figure below, a broker relays a message when a client requests a service or when an update is broadcast.

An Outbound worker that acts as a DXL client sends data and templates using the DXL protocol to the DXL brokers fabric. You can change the format of the DXL message using relevant template. A connection is established as soon as the outbound worker starts transmitting the data.

You can manually configure the list of DXL brokers that are used by DXL clients in NIOS or import the broker configuration file. The DXL endpoint configuration requires import of DXL brokers list and their certificates on the Infoblox side as well as import of Infoblox certificate on the McAfee side. Note that you must install the Security Ecosystem license before you configure a DXL endpoint.

For a McAfee ePolice Orchestrator, you must do the following:

1. Import NIOS certificate.
2. Export DXL broker certificates.
3. Export a DXL broker list.

To configure a DXL endpoint, complete the following:

1. From the **Grid/System** tab, select the **Ecosystem** tab -> **Outbound Endpoint** tab and then click **Add** -> **Add DXL Endpoint** from the Toolbar.
2. In the **Add DXL Endpoint** wizard, complete the following:
    - **Name**: Specify the name used to identify the endpoint.
    - **Vendor Type**: The DXL vendor type associated with the endpoint. This is optional.
    - **Client Certificate**: Click **Generate** to generate and upload both the client and CA certificates of the endpoint on NIOS. When you click **Generate**, the client certificate is automatically uploaded on NIOS and a copy of CA certificate is downloaded. Import this downloaded CA certificate to the DXL server. For information about how to import the CA certificate, refer to the McAfee documentation. If you already have the client certificate, you can upload it by clicking the Upload icon. Click **Upload** to upload the client certificate. In the *Upload* dialog box, click **Select** to navigate to the certificate, and then click **Upload**.
    - **CA Certificates**: Click **CA Certificates** to upload the broker Certificate. Download the broker certificate from the DXL server and upload it to NIOS. In the *CA Certificates* dialog box, click the Add icon, and then navigate to the certificate to upload it.
    - **WAPI Integration Username**: If you have included at least one “wapi” related field in your action template, you must configure WAPI integration; otherwise, the WAPI step will fail due to an authorization error. Enter the username of the admin user you want to designate for DXL notifications.
    - **WAPI Integration Password**: Enter the password of the admin user you have designated for DXL notifications.
    - **Member Source outbound API requests from**: Select one of the following to process for sending outbound notifications:
        - **Selected Grid Master Candidate (Recommended)**: Select this to use the Grid Master Candidate to process and send outbound notifications to the endpoint. If there are multiple Grid Master candidates, select a Grid Master Candidate from the drop-down list. This is the recommended choice and is selected by default because the CPU and memory required for processing and sending outbound events from the Grid Master Candidate can be offloaded or manually load balanced across multiple Grid Master Candidates if required.
        - **Current Grid Master**: Click this to use the Grid Master to send outbound notifications to the endpoint. When you use the Grid Master as the outbound member, ensure that it has enough CPU and memory to process all the workloads and processes, in addition to being an outbound member. Infoblox recommends that you use the Grid Master as an outbound member only for testing purposes to avoid overloading the Grid Master and to maintain optimal performance for the Grid.
    - **Comment**: Enter additional information about the DXL endpoint.
    - **Disable**: Select this if you want to save the configuration but do not want to use it yet. You can clear this checkbox when you are ready to use this configuration.
3. Click **Next** to add the DXL broker. There are two ways to configure the DXL broker. You can either manually enter the host name of the broker or you can import the broker configuration file using the **Import** option.
   To create your own file with brokers list:
   In the *Brokers* wizard, complete the following:
    - Click **Add** to open the *Add Broker* wizard. Enter the host name in the Host Name text box. Optionally, you can enter the following information as well:
        - **IP address**: Enter the IP address of the DXL broker.
        - **Unique ID**: A unique identifier for the broker. This is useful for identifying the DXL broker in log messages.
        - **Port information**: The port number used to communicate with the DXL broker.
          To import the broker configuration file:
          In the *Brokers* wizard, complete the following:
        - Click **Import** to upload the broker configuration file. In the *Upload* dialog box, click **Select** to navigate to the certificate. You can export the Broker configuration file `brokerlist.properties` file from McAfee ePolice Orchestrator (McAfee ePO). For information how to export, refer to the McAfee documentation. Click **Upload** to upload the broker configuration file.
          Click **Test Connection** to validate the connectivity between the DXL broker fabric and the Grid Master.
4. Click **Next** to add a DXL topic. DXL uses topics to send data. You can then add the topic to a notification rule so that NIOS can send notifications when an event related to the topic occurs.
   To add a topic:

- Click the **Topics** tab. Click the Add icon to enter a topic. Topics may be in the format defined in the session management template. For example, /infoblox/outbound/LEASE.

5. Click **Next** to set the severity level for the events.
   - **Timeout**: Specify the session timeout value for the endpoint. The default value is 30 seconds.
   - **Log Level**: From the drop-down list, select the severity level for the events. The severity level you select here determines the type of events that are being logged. This can be **Debug**, **Info**, **Warning**, or **Error**. When you select **Debug**, all fields or variables used in the events that were sent to the endpoint are logged, including deduplicated events for RPZ hits. For information about deduplication, see *Deduplicating Events*. Note that setting this to **Debug** might slightly affect the performance of your production system.
   - **Vendor Type**: Displays the vendor information for the endpoint.
   - **Template Type**: Displays the Session Management template.
   - **Parameters**: Displays the parameters of the template you select. You can access these values in the notification rules.
6. Click **Next** to add extensible attributes for the endpoint. For information, see *Managing Extensible Attributes*.
7. Save the configuration.

> ⚠ Note
> If your outbound member is a Grid Master Candidate and in case the Grid Master Candidate is promoted to the Grid Master, make sure that you modify the outbound member to the Grid Master on the endpoint configuration to avoid any outbound notification failures.

Configuring Syslog Endpoints

You can configure syslog endpoints to define syslog message format. When an event is triggered, the syslog message is sent based on the format you define. You can then analyze the data presented in the messages and take corrective measures. To do this, you must configure syslog endpoints. You can send syslog notifications either in raw or formatted text and also send a test syslog notification.

To configure a syslog endpoint, complete the following:

1. From the **Grid/System** tab, select the **Ecosystem** tab -> **Outbound Endpoint** tab and then click **Add** -> **Add Syslog Endpoint** from the Toolbar.
2. In the **Add Syslog Endpoint** wizard:
   - **Name**: Specify a name for the endpoint.
   - Click the + icon to add a syslog address:
   - **Address**: Enter the IP address of the syslog server.
   - **Transport**: Select the connection type that the syslog server will use. Supported types are UDP, TCP, and Secure TCP. If you select TCP or UDP, the default port number is 514 and you do not need to upload a certificate. If you select Secure TCP, the default port number is 6514 and you need to upload a certificate.
   - **Certificate**: If you selected Secure TCP, you must upload an HTTPS or a CA certificate. For more information, see *Managing Certificates*.
   - **Port**: Specify the port number that the syslog server will use to communicate with NIOS.
   - **Message Format**: Select the format of the sys log message. If you select Formatted, you must specify the facility and severity to be sent in the syslog message header.
   - **Host Name**: If you selected Formatted as the message format, then the value that you select from the **Host Name** drop-down list is sent in the syslog message header.
   - **Facility**: Select the location that determines the processes and daemons from which the log messages are generated.
   - **Severity**: Select a severity for the syslog message. The severity type that you select is sent in the syslog message header.
   - Click **Add**. The syslog server details are added to the table. You can add more syslog addresses by clicking the + icon. You can also generate a test syslog notification by clicking **Test**.
   - **Vendor Type**: Select the vendor information for the endpoint.
   - **WAPI Integration Username**: If you have included at least one "wapi" related field in your action template, you must configure WAPI integration; otherwise the WAPI step fails due to an authorization error. Enter the user name of the admin user you want to designate for Syslog outbound notifications. The appliance

ignores the **Auth Username** and **Auth Password** for WAPI related steps in any action templates if WAPI integration is configured.
    - **WAPI Integration Password**: Enter the password of the admin user you have designated for Syslog outbound notifications.
    - **Member Source outbound API requests from**: Select the one of the following to process and send outbound notifications:
    - **Comment**: Enter additional information about the REST API endpoint.
    - **Disable**: Select this if you want to save the configuration but do not want to use it yet. You can clear this checkbox when you are ready to use this configuration.
3. Click **Next** to set the duration of time that the endpoint waits for a response from the outbound member. Complete the following to specify session timeout value:
    a. **Timeout**: Specify the session timeout value for the endpoint. The default value is 30 seconds.
    b. **Log Level**: From the drop-down list, select the severity level for the events. The severity level you select here determines the type of events that are being logged. This can be **Debug**, **Info**, **Warning**, or **Error**. When you select **Debug**, all fields or variables used in the events that were sent to the endpoint are logged, including deduplicated events for RPZ hits. Note that setting this to **Debug** might slightly affect the performance of your production system.
    c. **Template**: Click **Select Template** to select a session management template.
    d. **Vendor Type**: Displays the vendor information for the endpoint.
    e. **Template Type**: Displays the Session Management template.
    f. **Parameters**: Displays the parameters of the template you select. You can access these values in the notification rules.
4. Click **Next** to add extensible attributes for the endpoint.
5. Save the configuration.

Configuring Cisco ISE Endpoints Using Outbound Endpoint

You can configure a Cisco ISE endpoint by either using the **Ecosystem** > **Cisco ISE Endpoint** tab or by using the **Ecosystem** > **Outbound Endpoint** tab. The instructions in this section pertain to configuring Cisco ISE 2.6, 2.7, 3.0, and 3.1 using the **Outbound Endpoint** tab.

You can configure Cisco ISE 3.1 only using the outbound endpoint.

To configure the Cisco ISE endpoint using the **Outbound Endpoint** tab, complete the following:

1. From the **Grid/System** tab, select the **Ecosystem** tab -> **Outbound Endpoint** tab and then click **Add** -> **Add Cisco ISE Endpoint** from the Toolbar.
2. In the **Add Cisco ISE Endpoint** wizard:
    - **Server Address**: Enter the IP address of the Cisco ISE.
    - **Name**: Specify a name for the endpoint.
    - **Subscribing Member**: Select a Grid Master Candidate that you want to subscribe as the client on the Cisco ISE. Or, you can select the current Grid Master as the subscribing member. This member interacts with the Cisco ISE to obtain contextual information for the subscribed data types.
    - **Vendor Type**: The vendor type associated with the endpoint. This is optional.
    - **Client Certificate**: Click **Select** to upload the client certificate. In the *Upload* dialog box, click Select to navigate to the certificate, and then click **Upload**.
    - **Manage Certificates**: Click **CA Certificates** to upload the self-signed certificate or CA certificate. In the *CA Certificates* dialog box, click the Add icon, and then navigate to the certificate to upload it.
    - **WAPI Integration Username**: If you have included at least one "wapi" related field in your action template, you must configure WAPI integration; otherwise the WAPI step fails due to an authorization error. Enter the user name of the admin user you want to designate for Cisco ISE outbound notifications. The appliance ignores the **Auth Username** and **Auth Password** for WAPI related steps in any action templates if WAPI integration is configured.
    - **WAPI Integration Password**: Enter the password of the admin user you have designated for Cisco ISE outbound notifications.
    - **Test Connection**: Click this to validate the endpoint settings and test the connectivity between the Grid Master and the endpoint. It also validates the certificate that you uploaded and tests the connection between the Grid Master Candidate that is assigned as the outbound member and the endpoint. Grid Manager displays a message indicating whether the connection is successful. Note that the test does not

validate the user name and password for the endpoint. It only tests the basic connection between the Grid Master and the endpoint, and validates the certificate.
    - **Comment**: Enter additional information about the Cisco ISE endpoint.
    - **Disable**: Select this checkbox if you want to save the configuration but do not want to use it yet. You can clear this checkbox when you are ready to use this configuration.
    - Click **Next** to set the duration of time that the endpoint waits for a response from the outbound member. Complete the following to specify session timeout value:
        i. **Timeout**: Specify the session timeout value for the endpoint. The default value is 30 seconds.
        ii. **Log Level**: From the drop-down list, select the severity level for the events. The severity level you select here determines the type of events that are being logged. This can be **Debug**, **Info**, **Warning**, or **Error**. When you select **Debug**, all fields or variables used in the events that were sent to the endpoint are logged, including deduplicated events for RPZ hits. Note that setting this to **Debug** might slightly affect the performance of your production system.
        iii. **Template**: Click **Select Template** to select a session management template.
        iv. **Vendor Type**: Displays the vendor information for the endpoint.
        v. **Template Type**: Displays the Session Management template.
        vi. **Parameters**: Displays the parameters of the template you select. You can access these values in the notification rules.
3. Click **Next** to specify the data types that you are interested to obtain from the Cisco ISE. The Cisco ISE shares information only for the subscribed data types. Complete the following to specify data types you want to collect from the Cisco ISE server:
    - **Subscription Settings**: Select the predefined data types to which you want to subscribe from the **Available Data Type** table. Use the arrows to move data types from the **Available Data Type** table to the **Selected Data Type** table. NIOS receives information for all data types in the **Selected Data Type** table.
    - **Map other data types to Extensible Attributes:** You can create extensible attributes and map these extensible attributes to receive additional Cisco ISE data values, such as IP address, MAC, NAS IP Address, NAS Port ID, EPS Status, Posture Status, Posture Timestamp, Endpoint Profile Name, Account Session ID, and Audit Session ID. Click the Add icon and map a Cisco ISE data type to an extensible attribute. You can also select a row and click the Delete icon to delete it.
4. Click **Next** to add data types that you want to publish to the Cisco ISE server. Use the arrows to move data types from the **Available** table to the **Selected** table. NIOS publishes information only for the data types that are added in the **Selected** table.
5. Click **Next** to add extensible attributes for the endpoint.
6. Save the configuration.

Modifying Outbound Endpoint Configuration

To modify an endpoint configuration:

1. From the **Grid/System** tab, select the **Ecosystem** tab -> **Outbound Endpoint** tab, click the **Action** icon next to the endpoint name and select **Edit** from the menu.
2. The <Endpoint Name> *Endpoint* editor provides the following tabs from which you can modify data:
    - **General**: You can modify the general information of an endpoint.
    - **Brokers**: You can modify the DXL broker configuration, as described in Configuring DXL Endpoints below. This tab is available only for DXL endpoints.
    - **Session Management**: You can edit the session timeout value and upload a new session management template.
    - **Extensible Attributes**: You can add, modify, and delete extensible attributes that are associated with an endpoint.
3. Save the configuration.

Viewing All Outbound Endpoints

The **Outbound Endpoint** tab displays all outbound endpoints that are configured on the NIOS appliance.
To view the list of outbound endpoints:

1. From the **Grid/System** tab, select the **Ecosystem** tab, and click the **Outbound Endpoint** tab.
2. Grid Manager displays the following information for each endpoint:
    - **Name**: The name of the endpoint.

- **Endpoint Type**: The endpoint type, such as DXL or REST API.
- **URI**: The URI to which the outbound notifications are sent.
- **Vendor Type**: The vendor type associated with the endpoint.
- **Outbound Member**: The outbound member that processes and sends outbound notifications. This can be either the Grid Master Candidate or the Grid Master. Infoblox recommends that you select the Grid Master Candidate and this is selected by default.
- **Comment**: Additional information about the endpoint configuration.
- **Client Certificate Valid From**: The timestamp when the client certificate for a notification endpoint is created.
- **Client Certificate Valid To**: The timestamp when the client certificate for a notification endpoint expires.
- **Disabled**: Indicates whether the endpoint is disabled.
- **Site**: This is a predefined extensible attribute.

You can also do the following in this tab:

- Click the Action icon  and do the following:
  - **Edit**: Select this to modify the endpoint information.
  - **Delete**: Select this to delete an endpoint. Click **Yes** in the *Delete Confirmation (REST API Endpoint)* dialog box to delete an endpoint.
  - **View Debug Log**: Select this to view debug messages about all events associated with the selected endpoint. Through a separate browser, you can view the debug logs from all Grid members.
- Edit an outbound endpoint information.
  - Select the endpoint, and then click the Edit icon.
- Delete an outbound endpoint.
  - Select the endpoint, and then click the Delete icon.
- Export the list of outbound endpoints.
  - Click the Export icon.
- Print the list of outbound endpoints.
  - Click the Print icon.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria:
  a. In the filter section, click **Show Filter** and define filter criteria for the quick filter.
  b. Click **Save** and complete the configuration In the Save Quick Filter dialog box.

  The appliance adds the quick filter to the quick filter drop-down list in the panel. Note that global filters are prefixed with [G], local filters with [L], and system filters with [S].
- Sort the outbound end points in ascending or descending order by column.

Configuring Notification Rules

You can configure notification rules after you have uploaded outbound templates and configured outbound endpoints on the NIOS appliance. For information about adding outbound endpoints, see *Configuring Outbound Endpoints*. To send outbound notifications from NIOS to the target endpoints, you must configure notification rules. When adding rules, you can select REST API, DXL, or Syslog endpoint and associate the correct action template to the rule. The appliance validates the event type specified in the template with the event type that you select in the notification rule. The parameters defined in a template decides the way NIOS specific data is presented to an endpoint. Each notification rule specifies the target endpoint, notification rule criteria, and the outbound template being used to take action for the matching events.

> **Note**
>
> When you remove all notification rules associated with an endpoint, all the debug logs for that endpoint will also be removed.

While configuring notification rules, you can decide whether you want to reduce the number of redundant RPZ hits, ADP hits, and object change discovery data events. Oftentimes, these hits come from the same client IPs, query FQDNs, or networks. To avoid receiving excessive events at the endpoint, you can configure the appliance to remove or deduplicate

subsequent events (after sending the first event) within a certain time period. Depending on your configuration, the appliance sends the first event and deduplicates subsequent events that match your filtering criteria within the configured lookback interval. For more information, see Deduplicating Events below.

Adding Notification Rules

To add notification rules, complete the following steps:

1. From the **Grid/System** tab, select the **Ecosystem** tab -> **Notification** tab, and then click the Add icon.
   or
   From the **Grid/System** tab, select the **Ecosystem** tab, and click **Add Notification Rule** in the Toolbar.
2. In the *Add Notification* wizard, complete the following.
   - **Name**: Enter the name of the notification rule.
   - **Target**: Click **Select Endpoint** to select the endpoint type. If there are multiple endpoints, the *All Endpoints Selector* dialog box is displayed, from which you can select an endpoint name, such as **Cisco ISE**.
   - **Target Type**: Displays the target type. You cannot change this.
   - **Comment**: Enter useful information about the notification rule.
   - **Disable**: Select this option to disable the notification rule.
3. Click **Next** and complete the following to configure notification rules for the selected endpoint:
   - **Event**: Depending on the licenses you have installed in the Grid, you can select the event types you want to apply to the notification rules. The outbound member collects data for the selected events based on your configuration. Note that if there is a significant amount of data or if the network bandwidth is not sufficient, the outbound member might drop some of the events. In this case, you can access the syslog to view the messages related to the dropped events. In addition to basic information (such as timestamp, member IP, network, and others), data collected for some event type might include enriched data, such as discovered data, parent network information, and associated extensible attributes.
     From the drop-down list, select the event types that you want to monitor for the notification rules:
     - **DNS RPZ**: Select this to collect data for RPZ events. The **DNS RPZ** event type is available only if you have installed the **RPZ** license in the Grid. When you select this event type, you can enable event deduplication in the next step so that the appliance can avoid sending excessive events to the endpoint based on your configuration.
     - **Object Change DNS Record**: Select this to collect data for DNS records. That is, if a DNS record is added, updated, or deleted, the notification rule is triggered and the event notification is sent to the target endpoint. Dynamic records are not supported.
     - **Object Change DNS Zone**: Select this to collect data for DNS zones. That is, if a zone is created, updated, or deleted, the notification rule is triggered and the event notification is sent to the target endpoint.
     - **DNS Tunneling**: Select this to collect data for DNS tunneling events.
     - **DHCP Leases**: Select this to collect data for DHCP leases. Since the same IP addresses might be used by multiple systems, the appliance matches both the IP and the MAC address or the DUID to ensure that the discovered data is most likely to be correct.
     - **DXL Events**: Select this to collect data from the topic to which you subscribed when configuring the DXL endpoint. For more information, see *Configuring DXL Endpoints*.
     - **IPAM**: Select this to send IPAM data. No notification rule is required for this event type. For more information, see *Publishing Data*.
     - **Security ADP**: Select this to collect data for threat protection events. You can specify the maximum domain level for query FQDN for outbound threat protection events. For more information, see Enabling Query FQDN for Outbound Notifications below. When you create outbound notifications for security ADP event types, the server collects event statistics every 15 seconds to avoid excessive threat protection events. Note that you can execute test rules in JSON format for Security ADP event types. For more information, see Deduplicating Events below.
     - **Object Change DHCP Fixed Address IPv4**, **Object Change DHCP Fixed Address IPv6**, **Object Change Network IPv4**, **Object Change Network IPv6**, **Object Change Range IPv4**, **Object Change Range IPv6**, **Object Change Host Address IPv4**, **Object Change Host Address IPv6**, **Object Change Discovery Data**: Select any of these event types to collect data for database changes in fixed addresses, DHCP ranges, networks, DNS host addresses, and discovery data. If you select **Object Change Discovery Data**, when unmanaged IP addresses or devices are created,

updated, or deleted, the notification rule is triggered and the event notification is sent to the target endpoint.

- **Schedule**: Select this to schedule the notification rule configuration. You can set up schedules on an hourly, daily, weekly, or on a monthly basis. You can also choose to schedule the event to occur only once. You cannot specify other event types when you select **Schedule** from the drop-down list. Note that you can execute test rules in JSON format when you schedule the notification rule configuration. You cannot choose an action rule when you schedule the notification rule configuration.
    - **Priority**: This field is displayed only if you select **Schedule** from the drop-down list. Select a priority value, **Normal** or **High**, for scheduled events from the drop-down list. When you select **Normal**, the event is added to the queue right after the existing events in the list and is executed after all events that are already scheduled. Select **High** if you want the event type to be executed soon after the execution of the current event in the list of events that are scheduled. For more information, see *Scheduling Tasks*.
- **Action**: This field is displayed only if you have selected **Cisco ISE** as the endpoint (the Target field). Otherwise, this field is hidden.

In the **Match the following rule** section, select the filters, operators, and values from the drop-down lists for the selected event type. You can use the + icon to construct nested expressions for the rule. The filters change depending on what you selected as the event type. Some of the filters are:

- **DNS RPZ**: Action Policy, BloxOne Threat Defense Cloud Hit Class, BloxOne Threat Defense Cloud Hit Property, BloxOne Threat Defense Cloud Hit Type, Query Name, RPZ Name, RPZ Type, Rule Name, Source IP, and Threat Origin.
- **DNS Tunneling**: Source IP.
- **DHCP Leases**: DHCP Fingerprint and Lease State.
- **DXL Events**: DXL topic that you entered in the **Topics** field when configuring the DXL endpoint. For more information, see *Configuring DXL Endpoints*.
- **Record Name**: Name of the DNS record. For example, AA, CNAME, SRV, and so on.
- **DNS Records**: Supported records are A, AAAA, AAA, CNAME, SRV, ALIAS, NS, PTR, MX, TXT, TLSA, CAA, SOA, DNAME, NAPTR, and UNKNOWN.
- **Zone Type**: Supported zones are Authoritative, Forward, Stub, Delegation, and RPZ.
- **User Name**: Name entered in the WAPI Integration Username field. For more information, see *Configuring Outbound Endpoints*.
- **IPAM**: In the *Notify the target* section, there are predefined data types in the **Available** table you can publish. Click **Override** and use the arrows to move data types from the **Available** table to the **Selected** table and vice versa. The appliance sends information for all data types that are added to the **Selected** table. If you do not override, the publication settings are inherited from those configured while adding the Cisco ISE server. Note that you can configure only one IPAM rule per Cisco ISE server. For more information, see *Publishing Data*.
- **Security ADP**: Rule Message, Hits Count, Member IP, Member Name, Query FQDN, Rule Action, Rule Category, Rule Severity, SID, and Source IP. When you select **Member Name**, the appliance displays all the ADP members that are available.
- **Object Change Fixed Address IPv4**: Disable, IPv4 Address, MAC, Name, Network, Network View, Username, and User Group.
- **Object Change Fixed Address IPv6**: Address Type, Disable, DUID, IPv6 Address, IPv6 Prefix, IPv6 Prefix Bits, Name, Network, Network View, Username, and User Group.
- **Object Change Network IPv4**: Disable, Network, and Network View.
- **Object Change Network IPv6**: Disable, Network, Network View, Username, and User Group.
- **Object Change Range IPv4**: Disable, Network, Network View, Server Association Type, Username, and User Group.
- **Object Change Range IPv6**: Address Type, Disable, Network, Network View, Server Association Type, Username, and User Group.
- **Object Change Host Address IPv4**: Host, IPv4 Address, MAC, Network, Network View Association Type, Username, and User Group.
- **Object Change Host Address IPv6**: Address Type, DUID, Host, IPv6 Address, IPv6 Prefix, IPv6 Prefix Bits, Network View, Username, and User Group.

- **Object Change Discovery Data:** Discoverer, IP Address, Is IPv4, Operation Type, Unmanaged, Username, and User Group.
- **Object Change DNS Record**: Auto Created Records, DNS View, Network View, Operation Type, Record Name, Record Type, User Group, Username, and Zone Name.
- **Object Change DNS Zone**: DNS View, Network View, Operation Type, User Group, Username, Zone Name, and Zone Type.

Note

An event may not be triggered and the template may not execute in the following scenarios:
- For events of type **Object Change DNS Record**.
- Microsoft synchronization of records, DDNS update of records, and nameserver update of records are not supported.
- For SOA records, serial numbers are not automatically incremented.
- For NS records, the **Comment** field is not updated.
- For an RPZ rule, add and update operations are not supported.
- For a shared record, add and update operations are not supported.
- For events of type **Object Change DNS Zone**, Microsoft synchronization of zones is not supported.
- Transfer of secondary zones is not supported.

4. Click **Next**. If you have selected **DNS RPZ**, or **Security ADP** or **Object Change Discovery Data** as the event type, go to Deduplicating Events below to configure deduplication. Otherwise, go to Selecting Action Template below to select an action template.

Note

- The event type you select here affects the templates that are available when you select the RESTful API template you want to use for the outbound notifications. For example, if you select **DNS RPZ** as the event type, only templates configured for DNS RPZ event type are available for selection.
- For the Cisco ISE endpoint, only the DNS RPZ, Security ADP, DHCP Leases, and ADP events are applicable.

Enabling Query FQDN for Outbound Notifications

Infoblox allows you to configure support for query FQDN for outbound threat protection events and choose maximum labels in FQDN that can be configured at the Grid and/or member level. When you enable query FQDN, event data will contain the `query_fqdn` field, if any, which is limited by the domain level. The outbound template executes the parameters and fields against the notification criteria to verify if the notification rule works for the selected security ADP event type.

Note that the maximum domain level is set to three and you can query for domain levels up to three. For example, if you set the domain level to two, you can query for domain a.com, but if you query a.b.com, then the outbound template does not execute the details against the notification criteria. When you set the domain level to three, you can query for a.b.com, but if you query for a.b.c.com, then the details are not executed. Query FQDN automatically prefixes a *. at the beginning of the domain name if the FQDN is longer.

You can enable query FQDN through the *Grid Security Properties* or *Member Security Properties* editor. A warning message is displayed if the notification rule uses Query FQDN for filtering or deduplication when it is not enabled on each member.

To enable query FQDN for outbound notifications, complete the following steps:

1. From the **Data Management** tab, select the **Security** tab, then click **Grid Security Properties** from the Toolbar.
   or
   From the **Data Management** tab, select the **Security** tab -> **Members** tab -> *member* checkbox, and then click the Edit icon.

2. In the *Grid Security Properties* or *Member Security Properties* editor, click **Toggle Advanced Mode**, select the **Ecosystem** tab, and complete the following:
    - **Enable Query FQDN for Threat Protection Events**: Select this checkbox to enable NIOS to use DNS query FQDNs for Outbound threat protection events in the Grid.
    - **Max domain level**: Select a value from the drop-down list to set the maximum domain level for query FQDNs. You can choose 2 or 3.

Deduplicating Events

> **Note**
>
> This step appears only if you have selected **DNS RPZ**, or **Security ADP**, **Object Change Discovery Data**, or **DXL Events** as the event type.

Depending on your configuration, the appliance sends the first RPZ, or threat protection, or object change discovery data event and deduplicates subsequent events that match your filtering criteria within the specified lookback interval. The hits are considered based on the following fields for each of these event types:

- **RPZ events:** Source IP, Query Name, RPZ Policy, and other related fields.
- **ADP hits:** Source IP, Rule ID, and other corresponding fields.
- **Object Change Discovery Data**: Discoverer, IP Address, and other fields.

1. To avoid excessive notifications received at the endpoint, complete the following to configure event deduplication:
    - **Enable event deduplication**: Select this to enable event deduplication for RPZ, or ADP, or data discovery hits. When you enable deduplication, the appliance suppresses redundant notifications based on your configuration.
    - **Log all dropped events due to deduplication to the syslog**: Select this if you want to log all the events that have been dropped due to deduplication. Selecting this allows the appliance to record all the dropped events to the syslog.
    - **Select the fields to use for deduplication**: From the **Available** table, pick the fields you want to use for filtering the deduplication and move them to the **Selected** table using the right arrow. You can also deselect any fields by selecting and moving them from the **Selected** table to the **Available** table using the left arrow. Event deduplication is done based on the conditions of the selected fields. The following example explains how deduplication works if two RPZ hits occur within the lookback interval, as follows:

      RPZ hit 1 / ADP hit 1 / Data Discovery 1: source_ip: 1.2.3.4, query_name: server1.bad.com, rpz_policy: NXDOMAIN, query_type: qname, network.network_view: internal, network.network: 1.2.3.0/24

      RPZ hit 2 / ADP hit 2 / Data Discovery 2: source_ip: 1.2.3.4, query_name: www.something.com, rpz_policy: NXDOMAIN, query_type: qname, network.network_view: internal, network.network: 1.2.3.0/24
      If you have selected only **Source IP** for deduplication, the appliance sends only the first RPZ event to the endpoint. If you have selected both **Source IP** and **Query Name**, both RPZ events are sent to the endpoint.
    - **Lookback Interval**: Enter the time interval during which the appliance evaluates RPZ hit, or ADP hit, or data discovery events and stops sending redundant events to the endpoint (based on your configuration). At the end of this interval, the appliance resumes scanning of the client IP, query FQDN, or network for RPZ events. The minimum interval is five seconds and the maximum is 15 minutes. The default is 10 minutes.
2. Click **Next** to select an action template for the endpoint, as described in the following section, Selecting Action Template.

Selecting Action Template

1. In this step, select the outbound template you want to use for outbound notifications. The appliance validates the event type that is added to the notification rule and then matches that with the event type configured in the template.
   In the **Template** field, click **Select Template** to associate an action template with the notification rule. If there are multiple templates, the <DXL or RESTful API> *Template Selector* dialog box is displayed, from which you can select an action template. Note that only templates that have the same event type configured for the notification rule appear in this dialog.
   The following information is displayed about the selected action template:
   - **Vendor Type**: The vendor type associated with the endpoint.
   - **Template Type**: The type of action that will be taken for the matching events.
   - **Parameters**: Displays the associated parameters of the template, such as **Name**, **Value**, and **Type**. You can click the **Value** cell and modify the value for the parameter.
2. Save the endpoint configuration.

Modifying Notification Rules

To modify a notification rule, complete the following steps:

1. From the **Grid/System** tab, select the **Ecosystem** tab -> **Notification** tab, click the **Action** icon next to the notification rule and select **Edit** from the menu.
2. The *Notification Rule* editor provides the following tabs from which you can modify data:
   - **General**: You can modify the **Target** and **Comment** fields.
   - **Rules**: You can edit the event type and the rule, as described in this section, Configuring Notification Rules.
   - **Templates**: You can select a new action template for the notification rule.
3. Save the configuration.

Viewing All Notification Rules

To view the list of notification rules, complete the following steps:

1. From the **Grid/System** tab, select the **Ecosystem** tab, and click the **Notification** tab.
2. Grid Manager displays the following information:
   - **Name**: Name of the notification rule.
   - **Target**: The target name.
   - **Action**: The action type.
   - **Comment**: Comments that were entered for the notification rule.
   - **Disable**: Displays whether the notification rule is disabled.

     You can perform the following on this tab:
   - Click the Action icon and perform the following:
     - **Edit**: Select this to modify the notification rule.
     - **Delete**: Select this to delete a notification rule.
     - **Test Rule**: Select this to execute the parameters and fields of a template against the notification criteria and verify whether the notification rule works for the event (specified in the template). Make changes to the template if required, and you can view this information in the debug log. The test rules go through the following stages: filtering, enrichment, and deduplication.
     - **View Debug Log**: Select this to view debugging messages for the selected notification rule.
   - Edit the notification rule information.
     - Select the notification rule, and then click the Edit icon.
   - Delete a notification rule.
     - Select the notification rule, and then click the Delete icon.

       Note when you remove all the notification rules associated with an endpoint, all the debug logs for that endpoint will also be removed.
   - Print the list of notification rules.

    - Click the Print icon.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.
- Create a quick filter to save frequently used filter criteria:
    i. In the filter section, click **Show Filter** and define filter criteria for the quick filter.
    ii. Click **Save** and complete the configuration In the *Save Quick Filter* dialog box.
    The appliance adds the quick filter to the quick filter drop-down list in the panel. Note that global filters are prefixed with [G], local filters with [L], and system filters with [S].
- Sort the notification rules in ascending or descending order by column.

Sample Templates

This section contains sample templates that illustrate the following:

- Session management using login and logout templates
- Viewing event types
- XML parsing and handling
- Steps execution through backtracking and loops in a template
- Operations using namespace variables
- IP-related XC operations
- WAPI integration
- Endpoint reference
- Active template functions

For more information about configuring outbound notification rules, templates, and endpoints, see *Outbound Notification Overview*.

> **Note**
>
> Some of the templates are specific for Rapid7 servers.

Session Management Template

Following is a sample session management template for REST API endpoint:

```
{
  "name": "session",
  "version": "2.0",
  "type": "REST_ENDPOINT",
  "vendor_identifier": "Rapid7",
  "path": "/api/1.1/xml",
  "keepalive": true,
  "login_template": "login",
  "logout_template": "logout",
```

```
   "session_duration": 60000
 }
```

> **Note**
>
> The login_template and logout_template lines specify the templates to be executed for login and logout. The session_duration line specifies the length of the session. You must upload the login and logout templates before configuring a session management template that refers them.

Following is a sample session management template for DXL endpoint:

```
{"name": "session_tmplate",
"version": "3.0",
"type": "DXL_ENDPOINT",
"vendor_identifier": "DXL",
"dxl_keep_alive_interval": 60,
"dxl_topic": "/outbound/session"
}
```

Following is a sample session management template for syslog endpoint:

```
{
"version": "5.0",
"vendor_identifier": "SyslogEP",
"name": "Syslog Session",
"type": "SYSLOG_ENDPOINT",
"comment": "Syslog session template",
"path": "/wapi/v2.3/",
"override_path": true,
"timeout": 123,
"keepalive": true,
"retry": 1,
"retry_template": 0,
"rate_limit": 200
}
```

Login Template

```
{
   "name": "login",
   "version": "2.0",
```

```
   "vendor_identifier": "Rapid7",
   "type": "REST_EVENT",
   "event_type": ["SESSION"],
   "content_type": "text/xml",
   "quoting": "XMLA",
   "steps": [
      {
         "body": "${XC:ASSIGN:{H:Authorization}:{S:}}",
         "operation": "NOP",
         "name": "login: clear basic auth"
      },
      {
         "parse": "XMLA",
         "operation": "POST",
         "no_connection_debug": false,
         "name": "login: request",
         "body_list": [
            "<?xml version=\"1.0\" encoding=\"UTF-8\"?>",
         "<LoginRequest user-id=\"${UT::USERNAME}\" password=\"$
{UT::PASSWORD}\"/>"
         ]
    },
    {
        "operation": "CONDITION",
        "name": "login: errorcheck",
        "condition": {
           "statements": [
              {
```

```
                "op": "!=",
                "right": "${P:A:PARSE[[name]]}",
                "left": "LoginResponse"
            },
            {
                "op": "!=",
                "right": "1",
                "left": "${P:A:PARSE{{success}}}"
            }
        ],
        "condition_type": "OR",
        "else_eval": "${XC:COPY:{S:SESSID}:{P:PARSE{{session-id}}}}",
        "error": true
      }
    }
  ]
}
```

> **Note**
> The else_eval line copies the session-id from the parsed reply (if successful); otherwise, it returns an error.

Logout Template

```
{
   "name": "logout",
   "version": "2.0",
   "type": "REST_EVENT",
   "vendor_identifier": "Rapid7",
   "event_type": ["SESSION"],
```

```
   "content_type": "text/xml",
   "quoting": "XMLA",
   "steps": [
      {
         "parse": "XMLA",
         "operation": "POST",
         "no_connection_debug": false,
         "name": "logout: request",
         "body_list": [
            "<?xml version=\"1.0\" encoding=\"UTF-8\"?>",
            "<LogoutRequest session-id=\"${S::SESSID}\"/>"
         ]
      },
      {
         "operation": "CONDITION",
         "name": "logout: errorcheck",
         "condition": {
            "statements": [
               {
                  "op": "!=",
                  "right": "${P:A:PARSE[[name]]}",
                  "left": "LogoutResponse"
               },
               {
                  "op": "!=",
                  "right": "1",
                  "left": "${P:A:PARSE{{success}}}"
```

```
                }
            ],
            "condition_type": "OR",
            "error": true
        }
    }
  ]
}
```

Action Template

Sample Action Template for DXL Endpoint

```
{
 "vendor_identifier": "DXL",
 "version": "5.0",
 "name": "action",
 "type": "DXL_EVENT",
 "event_type": [
 "FIXED_ADDRESS_IPV4"
 ],
 "dxl_topic": "/outbound/action",
"steps": [
{
"operation": "DXL_SEND_EVENT",
"name": "send_ip",
"body": "address ${E:A:values{ipv4addr}}",
"dxl_topic": "/outbound/step"
},
{
"operation": "DXL_SEND_REQUEST",
"name": "dxl_request",
"body_list": "address ${E:A:values{ipv4addr}}",
"dxl_topic": "/sample/service"
```

```
        }
        ]
    }
```

Sample Action Template for DXL Endpoint Outbound

```
{
"version": "5.0",
"name": "DXL_action_template",
"type": "DXL_EVENT",
"event_type": ["RPZ","DXL"],
"action_type": "RPZ Action",
"comment": "Outbound API phase 5",

"body_list": [
"Modified ${L::data}"
],
"dxl_topic": "/outbound/demo"
}
]
}
```

Sample Action Template for REST API Endpoint

Following is a sample action template for REST API endpoint:

```
{
   "name": "action",
   "vendor_identifier": "Rapid7",
   "version": "2.0",
   "content_type": "text/xml",
   "action_type": "add network or remove IP",
   "quoting": "XMLA",
   "type": "REST_EVENT",
   "event_type": [ "FIXED_ADDRESS_IPV4", "FIXED_ADDRESS_IPV6" ],
```

```
   "steps": [
     {
          "name": "check operation type",
          "operation": "CONDITION",
          "condition": {
   "statements": [
     {
          "op": "!=",
          "right": "${E:A:operation_type}",
          "left": "INSERT"
     },
     {
          "op": "!=",
          "right": "${E:A:operation_type}",
          "left": "DELETE"
     }
   ],
   "condition_type": "AND",
   "stop": true
      }
   },
   {
     "name": "send SiteListingRequest",
     "operation": "POST",
     "body_list": [
    "<?xml version=\"1.0\" encoding=\"UTF-8\"?>",
    "<SiteListingRequest session-id=\"${S::SESSID}\" />"
```

```
    ],
    "parse": "XMLA"
  },

    "wapi": "v2.6",
    "body": "{\"extattrs+\": {\"r7_added\": {\"value\": \"Added to the Rapid7 ${UT:A:TIME}\"}}}"
   }
 ]
}
```

Sample Action Template for Syslog Endpoint

```
{
"version": "5.0",
"name": "syslog_action_dns_record",
"type": "SYSLOG_EVENT",
"event_type": ["RPZ","DXL","DNS_RECORD","DNS_ZONE"],
"action_type": "Some Action",
"comment": "Syslog Events",
"content_type": "application/json",
"vendor_identifier": "syslog",
"steps":
[
{
"name": "syslog_send",
"operation": "SYSLOG_SEND_EVENT",
"body": "${E::object_type} ${E::operation_type} with name ${E::values{name}} on to zone ${E::values{zone}} for member ${E::member_ip} at timestamp ${E::timestamp}"
}
```

```
]
}
```

Action Template: Check Operation Type

```
{
            "name": "check operation type",
            "operation": "CONDITION",
            "condition": {
            "statements": [
              {
               "op": "!=",
               "right": "${E:A:operation_type}",
               "left": "INSERT"
              },
              {
               "op": "!=",
               "right": "${E:A:operation_type}",
               "left": "DELETE"
              }
          ],
          "condition_type": "AND",
          "stop": true
}
```

> **Note**
>
> The "`check operation type`" step checks the operation type. If it is neither INSERT nor DELETE, the template execution stops.

Action Template: Get the List of Sites

```
{
        "name": "send SiteListingRequest",
        "operation": "POST",
        "body_list": [
     "<?xml version=\"1.0\" encoding=\"UTF-8\"?>",
     "<SiteListingRequest session-id=\"${S::SESSID}\" />"
        ],
        "parse": "XMLA"
     },
     {
        "operation": "CONDITION",
        "name": "send SiteListingRequest (error check)",
        "condition": {
     "statements": [
        {
        "op": "!=",
        "right": "${P:A:PARSE[[name]]}",
        "left": "SiteListingResponse"
      },
      {
        "op": "!=",
        "right": "1",
        "left": "${P:A:PARSE{{success}}}"
       }
    ],
    "condition_type": "OR",
```

```
    "error": true,
    "else_eval": "${XC:COPY:{L:site_list}:{P:PARSE}"
        }
    }
```

> **Note**
>
> The "`send SiteListingRequest`" and "`send SiteListingRequest (error check)`" steps request the list of sites on a Rapid7 server. If the response is successful, it copies the list to the `L:site_list variable`.

Action Template: Locate the Site ID by Name

```
{
       "operation": "CONDITION",
       "name": "check whether site list is empty",
       "condition": {
  "statements": [{
     "op": "==",
     "right": "${L:L:site_list}",
     "left": "0"
  }],
  "condition_type": "AND",
  "stop": true
     }
  },
  {
     "operation": "VARIABLEOP",
     "name": "get the next site",
     "variable_ops": [{
  "operation": "POP",
```

```
  "type": "COMPOSITE",
  "destination": "L:a_site",
  "source": "L:site_list"
     }]
  },
  {
      "operation": "CONDITION",
      "name": "check site name",
      "condition": {
  "statements": [{
    "op": "!=",
    "right": "${L:A:a_site{{name}}}",
    "left": "${E:A:values{extattrs}{r7_site}{value}}"
  }],
  "condition_type": "AND",
  "next": "check whether site list is empty",
  "else_eval": "${XC:COPY:{L:site_id}:{L:a_site{{id}}}}"
      }
  }
```

NOTES:

- The "`check whether site list is empty`", "`get the next site`", and "`check site name`" steps form a loop for finding the site with specific name in the list of sites.
- The "`check whether site list is empty`" step checks to see if the list is empty. If it is empty, the site with the specific name is not found and the execution of the template stops.
- In the "`get the next site`" step, one element is copied to the `L:a_site` variable.
- In the "`check site name`" step, the "`name`" attribute of a site (`${L:A:a_site{{name}}}`) is compared to the value of the "`r7_site`" extensible attribute of the fixed address in (`${E:A:values{extattrs}{r7_site}{value}}`). If they are the same, the site ID is stored to the `L:site_id variable (${XC:COPY:{L:site_id}:{L:a_site{{id}}}})`. If they are not the same, the execution is continued by the "`check whether site list is empty`" step.

Action Template: Get Site Configuration

```
{
            "parse": "XMLA",
            "operation": "POST",
            "name": "send SiteConfigRequest",
            "body_list": [
   "<?xml version=\"1.0\" encoding=\"UTF-8\"?>",
   "<SiteConfigRequest session-id=\"${S::SESSID}\" site-id=\"${L:A:site_id}
\"/>"
          ]
   },
   {
        "operation": "CONDITION",
        "name": "send SiteConfigRequest (error check)",
        "condition": {
  "statements": [
    {
      "op": "!=",
      "right": "${P:A:PARSE[[name]]}",
      "left": "SiteConfigResponse"
  },
  {
      "op": "!=",
      "right": "1",
      "left": "${P:A:PARSE{{success}}}"
  }
 ],
```

```
 "condition_type": "OR",
 "else_eval": "${XC:COPY:{L:Site}:{P:PARSE{SiteConfigResponse}}}",
 "error": true
     }
 }
```

> **Note**
>
> Once `site-id` is known, steps "`send SiteConfigRequest`" and "`send SiteConfigRequest (error check)`" request and store the site configuration.

Action Template: Distinguish Between INSERT and DELETE

```
{
       "operation": "CONDITION",
       "name": "check operation type again",
       "condition": {
  "statements": [{
     "op": "==",
     "right": "${E:A:operation_type}",
     "left": "INSERT"
  }],
  "condition_type": "AND",
  "eval":
 "${XC:COPY:{L:network}:{E:values{network}}}${XC:NETWORKTORANGE:{L:network}:{L:range
 }}",
    "next": "insert network"
         }
    }
```

> **Note**
>
> The "`check operation type again`" step determines the operation type. If the operation is "`INSERT`", the network of the inserted fixed address is copied to the L:network variable (`${XC:COPY:{L:network}:{E:values{network}}}`) and transformed to a Rapid7 range to the `L:range variable (${XC:NETWORKTORANGE:{L:network}:{L:range}})`. After the range is stored, the template execution jumps to the "`insert network`" step.

Action Template: Delete an IP Address

```
{
        "operation": "CONDITION",
        "name": "remove ip",
        "condition": {
    "statements": [{
       "op": "==",
       "right": "${E:A:event_type}",
       "left": "FIXED_ADDRESS_IPV4"
    }],
    "condition_type": "AND",
    "eval":
 "${XC:COPY:{L:ip}:{E:values{ipv4addr}}}${XC:REMOVEIP:{L:ip}:
{L:Site{Hosts}}}",
   "else_eval":
 "${XC:COPY:{L:ip}:{E:values{ipv6addr}}}${XC:REMOVEIP:{L:ip}:
{L:Site{Hosts}}}"
     }
  },
  {
    "operation": "CONDITION",
    "name": "jump to send",
```

```
    "condition": {
  "statements": [{
    "op": "==",
    "right": "",
    "left": ""
  }],
  "condition_type": "AND",
  "next": "send SiteSaveRequest"
    }
   }
```

NOTES:

- If the operation is not "`INSERT`" (i.e. "`DELETE`"), the "`remove ip`" step is executed. The step determines the type of fixed address. The corresponding address (`{E:values{ipv4addr}` } or `{E:values{ipv6addr}}`) is copied to the `L:ip` variable, and then the `L:ip` address is removed from the list of hosts in the site `(${XC:REMOVEIP:{L:ip}:{L:Site{Hosts}}})`.
- The step "`jump to send`" skips the "`inserting`" step and jumps directly to the "`send SiteSaveRequest`" step.

Action Template: Add an IP Range

```
{
        "operation": "VARIABLEOP",
        "name": "insert network",
        "variable_ops": [{
    "operation": "PUSH",
    "type": "COMPOSITE",
    "source": "L:range",
    "destination": "L:Site{Site}{Hosts}"
        }]
     }
```

`The step "insert network" pushes the L:range to the list of site's "Hosts".`

```
Action Template: Saving New Configuration
{
        "parse": "XMLA",
        "operation": "POST",
        "name": "send SiteSaveRequest",
        "body_list": [
    "<?xml version=\"1.0\" encoding=\"UTF-8\"?>",
    "<SiteSaveRequest session-id=\"${S::SESSID}\">",
    "${L:x:Site}",
    "</SiteSaveRequest>"
        ]
     },
     {
       "operation": "CONDITION",
       "name": "send SiteSaveRequest (error check)",
       "condition": {
    "statements": [
     {
       "op": "!=",
       "right": "${P:A:PARSE[[name]]}",
       "left": "SiteSaveResponse"
     },
     {
       "op": "!=",
       "right": "1",
       "left": "${P:A:PARSE{{success}}}"
     }
```

```
],
"condition_type": "OR",
"error": true
    }
 }
```

> **Note**
>
> The "`send SiteSaveRequest`" and "`send SiteSaveRequest (error check)`" steps save new site configuration to the Rapid7 server.

Action Template: Add Extensible Attributes Using WAPI

```
{
          "operation": "CONDITION",
          "name": "check operation type once more",
          "condition": {
       "statements": [{
         "op": "!=",
         "right": "${E:A:operation_type}",
         "left": "INSERT"
     }],
     "condition_type": "AND",
     "stop": true
        }
    },
    {
       "operation": "PUT",
       "name": "add an attribute with WAPI",
       "transport": {"path": "${E:A:values{_ref}}"},
```

```
        "wapi": "v2.6",
        "body": "{\"extattrs+\": {\"r7_added\": {\"value\": \"Added to the
Rapid7 ${UT:A:TIME}\"}}}"
            }
```

NOTES:

- The "`check operation type once more`" step determines the operation type. If the operation is not "`INSERT`" (i.e. "`DELETE`"), the template execution stops.
- For the "`INSERT`" operation, the last step "`add an attribute with WAPI`" is executed. This step adds an extensible attribute "`r7_added`" to the fixed address through RESTful API. The value of the attribute has the current timestamp (`${UT:A:TIME}`).

Action Template: Add a Host Record

The following sample template, if assigned to a DHCP network notification rule, will insert a host record for any added network that matches the rule, with a hostname and domain name set by extensible attributes in the network. Detailed explanations about this sample are included in Action Template with Comments: Add a Host Record below.

```
{
        "version": "1.0",
        "name": "Insert host record",
        "comment": "Will automatically insert a host record for new network
insertions, assumes the network has a 'Zone' extensible attribute,
optionally a 'Hostname' extensible attribute as well",
        "type": "REST_EVENT",
        "event_type": [
            "NETWORK_IPV4"
        ],
        "action_type": "Insert a host record",
        "vendor_identifier": "WAPI 2.3",
        "transport": {
           "content_type": "application/json",
       },
       "steps":
```

```
        [
          {
              "name": "stop if it is not a network insert",
              "operation": "CONDITION",
              "condition": {
                 "condition_type": "AND",
                 "statements": [
                    {
                        "left": "${E:A:operation_type}",
                        "op": "!=",
                        "right": "INSERT"
                    }
                ],
                "stop": true
            }
        },
        {
            "name": "stop if we don't have the zone EA set, else save it",
            "operation": "CONDITION",
            "condition": {
                 "condition_type": "AND",
                 "statements": [
                    {
                         "left": "${E:A:values{extattrs}{Zone}{value}}",
                        "op": "==",
                        "right": ""
                     }
```

```
                ],
                "stop": true,
                "else_eval": "${XC:COPY:{L:ZONE}:{E:values{extattrs}{Zone}
{value}}}"
            }
        },
        {
            "name": "get the hostname or use a default value",
            "operation": "CONDITION",
            "condition": {
               "condition_type": "AND",
               "statements": [
                   {
                       "left": "${E:A:values{extattrs}{Hostname}{value}}",
                       "op": "!=",
                       "right": ""
                   }
               ],
               "eval":
   "${XC:COPY:{L:HOSTNAME}:{E:values{extattrs}{Hostname}{value}}}",
               "else_eval": "${XC:ASSIGN:{L:HOSTNAME}:{S:defaulthostname}}"
            }
       },
       {
            "name": "insert the host record with the next available IP",
            "operation": "POST",
            "transport": {
                 "path": "record:host"
```

```
            },
            "body_list": [
                "{",
                "\"name\": \"${L:A:HOSTNAME}.${L:A:ZONE}\",",
                "\"ipv4addrs\": [{\"ipv4addr\":
   \"func:nextavailableip:${E:A:values{network}}\"}],",
                "\"comment\": \"Inserted via outbound\"",
                "}"
             ]
         }
     ]
}
```

Action Template with Comments: Add a Host Record

The comments (labeled as **Note**:) embedded in the sample template explain the operation for each section of the template. Note that the execution of this sample template will cause a single **POST** request to be sent with the following body for an insertion of a **10.0.0.0/24** network with the Zone extensible attribute set to test.com and the Hostname extensible attribute set to **`name`** :

```
{"name": "name.test.com","ipv4addrs": [{"ipv4addr":
"func:nextavailableip:10.0.0.0/24"}],"comment": "Inserted via a template"}
```

Note: The preamble of the template specifies the version, version, name and other relevant fields.

```
{
       "version": "1.0",
       "name": "Insert host record",
       "comment": "Will automatically insert a host record for new network
insertions,assumes the network has a 'Zone' extensible attribute, optionally
a 'Hostname' extensible attribute as well",
       "type": "REST_EVENT",
```

Note: The `event_type` field specifies that this template is used for IPv4 network events only.

```
"event_type": [
          "NETWORK_IPV4"
       ],
```

Note: The `action_type` and `vendor_identifier` fields describe the template type and the vendor type.

```
  "action_type": "Insert a host record",
  "vendor_identifier": "WAPI 2.3",
```

Note: The following specifies that the template is going to send JSON to the server.

```
  "transport": {
       "content_type": "application/json",
  },
```

Note: The following are steps that will be executed sequentially.

```
  "steps":
  [
```

Note: The first step will stop the execution, without an error, if the network event received is not an insertion – it could be a modify, for example.

```
{
    "name": "stop if it is not a network insert",
    "operation": "CONDITION",
    "condition": {
```

Note: You can specify only one statement: either AND or OR would work.

```
        "condition_type": "AND",
        "statements": [
```

Note: The match is to check if `operation_type` in the event is different from INSERT. It is a good practice to put the event variable on the left side so if it is not present in the event, the template would not fail.

```
            {
                "left": "${E:A:operation_type}",
                "op": "!=",
                "right": "INSERT"
            }
        ],
```

Note: The directive that stops the execution if the condition matches.

```
        "stop": true
    }
},
```

Note: The second step will stop the execution if the inserted network does not have the Zone extensible attribute configured. If it has the extensible attribute, it will be put in a temporary local variable for easier access later on.

```
{
    "name": "stop if we don't have the zone EA set, else save it",
    "operation": "CONDITION",
    "condition": {
```

Note: Similar to the previous section, we have only one statement, so either AND or OR would work. The condition ensures that the Zone extensible attribute is set to a value.

```
        "condition_type": "AND",
        "statements": [
            {
```

Note: As previously mentioned, non-existent variable access in the left side of a condition will not cause an error, but instead return an empty value.

```
                "left": "${E:A:values{extattrs}{Zone}{value}}",
                "op": "==",
                "right": ""
            }
        ],
```

Note: If the extensible attribute is empty or nonexistent, the operation should stop here.

```
        "stop": true,
```

Note: Otherwise, it will copy the zone value to the local ZONE variable.

```
        "else_eval": "${XC:COPY:{L:ZONE}:{E:values{extattrs}{Zone}{value}}}"
    }
},
```

Note: This step is similar to the zone step above. However, if the host name is not set, it will put a default host name in a local variable to provide the default.

```
{
    "name": "get the hostname or use a default value",
    "operation": "CONDITION",
    "condition": {
        "condition_type": "AND",
        "statements": [
            {
                "left": "${E:A:values{extattrs}{Hostname}{value}}",
                "op": "!=",
                "right": ""
            }
        ],
```

Note: This is executed if the extensible attribute is present, by copying its value to HOSTNAME.

```
    "eval": "${XC:COPY:{L:HOSTNAME}:{E:values{extattrs}{Hostname}{value}}}",
```

Note: Otherwise, the following is executed if the extensible attribute is empty or not present, by assigning the `defaulthostname` string instead.

```
            "else_eval": "${XC:ASSIGN:{L:HOSTNAME}:{S:defaulthostname}}"
        }
    },
```

Note: This step will finally contact the endpoint and in this case insert the host.

```
        {
        "name": "insert the host record with the next available IP",
```

Note: This defines the HTTP operation to use.

```
        "operation": "POST",
```

Note: The endpoint is configured starting with *https://master_ip/....* The endpoint template overrides the path with */wapi/v2.3/* so by default all template requests would go to *https://master_ip/wapi/v2.3/.* In this step, we want to insert a host, so `record:host` is appended to the URI above (no override is set here) to arrive to the valid RESTful URI *https://master_ip/wapi/v2.3/record:host*.

```
            "transport": {
                "path": "record:host"
            },
```

Note: This is the text that will be sent to the server in the POST's BODY.

```
"body_list": [
    "{",
```

Note: This references the local variables that were previously assigned.

```
"\"name\": \"${L:A:HOSTNAME}.${L:A:ZONE}\",",
```

Note: This option signifies that the RESTful API will use the next available IP in the network as the address for this host.

```
"\"ipv4addrs\": [{\"ipv4addr\":
\"func:nextavailableip:${E:A:values{network}}\"}],",
```

Note: This is the comment stating that the action is done through the RESTful API template.

```
            "\"comment\": \"Inserted via outbound\"",
            "}"
        ]
    }
  ]
}
```

Endpoint reference

`UT::ENDPOINT` contains WAPI reference to the current endpoint object that can be used by WAPI steps. You can make changes to the endpoint configuration during a template execution.

Example:

```
{
"version": "4.0",
...
```

```
"steps": [
...
{
"operation": "PUT",
"name": "update_endpoint",
"transport": {"path": "${UT::ENDPOINT}"},
"wapi": "v2.7",
"body": "{\"comment\": \"outbound\"}"
},
...
],
...
}
```

Active Template Functions

Example:

```
{
"version": "4.0",
"name": "example",
"event_type": ["RPZ"],
"type": "REST_EVENT",
"functions": {
"functions": {
"is_ipv4_address": {
"steps": [
{
"operation": "CONDITION",
"condition": {
```

```
"statements": [
{
"left": "${L:A:address}",
"op": "!~",
"right": ":"
}
],
"condition_type": "AND",
"eval": "${XC:ASSIGN:{L:result}:{B:true}}",
"else_eval": "${XC:ASSIGN:{L:result}:{B:false}}"
}
}
]
}
},
"steps": [
...
{
"operation": "FUNCTION",
"function_name": "is_ipv4_address",
"body": "${XC:ASSIGN:{L:address}:{S:10.0.0.1}}"
},
...
]
}
```

Configuring BloxOne Threat Defense Cloud Clients for Outbound

The Infoblox BloxOne Threat Defense Cloud Client on NIOS allows the interaction between BloxOne Threat Defense Cloud and outbound endpoints so you can collect blocked/logged request via feeds or domains detected by Threat

Insight in BloxOne Threat Defense Cloud and send the outbound events to external endpoints. When you enable and configure BloxOne Threat Defense Cloud Client on an on-prem NIOS member, the client uses threat API calls to request RPZ events from BloxOne Threat Defense Cloud, and then convert the data into outbound events. These events are periodically synchronized (between BloxOne Threat Defense Cloud and NIOS) and sent to the configured outbound endpoints. Note that the client requests only subsequent data since the last data timestamp, and each synchronization happens based on the schedule and retrieves only the current data.

You can configure notification rules to filter incoming events using the following fields: Threat Origin (NIOS, BloxOne Threat Defense Cloud), BloxOne Threat Defense Cloud Hit Type (DNS RPZ, Threat Analytics), BloxOne Threat Defense Cloud Hit Class and BloxOne Threat Defense Cloud Hit Property. When you configure notification rules to filter incoming events using these fields for BloxOne Threat Defense Cloud Client, relevant information gets synchronized with the event types that you add to the list. This synchronization happens periodically based on the interval that you define. For more information about notification rules, see *Configuring Notification Rules.*

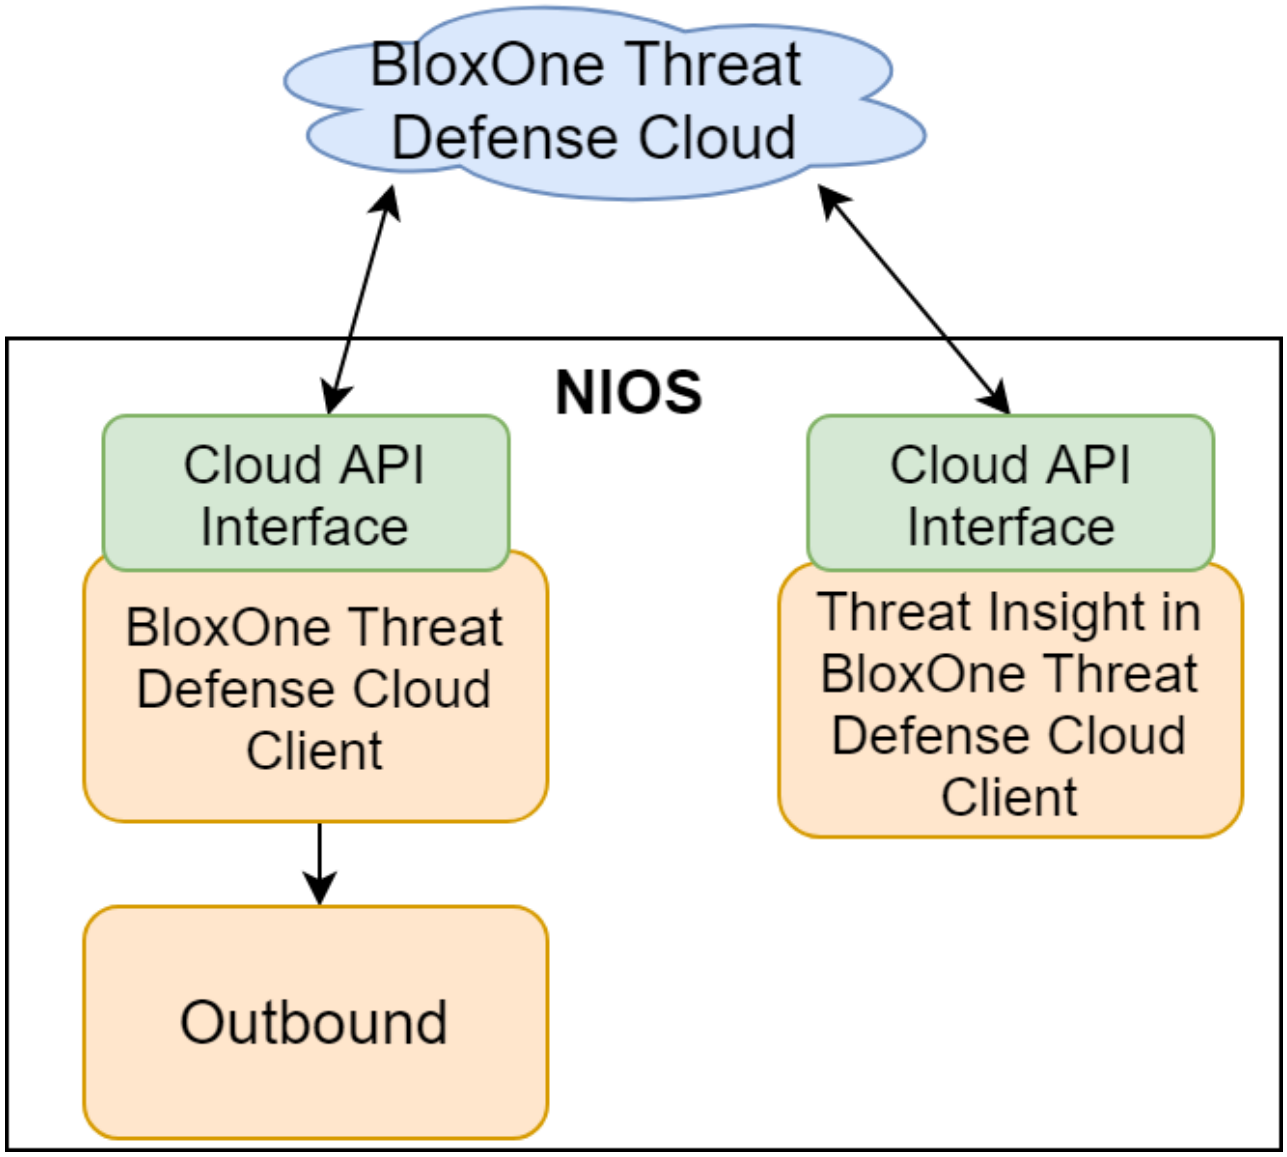
You can select any Grid member to execute the BloxOne Threat Defense Cloud Client. Infoblox uses event filters on the selected Grid Member to limit the amount of logs. For debugging purposes, information about the client connection status will be displayed in the infoblox.log file. An error is logged in the debug mode for any exceptions that appear when the data is requested and received from the BloxOne Threat Defense Cloud. NIOS logs any critical messages in the syslog.

You must specify the email address and password in the *Grid Properties Editor* before you enable the BloxOne Threat Defense Cloud Client. For more information about configuring Integration with BloxOne threat defense cloud, see below. The server stores the email address and the password so that it can request a new API key. The server requests an API key through the Cloud Services Portal, so that the cloud client is authorized to retrieve data from BloxOne Threat Defense Cloud.

Note

Before you configure the BloxOne Threat Defense Cloud Client for outbound, ensure that you have installed the **Security Ecosystem** license.

The following figure shows how Threat Insight in the BloxOne Threat Defense Cloud client and BloxOne Threat Defense Cloud Client use a common API interface to interact with BloxOne Threat Defense Cloud. For more information about enabling BloxOne threat defense cloud client for outbound, see below.



Best Practices for Configuring BloxOne Threat Defense Cloud Client

- Ensure that you have enabled the following on the BloxOne Threat Defense Cloud Client:
  - An email address and a password.
  - A Grid member that is online.
- Ensure that at least one outbound notification rule for DNS RPZ event type is active for outbound settings.
- Only superusers can update the BloxOne Threat Defense Cloud Client settings.
- If the timestamp for the data collected by the BloxOne Threat Defense Cloud Client is ahead of the current time in NIOS, then such events are logged in the syslog. In such an instance, the client does not request any data until the current time reaches the timestamp of the data that is collected and it logs a message in the Infoblox.log based on the time interval that you have set.

Configuring Integration with BloxOne Threat Defense Cloud

To integrate the BloxOne Threat Defense Cloud client with BloxOne Threat Defense Cloud, you must have already created a user profile and the API key for the user profile in the Cloud Services Portal.

To configure the BloxOne Threat Defense Cloud client to integrate with BloxOne Threat Defense Cloud, you must configure the URL of the Cloud Services Portal and credentials for logging in to the portal. Complete the following steps:

1. **Grid**: From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar.
   Standalone appliance: From the **System** tab, select the **System Manager** tab, and then select **System Properties** -> **Edit** from the Toolbar.
2. In the *Grid Properties Editor* or the *System Properties Editor*, click **Toggle Advanced Mode** to switch to the advanced mode.
   Note that if the editor is already in the advanced mode, then you will see the Toggle Basic Mode button.
3. On the **BloxOne Threat Defense Cloud Integration** tab -> **Basic** tab, specify the following in the *BloxOne Threat Defense Cloud Integration* section:
   BloxOne Threat Defense Cloud Integration
   - **URL**: Displays the REST API URL of the Infoblox Cloud Services Portal.
   - **Credentials**:
     - **Email**: Enter the email address that is registered in the Cloud Services Portal. This email address is used for authorization by the Cloud Services Portal.
     - **Password**: Enter the password that is registered in the Cloud Services Portal. This password is used for authorization by the Cloud Services Portal.
     - **Test Connection**: Click this to test the connectivity between NIOS and the Cloud Services Portal.
4. Save the configuration.

Enabling BloxOne Threat Defense Cloud Client for Outbound

To configure an BloxOne Threat Defense Cloud Client to collect event types from BloxOne Threat Defense Cloud and send them to external endpoints, complete the following steps:

1. From the **Grid** tab, select the **Ecosystem** tab -> **Outbound Endpoint** tab, and then click **BloxOne Threat Defense Cloud Client** from the Toolbar.
2. In the *BloxOne Threat Defense Cloud Client* editor, complete the following:
   - **Enable Cloud Client**: Select this checkbox to enable the BloxOne Threat Defense Cloud Client to send outbound events.
   - **Grid member**: Click **Select** to select a Grid member on which you run the configured client. Click **Clear** to clear the value. You can select any Grid member where the cloud client must be executed.
   - **Interval**: Specify how often to request the list of event types from BloxOne Threat Defense Cloud, in seconds or minutes. This value is set to one minute by default. The time interval is measured from the previous data synchronization.
   - **The list of requested event types**: Select the respective checkbox to enable or disable an event type. The event types that you request from the BloxOne Threat Defense Cloud are listed here. You cannot add or remove them.
3. Save the configuration.

Configuring Outbound Cloud Clients

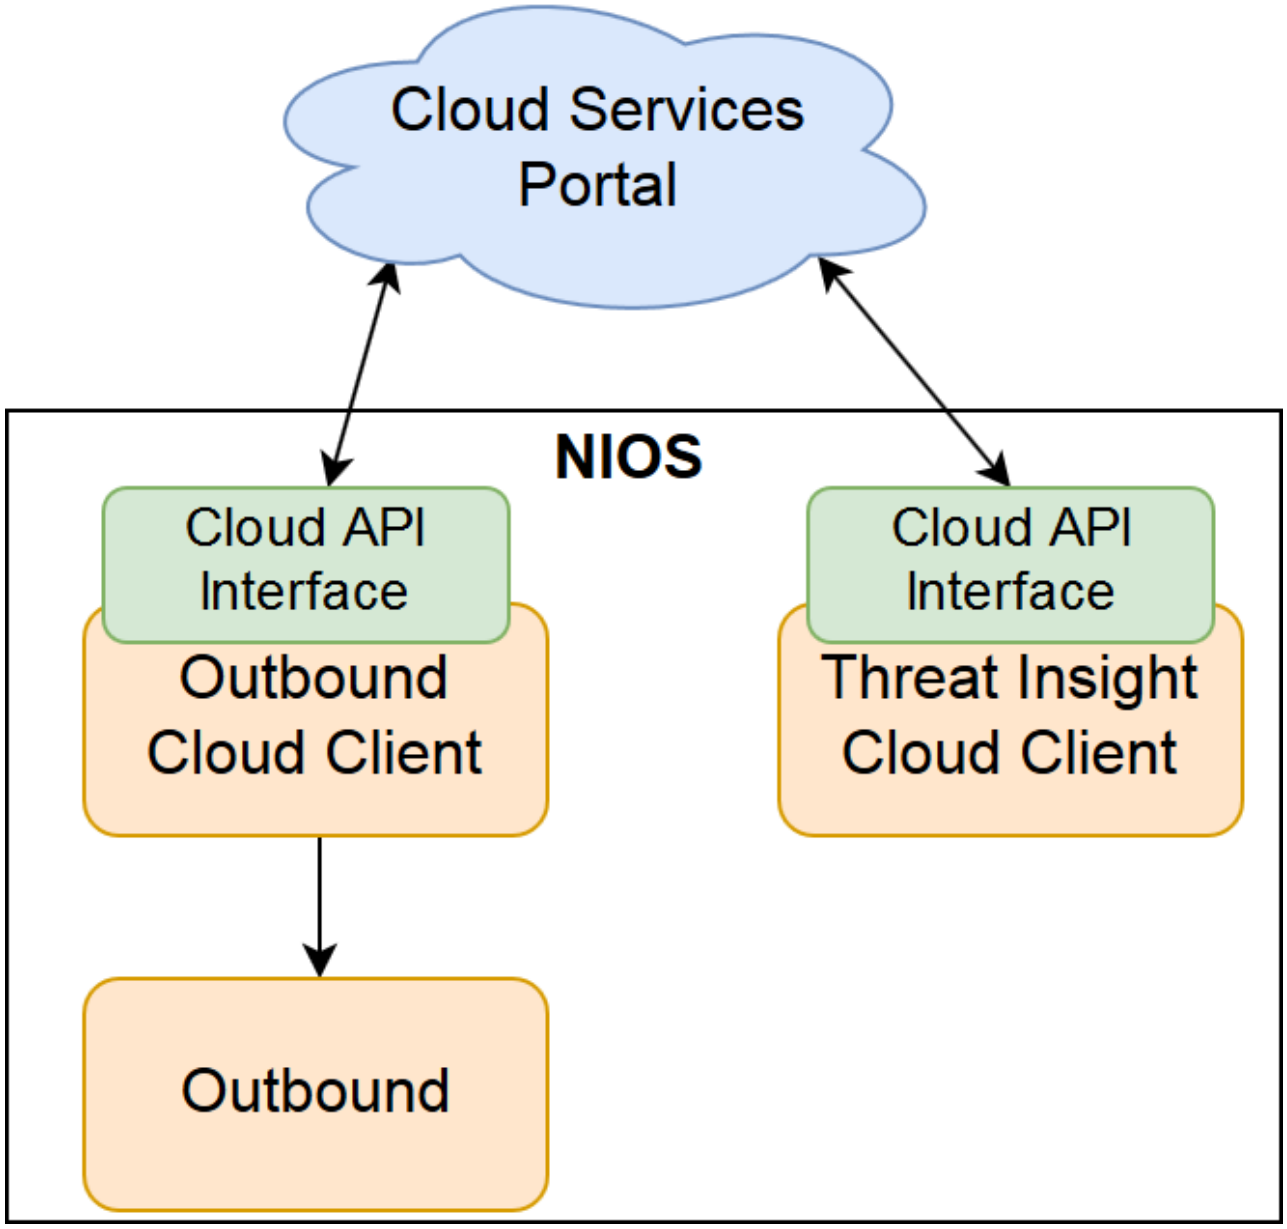
The Infoblox outbound cloud client allows interaction of the Cloud Services Portal with external endpoints. You can use the outbound cloud client, which in turn uses threat API calls, to request security events from the Cloud Services Portal and convert data to outbound events. These events are periodically published to outbound framework for filtering and enrichment before they are sent to the configured external endpoints. The outbound cloud client stores the last timestamp from data that is received from the Cloud Services Portal. For the next security event request, it requests data from the last timestamp until the current time. It does not request any historical data from the cloud service portal.

With the outbound cloud client, you can request security data such as DNS RPZ, threat analytics, content/domain category, a class/property, and a client type. Infoblox enables you to configure notification rules to filter incoming events using the following fields: Threat Origin (NIOS, Cloud), Threat Source (DNS RPZ, Threat Analytics, Content Category), Threat Class and Threat Property. For more information, see *Configuring Notification Rules.*

You must enable either the username or password and define an API key to enable a client. A client can be a threat insight in the cloud client or an outbound cloud client. The server stores the username and password to request a new API key when the existing API key expires. Note that all clients use a common API interface.

You can select any Grid member to execute the outbound cloud client. Infoblox uses event filters on the selected Grid Member to limit the amount of logs. The audit log displays information about the client connection status, exceptions during connection and data request, and data received from the Cloud Services Portal. NIOS logs any critical messages in the syslog.

> **Note**
>
> Before you configure the outbound cloud client, ensure that you have installed the Response Policy Zones and Security Ecosystem licenses.



Best Practices for Configuring Outbound Cloud Clients

- Ensure that you have enabled the following on the outbound client:
  - Define either a username or a password.
  - Enable at least one event type.
  - Specify a Grid member and ensure that the Grid member is online.
- Any changes to the API request or response format affects the feature.
- At least one outbound notification rule for DNS RPZ event type must be active for outbound settings.
- You cannot insert or delete outbound cloud clients.
- Only superusers can update an object.

Configuring Outbound Cloud Clients

To configure BloxOne Threat Defense Cloud API, complete the following:

1. From the **Grid** tab, select the **Grid Manager** tab, and then select **Grid Properties** -> **Edit** from the Toolbar.
2. In the *Grid Properties Editor*, click **Toggle Advanced Mode**, and click the **BloxOne Threat Defense Cloud Integration** tab.
3. Specify the following in the **Basic** tab:
   BloxOne Threat Defense Cloud API
   - **URL**: Displays the REST API URL of the Infoblox BloxOne Threat Defense Cloud Services Portal. You can use the `set cloud_services_portal` CLI command in maintenance mode to update the REST API URL.
   - **Credentials**
     - **Email:** Enter the email address that is registered in the Infoblox Cloud Services Portal.
     - **Password**: Enter the password that is registered in the Infoblox Cloud Services Portal.

   Test Connection: Click this to test the connectivity between the outbound cloud client and the BloxOne Threat Defense Cloud Services Portal.
4. Save the configuration.

3.3.2 Threat Insight in the Cloud Client Editor (update)

User will not be able to specify API key from the Editor. It should be removed.

Enabling Client for Outbound Events in the Cloud

To modify an outbound cloud client:

1. From the **Grid** tab, select the **Ecosystem** tab -> **Outbound Endpoint** tab, and then click **BloxOne Threat Defense Cloud Client** from the Toolbar.
2. In the *BloxOne Threat Defense Cloud Client* editor, complete the following:
   - **Enable Cloud Client:** Select this checkbox to enable the outbound events in the cloud client.
   - **Grid member:** Click **Select** to select a Grid member to execute the outbound cloud client. Click **Clear** to clear the value. You can select any Grid Member where the cloud client must be executed.
   - **Interval**: Specify how often to request outbound events detected in the cloud client in seconds or minutes. This value is set to one minute, by default. The time interval is measured from the previous request cycle.
   - **The list of requested event types:** Select the respective checkbox to enable or disable an event type. The event types that you request from the Cloud Services Portal are listed here. You cannot add or remove them.
3. Save the configuration.

Infoblox Subscriber Services

Important

Infoblox Subscriber Services is not supported in NIOS 8.6.0. Although Subscriber Services is supported in NIOS 8.6.1, Infoblox recommends that you do not use it in this version.

The Infoblox Subscriber Services provides a scalable, enterprise-grade solution that provides visibility to subscriber activities and complete filtering capabilities by combining advanced DNS services with subscriber identification, threat protection policies, and MSP (Multi-Services Proxy). The Infoblox Subscriber Services solution includes the following:

- **Infoblox Subscriber Insight** - Infoblox Subscriber Insight automates the process of identifying infected subscriber devices that are trying to connect to malicious domains. This solution augments the malware incident logs with the subscriber identity information received via RADIUS accounting messages and generates a report to display RPZ violations per subscriber ID. You can also identify subscribers who access specific domains for purposes other than security.
- **Infoblox Subscriber Policy Enforcement** - Infoblox Subscriber Policy Enforcement enables the selection of applicable policies for the subscriber. Policies are any combinations of RPZs. You can use this product to create value-added service plans or packages for different subscribers.
- **Infoblox Subscriber Parental Control** - Infoblox Subscriber Parental Control enables subscribers to manage Internet access and content for their mobility devices, houses, families, or corporations. Subscribers can restrict or allow access to content based on content categories and domains.

This section includes the following topics:

Infoblox Subscriber Insight and Subscriber Policy Enforcement

The Infoblox Subscriber Insight solution provides a mechanism to monitor events related to the subscriber session. This solution allows you to identify subscriber devices, such as laptops, computers, tablets, and smartphones on your data networks that are violating RPZ rules. It can also find the type of domain the subscriber tries to access.

The Infoblox Policy Enforcement solution analyzes the DNS queries, identify subscribers and correlates the information to enforce the subscriber security policies per subscriber.

The solution works by receiving RADIUS accounting messages from a RADIUS server through the NAS (Network Access Server) gateway. The DNS server caches the RADIUS accounting messages, which includes subscriber information and subscriber security policies. The subscriber security policy specifies the RPZs that are applicable for a subscriber. DNS RPZs are used to determine the bad FQDNs. If a subscriber, who has opted for the service, queries an FQDN that is listed in the RPZ, the DNS resolver performs RPZ actions for the subscriber query.

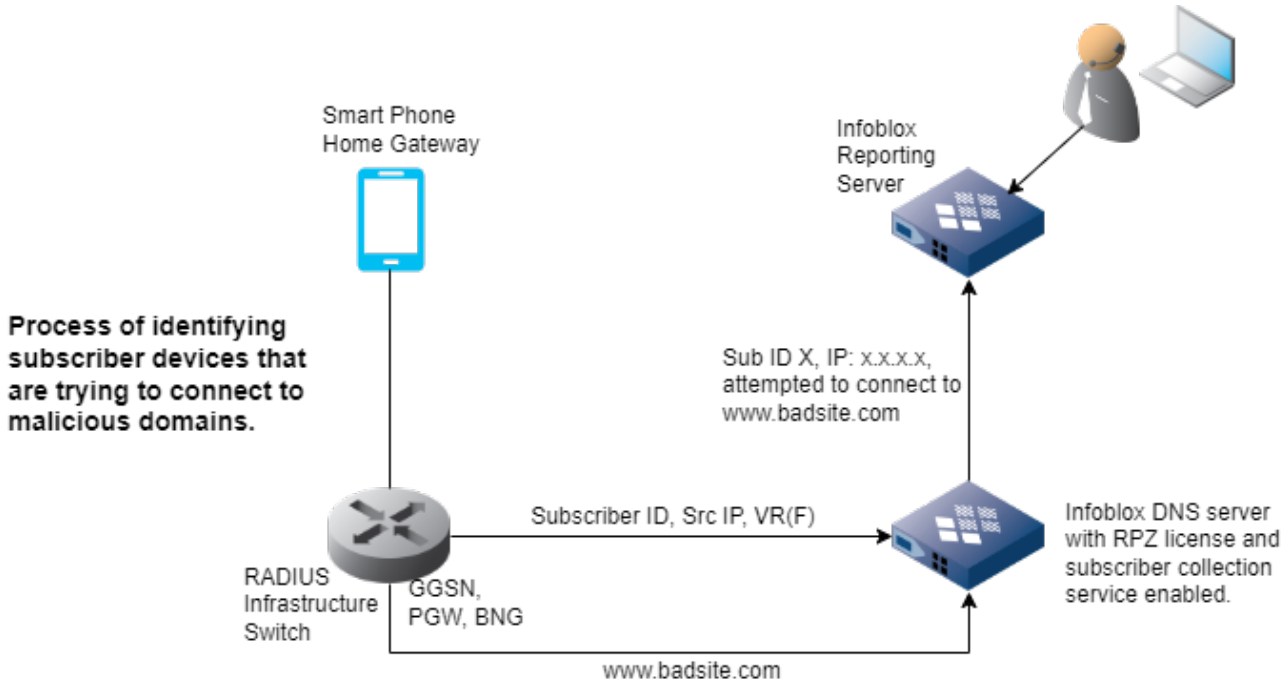
Subscribers behind a home gateway network are identified by their local ID or client ID, which is the MAC address of the subscriber device. The local ID is received by the DNS server as part of the RADIUS accounting message. As all subscribers behind a home gateway network will have the same IP address of the home router, the local ID is used to create separate records for each of the subscribers in the subscriber cache. Each subscriber behind the home gateway network can have their own policy. Note that if a guest connects through a home gateway network, then the default home router policy is applied to the guest device.

The Infoblox Subscriber Insight and Subscriber Policy Enforcement is currently supported on the following Infoblox appliances: IB-1415, IB-1425, IB-2215, IB-2225, PT-1405, PT-2205, IB-4030-10GE, IB-VM-1405, IB-VM-1415, IB-VM-1425, IB-VM-2205, IB-VM-2225, IB-VM-1425, and IB-FLEX. You can enable DNS cache acceleration feature on IB-4030-10GE, and IB-FLEX appliances.

As illustrated in the figure below, the Infoblox DNS member, with subscriber collection service enabled, receives RADIUS accounting messages, which includes subscriber information and the subscriber security policies, through the NAS gateway. The subscriber security policy specifies the RPZs that are applicable for a subscriber. When a subscriber queries an FQDN that is listed in the RPZ, the DNS resolver performs RPZ actions for the subscriber query. The NIOS appliance logs all RPZ related events, conformed to CEF (Common Event Format), in the syslog. The CEF logs include the subscriber identity information, thus identifying the subscribers that are violating RPZ rules. In a Grid with a reporting

server, you can view the *Detailed RPZ Violations by Subscriber ID* report that contains information about RPZ hits by the users. For information about detailed RPZ violations by subscriber ID, see *About Dashboards*.

Infoblox Subscriber Insight and Subscriber Policy Enforcement



License Requirements and Admin Permissions

To configure Infoblox Subscriber Services, you must install the **RPZ** license. But for IB-FLEX members, the **RPZ** license is included in the **FLEX Grid Activation** license. For information about how to install licenses, see *Managing Licenses*.

Only superusers can configure Infoblox Subscriber Services. Limited-access admin groups can perform this operation only if their administrative permissions are defined. For information about administrative permissions, see *About Administrative Permissions*.

Guidelines for Using Infoblox Subscriber Insight and Subscriber Policy Enforcement

Following are some guidelines to take into consideration when using Infoblox Subscriber Threat Insight and Subscriber Policy Enforcement:

- A Grid member can be associated with only one subscriber site.
- The Grid members in the subscriber site must be added as primary or secondary name servers for all RPZs.
- The subscriber collection service does not support an IPv6 only Grid member.
- All NAS gateways in a subscriber site must be configured for IPv4 only and must use the same port.
- The subscriber data is not persistent and will be cleared from the subscriber cache if you stop the subscriber collection service on all the members of a subscriber site.
- The NAS gateways can send the RADIUS accounting messages to only one Grid member (collector member) in a subscriber site.
- Overlapping networks are not supported in the Subscriber Insight and Subscriber Policy Enforcement solutions.

Configuring Infoblox Subscriber Insight and Subscriber Policy Enforcement

To set up Infoblox Subscriber Insight and Subscriber Policy Enforcement, you must install a Grid-wide or a member level **RPZ** license and configure the Grid members to serve recursive DNS queries. Note that for IB-FLEX members, you do

not need to install an **RPZ** license as the **FLEX Grid Activation** license includes the **RPZ** license. You must also configure a subscriber site and add Grid members (collector members and RPZ members) and NAS (Network Access Server) gateways to receive RADIUS accounting messages from a RADIUS server. The RADIUS accounting messages include subscriber information (such as subscriber source IP address, subscriber ID, local ID for networks with overlapping IP addresses) and subscriber security policies. The source IP address, subscriber ID, local ID, and the subscriber security policy is mapped in the DNS cache. The collector member caches the subscriber information and the policies, which are replicated to all Grid members within the subscriber site. The RPZ members in the subscriber site applies policies for incoming subscriber queries and performs RPZ actions.

The DNS Cache Acceleration processes incoming EDNS0 packets that contains the local ID. The NIOS appliance matches the local ID against the DNS server as part of the RADIUS accounting message and populates the subscriber cache in DNS Cache Acceleration with the parental control policy information. The DNS Cache Acceleration answers all queries that comes from the DNS Cache Acceleration for each of these subscribers listed in the subscriber cache. These changes are valid for individual IP addresses with local ID only and the subnet local ID is considered as 0. For more information, see *Using the NIOS CLI* and for viewing the DNS accelerator cache, *Clearing DNS Cache* in the *Infoblox DNS Cache Acceleration Administrator Guide*.

Note the following while configuring Infoblox Subscriber Insight and Subscriber Policy Enforcement:

- You can configure up to a total of 32 RPZs in the default view and set the priorities for the RPZs. Subscribers with subscriber security policies can set the policy to any of the 32 RPZs and the RPZs are applied to selective subscribers depending on the subscriber security policies. But for subscribers who have not opted for the service, only the first five (top priority) RPZs are applied. Note that once the first hit matches, the rest of the RPZs will not be looked up.
- For DNS queries received from unknown subscriber source IP addresses, the DNS server processes the queries based on the standard DNS query processing.

To configure the Infoblox Subscriber Insight and Subscriber Policy Enforcement on supported Infoblox appliances, complete the following:

1. Obtain and install a valid Grid-wide or member level **RPZ** license. But for IB-FLEX members, the **RPZ** license is included in the **FLEX Grid Activation** license. For information about licenses, see License Requirements and Admin Permissions below. You can also configure a reporting appliance in the Grid to see subscriber reports that contain statistics about RPZ related events.
2. Configure admin permissions so admin users can manage the Infoblox Subscriber Service related tasks. For information about how to configure admin permission, see *About Administrative Permissions*.
3. Create a subscriber site with at least one Grid member and a NAS gateway. For information, see *Adding Subscriber Sites*. It is recommended to add more than one Grid member to the subscriber site for redundancy. You can add a maximum of five Grid members to the subscriber site.
4. Start the subscriber collection service on all the members in the subscriber site, as described in Starting and Stopping the Subscriber Collection Service below.
5. Create RPZs in the default DNS view and specify the order of RPZs. Note that only the default DNS view is supported for configuring RPZs for Subscriber Services. For information about creating RPZs, see *Configuring Local RPZs*. For information about specifying the order of RPZs, see *Reordering RPZs*. You can create a total of 32 RPZs. Subscribers with subscriber security policies can set the policy to any combination of the 32 RPZs and the RPZs are applied to selective subscribers depending on the subscriber security policies. But for subscribers who have not opted for the service, only the first five (top priority) RPZs are applied. The NAS gateways must provide the subscriber security policies that enable the selection of RPZs applicable for the subscriber.
6. Enable all the members in the Grid to respond to recursive queries, as described in *Enabling Recursive Queries*.
7. Enable RPZ logging in the *Member DNS Properties* editor for each member of the subscriber site, to ensure that all events related to RPZ are logged to the syslog. Note that you can also enable logging of queries and responses, but it might significantly affect system performance. For information about how to set logging categories, see *Using a Syslog Server*.
8. After completing the DNS configuration on the Grid members, start the DNS service on the Grid members. For information about how to start and stop the DNS service, see *Starting and Stopping the Discovery Service*. Ensure that you enable IPv6 on the Grid members to support IPv6 subscribers. For information, see *Configuring IPv6 on a Grid Member*.

9. Add AVPs that are not available in the list of predefined AVPs. For information, see *Adding AVPs*.
10. Configure the subscriber ID settings to associate an AVP with the subscriber in the Subscriber Services Properties editor, as described in Configuring Subscriber Services Properties below.

After you set up the Infoblox Subscriber Insight and Subscriber Policy Enforcement, you can do the following:

- View the subscriber sites, as described in *Viewing Subscriber Sites*.
- View the NAS gateway message rates for the accounting servers of the subscriber site, as described in *Viewing NAS Gateway Message Rates*.
- Monitor RPZ related events and subscriber policy violations using predefined reports and the syslog, as described in *Monitoring Subscriber Policy Violations*.
- Configure Infoblox Subscriber Parental Control solution, as described in *Infoblox Subscriber Parental Control*.

Starting and Stopping the Subscriber Collection Service

To start the subscriber collection service, you must have at least one **RPZ** license installed (it can be a Grid-wide license or a member-level license.) You can also stop the service when necessary.

To start or stop the subscriber collection service:

1. From the **Grid** tab -> **Grid Manager** tab -> **Services** tab, click the **Subscriber Collection** link. Grid Manager displays only the members that are running the subscriber collection service. Select the member checkbox.
2. From the Toolbar, click **Start** to start the service or **Stop** to stop the service.

> ⚠ Note
>
> The subscriber data is not persistent and will be cleared from the subscriber cache if you stop the subscriber collection service on all the members of a subscriber site.

Configuring Subscriber Services Properties

To configure the subscriber services properties:

1. From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab, expand the Toolbar and click **Subscriber Services Properties**.
2. In the **General** tab, complete the following:

- **Subscriber ID**: Select the AVP that you want to use as the subscriber ID. Depending on the AVP you select in this field, the appliance extracts those AVPs from the RADIUS accounting messages. All the sites in the Grid will use the AVP selected in this field as the subscriber ID. You can select one of the following AVPs from the drop-down list: APN, Calling-Station-Id, Class, IMEI, IMSI, MSISDN, and User-Name.
  Note that for subscribers who have opted for Parental Control service, you can select Calling-Station-Id as the subscriber ID for mobile networks and for fixed line, you can select User-Name as the subscriber ID.
- **REGEX for Subscriber ID data extraction**: Specify the regular expression for subscriber ID if you want to extract specific data from the RADIUS accounting messages. The regular expression can contain as many sub-expression groups that you may specify in the next field.
- **Subexpression**: Choose a number of the sub-expression groups from the drop-down list. If the sub-expression is set to zero, then the text matching the entire regular expression is used for data extraction. If it is non-zero, then the REGEX must contain at least that many sub-expression groups.
- **Alternate Subscriber ID**: Select the AVP that you want to use as the alternate subscriber ID. For example, the alternate subscriber ID can be used to identify the fixed line or home gateway router. Depending on the AVP you select in this field, the appliance extracts those AVPs from the RADIUS accounting messages. All the sites in the Grid will use the AVP selected in this field as the alternate subscriber ID. Note that the alternate subscriber ID configuration will override the subscriber ID configuration when both the AVPs are available in the RADIUS account messages.
  You can select one of the following AVPs from the drop-down list: APN, Calling-Station-Id, Class, IMEI, IMSI,

MSISDN, and User-Name. Note that for subscribers who have opted for Parental Control service, you can select User-Name as the alternate subscriber ID.

- **REGEX for Alternate Subscriber ID data extraction**: Specify the regular expression for alternate subscriber ID if you want to extract specific data from the RADIUS accounting messages. The regular expression can contain as many sub-expression groups that you may specify in the next field.
- **Subexpression**: Choose a number of the sub-expression groups from the drop-down list. If the sub-expression is set to zero, then the text matching the entire regular expression is used for data extraction. If it is non-zero, then the REGEX must contain at least that many sub-expression groups.
- **Local ID**: Select **LocalId** AVP from the drop-down list to identify subscribers behind a gateway. For example, a home gateway. Each device behind the home gateway network is identified by their local ID/ client ID which is the MAC address of the subscriber device. The appliance extracts the local ID/client ID from the RADIUS accounting messages. Note that for subscribers who have opted for Parental Control service, must select **LocalID** AVP.
  The home gateway router attaches the MAC address of the host in an EDNS0 option to DNS query request. The DNS Cache Acceleration extracts the EDNS0 option and uses the value to look up for the relevant policy. The client identification information defined in dnsmasq version 2.78 is used to determine the client ID. The MAC address can only be added if the requestor is on the same subnet as the dnsmasq server. Note that the mechanism used to achieve this (an EDNS0 option) is not yet standardized, so this should be considered experimental. Also, note that exposing MAC addresses in this way may have security and privacy implications.
- **REGEX for Local ID data extraction**: Specify the regular expression for local ID if you want to extract specific data from the RADIUS accounting messages. The regular expression can contain as many sub-expression groups that you may specify in the next field.
- **Subexpression**: Choose a number of the sub-expression groups from the drop-down list. If the sub-expression is set to zero, then the text matching the entire regular expression is used for data extraction. If it is non-zero, then the REGEX must contain at least that many sub-expression groups.
- **IPv6 Anchor IP Address**: The ordered list of IPv6 anchor IP address AVP precedence. Note that you cannot modify the IPv6 anchor list, but you can change the order of the list.
- **Subexpression**: Choose a number of the sub-expression groups from the drop-down list. If the sub-expression is set to zero, then the text matching the entire regular expression is used for data extraction. If it is non-zero, then the REGEX must contain at least that many sub-expression groups.
- **NAS Contextual Information**: Select one of the following from the drop-down list: APN, NAS-IP-Address, NAS-IPv6-Address, NAS-Identifier, NAS-Port, or NAS-Port-Identifier.
- **Ancillary Fields**: You can select a list of ordered AVP ancillary fields. Select an ancillary field from the Available column and click the right arrow to move it to the **Selected** column.
- **Interim Accounting Interval**: Specify the time interval in minutes for the RADIUS accounting data to be fully populated in the subscriber collector. The Subscriber Service must be active (green state) before Anycast can serve. The green state is dependent on the value you specify in the Interim Accounting Interval field. That is, the time interval that the subscriber cache has been processing accounting RADIUS messages. RAIUS must send a START or an UPDATE accounting message for every active subscriber during the interim accounting interval. Once this interval passes, the cache is considered fully populated and then Anycast is allowed to serve. If Parental Control is enabled, Anycast needs to wait for the category database to be available before it is allowed to serve. Anycast is allowed to serve only if the Subscriber Service is green. If the Subscriber Service is yellow, it means that either the interim accounting interval has not passed, or that the category database is not available. Note that if you have configured DNS Anycast for the Grid member, then DNS Anycast is disabled for the member during the interim accounting interval.
- **Collect on the MGMT interface only**: Select this checkbox if you want the NAS RADIUS traffic to be accepted over the MGMT interface only.

Device Handling Performance Optimization for NIOS Subscriber Cache

The NIOS subscriber cache supports various subscribers, including mobile devices, households (CPEs), and devices behind each CPE. The devices behind a CPE include registered devices with policies provisioned or unregistered devices without policies in the Harmony database. Mobile devices and CPEs are classified as provisioned devices.

In NIOS, provisioned devices are not allowed in the Least Recently Used (LRU) classification, but all other devices including unregistered active devices can be allowed in the LRU. The devices in the LRU classification are not subject to garbage collection, and will be deleted as they age due inactivity. Unregistered devices are deleted first based on the LRU classification, to prevent the subscriber's cache from exceeding its limit.

The Harmony database accepts the NIOS modifications for more efficient use of the NIOS cache. Device handling performance optimization optimizes the use of NIOS subscriber cache by updating only the provisioned devices to NIOS thereby reducing the number of devices delivered to the NIOS cache.

Infoblox Subscriber Parental Control

The Infoblox Subscriber Parental Control provides a mechanism to enable subscribers to manage Internet access and content for their mobility devices, houses, families, or corporations based on the content categories and domains. This helps in restricting users from accessing certain specific content, especially restrict children from accessing specific websites, that are deemed inappropriate. Each subscriber who has opted for the service must be associated with a filtering profile that includes the categories to be blocked for the subscriber session. You can use the pre-defined profiles that address different population segments (such as child, youth, young adults, etc.) or you can create custom profiles for each subscriber in the Infoblox Subscriber Interface. For example, you can define profiles, such as to block children from accessing gambling websites, allow access to educational websites, and monitor access to entertainment websites. You can define profiles for a specific time of the day and for a specific duration. For example, parents can block children from accessing gaming websites from 7.00 AM to 9.00 PM every day. RPZs are used to perform content filtering for the subscribers who have opted for the service. Whenever a subscriber query matches the content of any RPZ, flagged by the blocked category, the traffic is blocked and redirected to the blocking VIP addresses.

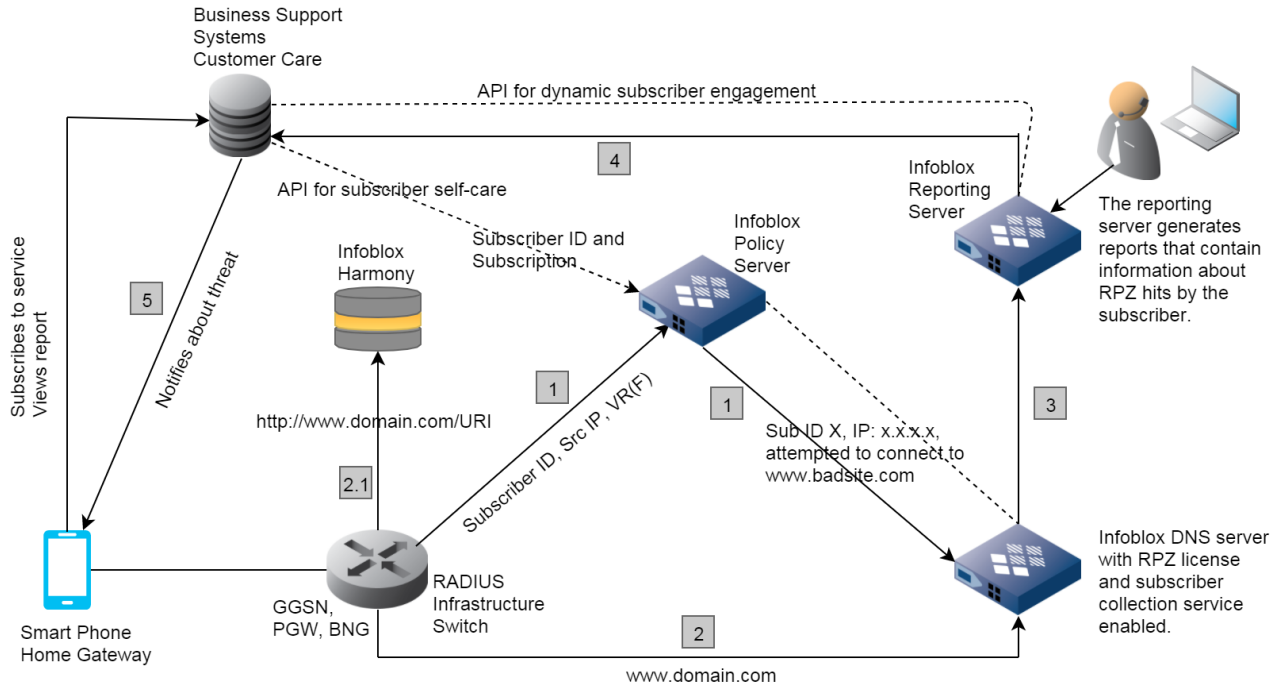
You can also add exceptions for the blocked or allowed categories for each profile or policy in the Infoblox Subscriber Interface. For example, you can block gambling websites but allow casino.com or allow alcohol websites but block vodka.com. You can add a maximum of 10 domains each to the blacklist and whitelist domains for each subscriber. The subscriber query is matched with the blacklist and whitelist domains and appropriate action is taken. If a query is matched with a blacklisted domain, the query is redirected to the blocking server and if a query is matched with a whitelisted domain, the query is resolved normally.

The Infoblox Subscriber Parental Control is currently supported on the following Infoblox appliances: IB-1415, IB-1425, IB-2215, IB-2225, PT-1405, PT-2205, IB-4030-10GE, IB-VM-1405, IB-VM-1415, IB-VM-1425, IB-VM-2205, IB-VM-2225, IB-VM-1425, and IB-FLEX.

As illustrated in the following Infoblox Subscriber Parental Control figure, the DNS server receives RADIUS accounting messages and AVPs (Attribute Value Pairs) from the Infoblox Harmony product. For information about Infoblox Harmony product, refer to Infoblox Harmony documentation. The AVP includes the policy vector that defines the blocked categories and domains for the subscribers who has opted for the service. RPZs perform the filtering of content for these subscribers by applying the parental control policies on incoming subscriber queries. The appliance either allows or blocks the traffic based on the parental control policies. The blocked traffic might also be redirected to the MSP server for evaluation of the traffic. When the traffic is blocked, a blocking page is displayed to the subscriber describing the reason for blocking the traffic. The parental control policies are configured on the Infoblox Harmony product using the Infoblox Subscriber Interface and the policies can have an expiration date.

The NIOS appliance logs all parental control related events, conformed to CEF (Common Event Format), in the syslog. You can get information about the hit when users try to access one of those websites on the blocking list. The reporting server in the Grid generates corresponding reports that contain statistics about parental control related events. For information about monitoring parental control hits by users, see *Monitoring Subscriber Policy Violations*.

Infoblox Subscriber Parental Control



Note:
2.1: DNS resolves to proxy if blocking is needed or if URI inspection is needed.
3: RPZ/PC logs sent to the reporting server for analytics.

Guidelines for Using Infoblox Subscriber Parental Control

Following are some guidelines to take into consideration when using Infoblox Subscriber Parental Control:

- Infoblox recommends that you configure Infoblox Subscriber Parental Control only on appliances that have a disk size greater than 250 GB.
- You must configure the subscriber collection service and ensure that it is running properly in order to enable Infoblox Subscriber Parental Control.
- The appliance processes DNS queries using the standard DNS query processing, for unknown subscribers.
- You must restart the DNS service after you enable or disable the Subscriber Parental Control.
- To enable Subscriber Parental Control, the Infoblox Harmony product is required. You must configure a DTC (DNS Traffic Control) health monitor to monitor the health of the Infoblox Harmony product.
- Enabling Subscriber Parental Control automatically creates an authoritative zone in the default DNS view with A, AAAA, and CNAME records for Infoblox Harmony and the blocking VIP addresses.
- Deleting a record from the parental control authoritative zone can lead to a service interruption.
- If you make any changes to the parental control policy configuration in the Infoblox Subscriber Interface, it might take up to 15 minutes for the changes to take effect.

Configuring Infoblox Subscriber Parental Control

To enable and configure Infoblox Subscriber Parental Control on the supported Infoblox appliances, complete the following:

1. Obtain and install a valid Grid-wide or member level **RPZ** license. But for IB-FLEX members, the **RPZ** license is included in the **FLEX Grid Activation** license. For information about licenses license requirements and admin permissions, see *Infoblox Subscriber Insight and Subscriber Policy Enforcement*. You can also configure a reporting appliance in the Grid to generate reports that contain statistics about RPZ related events.
2. Configure admin permissions so admin users can manage the Infoblox Subscriber Service related tasks. For information about how to configure admin permission, see *About Administrative Permissions*.

3. Create a subscriber site with at least one Grid member. For information about adding subscriber sites, see *Scaling Using Subscriber Sites*. It is recommended to add more than one Grid member to the subscriber site for redundancy. You can add a maximum of five Grid members to the subscriber site.
4. Start the subscriber collection service on all the members in the subscriber site, as described in starting and stopping the subscriber collection service, see *Infoblox Subscriber Insight Policy*.
5. Create RPZs in the default DNS view and specify the order of RPZs. Note that only the default DNS view is supported for configuring RPZs for Subscriber Services. For information about creating RPZs, see *Configuring Local RPZs*. For information about specifying the order of RPZs and Reordering RPZs, see *Managing RPZs*. You can create a total of 32 RPZs, out of which the first five RPZs are employed for DNS Firewall and are applied to all DNS lookups. The rest of the RPZs are applied to selective subscribers depending on the policies. The parental control policies received from Infoblox Harmony enables the selection of the RPZs applicable for the subscribers.
6. Enable all the members in the Grid to respond to recursive queries, as described in *Enabling Recursive Queries*. Add a forwarder and enable **Use Forwarders Only** option in the **Forwarders** tab of the *Member DNS Properties* editor.
7. Enable RPZ logging in the *Member DNS Properties* editor for each member of the site, to ensure that all events related to RPZ are logged to the Syslog. Note that you can also enable logging of queries and responses, but it might significantly affect system performance. For information about how to set DNS logging categories, see *Using a Syslog Server*.
8. After completing the DNS configuration on the Grid members, start the DNS service on the Grid members. For information about how to start and stop the DNS service, see *Starting and Stopping the DNS Service*. Note that you ensure to enable IPv6 on the Grid members to support IPv6 subscribers. For information about configuring IPv6 on a Grid Member, see *Understanding DNS for IPv6*.
9. You can add AVPs that are not available in the list of predefined AVPs. For information about adding AVPS, see *Managing AVPs (Attribute Value Pairs).*
10. Configure the subscriber ID settings to associate an AVP with the subscriber in the *Subscriber Services Properties* editor, as described in the Configuring Subscriber Services Properties, see *Infoblox Subscriber Insight Policy Enforcement*.
11. Enable Subscriber Parental Control in the *Subscriber Services Properties* editor, as described in Enabling Subscriber Parental Control below.
12. Configure the blocking VIP addresses and add IP addresses of the policy management server in the **Parental Control** tab of the *Subscriber Site Properties* editor for each subscriber site. For information about Modifying Subscriber Sites, see *Scaling Using Subscriber Sites*.
13. Define subscriber profiles and subscriber policies on the Infoblox Harmony product using Infoblox Subscriber Interface. For information, refer to Infoblox Harmony documentation.
14. Assign subscriber profile and subscriber policy for each subscriber who has opted for the service in the Infoblox Subscriber Interface. For information, refer to Infoblox Harmony documentation.
15. Publish parental control policies in the Infoblox Subscriber Interface. For information, refer to Infoblox Harmony documentation.

After you set up the Infoblox Subscriber Parental Control, you can monitor parental control related events using predefined reports and the syslog, as described in *Monitoring Subscriber Policy Violations*.

> ⚠ **Note**
>
> If the subscriber site has HA and the HA passive node is the first to upgrade, the data repository connectivity uses the IPv4 protocol for the site members. If you want the data repository to be connected over the IPv6 protocol, you must stop and restart the subscriber service in the upgraded Grid. The subscriber data is lost when the service is stopped and restarted. It is recommended to stop/start the service of each member at a time to synchronize the subscriber cache with the next active member on the same site.

Enabling Subscriber Parental Control

To enable Subscriber Parental Control, you must ensure that the subscriber collection service is configured and is running properly. After enabling Subscriber Parental Control, you must add Parental Control blocking VIP addresses and add at least one MSP server to the subscriber site. For information about adding Parental Control blocking IP addresses

and MSP addresses to the subscriber site and Modifying Subscriber Sites, see *Scaling Using Subscriber Sites*. Enabling Subscriber Parental Control, automatically creates an authoritative zone in the default DNS view with A, AAAA, and CNAME records for the MSP and the blocking VIP addresses.

> **Note**
>
> You can disable Subscriber Parental Control only when all the Parental Control blocking VIP addresses and the MSP addresses in all the subscriber sites are removed.

To enable Infoblox Subscriber Parental Control:

1. From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab, expand the Toolbar and click **Subscriber Services Properties**.
2. In the **Parental Control** tab, complete the following:
    - **Enable Parental Control**: Select this checkbox to enable Subscriber Parental Control globally.
    - **Category Information**: Complete the following to add information about the server for the category feed: Contact Infoblox Technical Support for the category feed account information.
        - **User Name**: Enter the logon name of the user.
        - **User Password**: Enter the password of the user.
        - **Server URL**: Enter the URL of the categorization feed server for the category feed.
        - **Update Interval in hours**: You can specify the time interval in hours that determines how often the category information is updated.
    - **Category Proxy**: Complete the following to add information about the proxy server for the category feed.
        - **Proxy URL**: Enter the URL of the proxy server for the category feed.
        - **Proxy User Name**: Enter the logon name of the user.
        - **Proxy User Password**: Enter the password of the user.
    - **Local Zone Name**: Enter the name of a local authoritative zone in the **Name** field.

Scaling Using Subscriber Sites

You can create subscriber sites and add a Grid member as a collector member and RPZ members to the site in order to scale the number of subscribers that the system can support. The subscriber collector caches the subscriber data received from the NAS gateways and parental control policies the from Infoblox Harmony product. The RPZ members use the cached subscriber data and the policies to resolve DNS queries. You can add a maximum of five Grid members to the subscriber site. Note that one Grid member can serve only one subscriber site. The subscriber identity information cached in the subscriber cache is replicated between the Grid members in the subscriber site.

You can configure the NAT port as an IPSD, where the subscribers first deterministic NAT port is used as IPSD, to distinguish from other subscribers using the same IP address. The NAT algorithms use the port range allocation where the first usable port for the subscriber is provided in a RADIUS accounting AVP. It also supports the first port in the range as a discriminator between subscribers using the same IP address. In a strict NAT configuration, where only the NATed subscribers are allowed, the value of the AVP **Deterministic NAT port** must be a non zero value in the RADIUS accounting message. The ports from 1-1023 (inclusive) are reserved in a deterministic port configuration.

You can manage the subscriber sites as discussed in the following sections:

- *Adding Subscriber Sites*
- *Bypassing Subscriber Secure Policy for Allowed Lists*
- *Modifying Subscriber Sites*
- *Deleting Subscriber Sites*
- *Viewing Subscriber Sites*
- *Viewing NAS Gateway Message Rates*

Additionally, you can Import subscriber site data by using the **CSV Import** option on the Toolbar.

Limitations using NAT port as IPSD

- No acceleration support using SNIC appliances, however, it is supported for all appliances including vDCA acceleration.
- You need to restart the DNS service.
- IPSD is a global configuration that applies to all Sites. IPSD may be set from CSV, WAPI, and CLI to a different AVP.
- A performance penalty for Dynamic subscribers (without Deterministic-Nat-Port AVP) in Deterministic Sites (Sites with block_size configuration) requires two lookups.
- NAT port can be configured as IPSD only if the subscriber services properties is set to **Deterministic-Nat-Port** and block size must be greater than zero.
- The site block size must be the same as the deployment CGNAT block size configuration.
- Changing the site block size will initialize the state of the subscriber collection.
- Static default network policies in a strict NAT configuration (Allow NATed Subscribers only) will not resolve at the DCA.

Adding Subscriber Sites

To add a subscriber site, complete the following:

1. From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab -> **Subscriber Sites** tab, click the Add icon.
2. In the *Add Subscriber Site* wizard, complete the following:
    a. **Name**: Enter the name of the subscriber site.
    b. **Maximum Subscribers**: Specify the maximum number of subscribers for the subscriber site. This represents the overall size of the subscriber cache. You can enter a value between 10000 to 10000000.
    c. **Comment**: You can enter additional information about the subscriber site.
    d. **Members**: In the Members table, click the Add icon to add Grid members to the site. If there are multiple members, the *Member Selector* dialog box is displayed, from which you can select a member. Click the required member name in the dialog box. You can also delete a member from the list.
    Note that a Grid member can support only one subscriber site.
    e. **Deterministic NAT Block Size**: The block size specifies the number of ports made available for each incoming subscriber address. In a deterministic NAT, zero means not using NAT. The value can be any number from 0 to 64512. The block size configuration is not allowed to change unless the global (subscriber service properties) IPSD is set to Deterministic-NAT-Port.
    f. **First port**: The value of the first usable port for the subscriber. The first usable port will have a default value of 1024, and the value can be any number from 1024 to 65535, both inclusive.
    g. **Allow NATed Subscribers only**: Select this option to restrict only NATed subscribers (Subscribers with IPSD). Here the IP address and port block allocations are made dynamically for the subscriber instance and the IPSD of the first port is assigned to the subscriber port block. For example, if the block size is 8 for the site, then the IPSD must be set to 1024, 2032, 3040, etc.
    Stop the anycast service when the subscriber service is in the interim state: Select this option to stop the anycast service from running when the subscriber service is in the interim state. By default, this option is selected.
3. Click **Next** to configure NAS gateways for the subscriber site. Complete the following
    a. **Listen on RADIUS port number**: Enter the UDP port number that the collector member uses to collect accounting information from the NAS gateway. You can enter an integer from 1 to 65535. The default is 1813.
    b. **NAS Gateways**: You must add at least one NAS gateway to the subscriber site in order to start the subscriber collection service. You can add up to 20 NAS gateways. Click the Add icon and complete the following to add a NAS gateway:
        i. **Name**: Enter the name of the NAS gateway.
        ii. **IP Address**: Enter the IP address of the NAS gateway.
        iii. **Shared Secret**: Enter a shared secret that can be used to authenticate the communication between the RADIUS accounting server and the collector member. This shared secret must match the one you entered on the RADIUS server.
        iv. **Confirm Shared Secret**: Enter the shared secret again.

v. **Send Protocol Acknowledgment**: Select this checkbox to send an acknowledgment to the client when the collector member receives accounting information from the NAS gateway.
vi. **Comment**: Enter additional information about the NAS gateway.
vii. Click **Add** to add the NAS gateway.
You can select a NAS gateway configuration and click the Edit icon to modify it or click the Delete icon to delete it.

4. *This step is required only if Infoblox Subscriber Parental Control is enabled*. For information about enabling Parental Control, see *Infoblox Subscriber Parental Control*. Click **Next** to configure the parental control blocking IP addresses. Complete the following:
   a. **Content Proxy Addresses**: You can add IP addresses of the Infoblox Harmony product. The appliance will forward the subscriber session to Infoblox Harmony for in-line processing of the subscriber session, depending on the policies. Click the Add icon. Grid Manager adds a row to the **Content Proxy Addresses** table. It is recommended that you enter two addresses in this field. The first address is considered the primary address and the second address is considered the secondary address. If you enter only one address, the same address is considered the primary and secondary address. Click the row and enter the IP address in the **Address** field. To delete an IP address, select the checkbox and then click the Delete icon.
   b. **Enforce the global proxy list**: Select this checkbox if you want to proxy the traffic to the MSP (Multi-Services Proxy) server. If you select this checkbox, and have categorized the queried domains in the incoming traffic to the global proxy list using the `set pc_domain add` command (category 104), then the query resolves to an MSP virtual IP address and NIOS generates a "synthetic resolution". This checkbox is disabled by default, and you must configure **Content Proxy Addresses** to enable it. If you do not select this checkbox, then the query resolves normally.
   Notes:
      - If you have configured queries to specific domains (categorized to 104) to be proxied to the MSP server and enabled the **Enforce the global proxy list** option, queries to these domains are proxied if subscriber secure policies with the NXDOMAIN rule are not set.
      - If you want to enable and run DNS over TLS, DNS over HTTPS, and Parental Control features simultaneously on a member, ensure that the appliance meets the base memory configuration requirements defined in *Configuration Requirements*. If you try to run these features when the required memory configuration is not available, all of these features will be disabled.
   c. **Additional Blocking Servers**: Besides the IP addresses you specify in the Parental Control Blocking IP Addresses fields, you can specify additional IP addresses that will act as blocking servers for the blocking policies you defined when *configuring blocking server policies*. Click the Add icon. Grid Manager adds a row to the **Additional Blocking Servers** table. Click the row and select a blocking policy. In the **Address** field, enter the IP address of the blocking server that will contain the selected blocking policy. To delete an IP address, select the checkbox and then click the Delete icon.
   d. **Parental Control Blocking IP Addresses**: You can configure two sets of IPv4 and IPv6 addresses that are used as blocking VIP addresses. The parental control subscribers are redirected to the following blocking IP addresses whenever the domain queried by the subscriber is blocked based in the subscriber parental control policy.
   Complete the following:
      i. **IPv4 Address (primary)**: Enter the primary blocking IPv4 address.
      ii. **IPv4 Address (secondary)**: Enter the secondary blocking IPv4 address.
      iii. **IPv6 Address (primary)**: Enter the primary blocking IPv6 address.
      iv. **IPv6 Address (secondary)**: Enter the secondary blocking IPv6 address.
   e. **Policy Management Addresses**: You can add IP addresses of the policy management servers to which the appliance sends APIs about the expired parental control policies. Click the Add icon. Grid Manager adds a row to the **Policy Management Addresses** table. Click the row and enter the IP address in the **Address** field. To delete an IP address, select the checkbox and then click the Delete icon
5. Save the configuration, or click **Next** to continue to the next step where you define extensible attributes as described in *Managing Extensible Attributes*.

Bypassing Subscriber Secure Policy for Allowed Lists

You can choose to let subscriber specific allowed domains to take priority over category-based policies, security policies and blocklist entries. Subscriber specific blocked domains take priority over category-based policies.

To bypass subscriber secure policy for allowed lists:

1. Navigate to the **Data Management** > **DNS** > **Subscriber Services Deployment** > **Subscriber Sites** tab.
2. Click the Edit icon to edit an existing subscriber site.
3. In the *Subscriber Site Properties* wizard, go to the **General** > **Advanced** tab.
    - **Enable Subscriber Secure Policy Bypass for Allowed list:** Select this checkbox to enable NIOS to generate a normal response for all domains in a subscriber's allow list. The allowed domains override RPZ rules if any (for example, NXDOMAIN), and categorize policy rules for the subscriber. This enables subscribers to override all policies for a specific domain. The subscribers allow list domain is cached in DNS Cache Acceleration and subsequent queries are answered by DNS Cache Acceleration.
      Note that the vDCA (virtual DNS Cache Acceleration) allows only 5% of its total number of subscribers to have allow block lists. The maximum number of allowed and blocked domains is 15. Domains in a subscriber’s blocked list take priority over category-based policies subject to RPZ rules. This ensures that the RPZ global allow list is always enforced. That is, a subscriber cannot override a domain in the global allow list.
    - **Set Global Allow List RPZ index range (0 to 30)**: Select this checkbox to specify an RPZ index value between 0 to 30. A domain is added to the RPZ specified as a passthru RPZ rule, and that domain is added as a global allowed list. This global allowed list is applicable to all subscribers.
      You can use both the **Enable Subscriber Secure Policy Bypass for Allowed list** and the **Set Global Allow List RPZ index range** options at the same time. Or you can choose to use the options independently irrespective of whether **Enable Subscriber Secure Policy Bypass for Allowed list** is enabled or disabled.

Modifying Subscriber Sites

To modify a subscriber site, complete the following:

1. From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab -> **Subscriber Sites** tab, click the **Action** icon next to the subscriber site name and select **Edit** from the menu.
2. The *Subscriber Site Properties* editor provides the following tabs from which you can modify data:
    a. In the **General** tab, you can modify the information you previously entered through the *Add Subscriber Site* wizard.
    Note that If the Grid Manager is IPv4-only and Grid members are IPv6 or dual-stack, modifying subscriber sites may not clear the subscriber cache. Import and export of subscriber data may also not work.
    b. In the **NAS Gateways** tab, you can edit the NAS gateways configured for the subscriber site, as described in the *Adding Subscriber Sites* section.
    Note that If you make any changes to the NAS gateway configuration, the subscriber collector will automatically restart within 30 seconds. However, the subscriber data collected in the subscriber cache is not affected by the NAS gateway configuration changes.
    c. If Subscriber Parental Control is enabled, the **Parental Control** tab is displayed. You can modify the information in the **Parental Control** tab, as described in the section Adding Subscriber Sites above.
        i. **Enable DCA subscriber Query count logging**: Select this checkbox to allow the DCA to generate subscriber logs and to record query counts greater than or equal to zero for subscriber query count updates and deletions. These logs are generated for deletions even when the query count is equal to zero. By default, this option is disabled.
        ii. **Enable DCA subscriber Allowed & Blocked list support**: Select this checkbox to support the blocked and allowed list of subscribers. This option is disabled by default. Once the domain is cached, the blocked lists are provided by DCA. Domains in the allowed list are transferred to BIND. There are several members on the site, but the memory requirement is 32GB or higher for all the vDCA capable members. You must manually restart NIOS after selecting this checkbox for the support to be successful.
        Notes:

- The allowed and blocked listing feature allows you to specify all possible top-level domains, (for example, *http://linkedin.com* , *linkedin.co.uk*) for well-known names. If a dotless name such as "facebook" is in the allowed list or blocked list and the qname is facebook.<suffix>, then:
    - If the suffix is a top-level domain (example "xxxyyy"), the two are matched regardless of whether "xxxyyy" is registered or not in the worldwide DNS.
      Example:
      facebook == *http://facebook.com*
      facebook == facebook.xxxyyy
    - If the suffix is not a top-level domain (example "xxx.yyy"), whether the two are matched or not depends on whether "xxx.yyy" is registered and present in the public_suffix_list.dat on the appliance or not.
      Example:
      facebook == *facebook.co.uk*
      facebook != facebook.xxx.yyy
- If you remove a policy from the Proxy-All allow list, wait for the time to leave (TTL) setting that is configured in DNS Cache Acceleration to expire, for the subscriber policy to work correctly.
- If a zvelo category database update failure occurs for three consecutive days:
    - Grid Manager displays a yellow background with the "Please correct the download credentials or the proxy configuration to get the latest database updates" message and the member status is displayed as "Domain category db is not latest" in the **Grid Manager** >**Subscriber Collection** > **Services**> **Service Status** column.
    - A new SNMP trap is sent with the message "Domain category db is not latest". Additionally, if email notifications are configured, an email is sent to the configured email address with the "Domain category db is not latest" message.
    - Post this event, if the zvelo download is successful, a new SNMP clear trap is sent, and an email with the “zvelo SNMP Clear Trap” message is also sent. The **Service Status** column is on green background will be displayed in Green with the “Subscriber Collection Service is working” message.
- If a zvelo category database update failure occurs for more than 60 days:
    - Grid Manager displays a red background with the "zvelo database expired. Subscriber secure queries will be fail-open" message and the member status is displayed as "zvelo db has expired" in the **Grid Manager** > **Subscriber Collection** > **Services** > **Service Status** column.
    - A new SNMP trap is sent with the "zvelo db has expired" message. Additionally, if email notifications are configured, an email is sent to the configured email address, with the "zvelo db has expired" message.
    - Post this event, if the zvelo download is successful, a new SNMP clear trap is sent, and an email with the “zvelo SNMP Clear Trap” message is also sent. The **Service Status** column is on green background will be displayed in Green with the “Subscriber Collection Service is working” message.
- If you have not downloaded the zvelo database earlier:
    - If the zvelo database download fails for 3 consecutive days, a critical SNMP trap is sent, and “Domain category db is not latest“ is displayed as the member status instead of “Category information data is unavailable“.
    - If the zvelo database download fails for 60 consecutive days, a critical SNMP trap is sent, and “Domain category db is expired“ is displayed as the member status instead of “Category information data is unavailable“.

d. You can enter or edit information in the **Extensible Attributes** tab, as described in *Managing Extensible Attributes*.
e. You can export subscriber site data into a CSV file by selecting the **Export** option. For more information, see *Importing and Exporting Data using CSV Import.*

3. Save the configuration.

Deleting Subscriber Sites

To delete a subscriber site, complete the following:

From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab -> **Subscriber Sites** tab, click the Action icon next to the subscriber site name and select **Delete** from the menu.

In the *Delete Confirmation (Subscriber Site)* dialog box, click **Yes**.

Viewing Subscriber Sites

To view subscriber sites, complete the following:

From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab -> **Subscriber Sites** tab.

Grid Manager displays the following information for each subscriber site:

1. **Actions**: Click the Action icon next to a selected subscriber site and choose from the following:
    a. **Edit**: Modify certain general properties.
    b. **Delete**: You can delete the subscriber site.
    c. **Extensible Attributes**: Add or modify extensible attributes.
    d. **View NAS Gateway Message Rates**: Displays the message rates of the NAS gateways configured for the subscriber site.
2. **Name**: The name of the subscriber site.
3. **Comment**: Information about the subscriber site.
4. **Site**: Displays values that were entered for this predefined attribute.

You can also perform the following:

1. Edit the subscriber site information. Select the subscriber site, and then click the Edit icon.
2. Delete a subscriber site. Select the subscriber site, and then click the Delete icon.
3. Export the list of subscriber sites. Click the Export icon.
4. Print the list of subscriber sites. Click the Print icon.

Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches.

Create a quick filter to save frequently used filter criteria:

1. In the filter section, click **Show Filter** and define filter criteria for the quick filter.
2. Click **Save** and complete the configuration In the *Save Quick Filter* dialog box.

The appliance adds the quick filter to the quick filter drop-down list in the panel. Note that global filters are prefixed with [G], local filters with [L], and system filters with [S].

Sort the subscriber sites in ascending or descending order by column.

Viewing NAS Gateway Message Rates

You can view the NAS gateways (accounting log servers) configured for the subscriber site and the message rate for each NAS gateway.

To view the NAS gateway message rates, complete the following:

From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab -> **Subscriber Sites** tab.

In the **Subscriber Sites** tab, click the **Action** icon next to the respective subscriber site and select **View NAS Gateway Message Rates** from the list.

The *NAS Gateway Message Rates* dialog box displays the following information for the selected subscriber site:

Name: The name of the NAS gateway.

IP Address: The IP address of the NAS gateway.

Message Rate: The message rate of the NAS gateway.

Configuring Blocking Server Policies

In addition to the default blocking servers that you specify when adding subscriber sites, you can also create service policies that can be associated with specific servers. These servers act as blocking servers and any traffic or web pages that conform to the service policies that you create are blocked and redirected to the blocking VIP addresses.

Adding a Blocking Server Policy

To create or add a blocking server policy:

1. From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab, expand the vertical Toolbar and click **Blocking Server Associations**.
2. Click the Add icon.
3. In the **Name** field, specify a name for the policy.
4. In the **Parental Control Policy** field, specify the hexadecimal value of the parental control policy that you want to add. For a list of the different types of parental control policies and their hexadecimal values, refer to the supplemental documentation provided by Infoblox or contact your Infoblox representative.
5. Click the **Add** button.

The policy that you created is displayed in the table. You can then associate IP addresses with the policy that you created. For more information, see *Scaling Using Subscriber Sites*.

Editing a Blocking Server Policy

To edit an existing blocking server policy:

1. From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab, expand the vertical Toolbar and click **Blocking Server Associations**.
2. Select the policy that you want to edit and click the Edit icon.
3. Edit either the name of the policy or its hexadecimal value.
4. Click **Save**.

Deleting a Blocking Server Policy

To delete an existing blocking server policy:

1. From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab, expand the vertical Toolbar and click **Blocking Server Associations**.
2. Select the policy that you want to delete and click the Delete icon.
3. Click **Save**.

Managing AVPs (Attribute Value Pairs)

The subscriber site receives the subscriber security policies and parental control policies as AVPs from the RADIUS server. You can create AVPs that are not available in the list of predefined AVPs and manage the AVPs in the following ways:

- *Adding AVPs*
- *Modifying AVPs*
- *Deleting AVPs*
- *Viewing AVPs*

- Create an user-defined AVP, as described in Adding AVPs below.
- View the list of AVPs, described in Viewing AVPs below.
- Modify the properties of an user-defined AVP, as described in Modifying AVPs below.
- Delete an user-defined AVP, as described in Deleting AVPs below.

> **Note**
>
> The configured AVPs are applicable for all the subscriber sites.

Adding AVPs

To add an user-defined AVP:

1. From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab -> **AVPs** tab, and then click the Add icon.
2. In the *Add AVP* wizard, complete the following:
    - **Name**: Enter the name of the AVP (Attribute Value Pair).
    - **User Defined**: Indicates whether the AVP is an user-defined AVP.
    - **Type**: Enter the AVP type as defined in RFC 2865 and RFC 2866. If the AVP type is vendor specific, you can enter the value 26.
    - **Vendor ID**: Specify the vendor ID, if the AVP ID is vendor specific.
    - **Vendor Type**: Specify the vendor type, if the AVP type is vendor specific.
    - **Value Type**: Select the type of value from the drop-down list:
    - **Comment**: You can enter additional information about the AVP.
    - **Make this AVP available as an option in**: Select one of the following:
        - **All fields**: Select this if you want the AVP to be available in all lists in *Subscriber Secure Properties* editor.
        - **Only to these fields**: Select this if you want the AVP to be available only in specific fields in the *Subscriber Secure Properties* editor. Click the Add icon in the table. The appliance adds a row to the table. Click the row and select the field name from the drop-down list.
3. Save the configuration.

Modifying AVPs

To modify an user-defined AVP:

1. From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab -> **AVPs** tab, click the **Action** icon next to the user-defined AVP name and select **Edit** from the menu.
2. In the *AVP Properties* editor, modify the AVP information, as described in the previous section, Adding AVPs.
3. Save the configuration.

Note that you cannot modify the properties of a predefined AVP. You can only view the information in the *AVP Properties* editor.

Deleting AVPs

You can delete only user-defined AVPs.

To remove an user-defined AVP:

1. From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab -> **AVPs** tab, click the **Action** icon next to the user-defined AVP name and select **Delete** from the menu.
2. In the *Delete Confirmation (AVP)* dialog box, click **Yes**.

Viewing AVPs

To view all the predefined and user-defined AVPs:

1. From the **Data Management** tab -> **DNS** tab -> **Subscriber Services Deployment** tab -> click the **AVPs** tab.
2. Grid Manager displays the following information for each AVP:

- **Actions**: Click the Action icon next to a selected user-defined AVP and choose from the following:
  - **Edit**: Modify certain general properties.
  - **Delete**: You can delete only user-defined AVP.
- **Name**: The name of the AVP.
- **User Defined**: Indicates whether the AVP is predefined or user-defined AVP.
- **Type**: The type of AVP.
- **Vendor ID**: The vendor ID.
- **Vendor Type**: The vendor type.
- **Value Type**: Indicates the value type. Example: string, integer, IPv4 address, IPv6 address, byte, etc.
- **Comment**: Information about the AVP.
- **Restricted To**: Indicates whether the AVP is restricted to domains.

You can also do the following:

- Edit the AVP information.
  - Select the AVP, and then click the Edit icon.
- Delete an user-defined AVP.
  - Select the user-defined AVP, and then click the Delete icon.
- Export the list of AVPs.
  - Click the Export icon.
- Print the list of AVPs.
  - Click the Print icon.
- Use filters and the **Go to** function to narrow down the list. With the autocomplete feature, you can just enter the first few characters of an object name in the **Go to** field and select the object from the possible matches. This is not applicable for **Restricted To** column.
- Create a quick filter to save frequently used filter criteria:
  - In the filter section, click **Show Filter** and define filter criteria for the quick filter.
  - Click **Save** and complete the configuration In the *Save Quick Filter* dialog box.
- The appliance adds the quick filter to the quick filter drop-down list in the panel. Note that global filters are prefixed with [G], local filters with [L], and system filters with [S].
- Sort the AVPs in ascending or descending order by column. This is not applicable for **Restricted To** column.

Monitoring Subscriber Policy Violations

You can monitor RPZ hits based on subscriber security policies and parental control policies through the following:

- *Monitoring through Syslog*
- *Handling Splunk REST API Request*

- Syslog, as described in Monitoring through Syslog below.
- *Detailed RPZ Violations by Subscriber ID* report, as described in Detailed RPZ Violations by Subscriber ID below.

Monitoring through Syslog

To receive information about RPZ hits based on subscriber security policies and parental control policies in the syslog, make sure that you enable the **RPZ** option in the **Logging** tab of the Grid DNS Properties editor or Member Properties editor. For information about configuring logging properties, setting DNS Logging Categories, see *Using a Syslog Server*. Once the RPZ option is enabled, the appliance logs RPZ hits based on subscriber security policies and parental control policies in CEF (Common Event Format) in the syslog. For information about how to configure the syslog server, see *Using a Syslog Server*.

Following is a sample RPZ hit log message:

```
CEF:0|Infoblox|NIOS|8.2.0-359884|RPZ-QNAME|PASSTHRU|7|app=DNS
dst=10.35.41.18 src=10.32.1.145 spt=52100 view=_default qtype=A msg="rpz
QNAME PASSTHRU rewrite child.com [A] via child.com.bit6subscribers" IPSD=N/A
Acct-Session-Id=29de847acde415ab User-Name=john NAS-IP-Address=10.36.120.10
MSISDN=9956182386 Subscriber-Secure-
Policy=0000507f CAT=0x00000000000000000000000000008000
```

Each log message contains the following information:

- **Infoblox|NIOS |x.x.x**: Indicates the Infoblox product, and `x.x.x` represents the NIOS version.
- The string following the NIOS version is a hard-coded constant. In this example, it is RPZ QNAME.
- The hard-coded constant is followed by mitigation action. In this example, it is PASSTHRU.
- The number following the mitigation action is the threat severity level. The following numbers indicate the severity levels:
  - **8** = **Critical**
  - **7** = **Major**
  - **6** = **Warning**
  - **4** = **Informational**
- **app**: DNS
- **dst**: Destination IP address.
- **src**: Source IP address.
- **spt**: Source port.
- **view**: DNS view.
- **qtype**: Query type.
- **msg**: RPZ rule.
- **IPSD**: IP space discriminator.
- **Acct-Session-Id**: Session ID.
- **User-Name**: Username of the subscriber.
- **NAS-IP-Address**: NAS IP address.
- **MSISDN**: The mobile phone number of the subscriber.
- **Subscriber-Secure-Policy**: Subscriber Secure Policy.
- **CAT**: The category bits that match the query name. This indicates the reason for blocking the domain listed in the event.

To view RPZ violation by subscriber related log messages:

1. From the **Administration** tab, select the **Logs** tab -> **Syslog** tab.
2. From the drop-down list at the upper right corner, select the Grid member on which you want to view the syslog.
3. From the **Quick Filter** drop-down list, select **RPZ Incident Logs** to view RPZ violation by subscriber related events. To narrow down the system messages you want to view, click **Show Filter** and then select the filters you want to use. For information about how to use filters, see *Finding and Restoring Data*.

Handling Splunk REST API Request

You can retrieve pre-defined reports by sending Splunk REST API requests. Before you send any Splunk REST API request, ensure that reporting service is enabled on the Grid. To accept the Splunk REST API requests, the apache httpd process is started on the reporting member. The Splunk REST API request process uses TCP port 9185 and you can use NIOS user credentials to send Splunk REST API requests. For information about Splunk REST API, see *http://docs.splunk.com/Documentation/Splunk/latest/RESTUM/RESTusing*.

Note:

- Only searches(/search/jobs/), saved searches(/saved/searches/) and auth login(*/auth/login) are supported and any other Splunk REST API requests are not supported.
- Splunk REST API requests cannot be sent by remote users.

Following are the supported Splunk REST API requests:

`authentication` /URI	Summary	GET	PUT	POST	DEL
auth/login	Access control Provide user authentication			Yes	

`saved` /URI	Summary	GET	PUT	POST	DEL
saved/searches	Search Manage saved search configuration	Yes		Yes	
saved/searches/{name}	Search Manage specific saved search	Yes		Yes	Yes
saved/searches/{name}/acknowledge	Search Manage saved search alerts			Yes	
saved/searches/{name}/dispatch	Search Dispatch saved search			Yes	
saved/searches/{name}/history	Search Access saved search job history	Yes			
saved/searches/{name}/reschedule	Search Manage saved search job schedules			Yes	
saved/searches/{name}/scheduled_times	Search Access saved search scheduled time	Yes			
saved/searches/{name}/suppress	Search Access saved search alert state	Yes			

`search` /URI	Summary	GET	PUT	POST	DEL
search/jobs	Search Manage search jobs	Yes		Yes	
search/jobs/{search_id}	Search Manage specific search job	Yes		Yes	Yes
search/jobs/{search_id}/control	Search Execute job control command for a specific search			Yes	
search/jobs/{search_id}/events	Search Access events for a specific search	Yes			

search /URI	Summary	GET	PUT	POST	DEL
search/jobs/{search_id}/results	Search Access results of a specific search	Yes			
search/jobs/{search_id}/ results_preview	Search Access preview results for a specific search	Yes			
search/jobs/{search_id}/search.log	Search Access search.log file for a specific search	Yes			
search/jobs/{search_id}/summary	Search Access getFieldsAndStats output of so-far-read events	Yes			
search/jobs/{search_id}/timeline	Search Access event distribution over time	Yes			
search/jobs/export	Search Stream search results	Yes		Yes	

Samples of Splunk REST API requests:

- To search for subscriber IDs:

```
curl -k -u splunk-api-usr:"tru[kl0ad" https://10.61.41.36:9185/services/search/jobs/ -d search="search source=ib:dns:query:top_rpz_hit index=ib_dns| stats count by SUB_VAL"
```

The response is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<response>
 <sid>1516833486.5665</sid>
</response>
```

To get the job status:

```
curl -k -u splunk-api-usr:"tru[kl0ad" https://10.61.41.36:9185/services/search/jobs/1516833486.5665 | grep "isDone"
```

```
% Total % Received % Xferd Average Speed Time Time Time Current
 Dload Upload Total Spent Left Speed
100 14702 100 14702 0 0 14702 0 0:00:01 --:--:-- 0:00:01 358k
 <s:key name="isDone">1</s:key>
```

To get the job output in CSV format:

```
curl -k -u splunk-api-usr:"tru[kl0ad" https://10.61.41.36:9185/services/search/jobs/1516833486.5665/results --get -d output_mode=csv
```

```
"SUB_VAL",count

"+123 (12) 123-0001",2049
"+123 (12) 123-0002",1978
"+123 (12) 123-0003",2105
"+333 (33) 333-3333",121
"+555 (55) 555-5555",3
"+911 (12) 123-0066",1916
"+911 (55) 555-5555",114

16661230001,11447
16661230002,15464
16661230003,15226
911121230066,11245
```

- To search for RPZ event by a subscriber:

```
curl -k -u splunk-api-usr:"tru[kl0ad" https://10.61.41.36:9185/services/search/jobs/ -d search='search source=ib:dns:query:top_rpz_hit index=ib_dns SUB_VAL=16661230002 earliest=-4h latest=-1h | transaction fields="DOMAIN_NAME" maxspan=1h | eval MITIGATION_ACTION=case(MITIGATION_ACTION
 == "PT", "Passthru", MITIGATION_ACTION == "NX", "Block (No Such Domain)", MITIGATION_ACTION == "ND", "Block (No Data)", MITIGATION_ACTION == "SB", "Substitute", MITIGATION_ACTION == "A1", "Substitute (A)", MITIGATION_ACTION == "A4", "Substitute (AAAA)", MITIGATION_ACTION
 == "AA", "Substitute (A/AAAA)", MITIGATION_ACTION == "DN", "Substitute (Domain Name)", MITIGATION_ACTION == "ER", "None") | table TIMESTAMP DOMAIN_NAME MITIGATION_ACTION'
```

The response is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<response>
 <sid>1516834187.5702</sid>
</response>
```

To get the job status:

```
curl -k -u splunk-api-usr:"tru[kl0ad" https://10.61.41.36:9185/services/search/jobs/1516834187.5702 | grep "isDone"

<s:key name="isDone">1</s:key>
```

To get the job output in csv format:

```
curl -k -u splunk-api-usr:"tru[kl0ad" https://10.61.41.36:9185/services/search/jobs/1516834187.5702/results --get -d output_mode=csv

TIMESTAMP,"DOMAIN_NAME","MITIGATION_ACTION"

```

VLAN Management

NIOS allows you to track the VLAN usage in your network thereby allowing you to compare an assigned VLAN with VLANs discovered by Network Insight. You can then generate inventory and conflict reports based on this data.You can:

- Create VLAN resource pools to use in the future
- Track the VLANs that are in use and those that are not in use
- Organize VLAN views and ranges by organization or group
- Assign VLANs to defined networks
- View conflicts if any between assigned and discovered VLANs

To configure VLAN management, perform these steps in the following order:

1. *Create a VLAN view*.
2. *Create one or multiple VLAN ranges within a VLAN view*.
3. *Create VLAN objects that you can group into a range or view*.
4. *Assign a VLAN object to a network*.
5. *Generate inventory and conflict reports to view conflicts between an assigned VLAN object and a VLAN object discovered by Network Insight*.

You can use the *global search* function (**Advanced** tab) to search for VLAN views, ranges, and objects. You can also perform a CSV import or export of the VLAN data. For more information, see *Importing and Exporting Data using CSV Import*.

All VLAN configuration operations can be scheduled and are subject to administrator approval. For more information, see *Configuring Approval Workflows*.

For information about permissions related to VLAN objects, see *Administrative Permissions for VLAN Management*.

Configuring VLAN Views

You can create a VLAN view and group VLAN objects and VLAN ranges into that VLAN view. A VLAN view allows you to view grouped VLANs in an hierarchical format.

A VLAN view named **default** is automatically created for all NIOS installations starting from NIOS 8.4 and upgrades from earlier versions.

Viewing a VLAN View

To view the list of VLAN views, perform the following steps:

1. From the **Data Management** tab, click the **VLANs** tab. A list of all the VLAN views is displayed. The following details of the VLAN view are displayed:
    - **Name**: Name of the VLAN view
    - **Start VLAN ID**: Integer from which the VLAN ID can start.
    - **End VLAN ID**: Integer till which the VLAN ID can end.
    - **Comment**: Information for the VLAN view if any.
    - **Allow Range Overlapping**: Whether VLAN ranges with overlapping VLAN IDs are allowed in the VLAN view. For information about overlapping VLAN IDs, see Allow VLAN Range Overlapping below.
    - **Site**: Extensible attribute for the VLAN view.
2. Click a VLAN view name to view all the VLAN objects and VLAN ranges that belong to the VLAN view.

Adding a VLAN View

To add a VLAN view:

1. From the **Data Management** tab, click the **VLANs** tab.
2. From the Toolbar, click **Add**-> **VLAN View**. The *Add VLAN Wizard* dialog box is displayed.
3. In the **VLAN View Name** field, enter a name for the VLAN view.
4. In the **Start VLAN ID** field, enter the minimum ID that can be used by a child VLAN range or VLAN object. VLANs can acquire an ID that is in between the values you enter in the **Start VLAN ID** and **End VLAN ID** fields. The VLAN ID must be greater than or equal to 1 and less than or equal to 4094. A VLAN ID is unique. No VLAN object can share the same VLAN ID.
5. In the **End VLAN ID** field, enter the maximum ID that can be used by a child VLAN range or VLAN object. The VLAN ID must be greater than or equal to 1 and less than or equal to 4094. A VLAN ID is unique. No VLAN object can share the same VLAN ID.
6. Select the **Pre-create VLANs** checkbox if you want NIOS to automatically create VLANs. When you select this checkbox, the **VLAN Name Prefix** field becomes enabled and NIOS creates VLANs between the range you specified in the **Start VLAN ID** and **End VLAN ID** fields. You cannot edit the **Pre-create VLANs** checkbox.
7. In the **VLAN Name Prefix** field, enter a prefix that will be added to the VLAN name. The VLAN name is constructed using the following pattern: `<VLAN Prefix Name> + <VLAN ID>` (the VLAN ID is optionally prefixed with zeros). VLANs are automatically created with the prefix name and VLAN ID. You cannot edit the **VLAN Name Prefix** field.
8. Select the **Allow VLAN Range Overlapping** checkbox if you want to allow different VLAN ranges in the same VLAN view to have overlapping start and end VLAN IDs. Overlapping VLAN ranges will have unique VLAN IDs. For example, if you create a VLAN view with two ranges from 1 to 15 and from 2 to 18, and a VLAN object with ID 14 under the first range, the VLAN object will belong to both VLAN range 1 and VLAN range 2. However, its parent VLAN range is the range under which it was created; in this case, the first VLAN range. The parent VLAN range is displayed in the **Parent VLAN Range** column when viewing a VLAN range details. If there are overlapping ranges in a VLAN view, you cannot disable the checkbox. If you want to disable the checkbox, you must reconfigure the VLAN ranges to avoid conflicts and then disable the option.
9. In the **Comment** field, enter comments if any.
10. Click **Next** to define extensible attributes. For more information, see *Managing Extensible Attributes*.
11. Click **Save & Close** to save your configuration.

Editing a VLAN View

To edit the details of a VLAN view:

1. From the **Data Management** tab, click the **VLANs** tab.

2. Select the VLAN view that you want to edit, select the Action icon and click **Edit**.
   Note: Changing the start or end VLAN ID values in a VLAN view may lead to errors. For example, if the VLAN IDs of a VLAN view are from 1 to 5, you cannot change them to 1 to 2 in case there is a child VLAN with ID 3 or 4 or 5 in the VLAN view.
3. Edit the details as required.
4. Click **Save & Close**.

Deleting a VLAN View

You cannot delete a VLAN view that contains VLANs assigned to a network. To delete a VLAN view:

1. From the **Data Management** tab, click the **VLANs** tab.
2. Select the VLAN view that you want to delete, select the Action icon and click **Delete**.
3. Click **Yes** in the *Delete Confirmation* dialog box.

> **Note**
>
> When you delete a VLAN view, all child VLANs and ranges will also be deleted.

Configuring VLAN Ranges

A VLAN range is used by NIOS to group VLAN objects. A VLAN range ID must be in between 1 and 4094 (1 and 4094 included). A VLAN view can include one or more ranges. However, it is not mandatory that a VLAN view must include a range.

Adding a VLAN Range

To add a VLAN range:

1. From the **Data Management** tab, click the **VLANs** tab.
2. From the Toolbar, click **Add**-> **VLAN Range**. The *Add VLAN Range Wizard* is displayed.
3. Click **Select VLAN View** to select the view to which the range must belong.
4. In the **VLAN Range Name** field, enter a name for the VLAN range.
5. In the **Start VLAN ID** field, enter the minimum ID that can be used by a VLAN object.
6. In the **End VLAN ID** field, enter the maximum ID that can be used by a VLAN object.
7. Select the **Pre-create VLANs** checkbox if you want NIOS to automatically create VLANs. When you select this checkbox, the **VLAN Name Prefix** field becomes enabled and NIOS creates VLANs between the range you specified in the **Start VLAN ID** and **End VLAN ID** fields. If you select this checkbox when adding a VLAN range, VLANs are created inside of the range. If you create an empty VLAN range, all existing VLANs (in a VLAN view) are re-parented by range if their IDs are in the start to end range IDs of the VLAN range. Therefore, if there are VLANs to re-parent by the newly created range, you cannot pre-create VLANs in this range. You cannot edit the **Pre-create VLANs** checkbox.
8. In the **VLAN Name Prefix** field, enter a prefix that will be added to the VLAN name. The VLAN name is constructed using the following pattern: `<VLAN Prefix Name> + <VLAN ID>` (the VLAN ID is optionally prefixed with zeros). VLANs are automatically created with the prefix name and VLAN ID. You cannot edit this field.
9. In the **Comment** field, enter additional information if any.
10. Click **Next** to define extensible attributes. For more information, see *Managing Extensible Attributes*.
11. Click **Save & Close** to save your configuration.

Editing a VLAN Range

To edit the details of a VLAN range:

1. From the **Data Management** tab, click the **VLANs** tab.

2. Click the VLAN view that the range belongs to, select the Action icon and click **Edit**.
3. Edit the details as required. You cannot edit the **VLAN Name Prefix** field and the **Pre-create VLANs** checkbox.
4. Click **Save & Close**.

> **Note**
>
> Changing the start and end VLAN IDs may lead to re-parenting of the child VLANs. Based on how the start and end VLAN IDs of the range changed, new VLANs may be added to the range or removed from it (in which case the VLAN view becomes the new parent). Also, changing parent field allows you to move ranges between views.

Deleting a VLAN Range

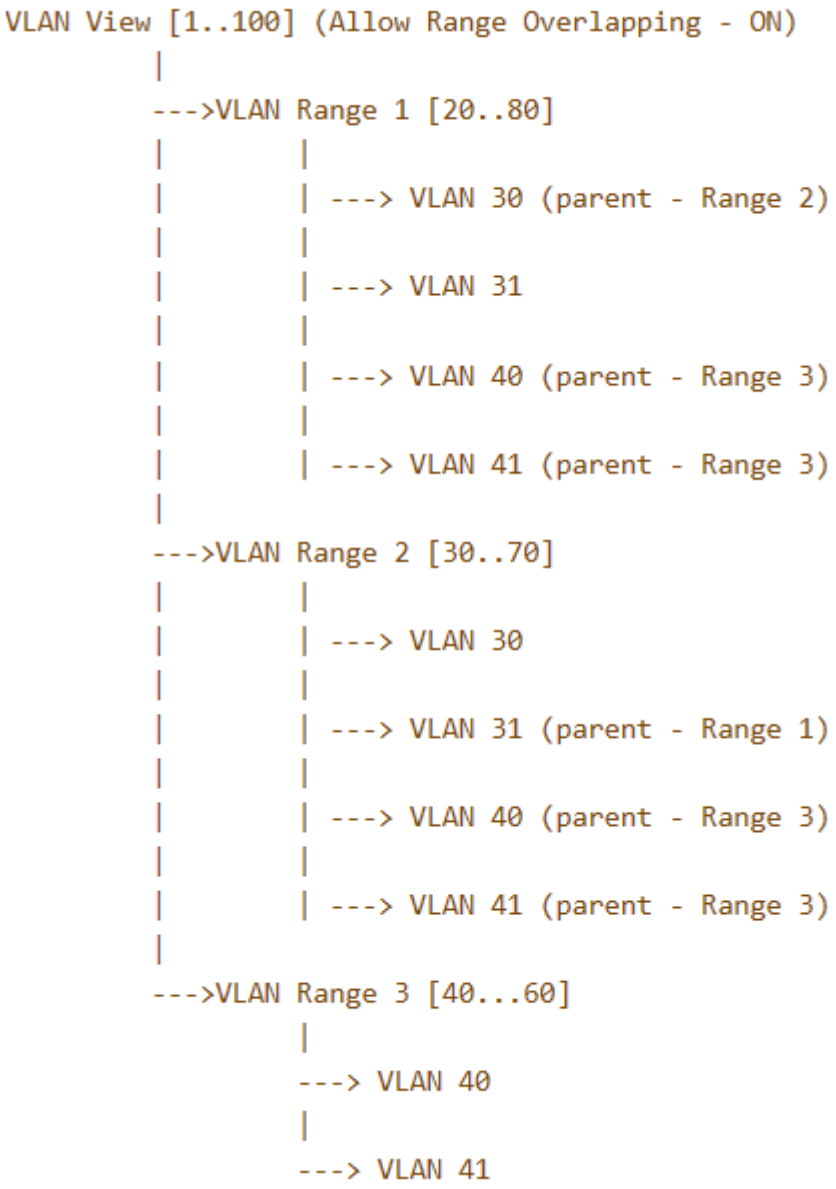
To delete a VLAN range:

1. From the **Data Management** tab, click the **VLANs** tab.
2. Click the VLAN view that the range that you want to delete belongs to.
3. Select the VLAN range, select the Action icon and click **Delete**.
4. Select the **Delete only the VLAN Range and re-parent the VLANs** option if you want to delete only the VLAN range and not the VLAN child objects under the range. In this case, if you had selected the **Allow VLAN Range Overlapping** option when creating the VLAN view:
   - If the VLAN IDs of the VLAN objects can be categorized into another VLAN range, then the child objects are automatically categorized under the new VLAN range.
   - If the VLAN IDs cannot be categorized under a VLAN range, then the VLAN child objects are categorized under the VLAN view.
   - If the VLAN IDs can be categorized into more than one VLAN range, then NIOS displays an error message because it cannot determine the VLAN range under which to categorize the VLAN IDs and the VLAN range is not deleted.
5. Select the **Delete the VLAN Range and all VLANs below it** option if you want both the VLAN range and the VLAN child objects that belong to the VLAN range to be deleted.
6. Click **Yes** in the *Delete Confirmation* dialog box.

> **Note**
>
> You cannot delete or modify a VLAN object that is already assigned to a network. If a child VLAN object is assigned to a network and you select the Delete the VLAN Range and all VLANs below it option or the Delete only the VLAN Range and re-parent the VLANs option, NIOS displays an error message. You can resolve the error by manually restructuring the VLAN objects.

Example - VLAN Range Deletion

The following example illustrates how VLAN objects are categorized when you delete a VLAN range.



This example illustrates 3 VLAN ranges that allow overlapping VLAN IDs. If you try to delete VLAN Range 3, NIOS displays an error message because the child VLAN objects VLAN 40 and VLAN 41 can either be categorized under VLAN Range 1 or VLAN Range 2, and the VLAN Range 3 is not deleted. In this scenario, you must manually change the parent of the VLAN objects.

Configuring VLAN Objects

You can create a VLAN topology or hierarchy by adding VLAN objects and grouping them together to create a VLAN view or range. You can then track statuses of the VLANs, set some additional details (such as department, contact, description). You can also assign VLANs to DHCP/IPAM networks.

Viewing VLAN Objects in a VLAN View

To view all the VLAN objects that belong to a particular view:

1. From the **Data Management** tab, click the **VLANs** tab. A list of all the VLAN views is displayed. If the VLAN object belongs to a particular VLAN range, click the VLAN range.
2. Click the VLAN view whose details you want to see. All the VLAN objects and VLAN ranges belonging to the view are displayed with the following details:
    - **Name**: Name of the VLAN.
    - **Type**: VLAN or VLAN range.
    - **VLAN ID**: ID of the VLAN.
    - **Start VLAN ID**: Integer from which the VLAN view ID starts. This is applicable only to VLAN views and ranges.
    - **End VLAN ID**: Integer from which the VLAN view ID ends. This is applicable only to VLAN views and ranges.
    - **Description**: Description of the VLAN.
    - **Contact**: Contact information of the person or team managing or using the VLAN
    - **Department**: Name of the department using the VLAN
    - **Status**: Status can be **Assigned**, **Unassigned**, or **Reserved**. An Assigned status indicates that the VLAN is linked to an IPAM network object. An Unassigned status indicates that the VLAN is not linked to an IPAM object. A Reserved status indicates that the VLAN will be excluded from the list of VLANs that are proposed to be assigned to an IPAM object.
    - **Comment**: Any comment entered for the VLAN
    - **Assigned to**: IPAM objects that the VLAN is linked to. This is a read-only value and you cannot edit it.
    - Extensible attributes if any

> **Note**
>
> The details you see vary depending on whether you are viewing the details of the VLAN view or the VLAN range.

Except the **Assigned to** value, you can double-click any of the VLAN details to edit them.

Adding a VLAN Object

To add a VLAN object to your network:

1. From the **Data Management** tab, click the **VLANs** tab.
2. From the Toolbar, click **Add**-> **VLAN**.
3. In the *Add VLAN Wizard*, from the **VLAN Parent Type** drop-down list, select whether you want to add the VLAN to the VLAN view or VLAN range.
4. In the **VLAN Parent** field, select the specific VLAN view or range to which you want the VLAN to belong.
5. In the **VLAN Name** field, specify a name for the VLAN.
6. Click **Next Available VLAN ID** for NIOS to automatically assign an ID for the VLAN. You can also manually specify the VLAN ID. The value of the VLAN ID must be greater than or equal to 1 and lesser than or equal to 4094. When you click **Next Available VLAN ID**, NIOS searches for the lowest unused ID in the specified VLAN view or range.
7. Select the **Reserved** checkbox if you want the VLAN to be excluded from the list of VLANs that are proposed for assignment to an IPAM network object by clicking **Next Available VLAN**.
8. In the **Description** field, enter a description for the VLAN.
9. In the **Contact** field, enter the contact information of the person or team managing or using the VLAN. It can be a name, email ID, telephone number or so on.
10. In the **Department** field, enter the name of the department for which the VLAN will be used.
11. In the **Comment** field, enter additional information if any.
12. Click **Next** to define extensible attributes. For more information see *Managing Extensible Attributes*.
13. Click **Save & Close** to save your configuration.

You can now add the VLAN to a VLAN view.

Editing a VLAN Object

To edit the details of an existing VLAN object:

1. From the **Data Management** tab, click the **VLANs** tab.
2. From the list of VLAN views, click the VLAN view that the VLAN object to be edited belongs to. If the VLAN object belongs to a VLAN range, click the VLAN range.
3. Select the VLAN object that you want to edit, select the Action icon and click **Edit**.
4. Edit the details as required. You cannot edit the **Assigned to** field. You cannot change the ID, parent, and status for VLAN objects that are assigned to a network.
5. Click **Save & Close**.

Editing Multiple VLAN Objects at the Same Time

You can select and edit multiple VLAN objects at the same time. To do this:

1. From the **Data Management** tab, click the **VLANs** tab.
2. From the list of VLAN views, click the VLAN view that the VLAN objects to be edited belong to. If the VLAN objects belong to a VLAN range, click the VLAN range.
3. Select all the VLAN objects that you want to edit, select the Action icon and click **Edit**.
4. Edit the details as required. You can edit the parent VLAN, **Reserved** checkbox, **Description**, **Contact**, **Department**, and **Comment** fields. However, you cannot edit the parent of a VLAN object that does not belong to a VLAN range and belongs directly to a VLAN view.
5. Click **Save & Close**.

Notes

- You can select multiple VLAN objects to edit only if all the selected VLAN objects belong to the same VLAN range.
- You can edit the **VLAN Parent** field to select only another VLAN range as the new parent. You cannot select a VLAN view as the new parent. The new VLAN range must belong to the same VLAN view.
- You cannot edit the **VLAN Parent** field for multiple VLAN objects that belong directly to a VLAN view and not to a VLAN range.
- You cannot edit the VLAN parent of VLAN objects that are assigned to a network.

Deleting a VLAN Object

You cannot delete a VLAN object that is assigned to a network. For more information, see *Assigning VLANs to a Network*.

To delete a VLAN object:

1. From the **Data Management** tab, click the **VLANs** tab.
2. From the list of VLAN views, click the VLAN view that the VLAN to be deleted belongs to. If the VLAN object belongs to a VLAN range, click the VLAN range.
3. Select the VLAN object that you want to delete, select the Action icon and click **Delete**.
4. Click **Yes** in the *Delete Confirmation* dialog box.

Assigning VLANs to a Network

You can assign a VLAN object to different networks. You can also assign multiple VLAN objects to a single network. You can also assign multiple networks to a single VLAN. Once a VLAN object is assigned to a network, the status of VLAN

object changes from Unassigned or Reserved to **Assigned**. For information about the types of VLAN status, see *Configuring VLANs*.

Assigning a VLAN object enables you to compare an assigned VLAN object with the VLAN objects discovered by Network Insight. You can then generate inventory and conflict reports based on this data.

You can also create *smart folders* and obtain a list of networks by the assigned VLAN ID or name.

> **Note**
>
> - You can assign VLAN objects only to IPv4 or IPv6 networks.
> - You cannot assign VLAN objects to a network container.
> - If a VLAN object is assigned to a network, you cannot convert that network into a network container.
> - You cannot split or join a network that has VLAN objects assigned to it.

Viewing VLAN Objects Assigned to a Network

You can view the VLAN objects assigned to a network on the **IPAM** tab or the **DHCP** tab. The **Assigned VLAN ID** and **Assigned VLAN Name** columns display the VLAN ID and name of the assigned object. If multiple VLANs are assigned to a network, **Multiple** is displayed in the **Assigned VLAN ID** and **Assigned VLAN Name** columns. You can then compare it to the data in the **Discovered VLAN ID** and **Discovered VLAN Name** columns and view conflicts if any.

Adding VLAN Objects to a Network

To add or assign a VLAN object to a network, perform the following steps:

1. From the **Data Management** tab, select the **IPAM** tab or **DHCP** tab -> *network* checkbox of the network to which you want to assign the VLAN object.
2. Select the Action icon and then click **Edit**.
3. Click **VLAN Assignment**. A list of all the VLAN objects associated with the network is displayed.
4. Click the Add icon.
5. From the **VLAN Parent Type** drop-down list, select the parent type of the VLAN object that you want to add. The parent type can either be a VLAN view or a VLAN range. For more information, see *Configuring VLANs*.
6. From the **VLAN Parent** field, select the VLAN view or VLAN range that the VLAN object belongs to.
7. From the **VLAN Name** field, select the VLAN object. Alternatively, click **Next Available VLAN** if you want NIOS to assign a VLAN object. NIOS searches for a VLAN object with the lowest ID in the specified VLAN view or range. VLAN objects whose status is **Assigned** or **Reserved** are ignored. However, you can still select a reserved or assigned VLAN object by clicking the **VLAN Name** field and selecting the VLAN object. The **VLAN ID** field is populated with the ID of the selected VLAN object.
8. Click **Add** to add the VLAN objects The table is populated with the VLAN object details.
9. You can click the Add icon to add more VLAN objects.
10. Click **Save & Close**.

You can also assign a VLAN object when creating an IPv4 or IPv6 network. For more information, see *Configuring IPv4 Networks* and *Managing IPv6 Networks*.

Editing Assigned VLAN Objects

To edit a VLAN object that is already assigned, perform the following steps:

1. From the **Data Management** tab, select the **IPAM** tab or **DHCP** tab -> *network* checkbox of the network that you want to edit.
2. Select the Action icon and then click **Edit**.
3. Click the **VLAN Assignment** tab.
4. Select the VLAN object that you want to edit and click the Edit icon. Details of the VLAN object are displayed. You can edit and select another VLAN object in another VLAN view for example.
5. Click **Save & Close**.

Deleting Assigned VLAN Objects

You cannot delete a VLAN object that is assigned to a network. You must first unassign the VLAN object and then delete it. Deleting an unassigned VLAN object from the list of VLAN objects that are assigned to a network does not delete it from NIOS. Also, you cannot delete a network, network view, or a parent network container that have VLAN objects assigned to them.

To unassign a VLAN object, perform the following steps:

1. From the **Data Management** tab, select the **IPAM** tab or **DHCP** tab -> *network* checkbox of the network that you want to edit.
2. Select the Action icon and then click **Delete**.
3. Click the **VLAN Assignment** tab.
4. Select the VLAN object that you want to edit and click the Delete icon. The VLAN object is deleted from the assignment.
5. Click **Save & Close**.

Using the NIOS CLI

The Infoblox NIOS CLI (Command Line Interface) allows you to configure and monitor the appliance from a remote console using a set of commands. Some administrative tasks, such as resetting the appliance, can be done only through the CLI. CLI commands do not support IDNs. These commands display IDN data in punycode only. For more information about IDN, see *Multilingual Support*.

This section explains the CLI commands that you can use to configure and manage the NIOS appliance from a remote terminal. For the latest Infoblox documentation, visit the Infoblox Support web site at *https://support.infoblox.com/*.

Topic	Content
Overview	Explains how to access the Infoblox CLI using a console port or SSHv2 client. This topic also describes the CLI conventions and outlines the basic CLI commands.
CLI Commands	Explains the function and usage of each command, and provides an example of the command usage and expected results.

Conventions

The conventions used in this section follow the Infoblox documentation style conventions, as listed in the following table.

Style	Usage
`screen`	Indicates session text or system information displayed on the screen
`boldface screen`	Signifies command line entries that you type.
`italic screen`	Signifies variables that you enter for your configuration, such as file names and group names.

CLI syntax uses conventions that are unique to documenting command line tools. The following table provides a list of syntax delimiters and their meanings.

Item	Convention
{ } brackets	Indicates a mandatory feature.
[ ] brackets	Indicates an optional feature.
| pipe symbol	Indicates an “or” relationship between two features.

Variables

Infoblox uses the following variables to represent the values of the configurations that exist on your appliance. You should substitute the variables with the actual values that match your site configuration.

Variable	Value
admin_group	Name of a group of administrators
admin_name	Name of the appliance administrator
addr_range	IP address range
domain_name	Domain name
directory	Directory name
dns_view	DNS view
filter_name	Filter name
grid_master	Grid master
grid_member	Grid member
hostname	Host name of an independent appliance
id_grid	Grid name
ip_addr	IPv4 address
member	Grid member name
netmask	Subnet mask
network	IP address of a network
numerical	Numerical entry
zone	DNS zone

The following is a list of commands that NIOS supports:

- *ping*
- *quit*
- *reboot*
- *reset all*
- *reset arp*
- *reset cli*
- *reset database*
- *reset reporting_data*
- *reset snmp*
- *reset ssh_keys*
- *restart service*
- *rotate log*
- *set admin_group_acl*

Accessing the Infoblox CLI

You can access the Infoblox CLI from a management system. The management system is the computer from which you configure and monitor the NIOS appliance. You can access the Infoblox CLI from the management system directly through a serial cable or remotely across an Ethernet network.

- Console port access—Access the Infoblox CLI through a direct console connection from your management system to the appliance.
- SSHv2 client access—Accessing the Infoblox CLI remotely by making an SSHv2 connection across an Ethernet network.

> **Note**
>
> Only superusers can log in to the appliance through a console connection.

Console Port Access

You can access the Infoblox CLI by using a terminal emulation program from the management system through a direct console connection.

To access the Infoblox CLI through the console port:

1. Connect a serial cable from the console port on your management system to the console port on the appliance. The appliance has a male DB-9 console port on its front panel.
2. Use the following connection settings to launch an emulation session through a serial terminal emulation program such as Hilgraeve Hyperterminal® (provided with the Windows® operating systems):

- Bits per second: `9600`
- Data bits: 8
- Parity: None
- Stop bits: 1
- Flow control: Xon/Xoff

3. Use the following default user name and password to log in to the Infoblox appliance:
   `admin`
   `infoblox`

> **Note**
>
> User names and passwords are case-sensitive.

SSHv2 Client Access

You can access the Infoblox CLI from a remote management system. You must first enable remote console access before you can remotely access the Infoblox CLI. By default, remote console access (SSHv2 access) is disabled on the Infoblox appliance.

You can enable remote console access on the Infoblox appliance through either the Infoblox GUI or the CLI. To enable remote console access through the Infoblox GUI:

1. Make an HTTPS or console connection to the appliance and log in to the appliance.
2. For a Grid member or Grid Master, complete the following:
   1. From the **Grid** tab, select the **Grid Manager** tab, and then click **Grid Properties** -> **Edit** from the Toolbar.
   2. In the *Grid Properties* editor, select the **Security** tab, and then select **Enable Remote Console Access**.
   3. Click **Save & Close**.

For an independent appliance, complete the following:

1. From the **System** tab, select the **System Manager** tab, and then click **System Properties** -> **Edit** from the Toolbar.
2. In the *System Properties* editor, select the **Security** tab, and then select **Enable Remote Console Access**.
3. Click **Save&Close**.

To enable remote console access through the CLI:

1. From the command line, enter the following after the *Infoblox >* prompt:
   `set remote_console`
2. Enter **y** at the *Enable remote console access (grid-level)? (y or n):* prompt.
3. Confirm the settings.

After you enable the remote console access, you can access the Infoblox CLI from a remote location using an SSHv2 client.

To access the Infoblox CLI using an SSHv2 client:

1. On the management system, open a remote console connection through an SSHv2 client.
2. In a shell window or terminal window, log in with an account that has superuser privileges.
3. Enter the user name and host name or IP address of the appliance. For example:
   `ssh admin@192.168.1.2`
4. Optionally, you can launch a graphical SSHv2 client and enter the information in the appropriate fields.

CLI Commands

The basic Infoblox CLI commands are alphabetically listed in the following table.

CLI Command	Description
?	Displays the help information.
ddns_add	Sends DDNS updates to add records.
ddns_delete	Sends DDNS updates to delete records.
delete	Deletes specific files.
dig	Performs a DNS lookup and prints the results.
dns_a_record_delete	Delete a DNS A record
exit	Exits the command interpreter.
help	Displays the help information.
ping	Sends ICMP ECHO requests to verify that the host is functioning properly.
quit	Exits the command interpreter.
reboot	Reboots the Infoblox appliance.
reset	Resets the system settings.
rotate	Rotates specific files.
set	Sets the current system settings. This command has other related commands.
show	Shows the current system settings. This command has other related commands.
shutdown	Shuts down the Infoblox appliance.
traceroute	Displays the path or route diagnostic information of the IPv4/IPv6 packets.

The `reset` , `set` , and `show` commands each have related commands. To view a complete list of the related commands on the remote console , go to the command prompt and enter `help set` or `help show` .

> **Note**
>
> For the CLI `set traffic_capture` password field will support only these special characters, A-Z, a-z, 0-9, [,], ., _(underscore), /, \, #, &, @, %, ,(Comma), ~, !, $, `(grave accent), {, }, (,), =,- (dash), *, ^, +, ?.

Using CLI Help

You can display a list of available CLI commands by typing `help` at the command prompt. For example:

```
> help
```

```
?                    Display help
ddns_add             Send DDNS update to add a record
ddns_delete          Send DDNS update to delete a record
delete               Delete files
dig                  Perform a DNS lookup and print the results
dns_a_record_delete  Delete a DNS A record
exit                 Exit command interpreter
help                 Display help
ping                 Send ICMP ECHO
quit                 Exit command interpreter
reboot               Reboot device
reset                Reset system settings
rotate               Rotate files
set                  Set current system settings
show                 Show current system settings
shutdown             Shutdown device
traceroute           Route path diagnostic
```

To view a detailed explanation about a CLI command and its syntax, type help ***<command>*** after the command prompt. For example:

```
> help rotate
```

```
Synopsis:
```

```
rotate log [ syslog | debug | audit | ifmapserver]
rotate file groupname filename [ filename2, filename3, ...]
```

```
Description:
```

```
Rotates the specified log file, up to 10 previous.
logfiles will be preserved
```

?

The **?** command displays information about a specified CLI command. If you do not specify a command, a list of all available commands is shown.

Syntax

```
? [command]
```

Argument	Description
command	A variable that you substitute with any CLI command to display a description of the function and a synopsis of its usage.

Examples

Display a list of commands

```
Infoblox > ?
=====================================================================
Command Summary

```

Display details for a single command

```
Infoblox > ? exit
Synopsis:
    exit, quit
Description:
    Exits the command interpreter. There are no arguments to exit.
```

ddns_add

The **ddns_add** command sends DDNS updates to the appliance when you add new resource records. To use this command, ensure that you have properly configured the appliance for DDNS updates. For information, refer to the *Infoblox NIOS Administrator Guide*. To update a record that contains IDN, you must enter the domain name in punycode. The appliance retains the record in punycode and does not convert punycode to IDN.

Syntax

```
ddns_add <domain-name> <ttl> <type> <data> [keyname:secret]
```

Argument	Description
`domain-name`	The FQDN of the resource record being added. For example, if the name of the record is **`dns1`** and the forward-mapping zone name is `corp100.com`, the FQDN is `dns1.corp100.com`. For an IDN, use the punycode representation of the IDN. For example, if the name of the record is 域 and the forward-mapping zone name is `corp100.com`, the FQDN is **`xn--cjs.corp100.com`**.
`ttl`	The TTL value (in seconds) of the new resource record.
`type`	The record type of the new resource record. For example, enter A for an A record and PTR for a PTR record.
`data`	The RDATA of the resource record. For an IDN, use the punycode representation of the IDN. For example, enter the IP address of an A record or the domain name of a PTR record.
`[keyname:secret]`	The TSIG key name and the secret for sending DDNS updates. You must enter the TSIG key name and shared secret if the DNS zone to which the record belongs is configured with a TSIG key.

Example

```
Infoblox > ddns_add dns1.corp100.com 20 A 10.0.0.11
```

ddns_delete

The **ddns_delete** command sends DDNS updates to the appliance when you delete existing resource records. To use this command, ensure that you have properly configured the appliance for DDNS updates. For information, refer to the *Infoblox NIOS Administrator Guide*. To delete a record that contains IDN, you must enter the domain name in punycode.

Syntax

```
ddns_delete <domain-name> [type[keyname:secret]]
```

Argument	Description
domain-name	The FQDN of the resource record being deleted. For example, if the name of the record is `dns1` and the forward-mapping zone name is `corp100.com`, the FQDN is `dns1.corp100.com`. For an IDN, use the punycode representation of the IDN. For example, if the name of the record is 域 and the forward-mapping zone name is corp100.com, the FQDN is xn--cjs.corp100.com.
type	The record type of the resource record. For example, enter A for an A record and PTR for a PTR record. This is optional.
[keyname:secret]	The TSIG key name and the secret for sending DDNS updates. You must enter the TSIG key name and shared secret if the DNS zone to which the record belongs is configured with a TSIG key.

Example

Infoblox > **ddns_delete dns1.corp100.com**

delete

The **delete** command deletes a specific file or a set of files.

Syntax

```
delete [file]
```

Argument	Description
file	The name of the file which needs to be deleted

Example

Infoblox > **delete abc.csv**

dig

The **dig** command performs a DNS lookup on a specified server and displays the results. You can also use the inverse command to perform a reverse DNS lookup. This command displays IDN data in punycode, if any, for the specified server. If you specify IP address of the Microsoft server in this command, the IDN data is displayed in \xyz format.

Syntax

```
dig [@server_address] <hostname> [type] [opt...]
dig [@server_address] <ip-address> inverse
```

Argument	Description
server_address	The IP address of the host on which you want to perform a DNS lookup.
hostname	The name of the host on which you want to perform a DNS lookup.
ip-address	The IP address of the host on which you want to perform a DNS lookup.
type	You can enter any of the following for the object type (case sensitive): `a, a6, aaaa, afsdb, any, apl, axfr, cert, cname, dhcid, div, dname, dnskey, ds, gpos, hinfo, hip, ipseckey, isdn, ixfr, key, keydata, kx, loc, maila, mailb, mb, md, mf, mg, minfo, mr, mx, naptr, none, ns, nsap, nsap_ptr, nsec, nsec3, nsec3param, null, nxt, opt, ptr, px, rp, rrsig, rt, sig, soa, spf, srv, sshfp, tkey, tsig, txt, unspec, wks, and x25`. The default is `a`.

Argument	Description
opt	You can enter one or more of the following options: • `-x` (specifies the in-addr lookup) • `-b` *address* (specifies the binding to the source address) • `-y` *name:key* (specifies the named base64 tsig key) • *+vc* (enables the TCP mode) • *+norecurse* (disables the recursive mode) • *+short* (disables everything except the short forms of answers) • *+nssearch* (searches all the authoritative nameservers) • *+trace* (traces all the delegations from the root) • *+cdflag* (requests the server not to perform a DNSSEC validation) • *+dnssec* (requests the server to send DNSSEC records) • *+multiline* (displays records in multiple lines)

Examples

Perform a DNS lookup

```
Infoblox > dig @10.0.2.60 www.infoblox.com a
 : <<>> DiG 9.6.1-p3 <<>> @10.0.2.60 -x www.infoblox.com a

```

dns_a_record_delete

The **dns_a_record_delete** command deletes a DNS record of A record type.

Syntax

```
dns_a_record_delete <dns view> <record name> <zone name> <ip address>
```

Argument	Description
<dns view>	The DNS view where the target DNS A record belongs.
<record name>	The name of the target DNS A record.
<zone name>	The name of the parent zone.
<ip address>	The IP address of the target record.

Example

Infoblox > **dns_a_record_delete default_view my_record.with.long.name test.com 1.2.3.4**

exit

The **`exit (quit)`** command terminates the command line interface and halts the CLI session.

Syntax

```
exit, quit
```

Both commands produce the same results. There are no arguments for either command.

Command	Description
exit	Terminates the current CLI session.
quit	Terminates the current CLI session.

Examples

```
Infoblox > exit
 Good Bye
 Connection to <IP address> closed.
 Infoblox > quit
 Good Bye
 Connection to <IP address> closed.
```

help

The **help** command displays information about a specified CLI command. If you do not specify a command, a list of all available commands is shown.

Syntax

```
help [command]
```

Argument	Description
command	A variable that you substitute with any CLI command to display a description of the function and a synopsis of its usage.

Examples

Display a list of commands

```
Infoblox > help

```

Display details for a single command

```
Infoblox > help exit
 Synopsis:

    exit, quit

Description:

    Exits the command interpreter. There are no arguments to exit.
```

ping

The **`ping`** command verifies if a remote IPv4/IPv6 host is functioning and accessible across the network. When you execute the ping command, it sends five (default) sequential ICMP ECHO requests to the host and displays the results.

Syntax

```
ping {hostname | ip_address} [ opt ]
```

Argument	Description
`hostname`	The name of the remote host that you want to verify.
`ip_address`	The IP address of the remote host that you want to verify.
`opt`	• `numerical` (specifies to not interpret the IP address as a DNS name) • *`src_addr`* (specifies the starting or "from" address) • *`v6`* (specifies you are using an IPv6 hostname) • *`broadcast`* (allows pinging to a broadcast address) • *`ttl<hops>`* (specifies the time-to-live setting for outgoing packets) • *`packetsize<bytes>`* (specifies the number of data bytes to send) • *`count<packets>`* (specifies number of echo_requests packets sent, default is 5, maximum is 250)

Examples

Valid host

```
Infoblox > ping 10.1.1.1
 pinging 10.1.1.1
 PING 10.1.1.1 (10.1.1.1) 56(84) bytes of data.
 64 bytes from 10.1.1.1: icmp_seq=1 ttl=64 time=0.295 ms
 64 bytes from 10.1.1.1: icmp_seq=2 ttl=64 time=0.102 ms
 64 bytes from 10.1.1.1: icmp_seq=3 ttl=64 time=0.155 ms
 64 bytes from 10.1.1.1: icmp_seq=4 ttl=64 time=0.211 ms
 64 bytes from 10.1.1.1: icmp_seq=5 ttl=64 time=0.265 ms
```

```
 — 10.1.1.1 ping statistics —
 5 packets transmitted, 5 received, 0% packet loss, time 4005ms rtt min/avg/
max/mdev = 0.335/0.562/1.245/0.343 ms
```

Invalid host

```
Infoblox > ping jsparrow
 pinging jsparrow
 ping: unknown host jsparrow
```

quit

The **quit** command terminates the command line interface and halts the CLI session.

Syntax

```
quit, exit
```

Both commands produce the same results. There are no arguments for either command.

Command	Description
quit	Terminates the current CLI session.
exit	Terminates the current CLI session.

Examples

```
Infoblox > quit
Good Bye
Connection to <IP address> closed.
```

```
Infoblox > exit
Good Bye
Connection to <IP address> closed.
```

reboot

The **reboot** command halts and then restarts the appliance. Use this command as a last measure when the appliance appears to be hung. Rebooting the appliance clears the cache and resets the system.

Syntax

```
reboot
```

There are no arguments for this command.

Example

```
Infoblox > reboot
 REBOOT THE SYSTEM? (y or n) y
```

reset all

The **`reset all`** command clears the NIOS appliance of database, configuration, and network settings. It then re-establishes the factory settings with the default IP address, gateway, and subnet mask.
The **`reset all licenses`** command clears database, configuration, and network settings. It also clears all licensing information from the appliance before re-establishing the factory settings.
The **`reset all auto_provision`** command clears database, configuration, and network settings. It also re-enables auto-provisioning and a dynamic IP address is assigned to the appliance.

> **Note**
> No previous data remains on the appliance after using these commands.

Syntax

```
reset all [licenses | auto_provision]
```

Argument	Description
licenses	Specifies the removal of all licenses during the process of re-establishing the factory settings on the appliance.
auto_provision	Auto-provisioning is re-enabled and a dynamic IP address is assigned after re-establishing the factory settings on the appliance.

Examples

Re-establish factory settings

```
Infoblox > reset all
 The entire system will be reset to default settings.
```

```
 WARNING: THIS WILL ERASE ALL DATA AND LOG FILES THAT HAVE BEEN CREATED ON
THIS SYSTEM. ARE YOU SURE YOU WANT TO PROCEED? (y or n): y
```

Re-establish factory settings and remove all licenses

```
Infoblox > reset all licenses
 The entire system will be reset to default settings and all licenses will
be removed. WARNING: THIS WILL ERASE ALL DATA AND LOG FILES THAT HAVE BEEN
CREATED ON THIS SYSTEM. ARE YOU SURE YOU WANT TO PROCEED? (y or n): y
```

Re-establish factory settings and re-enable auto-provisioning

```
Infoblox > reset all auto_provision
 The entire system will be reset to default settings and system will try to
obtain a dynamic address.
 WARNING: THIS WILL ERASE ALL DATA AND LOG FILES THAT HAVE BEEN CREATED ON
THIS SYSTEM. ARE YOU SURE YOU WANT TO PROCEED? (y or n): y
```

reset arp

The **`reset arp`** command clears the ARP (Address Resolution Protocol) cache. The ARP maps IP addresses to the hardware MAC addresses and logs them in a table which is stored in the cache. Over time, the IP address leases expire and are assigned to new devices (MAC addresses). Infoblox recommends that you periodically clear this cache to maintain valid mappings between IP addresses and MAC addresses.

Syntax

```
reset arp
```

This command has no arguments.

Example

```
Infoblox > reset arp
 ARP cache cleared.
```

reset cli

This command clears obsolete CLI credentials (community strings) of devices polled by Network Insight. After that, Network Insight reguesses the CLI credentials for each device.

You can run this command on the following Grid members:

- Grid Master
- Discovery Consolidator

- Discovery Probes

When the command is executed on the Grid Master or discovery Consolidator, the CLI credentials are reset for all devices on all discovery Probes. When the command is executed on a discovery Probe, the CLI credentials are reset for devices only on this Probe.

Syntax

```
reset cli
```

This command has no arguments.

Example

```
Infoblox > reset cli
```

```
Resetting CLI credentials will clear all assigned CLI credentials and cause to reguess them for each device.
```

```
Do you wish to continue to the CLI credentials (y or n): y
```

```
Probe probe.blox: Success
```

```
The command 'reset cli' completed successfully.
```

```
Infoblox >
```

reset database

The **reset database** command removes configuration files and DNS and DHCP data from the NIOS appliance database. However, the network and licensing information remains intact. The network settings of the appliance include the IP address and subnet mask for the appliance, the IP address of the gateway, the host name, and the remote access setting.
You can use this command to diagnose problems such as the following:

- Misplacing the administrator account and password.
- Preserving the log files when clearing the database.

The **reset database auto_provision** command resets the NIOS appliance to default settings, re-enables auto-provisioning, and a dynamic IP address is assigned to the appliance.

Syntax

```
reset database [auto_provision]
```

Argument	Description
`auto_provision`	Auto-provisioning is re-enabled and a dynamic IP address is assigned after resetting the database of appliance.

Reset the database

```
Infoblox > reset database
 The following network settings can be restored after reset: IP Address: 10.1.1.10
 Subnet Mask: 255.255.255.0
 Gateway: 10.1.1.1
 Host Name: ns1.corp100.com
 Remote Console Access: true The entire database will be erased. Do you wish to preserve basic network settings? (y or n) y
```

Reset the database and re-enable auto-provisioning

```
Infoblox > reset database auto_provision
 The entire system will be reset to default settings and system will try to obtain a dynamic address.
 WARNING: THIS WILL ERASE ALL DATA AND LOG FILES THAT HAVE BEEN CREATED ON THIS SYSTEM. ARE YOU SURE YOU WANT TO PROCEED? (y or n): y
```

reset reporting_data

The **reset reporting_data** command resets all reporting data.

Syntax

```
reset reporting_data
```

This command has no arguments.

Example

```
Infoblox > reset reporting_data
 WARNING: THIS WILL RESET ALL REPORTING DATA. DO YOU WANT TO PROCEED? (y or n): y
 ARE YOU SURE YOU WANT TO PROCEED? (y or n): y
```

reset snmp

This command clears obsolete SNMP credentials (community strings) of devices polled by Network Insight. After that, Network Insight reguesses the SNMP credentials for each device.

You can run this command on the following Grid members:

- Grid Master
- Discovery Consolidator
- Discovery Probes

When the command is executed on the Grid Master or discovery Consolidator, the SNMP credentials are reset for all devices on all discovery Probes. When the command is executed on a discovery Probe, the SNMP credentials are reset for devices only on this Probe.

Syntax

```
reset snmp
```

This command has no arguments.

Example

```
Infoblox > reset snmp
```

```
Resetting SNMP credentials will clear all assigned SNMP credentials and cause to reguess them for each device.
```

```
Do you wish to continue to the SNMP credentials (y or n): y
```

```
Probe probe.blox: Success
```

```
The command 'reset snmp' completed successfully.
```

```
Infoblox >
```

reset ssh_keys

The **`reset ssh_keys`** command resets the SSH keys of the system.

Syntax

```
reset ssh_keys
```

This command has no arguments.

Example

```
Infoblox > reset ssh_keys
 The system's SSH keys were reset.
```

restart service

Use the **restart service** command to restart services on a member. You can start individual service on the member, provided that the service is enabled. Note that you can use this command to restart services only on single independent appliances and the active nodes of HA pairs. You cannot use this command on the Grid Master.

Syntax

```
restart service [dhcp | dns | tftp | http-fd | ftp | ntp | bloxTools |
captive_portal]
```

Argument	Description
`dhcp`	Restart the DHCP service
`dns`	Restart the DNS service
`tftp`	Restart the TFTP service
`http-fd`	Restart the HTTP file distribution service
`ftp`	Restart the FTP service
`ntp`	Restart the NTP service
`bloxTools`	Restart the bloxTools service
`captive_portal`	Restart the captive portal service

Examples

```
Infoblox > restart service dhcp
```

rotate log

The **rotate log** command rolls, or rotates, specified log files. When the audit log, syslog file, and IF-MAP log each reaches its maximum size, the NIOS appliance automatically writes the file into a new file by adding a .0 extension to the first file and incrementing subsequent file extensions by 1. The maximum file size is 100 MB for the audit log, 300 MB for the syslog file, and 120 MB for the IF-MAP log.
Files are compressed during the rotation process, adding a .gz extension following the numerical increment (*file.#*.gz). The first file starts with .0 and subsequent file extensions are incremented by one until it reaches nine. For example, the current log file moves to *file*.0.gz, the previous *file*.0.gz moves to *file*.1.gz, and so on through *file*.9.gz. A maximum of 10 log files (0-9) are kept. When the eleventh file is started, the last log file (*file*.9.gz) is deleted, and subsequent files are renumbered accordingly.

When the debug log file reaches its maximum size, which is 300 MB, the appliance rotates it, but does not compress it. The appliance retains only one previous debug log file to which it adds a .old extension.
This command is useful for diagnostic purposes. To export a file to the management system for viewing, you can include it in the support bundle.
To download the support bundle:

1. From the **Grid** tab or **System** tab, select the **Grid Manager** tab or **System Manager** tab, and then click **Download**-> **Support Bundle** from the Toolbar.
2. Select all options to include configuration and core file information in the output file, then save the tar file to a secure location on the management system.

Syntax

```
rotate log {syslog | debug | audit}
rotate file groupname filename [filename2, filename3, ...}
```

Argument	Description
`syslog`	Syslog file
`debug`	Debug log file
`audit`	Audit log file

Examples

```
Infoblox > rotate log debug
 The selected log file has been rotated to infoblox.log.0.gz
```

```
Infoblox > rotate log audit
 The selected log file has been rotated to audit.log.0.gz
```

set admin_group_acl

Use the set admin_group_acl disable command to disable ACL settings for a specific admin group. You will receive an error message when you try to disable a non-existing admin group.

Syntax

```
set admin_group_acl disable <Admin Group name>
```

Argument	Description
`name`	Disables ACL settings for a specific admin group.

Examples

```
Infoblox > set admin_group_acl disable some group
 ACL setting for 'some group' was disabled.
 Infoblox > set admin_group_acl disable nonexistinggroup
 Invalid name.
```

set adp

The **set adp** command enables or disables ADP (Advanced DNS Protection) on the supported platform. You can use this command only if **Threat Protection** (hardware based) or **Threat Protection (software add-on)** licenses are installed on the platform.

Syntax

```
set adp
```

Commands for Threat Protection (software add-on):

- `set adp log <level>:` Use this command to set the threat protection log level, where log level is between **0 (emergency)** and **6 (info)**. The default value is **6 (info)**.
- `set adp log <emergency|alert|critical|error|warning|notice|info>:` Use this command to set the threat protection log level.
- `set adp monitor-mode <on|off>:` Use this command to enable or disable the threat protection monitor mode on the respective member. The default value is **off**.

Syntax

```
set adp log <level>
 set adp log <emergency|alert|critical|error|warning|notice|info> set adp monitor-mode <on|off>
```

Commands for Threat Protection (hardware-based):

- `set adp log <level>` : Use this command to set the threat protection log level, where log level is between **0 (emergency)** and **7 (debug)**. The default value is **6 (info)**.
- `set adp log <emergency|alert|critical|error|warning|notice|info|debug>` : Use this command to set the threat protection log level.

- `set adp monitor-mode <on|off>` : Use this command to enable or disable the threat protection monitor mode on the respective member. The default value is **off**.

Syntax

```
set adp log <level>
 set adp log <emergency|alert|critical|error|warning|notice|info|debug> set adp monitor-mode <on|off>
```

set allow_query_domain

You can use the **`set allow_query_domain`** command to add, update, or delete an allow query domain ACL for the domain of a DNS view. The allow query domain is an ACL that allows or denies the client's request for query access to a domain. To view the list of all domains that have allow query domain ACLs, see *show allow_query_domain*. To view the list of DNS views that have allow query domain ACLs, see *show allow_query_domain_views*.

Note

You can set the allow query domain named ACL for the domain of a DNS view on the Grid Manager, and all the Grid members will inherit the setting. However, make sure that you do not set the allow query domain named ACL on parental control domain.

Limitations

- The allow query domain ACL is a named ACL and the `set allow_query_domain` CLI accepts a single named ACL per domain.
- The allow query domain ACL supports BIND. It does not support Unbound and DNS Cache Acceleration. Hence, DNS Cache Acceleration caching is bypassed for domains that are listed in the allow query domain ACL.

Syntax

```
set allow_query_domain add [view-name] <domain-name> <named-acl>
```

```
set allow_query_domain update [view-name] <domain-name> <named-acl>
```

```
set allow_query_domain delete <view-name> [domain-name]
```

Argument	Description
`add`	Adds an ACL for allow query domain for the domain of a DNS view.
`update`	Updates an ACL for allow query domain for the domain of a DNS view.
`delete`	Deletes an ACL from allow query domain for the domain of a DNS view. To delete an ACL from the allow query domain, provide the view name of the domain.

Argument	Description
`view-name`	View in which ACL is configured.
`domain-name`	Domain to which the ACL is applied.
`named-acl`	The named ACL defined.

Examples

To add an ACL, complete the following:

```
Infoblox > set allow_query_domain add default foo.com Named_ACL
```

```
Adding ACL 'Named_ACL' for domain ' foo.com ' under view 'default'
Added successfully.
```

```
A DNS service restart is required in order for the configured ACLs to take effect
```

To update an ACL, complete the following:

Infoblox > **`set allow_query_domain update default foo.com Named_ACL2`**

```
Updating ACL 'Named_ACL2' for domain ' foo.com ' under view 'default'
Updated successfully.
```

```
A DNS service restart is required in order for the configured ACLs to take effect
```

To delete an ACL, complete the following:

```
Infoblox >set allow_query_domain delete default foo.com
```

```
Deleting ACL of domain ' foo.com ' from view 'default'
Deleted successfully.
```

```
A DNS service restart is required in order for the configured ACLs to take effect
```

set apache_https_cert

Use the **set apache_https_cert** command to select one of the previously uploaded HTTPS certificates. NIOS displays the current certificate and all the previously uploaded certificates. You must choose the certificate that you want to use. The current certificate is then replaced with the certificate that you choose.

Syntax

```
set apache_https_cert
```

Example

```
Infoblox > set apache_https_cert
Current apache certificate:
    Serial: 7976560e71f701e1a7ee7865fe87d5a4
    Common name: ib-10-34-128-114.infoblox.com
Available certificates:
    1. Serial: 0c8af1b24b1f58bb3d0d05e159841656 , Common name: www.infoblox.com
    2. Serial: 4a73ac27c92a3f731696c1ec0874143d , Common name:
ib-10-34-128-114.infoblox.com
    3. Serial: 26a52734a316c30d43e30b66a6782b18 , Common name:
ib-10-34-128-114.infoblox.com
    4. Serial: 0720ccf94062234db372dd4c8df39dbb , Common name:
ib-10-34-128-114.infoblox.com
    5. Serial: 6bb99aedde38bfe1e1402aa19507a0e1 , Common name:
ib-10-34-128-114.infoblox.com
    6. Serial: 1dc7624dd221e1900aae0e1eec97fb59 , Common name:
ib-10-34-128-114.infoblox.com
    7. Serial: 7976560e71f701e1a7ee7865fe87d5a4 , Common name:
ib-10-34-128-114.infoblox.com

Select certificate (1-7) or q to quit: 2
Are you sure you want to do this? (y or n): y
Certificate updated
```

set auto_provision

The **set auto_provision** command enables and disables auto-provisioning for the NIOS appliance. You cannot enable auto-provisioning for an appliance if a static IP address is already set for an appliance. Note that auto-provisioning can be enabled only on single appliances. To view the status of auto-provisioning for a NIOS appliance, see *show auto_provision*.

Syntax

```
set auto_provision {on | off}
```

Argument	Description
on	Enables auto-provisioning on an appliance.
off	Disables auto-provisioning on an appliance.

Examples

Turn on auto-provisioning on an appliance

```
Infoblox > set auto_provision on
```

Turn off auto-provisioning on an appliance

```
Infoblox > set auto_provision off
```

set bfd

You can use the set bfd command to set the BFD logging level. The default logging level is 'informational'. Changing the BFD logging level might cause disruption in advertising due to `bfdd.conf` change. To view the BFD session details, see *show bfd*.

Syntax

```
set bfd log [ debugging | informational | notifications | warnings | errors
| critical | alerts | emergencies ]
```

This command has no arguments.

Example

```
Infoblox > set bfd log debugging
```

set bgp log

The **set bgp log** command sets the verbosity level of the BGP routing services and writes statistical information to the syslog. The information in syslog can be helpful for diagnostic purposes. When viewing the syslog file, lines with names such as bgp statistics are the BGP statistical information. To view information about the BGP protocol running on the member, see *show bgp*.

> ⚠ **Note**
>
> To use this command, the NSQ software package must be installed.

Syntax

```
set bgp log {debugging | informational | notifications | warnings | errors |
critical | alerts | emergencies }
```

Argument	Description
`debugging`	The verbosity level at which you select to write BGP statistics to syslog.
`informational`	
`notifications`	
`warnings`	
`errors`	
`critical`	
`alerts`	
`emergencies`	

Example

```
Infoblox > set bgp log debugging
```

set bloxtools

You can use the **`set bloxtools`** command to permanently remove the bloxTools environment and all its data from the appliance. You can also use this command to clear only the user uploaded data and reset the bloxTools environment to the factory default.

> **WARNING**
>
> When you use this command, bloxTools data is permanently removed from the appliance.

To view the bloxTools status, see *show bloxtools*.

You can download a copy of the existing bloxtools data using an FTP or SFTP client before you use this command to permanently delete the data. For information, refer to the *Infoblox NIOS Administrator Guide*.

> **Note**
>
> bloxTools data files are not automatically removed when the bloxTools environment is disabled. You must use this command to manually delete bloxTools data.

Syntax

```
set bloxtools reset {all | data}
```

Argument	Description
all	Clears all bloxtools related files, which include both the system and data files. You can use this argument to remove the entire bloxtools environment and its data from your appliance.
data	Clears only the user uploaded data that is related to bloxTools and reset the bloxTools environment to the factory default.

Examples

Delete all bloxtools data files

```
Infoblox > set bloxtools reset all
 This will erase all Bloxtools data permanently. Do you want to proceed? (y or n):y
 Are you sure you want to do this (y or n): Bloxtools reset.
```

Delete bloxtools user data

```
Infoblox > set bloxtools reset data
 This will erase all Bloxtools data permanently. Do you want to proceed? (y or n):y
 Are you sure you want to do this (y or n): Bloxtools reset.
```

set cc_mode

You can use the **`set cc_mode`** command to set the Common Criteria mode. To enable or disable Common Criteria configuration, connect to the CLI console, and then enter the `set cc_mode` command. This command will restart the system when it exits the Common Criteria mode. If the system is enabled for Common Criteria, it will reboot in order to go through boot time self tests. You can use this command only on the Grid Master. The setting is propagated to all Grid members. You must restart the members after the configuration change. You can use the **`reset all`** command to clear the Common Criteria mode. For information about `reset all`, see *reset all*.

> **Note**
> Factory reset must be done before using the Common Criteria mode.

Syntax

```
set cc_mode
```

This command has no arguments.

Examples

```
Infoblox > set cc_mode
 Enable Common Criteria mode (grid-level)? (y or n): y New Common Criteria
Mode Settings:
 Common Criteria mode enabled: Yes is this correct? (y or n): y
 Please refer to the Guidance Documentation Supplement Appendix of the
 NIOS Administrator Guide for the requirements to operate a grid in a common
criteria compliant manner.
 The system will be rebooted to place it into common criteria mode. Are you
sure you want to continue (y or n): y

SYSTEM REBOOTING!

 Connection to 10.35.111.3 closed.
```

set certificate_auth_admins

Use the `set certificate_auth_admins` command to disable the certificate authentication service and allow users to log in without validation. Note that when you disable the certificate authentication service, the appliance terminates administrative sessions for all admin users.

Syntax

```
set certificate_auth_admins disable username
```

Argument	Description
username	Disables certificate authentication service and allows users to log in without validation.

Examples

```
Infoblox > set certificate_auth_admins disable admin
 Certificate authentication for 'admin' was disabled.
```

set certificate_auth_services

Use the `set certificate_auth_services disable name` command to disable a specific certificate authentication service. You will receive an error message when you try to disable a non-existing certificate authentication service.

Syntax

```
set certificate_auth_services disable name
```

Argument	Description
name	Disables specified certificate authentication service.

Examples

```
Infoblox > set certificate_auth_services disable name
 Certificate authentication for 'name' was disabled.
Infoblox > set certificate_auth_services disable DoD CaC
 Certificate Authentication Service for 'DoD CaC' was disabled.
Infoblox > set certificate_auth_services disable Some Name
 Invalid Name.
```

set check_auth_ns

The `set check_auth_ns` command enables/disables new functionality of checking NS RRset in a response's authority section before overriding delegation NS RRset in recursive cache.

Syntax

```
set check_auth_ns <true|false>
```

Argument	Description
`true`	Enables new functionality of checking NS RRset in a response's authority section.
`false`	Disables new functionality of checking NS RRset in a response's authority section.

Examples

```
Infoblox > set check_auth_ns true
```

set circ_txn_trace

The **`set circ_txn_trace`** command enables or disables a circular trace buffer for DB transaction. The file used for capturing the trace buffer is of fixed size, so tracing can be left running for an indefinite period without considering the disk space when trying to capture a problem.

Syntax

```
set circ_txn_trace [on|off]
```

Argument	Description
on	Enable tracing for circular DB transactions
off	Disable tracing for circular DB transactions

Example

```
Infoblox > set circ_txn_trace on
```

```
Infoblox > set circ_txn_trace off
```

```
Circular txn trace generated /storage/cores/circ.1632251896.gz
```

set cloud_services_portal_force_refresh

The **`set cloud_services_portal_force_refresh`** command set the flag to request all domains detected by Infoblox Threat Analytics engine in the Cloud.

.

Syntax

```
set cloud_services_portal_force_refresh
```

There are no arguments for this command.

Examples

Infoblox > `set cloud_services_portal_force_refresh`

```
Do you want to proceed? (y or n):n
```

set connection_limit

You can use the set **connection_limit** command to set the per client IP address maximum connection limit for the following protocols: HTTP and HTTPS. Note that maximum connections here refer to the network level connections, not application level connections. For example, an HTTPS connection limit of 4 means that there can be a maximum of four TCP connections between any given client IP address and the appliance using the HTTPS protocol. Valid values are from 0 to 2147483647, where 0 means no limit. The default value is 20 for all protocols.

> **Note**
>
> Setting a low connection limit may have a negative effect on client functionality. For example, some versions of the Firefox browser require at least four TCP connections to function correctly with the appliance. Setting an HTTPS connection limit below four may result in certain browser issues.

To view the current connection limit, see *show connection_limit*.

Syntax

```
set connection_limit {http | https}
```

Argument	Description
http	Setting maximum connection limit for the HTTP protocol. Valid values are from 0 to 2147483647. The default value is 20.
https	Setting maximum connection limit for the HTTPS protocol. Valid values are from 0 to 2147483647. The default value is 20.

Examples

Set the Per Client Address Maximum Connection Limit for the HTTP Protocol

```
Infoblox > set connection_limit http 150
```

set debug

The **set debug** command enables and disables debug logging for the NIOS appliance. Debug logging is the most extensive and verbose logging that is available on the appliance. It captures all levels of messaging. The output is written into the debug log file. For information on how to view this output, see *show debug*.
Use this command to capture specific occurrences. However, only use it for short periods of time. Do not leave it running for extended periods of time. Due to the amount of data that is captured, leaving this feature running for any length of time can affect the performance of the appliance. For this reason, it is best to use this command during non-peak hours.

> **Note**
>
> Infoblox recommends that you turn debug logging off, unless Infoblox Support specifically directs you to turn this feature on. If you leave debug logging turned on, it can cause performance issues.

Syntax

```
set debug [distribution|upgrade|firewall|ntp|slog|all] [on|off]
```

Argument	Description
all	Specifies debug logging for all services as enabled or disabled.
on	Enables debug logging.
off	Disables debug logging.

Examples

Enable debugging

```
Infoblox > set debug all on
 Enabled debug logging for : all
```

Disable debugging

```
Infoblox > set debug all off
 Disabled debug logging for: all
```

set debug_analytics

The `set debug_analytics` command enables or disables debugging of Analytics service.

Syntax

```
set debug_analytics [on|off]
```

Argument	Description
on	Enables debugging of Analytics service
off	Disables debugging of Analytics service

Examples

Enable debugging

```
Infoblox > set debug_analytics on
```

Disable debugging

```
Infoblox > set debug_analytics off
```

set default_revert_window

Use the **`set default_revert_window`** command to configure the Grid default time window for reverting a member after it was upgraded from NIOS 6.4.0 to a later release. Note that you can only change the default value on the Grid Master. When you change the default value, the new revert window affects only the members that have not been upgraded.

Syntax

```
set default_revert_window hours
```

Argument	Description
hours	The number of hours configured for the default revert window. The minimum value is 1 and the maximum is 48. The default is 24.

Example

```
Infoblox > set default_revert_window 36
 Member revert window is currently: 24h
 Member Revert Window being changed to 36 hours Is this correct? (y or n): y
 Member Revert Window change will only affect members which are not yet
upgraded. Member Revert Window is changed.
```

set default_route

The **`set default_route`** command allows you to configure the default gateway for the NIOS appliance. You can set the gateway address of LAN1 or LAN2 as the default route. You can also specify the IPv4 or IPv6 gateway address. You can also set an optional VLAN gateway address and make it the default route.

Syntax

```
set default_route LAN1|LAN2
set default_route IPv4gateway [IPv6gateway] | IPv6gateway [IPv4gateway]
```

Argument	Description
`LAN1` `LAN2`	Specifies the LAN1 gateway address. Specifies the LAN2 gateway address.
`IPv4gateway` `IPv6gateway`	Specifies the IPv4 gateway address. Specifies the IPv6 gateway address.

Example

```
Infoblox > set default_route LAN1
Infoblox >set default_route LAN2
 Infoblox > set default_route 10.35.0.1 2620:10a:6000:2400::1
Infoblox > set default_route 2620:10a:6000:2400::1
```

set delete_tasks_interval

Use the **`set delete_tasks_interval`** command to configure the time interval the appliance waits until it deletes completed and rejected tasks from the system. Grid Manager displays these tasks in the **Task Manager** tab until they are deleted from the system. By default, Grid Manager displays these tasks for 14 days. You can configure this time interval. Valid values are from 1 to 30 days.

Use the **`show`** **delete_tasks_interval** command to view the current time interval. For information, see *show delete_tasks_interval*.

Syntax

```
set delete_tasks_interval days
```

Argument	Description
days	The number of days completed and rejected tasks are displayed in the **TaskManager** tab before they are deleted. The minimum value is 1 and the maximum is 30. The default is 14.

Example

```
Infoblox > set delete_tasks_interval 25
 Current delete tasks interval is 14 days
```

```
 The delete tasks interval has been changed to 25 days Is this correct? (y
or n): y
 The delete tasks interval has been changed.
```

set dhcpd_recv_sock_buf_size

You can use the **set dhcpd_recv_sock_buf_size** command to tune the DHCP receive socket buffer memory. The DHCP receive socket buffer holds DHCP packets that are queued on the UDP (User Datagram Protocol) port from the NIC (Network Interface Controller). This command is useful when you want to increase the DHCP receive buffer size to accommodate occasional burst traffic and high volume DHCP requests. Use the *show dhcpd_recv_sock_buf_size* to view the current buffer size.

> **Note**
>
> Ensure that you use this command only when you are dealing with burst traffic situations in high volume deployments.

Syntax

```
set dhcpd_recv_sock_buf_size N [120 <= N <= 8192, 1536=default]
```

Examples

Argument	Description
N	The number of kilobytes to which you want to set the BIND receive socket buffer size. The minimum is 120 kilobytes and the maximum is 8192. The default is 1536.

```
Infoblox > set dhcpd_recv_sock_buf_size 1500
 DHCP service restart is required in order for the changed value to take effect
```

set extra_dns_name_validations

Use the **set extra_dns_name_validations** command to enable or disable additional validation on host names that takes place at the time of data entry when creating zones, subzones, and records of type A, AAAA, host record, ALIAS, CAA, MX, and NS. The additional validation invokes the same functions in the BIND library that the DNS service invokes when it is loading a zone and this can impact the performance of your current operation.

By default, the additional validation is disabled. When the validation is enabled, if you enter an invalid name, NIOS displays an error message and does not save the record until the name that you enter passes the additional validation.

Syntax

```
set extra_dns_name_validations [on|off]
```

Argument	Description
`on`	Enables the additional DNS name validation that takes place when you create a zone or a resource record.
`off`	Disables the additional DNS name validation that takes place when you create a zone or a resource record.

Example

```
Infoblox > set extra_dns_name_validations on
WARNING: This has a performance impact when creating or importing multiple
records at a time. Do you want to continue? (y or n): y
Extra DNS name validations is turned on
```

set disable_gui_one_click_support

The **`set disable_gui_one_click_support`** command permanently disables the feature to submit technical support requests through the Infoblox GUI.

Syntax

```
set disable_gui_one_click_support
```

There are no arguments for this command.

Example

```
Infoblox > set disable_gui_one_click_support
WARNING: Once you permanently disable this feature, you cannot enable it
again.
Are you sure you want to proceed? (y or n): y
```

set disable_https_cert_regeneration

Use the **`set disable_https_cert_regeneration`** command to turn on or off the automatic regeneration of a self-signed HTTPS certificate.

NIOS regenerates a certificate in the following scenarios:

- If you change a host name and the new name does not match the name of the existing certificate. This is especially useful for wildcard certificates.

- If the certificate is self-signed and the regeneration is enabled (it is enabled by default) , restarting NIOS or changing the host name or IP address causes NIOS to regenerate the certificate.

Syntax

```
set disable_https_cert_regeneration [on|off]
```

Argument	Description
on	Disables the automatic regeneration of the self-signed HTTPS certificate. Automatic certificate regeneration is enabled by default.
off	Enables the automatic regeneration of the self-signed HTTPS certificate

Example

```
Infoblox > set disable_https_cert_regeneration off
HTTPS certificate regeneration enabled.
```

set dns

The **`set dns`** command enables you to control the DNS cache. You can flush the cache file of a DNS view or flush a particular entry from a cache file. You can also flush a specific domain and its subdomains from the DNS cache. In addition, you can schedule an inbound zone transfer from an external primary server. This command displays IDN data in punycode. You can also use this command to delete cache files from the default DNS view for DNS cache acceleration on IB-FLEX.

Syntax

```
set dns flush all [dns_view]
set dns flush name name [dns_view]
set dns transfer zone [dns_view]
set dns flush tree <part-of-domain-name> [dns_view]
```

Argument	Description
`all`	Flushes the cache file from the default view.
`dns_view`	Specifies a particular DNS view.
`name`	Flushes the specific entry from the cache.
`zone`	Specifies the zone for the inbound transfer from an external primary server.

Argument	Description
`tree <part-of-domain-name>`	Flushes the specified domain and its subdomains from the DNS cache. For example, if you enter the domain name corp100.com, then the specified domain and its subdomains such as www.corp100.com, corp100.com, x.corp100.com, etc. are cleared from the DNS cache.

Example

Flush the cache file from the default DNS view

```
Infoblox > set dns flush all
```

Flush the specified domain and its subdomains from the default DNS view

```
Infoblox > set dns flush tree corp100.com default
```

set dns-accel

The **`set dns-accel`** command enables you to set certain parameters for the **DNS Cache Acceleration** feature. This command is available for:

- IB-FLEX only if the **Flex Grid Activation** license is present in the Grid.

Syntax

```
set dns-accel log <level>
set dns-accel log <emergency|alert|critical|error|warning|notice|info|debug>
```

Argument	Description
`level`	The DNS Cache Acceleration log level, where log level is between 0 and 7, and the default value is 6.
`<emergency|alert|critical|error|warning|notice|info|debug>`	Specifies one of these log levels.

Example

```
Infoblox > set dns-accel log 2
```

```
Infoblox > set dns-accel log notice
```

set dns_rrl

Use the **set dns_rrl** command to configure RRL (Response Rate Limiting) settings for the Grid or members. Changes made using this command are applied immediately to an active DNS resolver, although there could be replication delays for Grid Master configuration of other members. Use the *show dns_rrl* to view the current RRL settings.

Syntax

```
set dns_rrl enable
set dns_rrl disable
set dns_rrl [member <hostname> | view <viewname>] [override|inherit]
set dns_rrl [member <hostname> | view <viewname>] [enable|disable]
set dns_rrl [member <hostname> | view <viewname> | grid]
    [responses_per_second <number>|disable] [window <number>|default]
    [slip <number>|default|disable] [logging enable|disable|default]
    [log_only true|false|default]
```

> **Note**
> The set dns_rrl command accepts the member, view, and grid options only on the Grid Master.

Argument	Description
`enable`	Enable RRL with previously configured values.
`disable`	Disable RRL
`member <hostname>`	The FQDN of the Grid member.
`view <viewname>`	The name of the DNS view.
`override|inherit`	For a Grid member, specify whether you want to override the Grid RRL settings or inherit them from the Grid.
`responses_per_second <number>`	The number of DNS responses per second for the RRL. Valid values are from 1 to 1000. Although the BIND default is 0, which means there is no limit or RRL is disabled, you cannot set this to 0 in NIOS. Use the “disable” argument to disable this feature. The default is 100.
`window <number>|default`	A rolling window of time (in seconds) within which DNS responses are tracked. Valid values are from 1 to 3600 seconds. The default is 15 seconds.

Argument	Description
`slip <number>|default|disable`	The number of UDP requests that the appliance skips before answering with a truncated response. For example, if you set the slip number to 2, the appliance responds to every other UDP request. Valid numbers are from 0 to 10. The appliance does not “slip” if the number is set to 0. The default is 2.
`logging enable|disable|default`	Enable or disable the logging of RRL events to the “rate-limit” logging category in syslog. This is enabled by default; however, RRL events are logged to the “rate-limit” category only if RRL is enabled. Note that inheritance for logging categories applies; therefore, you must explicitly override Grid logging categories on a member for changes to the member logging setting to take effect. You cannot use the dns_rrl override command to override logging configuration for a member. Changes made to this setting require a service restart.
`log_only true|false|default`	Set this to true to test the RRL settings without dropping any requests. Set this to false to enable RRL. The default is false.

Examples

Configure the Grid RRL settings on the Grid Master

Infoblox > **set dns_rrl responses_per_second 100 log_only false window default slip 2 logging disable**

> **Note**
> You can also execute the above command on a Grid member to change the RRL settings for that member.

Override the Grid RRL settings on a Grid member

```
Infoblox > set dns_rrl corp100.com override responses_per_second 300
log_only false window 200 slip 3
```

Inherit the Grid RRL settings on a Grid member

```
Infoblox > set dns_rrl corp100.com inherit
```

set docker_bridge

The `set docker_bridge` command resets the IP address of the current Docker bridge to the IP address that you specify. You can view the IP address of the current Docker bridge by running the *show docker_bridge* command.

Syntax

```
set docker_bridge
```

This command has no arguments.

Example

```
Infoblox > set docker_bridge
Enter Bridge Gateway/CIDR: 172.17.0.1/16
New Docker Bridge settings:
Bridge Gateway/CIDR:   172.17.0.1/16
Current Docker Bridge settings:
Bridge Gateway/CIDR:   172.16.0.1/16
WARNING: This operation will restart the system to reset the current docker
bridge settings.
Do you want to proceed? (y or n):y
Docker bridge settings have been updated.
System will be restarted.
```

Note

- The warning message to restart the system is displayed only if the **Enable Recursive Queries Forwarding to BloxOne Threat Defense Cloud** checkbox is selected.
- Infoblox recommends that you run the `set docker_bridge` command only on non-routable IP addresses.
- Infoblox does not recommend that you run the `set docker_bridge` command on a passive HA node

set dscp

Use the **`set dscp`** command to configure the DSCP value, which determines the PHBs (per-hope behaviors) on DiffServ compliant nodes and enables priorities of services to be assigned to network traffic. When you set the DSCP value, the appliance implements QoS (quality of service) rules based on your configuration so you can effectively classify and manage your critical network traffic. Note that on an appliance, all outgoing IP traffic on all interfaces uses the same DSCP value. You can configure this value for the Grid. You can also override the Grid setting for individual members. DSCP is supported on both IPv4 and IPv6 transports. This feature is currently supported on the following Infoblox appliances: Trinzic 2210, Trinzic 2220, and Infoblox-4010. For information about these appliances, refer to the respective installation guides.

Syntax

```
set dscp grid [value]
set dscp member [value]
set dscp member inherit
```

Argument	Description
value	The DSCP value. You can enter a value from 0 to 63. The default is 0 and it represents the lowest priority.

Example

Set the Grid DSCP value

```
Infoblox > set dscp grid 32
```

Override the Grid DSCP value for a specific member

```
Infoblox > set dscp member 20
```

Inherit the Grid DSCP value

```
Infoblox > set dscp member inherit
```

set enable_dnstap

Use the `set enable_dnstap` command to enable or disable using dnstap to log DNS queries and responses. For information about using dnstap, see *Capturing DNS Queries and Responses*. To view the status of the dnstap configuration, see *show dnstap-status*.

Syntax

```
set enable dns_tap [on|off]
```

Argument	Description
on	Enables the use of the dnstap log format to log DNS queries and responses at high rates to well-known destinations.
off	Disables the use of the dnstap log format to log DNS queries and responses.

Examples

To enable the use of the dnstap log format:

```
Infoblox > set enable_dnstap on
Override Grid settings and configure DNSTAP on member level? (y or n):
```

The input `y` overrides Grid settings and enables member-level dnstap configuration. The input `n` inherits Grid settings; no further configuration is performed.

To disable the use of the dnstap log format:

```
Infoblox > set enable_dnstap off
```

set enable_match_recursive_only

Use the **`set`** **enable_match_recursive_only** command to enable or disable the match-recursive-only option for a specific DNS view on a specific Grid member. You can also use the match-recursive-only option in combination with the Match Clients and Match Destinations settings to restrict and filter client access for specific DNS views on specific Grid members. For information about how to use these features, refer to the *Infoblox NIOS Administrator Guide*.
If you want to enable this setting for a DNS view, ensure that the **Enable Recursion** setting is enabled for the DNS view on the specified member.

To check the status of this setting for all DNS views on a Grid member, use the `show enable-match-recursive-only` CLI command. For information, see *show enable_match_recursive_only*.

Syntax

```
set enable_match_recursive_only <true|false|inherit> [dns_view]
```

Argument	Description
`<true|false|inherit>`	Set the **`enable_match_recursive_only`** setting to `true`, `false`, or `inherit`. The default value is inherit. The `true` setting enables the match-recursive-only option for the specified DNS view on the specific member; `false` disables it for the specified DNS view on the specific member. `Inherit` represents the setting for the DNS view `(true or false)` that is populated across all members serving that DNS view. By specifying `true` or `false`, you override the `inherit` setting for the specific member. Specifying `inherit` restores the inherited setting for the specific member.
`dns_view`	Optional parameter to specify the DNS view. If this parameter is omitted, the setting affects only the default DNS view. If the specific Grid member does not serve the default DNS view, you will receive an error message by omitting this parameter.

Example

```
Infoblox > set enable_match_recursive_only true (affects default DNS view only if default DNS view is served by member)
 Infoblox > set enable_match_recursive_only true external
Infoblox > set enable_match_recursive_only false corp100sales
Infoblox > set enable_match_recursive_only inherit external
```

set fips_mode

You can use the **`set fips_mode`** command to enable the FIPS mode. This command restarts the appliance to go through the boot time self tests when it exits the FIPS mode.

- In a Grid, you can set the FIPS mode only on the Grid Master. The setting is propagated to all Grid members during the joining process. After the configuration is changed, the members will be restarted.
- You can set the FIPS mode on standalone systems.
- In an HA setup, you can set the FIPS mode only on the standalone Grid Master, and then configure it as a node in the HA pair. Perform the same step for the second node of the HA pair. You cannot change the FIPS mode setting on the HA Grid Master or the HA member.

To enable or disable the FIPS configuration, connect to the CLI console, and then enter the `set fips_mode` command. For more information, see *Enabling / Disabling the FIPS Mode*.

To clear the FIPS mode, you can use the `reset all` command. For more information, see *reset all*.

> **Note**
>
> You must perform a factory reset to reset the appliance to its original factory settings before using the FIPS mode.

Syntax

```
set fips_mode
```

This command has no arguments.

Examples

```
Infoblox > set fips_mode
Enable FIPS mode? (y or n): y
New FIPS Mode Settings:
  FIPS mode enabled: Yes
    is this correct? (y or n): y
Please refer to the Guidance Documentation Supplement Appendix of the NIOS Administrator Guide for the requirements to operate a grid in a FIPS compliant manner.
The system will be rebooted to place it into FIPS mode. Are you sure you want to continue (y or n): y
Integrity private key and certificate were generated successfully.
Sign executable files by sha256sum...
```

set hardware-type

Use the **set hardware-type** command for IB-FLEX only. This command enables you to set a supported virtual appliance as an IB-FLEX. For more information, see *About IB-FLEX*.

To see if an appliance has been configured as an IB-FLEX, you can use the **show hardware-type** command.

Syntax

```
set hardware-type
```

This command has no arguments.

Example

When setting a supported virtual appliance as an IB-FLEX:

```
Infoblox > set hardware-type IB-FLEX
```

set ibtrap

The **set ibtrap** command allows you to specify whether the appliance sends SNMP notifications (traps) and email notifications to the configured trap receivers and email recipients for the specified event category.

Syntax

```
set ibtrap [category] snmp [true|false] email [true|false]
```

Argument	Description
category	The event category that triggers the trap and/or email notification. Valid values are: Fan, Bloxtools, Disk, Memory, CPU, MGM, HSM, Login, PowerSupply, FTP, TFTP, HTTP, NTP, DNS, DHCP, RootFS, Database, RAID, HA, MSServer, Backup, Clear, SNMP, LCD, SSH, SerialConsole, ENAT, Network, Cluster, Controld,OSPF,OSPF6, IFMAP, BGP, CaptivePortal, DuplicateIP, License, System, Syslog, DiscoveryConflict, Reporting, FDUsage, OCSPResponders, DisconnectedGrid, LBDevice, LDAPServers, RIRSWIP
snmp true | false	Specify `true` to send SNMP traps. Otherwise, specify **false.**
email true | false	Specify `true` to send email notifications. Otherwise, specify **false.**

Example

```
Infoblox > set ibtrap FTP snmp true email true
```

set interface

The `set interface` command allows you to configure the speed and duplex settings of the network interfaces (MGMT, HA, LAN1, and LAN2) on single independent appliances only. You cannot configure the network interface settings of appliances after they join a Grid or become HA pairs.

You can use `set interface mgmt` to enable the MGMT port and configure its IP address, netmask, and gateway address. You can configure either IPv4 address, IPv6 address or both for the MGMT interface of the appliance. Once the MGMT port is enabled, you can use the command to configure the speed and duplex settings of the MGMT port. You can also use `set interface mgmt off` to disable the MGMT port.

Use the *show interface* command to view the interface settings.

Syntax

```
set interface [lan1|ha|lan2] speed [auto|10M|100M|1000M] duplex {auto|half|full]
set interface mgmt [speed [auto|10M|100M|1000M] duplex {auto|half|full]]
set interface mgmt off
```

Argument	Description

`lan1`
`lan2`
`ha`
	Specifies the LAN1 interface.
	Specifies the LAN2 interface on the Infoblox-250-A, -550-A, -1050-A, -1550-A, -1552-A, and -2000-A appliances.
	Specifies the HA interface.

`speed`
`auto`
`10M |100M | 1000M`
	Specifies the speed of the incoming line rate in Mbps, or allows the appliance to automatically match the line speed.

Argument	Description
`duplex auto half full`	Specifies the duplex speed: • Automatically adjusts the speed • Sets it at half speed • Set it at full speed
`mgmt`	Specifies the management interface.
`mgmt off`	Disables the management system interface. **Note:** If this port is not being used, it should be set to off for security reasons.

Examples

Enable and configure IPv4 address for the MGMT interface

```
    Infoblox >
     set interface mgmt

    Enable Management port? (y or n):
     y

    Enter Management IP address:
     10.36.1.157

    Enter Management netmask [Default: 255.255.255.0]:
     255.255.0.0

    Enter Management gateway address [Default: 10.36.0.1]:
Configure Management IPv6 network settings? (y or n): n
Restrict Support and remote console access to MGMT port? (y or n):
    n
```

```
    Management Port Setting:
Management Port Enabled: true
Management IP address: 10.36.1.157
Management netmask: 255.255.0.0

    Management Gateway address: 10.36.0.1
Restrict Support and remote console access to MGMT port:false

    Is this correct? [ y or n]:
    y

    Are you sure? (y or n):
    y

The management port settings have been updated.
```

Enable and configure IPv6 address for the MGMT interface

```
    Infoblox > set interface mgmt
Enable Management port? (y or n): y
Enter Management IP address: 2620:010A:6000:2400::6508
Enter Management IPv6 Prefix Length [Default: none]: 64
Enter Management IPv6 gateway address [Default: none]:
2620:010A:6000:2400::0001
Configure Management IPv4 network settings? (y or n): n
Restrict Support and remote console access to MGMT port? (y or n): n

    Management IPv6 address: 2620:10a:6000:2400::6508/64
```

```
Management IPv6 Gateway address: 2620:10a:6000:2400::1
Restrict Support and remote console access to MGMT port: false

    Is this correct? (y or n): y
Are you sure? (y or n): y

The management port settings have been updated
```

Specify the MGMT interface speed after the port is enabled

```
Infoblox >
 set interface mgmt speed 10M duplex full

Setting Management interface speed to: 10M and duplex to: full
Is this correct? [ y or n]:
 y

The netwrok interface settings have been updated.
```

Specify the LAN interface speed

```
Infoblox >
 set interface lan1 speed 10M duplex full

Setting LAN1 interface speed to: 10M and duplex to: full
Is this correct? [ y or n]:
 y
```

```
    The netwrok interface settings have been updated.
```

Specify the HA interface speed

```
    Infoblox >
     set interface ha speed 100M duplex half

    Setting HA interface speed to: 100M and duplex to: half
Is this correct? [ y or n]:
     y

    The netwrok interface settings have been updated.
```

> **Note**
> This command is not supported on vNIOS appliances

set ip_rate_limit

The **set ip_rate_limit** commands enable and disable rate limiting UDP traffic from source port 53, configure rate limiting rules that control the traffic, and remove rate limiting rules. Once you enable rate limiting, the current rate limiting rules take effect.
This command is useful when you want to mitigate cache poisoning on your DNS server by limiting the UDP traffic or blocking connections from source port 53.

Syntax

set ip_rate_limit {on | off}
set ip_rate_limit remove {source all | all | source *ip-address[/mask]*}
set ip_rate_limit add source {all | *ip_address [/mask]}* limit 0
set ip_rate_limit add source {all | *ip_address [/mask]}* limit packets/m [burst *burst_packets*]

Argument	Description
`On`	Enables rate limiting from UDP port 53.
`Off`	Disables rate limiting from UDP port 53.

Argument	Description
`add source` `all` `ip_address/mask` `limit packets` `burst` ***burst_packets***	Configures the rate limiting rules. Enter all or 0.0.0.0 if you want to limit all traffic from all sources. Enter the IP address, and optionally the netmask, from which you want to limit the UDP traffic on port 53. Enter the number of packets per minute that you want to receive from the source. Optionally, enter burst and the number of packets for burst traffic. Burst is the maximum number of packets accepted.
`remove` `source all` `all` `source` ***ip-address/mask***	Removes rate limiting rules from all sources or an existing host on UDP port 53. Removes the rate limiting rule that limits traffic from all sources on UDP port 53. Removes all of the rate limiting rules from all sources on UDP port 53. Removes the existing rules for an existing host.

Examples

Turn on rate limiting

```
Infoblox > set ip_rate_limit on
 Enabling rate limiting will discard packets and may degrade performance.
 Are you sure? (y or n):
```

Turn off rate limiting

```
Infoblox > set ip_rate_limit off
```

Block all traffic from host 10.10.1.1

```
Infoblox > set ip_rate_limit add source 10.10.1.1 limit 0
```

Limit the traffic to five packets per minute from host 10.10.1.2/24, with an allowance for burst of 10 packets

```
Infoblox > set ip_rate_limit add source 10.10.1.2/24 limit 5/m burst 10
```

Remove the rate limiting rule from host 10.10.1.1/24

```
Infoblox > set ip_rate_limit remove source 10.10.1.1/24
```

set ipam_web_ui

The **set ipam_web_ui** command enables and disables Grid Manager on vNIOS appliances on Cisco. For information about Grid Manager, refer to the *Infoblox Administrator Guide*.

Syntax

```
set ipam_web_ui
```

This command has no arguments.

Example

```
Infoblox > set ipam_web_ui
```

set ipv6_disable_on_dad

The **`set ipv6_disable_on_dad`** command enables or disables IPv6 on an interface if a duplicate IPv6 address is detected.

Syntax

```
set ipv6_disable_on_dad {on | off}
```

Argument	Description
`on`	Enables IPv6 on an interface.
`off`	Disables IPv6 on an interface.

Examples

Turn on IPv6 on an interface

```
Infoblox > set ipv6_disable_on_dad on
 WARNING: This operation will reboot the system.
Do you want to proceed? (y or n): y
 SYSTEM REBOOTING!
```

```
Infoblox > set ipv6_disable_on_dad on
 Already on, nothing do be done
```

Turn off Pv6 on an interface

```
Infoblox > set ipv6_disable_on_dad off
WARNING: This operation will reboot the system.
Do you want to proceed? (y or n): y
 SYSTEM REBOOTING!
```

set ipv6_neighbor

The **`set ipv6_neighbor`** command enables definition of an IPv6 neighbor for any of the following: LAN1, LAN2 or MGMT. **`Set`** **ipv6_neighbor** also allows deletion of an existing IPv6 neighbor entry on the specified interface. For adding a new neighbor entry, the second required argument is for the link-local MAC address ID of the neighboring interface for the specified LAN/LAN2/MGMT port.
Another form of this command allows the flushing of specific or general IPv6 neighbor values from the specified interface. Prefixes and polled neighbor states can also be specified and combined in a statement.

Syntax

```
set ipv6_neighbor {add|clear} {LAN|LAN2|MGMT} [all] [prefix] ipv6-address
ll_address [state]
```

Argument	Description
ipv6_address	The IPv6 address of the neighboring interface.
ll_address	The 48-bit link-local MAC ID of the neighboring interface. Argument is required for addition of a new IPv6 neighbor entry for the interface.
[all]	Optional argument to clear the entire list of IPv6 entries for the specified interface.
[prefix]	Optional argument needed if all entries are to be flushed for an IPv6 prefix. CIDR mask is required as part of the address specification.
[state]	Optional argument needed if entries of a specific type are to be flushed or defined for an IPv6 prefix. Permitted values for the **state** argument include the following: **permanent, noarp, reachable,** and **stale.**

Example

```
Infoblox > set ipv6_neighbor add LAN 2001:db8::256:180:c223:214e
02:80:C2:03:DE:05
 Infoblox > set ipv6_neighbor add LAN 2001:db8::256:180:c223:214e
```

```
02:80:C2:03:DE:05 permanent
 Infoblox > set ipv6_neighbor clear LAN2 2001:db8::256:180:c223:214e
02:80:C2:03:DE:05
 Infoblox > set ipv6_neighbor clear LAN prefix 2001:db8:12:256::/64 stale
 Infoblox > set ipv6_neighbor clear LAN all
```

set ipv6_ospf

The **set ipv6_ospf** command writes statistical information to syslog. This command provides informational data that can be helpful for diagnostic purposes. Setting the log level for OSPFv3 is the only configuration that can be done for the routing protocol in the NIOS CLI. The statistical information is written (dumped) to syslog. When viewing the syslog file, lines with names such as `ipv6_ospf statistics` are the OSPF statistical information. Use the *show ipv6_ospf* command to view the OSPF settings.
Syslog level describes the types of messages that are sent to syslog. You can identify the syslog information by using the `level` option.

> **Note**
> To use this command, the NSQ software package must be installed.

Syntax

```
set ipv6_ospf log {level}
```

Argument	Description
level	Writes OSPF statistics to syslog with a specific associated level. The sup- ported log levels are: `debugging, informational, notifications, warnings, errors, critical, alerts,` and `emergencies.`

Example

```
Infoblox > set ipv6_ospf log alerts
```

set ipv6_status

The **set ipv6_status** command enables or disables IPv6 on all interfaces. This is not a permanent enable or disable. If you restart your system, IPv6 is enabled once again.

Syntax

```
set ipv6_status {enable / disable}
```

Argument	Description
enable	Enables IPv6 on all interfaces.
disable	Disables IPv6 on all interfaces.

Example

```
Infoblox > set ipv6_status enable
WARNING: This operation will restart the product
Do you want to proceed? (y or n):y
Infoblox > show interface
 MGMT:
    IP Address:  10.36.111.3      MAC Address: 00:0C:29:70:D5:F5
    Mask:        255.255.0.0      Broadcast: 10.36.255.255
    MTU:         1500             Metric:   1
    IPv6 Link:           fe80::20c:29ff:fe70:d5f5/64
    IPv6 Status:         Enabled
    Negotiation: Disabled
    Speed:       1000M            Duplex:      Full
    Status:      UP BROADCAST RUNNING MULTICAST
    Statistics Information
    Received

```

set lcd keys or set lcd

The set lcd keys or set lcd command enables and disables the LCD input keys. Turning off the LCD input keys prevents anyone from manually changing the IP address on the NIOS appliance. Infoblox recommends this practice as a security measure for remote appliances.

Syntax

```
set lcd keys {off | on}
```

Argument	Description
`off`	Disables the LCD input keys on the appliance.
`on`	Re-enables the LCD input keys on the appliance.

Examples

Disable the lcd keys

```
Infoblox > set lcd keys

```

Enable the lcd keys

```
Infoblox > set lcd keys on

 Turning ON the LCD display...
```

> **Note**
>
> You cannot enable or disable the LCD input keys on vNIOS appliances. You can configure the LCD input keys only on a Grid Master. On a vNIOS appliance, the **set lcd keys** or **set lcd** command generates an error.

set lcd_settings

The **`set lcd_settings`** command enables you to set the display settings of an LCD. You can specify the number of seconds after which the LCD screen must reduce the brightness if there is no keypad activity and specify the brightness level. You can also use this command to set the UID (unit identification) button on Trinzic appliances. For more information, see *set lcd_settings hwident*.

Syntax

Argument	Description
<seconds>	Sets the number of seconds after which the LCD screen should automatically dim. The auto-dim value should be in the range of 5 to 3600.
<level>	Sets the brightness of the LCD screen. Brightness levels are from 1 to 10.

Example

```
Infoblox > set lcd_settings autodim 8
 Infoblox > set lcd_settings brightness 5
```

set lcd_settings hwident

The **set lcd_settings hwident** command enables and disables the UID (unit identification) button on Trinzic appliances. When you enable the UID button, the LCD panel on the front panel blinks and the UID LED on the rear panel glows blue. In a rack environment, the UID feature allows you to easily identify the appliance when moving between the front and rear of the rack.

Syntax

```
set lcd_settings hwident {off | on}
```

Argument	Description
off	Disables the UID feature on the Trinzic appliance.
on	Enables the UID feature on the Trinzic appliance.

Examples

Disable the UID feature

```
Infoblox > set lcd_settings hwident off

 Turning OFF the UID feature
```

Enable the UID feature

```
Infoblox > set lcd_settings hwident on

 Turning ON the UID feature
```

> **Note**
>
> You cannot enable or disable the UID feature on vNIOS appliances. You can configure the UID feature only on Trinzic appliances. On a vNIOS appliance, the **set lcd_settings hwident** command generates an error.

set license

The **set license** command installs a license upon entering a valid license string. You must send an email request to Infoblox to receive a unique license string for your NIOS appliance. Copy the string directly from the email, and then use CTRL + V to insert it after the CLI command prompt. Use the *show license* command to view the license settings. This command is used to install both static (per member) and Grid-wide licenses.

> **Note**
>
> You can install a temporary 60-day license that allows your system to be fully functional while waiting to receive your permanent license. For more information, see *set temp_license*.

Syntax

```
set license
```

This command has no arguments.

Example

```
Infoblox > set license
 Enter license string: EQAAAAKS4n90WFGNUSirwvyUT9/z
 Install license? (y or n): y
 Infoblox > set license
 Enter license string: HQAAALsakOzDKirMdaUsG2Yfk/j0BkhoFjhVfEtu36dJ
 Install license? (y or n): y

License (grid-wide) is installed.

The UI needs to be restarted in order to reflect this license change.

Restart UI now, this will log out all UI users? (y or n):y
```

set lines

The **set lines** command specifies the number of lines that the appliance displays when you execute a **show** command during a session. The default is 20 lines. You can also configure permanent page settings or enter zero (0) to set paging off.

Syntax

```
set lines [num | permanent]
```

Argument	Description
`num`	The number of lines the appliance displays when you execute a **`show`** command.
`permanent`	Configures permanent page settings.

Examples

Set the number of lines displayed on each page to 4:

```
Infoblox > set lines 4
Number of scroll lines set to 4.
Infoblox > show log
May 31 13:30:05 (none) syslog-ng[892]: syslog-ng version 1.6.11 starting
May 31 13:30:05 (none) kernel: Linux version 2.6.17.4 (root@build-aslan)
(gcc version
3.2.1) #1 SMP Fri May 18 19:44:21 EDT 2013
May 31 13:30:05 (none) kernel: BIOS-provided physical RAM map:
May 31 13:30:05 (none) kernel: BIOS-e820: 0000000000000000 -
000000000009f800 (usable)
Enter <return> for next page or q<return> to go back to command line.
```

Turn paging off for this session:

```
Infoblox > set lines 0
 Number of scroll lines set to 0.
```

Set a permanent line number:

```
Infoblox > set lines permanent 24
 Number of scroll lines set to 24.
```

set log_txn_id

The **`set log_txn_id`** command enables or disables the display of DHCP transaction IDs in syslog messages. By default, DHCP transaction ID logging is enabled. When you enable DHCP transaction ID logging, the appliance displays transaction IDs for the following packets:

- DHCPDISCOVER
- DHCPREQUEST
- DHCPRELEASE

- DHCPDECLINE
- DHCPINFORM

In Grid Manager, the transaction IDs are appended to the end of the corresponding syslog messages with a prefix of "TransID." You can view this information in the **Administrator** tab -> **Logs** tab -> **Syslog** tab of Grid Manager.
When you enable this feature, you must restart DHCP service for the feature to take effect. When you disable this feature, you must perform a force restart services for the change to take effect. Use the *show log_txn_id* to display the current status of DHCP transaction ID logging.

Syntax

```
set log_txn_id (ON|OFF)
```

Argument	Description
ON	Enables DHCP transaction ID logging on an appliance.
OFF	Disables DHCP transaction ID logging on an appliance.

Example

Enable DHCP transaction ID logging on an appliance

```
Infoblox > set log_txn_id ON
 DHCP Transaction id logging turned ON
 DHCP force restart services is required in order for the changed value to
take effect
```

Disable DHCP transaction ID logging on an appliance

```
Infoblox > set log_txn_id OFF
 DHCP Transaction id logging turned OFF
 DHCP force restart services is required in order for the changed value to
take effect
```

Sample syslog messages in the Syslog tab of Grid Manager:

When DHCP transaction ID logging is on:

```
2013-03-25T09:39:41+00:00 daemon (none) dhcpd[14434]: info DHCPINFORM
from 10.0.0.199
via 10.120.20.182 TransID 78563412: not authoritative for subnet
10.0.0.0
2013-03-25T09:39:36+00:00 daemon (none) dhcpd[14434]: info DHCPDISCOVER
```

```
from
cc:bb:cc:dd:ee:ff via 10.120.20.182 TransID 78563412
```

When DHCP transaction ID logging is off:

```
2013-03-25T09:39:39+00:00 daemon (none) dhcpd[14434]: info DHCPREQUEST
for 10.0.0.199
from cc:bb:cc:dd:ee:ff (dhcp-10-0-0-199) via 10.120.20.182
```

set lom

The **`set lom`** command configures the LOM (Lights Out Management) settings for the IPMI interface. To view the current network settings for the IPMI interface, use the *show lom* command.

Syntax

```
set lom
```

This command has no arguments.

Example

```
Infoblox > set lom
Enter LOM IP address: 10.1.1.22
Enter LOM netmask: 255.255.255.0
Enter gateway address [Default: 10.34.10.1]:
LOM network settings:
    IP address: 10.34.10.42
    Netmask:255.255.255.0
    Gateway address: 10.34.10.1
Is this correct? (y or n): y
Are you sure? (y or n): y
```

set max_recursion_depth

The **`set max_recursion_depth`** command sets the limit on the allowed number of levels of recursion named.

Syntax

```
set max_recursion_depth <value>
```

Argument	Description
`value`	The depth value in the range 1 - 100. Default depth value is 7.

Examples

Infoblox > `set max_recursion_depth`

set max_recursion_queries

The **`set max_recursion_queries`** command sets the limit on the number of queries sent before terminating a recursive query.

Syntax

```
set max_recursion_queries <value>
```

Argument	Description
`value`	The queries value in the range 1 - 1000. Default depth value is 150.

Examples

Infoblox > `set max_recursion_queries`

set membership

The **`set membership`** command specifies a Grid for the NIOS appliance. Use this command when the network address has been set (see *set network*) and you want to put the appliance in a Grid. You can join an IPv4 appliance to an IPv4-only or a dual mode Grid and an IPv6 appliance to an IPv6-only or a dual mode Grid.
If the IP address is acceptable to the Grid Master, use this command to join the Grid. You can specify either an IPv4 or an IPv6 address of the Grid Master. If you need to re-address the appliance, use the *set network* command.

> **Note**
>
> When you join a dual mode Grid member to a dual mode Grid, you can enter IPv4 address of the Grid Master if the Grid communication protocol for the Grid member is set as IPv4 and you can enter IPv6 address of the Grid Master if the Grid communication protocol for the Grid member is set as IPv6. For information about setting the communication protocol for a dual mode appliance, refer to the *Infoblox Administrator Guide*.

Syntax

```
set membership
```

This command has no arguments.

Example

```
Infoblox > set membership
Join status: No previous attempt to join a Grid.
Enter new Grid Master VIP: 10.1.1.22
Enter Grid Name [Default Infoblox]: DaveyJones
Enter Grid Shared Secret: L0ck37
Join Grid as member with attributes:
Join Grid Master VIP: 10.1.1.22
Grid Name: DaveyJones
Grid Shared Secret: L0ck37
WARNING: Joining a Grid will replace all the data on this node!
Is this correct? (y or n): y
Are you sure? (y or n): y
```

set mgm attached

The set mgm attached command forces a Grid to attach to a Master Grid. Use this command only if a Grid is in the Attached state on the Multi-Grid Manager and Detached on the Grid Manager. This command recovers the Grid status when it is out of sync with the Grid status on the Multi-Grid Manager.

Syntax

```
set mgm attached [MGM IP Address] [Port Number]
```

Argument	Description
`MGM IP Address`	IP address of the Master Grid
`Port Number`	Port number of the Master Grid

Example

The following example uses the set mgm attached command.

```
Console connect [@ Grid IP address]
Infoblox > set maintenancemode
Maintenance Mode > set mgm attached [MGM IP address] [Port Number]
```

```
This command will force the Grid to get attached.
Are you sure you want to continue? (y or n): y
```

set mld_version_1

The `set mld_version_1` command sets the IPv6 MLD (Multicast Listener Discovery) protocol to version 1, as described in *RFC 2710, Multicast Listener Discovery for IPv6*. MLD enables the appliance to detect multicast listeners on its directly attached links and discover which multicast addresses are of interest.
The appliance runs MLD version 2, as described in *RFC 3810, Multicast Listener Discovery Version 2 for IPv6*, by default. MLD version 2 is interoperable with version 1.

Syntax

```
set mld_version_1
```

This command has no arguments.

Example

```
Infoblox > set mld_version_1
 Current MLD version: 2
 Set Multicast Listener Discovery Version 1? (y or n): y New MLD Settings:
 Use MLD version 1: Yes
 Is this correct? (y or n): y MLD version: 1 is saved to database. MLD
version is set for IPv6.
```

set monitor dns

The **`set monitor dns`** command enables network monitoring for DNS. Once enabled, you can do the following:

- View the average latency of authoritative and non-authoritative replies to DNS queries in 1, 5, 15, and 60 minute time intervals. Use the *show monitor* command to view the DNS network data.
- Monitor invalid DNS responses from UDP port 53. Use the *show monitor dns alert status* command to view the DNS alert status.

This command is useful when troubleshooting DNS and network issues.

> **Note**
>
> This command is not supported for IPv6 in NIOS 7.0 and later releases. When you enable DNS network monitoring, there is a significant impact on DNS query performance.

Syntax

```
set monitor dns {on | off}
```

Argument	Description
`on`	Enables network monitoring for DNS.
`off`	Disables network monitoring for DNS.

Examples

Turn on DNS network monitoring

```
Infoblox > set monitor dns on
 Turning On DNS Network Monitoring...
```

Turn off DNS network monitoring

```
Infoblox > set monitor dns off
 Turning Off DNS Network Monitoring...
```

set monitor dns alert

The **`set monitor dns alert`** commands enable DNS alert monitoring and set the thresholds for invalid DNS responses. After you enable DNS alert monitoring, the appliance monitors the UDP traffic on port 53 for recursive DNS queries, and then reports invalid DNS responses on UDP ports that are not open and with mismatched TXIDs. You must enable DNS network monitoring when you enable DNS alert monitoring. For information, see the *set monitor dns* command.
You can also configure the thresholds for invalid DNS responses. When the number of invalid responses exceeds the thresholds, the appliance logs the event and sends SNMP traps and notifications, if previously enabled. The default thresholds for both invalid ports and invalid TXIDs are 50%. You can configure the thresholds either as absolute packet counts or as percentages of the total traffic during a one minute time interval.
This command is useful for monitoring possible cache poisoning. Use the *show monitor dns alert status* command to view invalid port and invalid TXID data.

> **Note**
> This command is not supported for IPv6 in NIOS 7.0 and later releases.

Syntax

```
set monitor dns alert {on | off}
 set monitor dns alert modify {port | txid} over threshold_value {packets |
percent}
```

Argument	Description
`on`	Enables DNS alert monitoring.
`off`	Disables DNS alert monitoring.

`modify`
`port`
`txid`
`threshold_value`
`packets`
`percent`
	Sets the thresholds for invalid DNS responses
	Enter `port` to set the threshold for invalid ports.
	Enter `txid` to set the threshold for invalid TXIDs.
	Enter the number of packets or percentage for the threshold.
	Enter `packets` if you want to set the threshold as a total packet count.
	Enter **`percentage`** if you want to set the threshold as a percentage of the total traffic. For a percentage-based threshold, the appliance does not generate a threshold crossing event if the traffic level is less than 100 packets per minute.

Examples

Turning on and off DNS alert monitoring

```
Infoblox > set monitor dns alert on
 Infoblox > set monitor dns alert off
```

Triggering a DNS alert when the percentage of invalid DNS responses on UDP ports exceeds 70% per minute

```
Infoblox > set monitor dns alert modify port over 70 percent
```

Triggering a DNS alert when the total packet count of invalid DNS responses with mismatched TXIDs is over 100 packets per minute

```
Infoblox > set monitor dns alert modify txid over 100 packets
```

set ms_dns_reports_sync_interval

You can use the `set ms_dns_reports_sync_interval` command to specify the time interval at which the DNS reporting data from the Microsoft server is synchronized with the NIOS appliance.

Syntax

```
set ms_dns_reports_sync_interval <MS Server IP address> <seconds>
```

Argument	Description
`<MS Server IP address>`	Specify the IP address of the Microsoft server.
`<seconds>`	Specify the time interval in seconds at which the DNS reporting data from the Microsoft server is synchronized with the NIOS appliance. The default synchronization interval is 15 seconds.

Example

```
Infoblox > set ms_dns_reports_sync_interval 10.102.30.2 14
Current DNS reports sync interval is 15 second(s).
The DNS reports sync interval will be changed to 14 second(s).
Is this correct? (y or n): y
The DNS reports sync interval has been changed to 14 second(s).
```

set ms_sticky_ip

The **`set ms_sticky_ip`** command enables/disables ms_sticky_ip.

Syntax

```
set ms_sticky_ip [on|off]
```

Argument	Description
on	Enables ms_sticky_ip.
off	Disables ms_sticky_ip.

Examples

Infoblox > `set ms_sticky_ip`

set named_recv_sock_buf_size

You can use the **`set named_recv_sock_buf_size`** command to tune the BIND receive socket buffer memory to a maximum of 8 MB. The DNS receive socket buffer holds BIND packets that are queued on the UDP (User Datagram Protocol) port from the NIC (Network Interface Controller). This command is useful when you want to increase the BIND receive buffer size to accommodate occasional burst traffic and high volume DNS recursive queries. Note that the same buffer is also used for updates and non-recursive queries. Use the *show named_recv_sock_buf_size* to view the current buffer size.

> **Note**
>
> Ensure that you use this command only when you are dealing with burst traffic situations in high volume deployments.

Syntax

```
set named_recv_sock_buf_size {N}
```

Argument	Description
N	The number of kilobytes to which you want to set the BIND receive socket buffer size. The minimum is 120 kilobytes and the maximum is 8192. The default is 1536.

Example

Set the BIND receive socket buffer size to 5000 KB

```
Infoblox > set named_recv_sock_buf_size 5000
 Infoblox >
```

set named_tcp_clients_limit

You can use the **`set named_tcp_tcp_clients_limit`** command to set the maximum number of simultaneous DNS clients that can be handled with TCP connections. It does not account for UDP connections.

Syntax

```
set named_tcp_clients_limit <number of TCP clients}
```

Argument	Description
Number of TCP clients	Maximum number of simultaneous DNS clients that can be handled with TCP connections. The number must be between 200 and 25000. The default value is 1000.

Example

```
Infoblox > set named_tcp_clients_limit 2500
```

set network

The **set network** command specifies an address for a NIOS appliance so that it can join a network, with the option of joining a Grid. You can configure either IPv4 address, IPv6 address, or both for a NIOS appliance. If the appliance is configured with an IPv6 address, it can join a Grid using the IPv6 address of the Grid Master. Use the *show network* command to view the network settings.

set network supports configuration of both IPv4 and IPv6 interface addresses.

Syntax

```
set network
```

This command has no arguments.

Example

Specifying an IPv4 address

```
Infoblox > set network
NOTICE: All HA configuration is performed from the GUI. This interface is
used only to
configure a standalone node or to join a grid.
Enter IP address:10.35.1.104
Enter netmask [Default: 255.255.255.0]:
Enter gateway address [Default: 10.35.0.1]:

    IPv6 Gateway address: 2620:10a:6000:2400::1
    IPv6 VLAN tag: Untagged
    IPv6 DSCP Value: Inherited from Grid: 0
```

Specifying both IPv4 and IPv6 address

```
Infoblox > set network
NOTICE: All HA configuration is performed from the GUI. This interface is
used only to
configure a standalone node or to join a grid.
Enter IP address : 10.35.1.104
Enter netmask [Default: 255.255.255.0]: 255.255.0.0
Enter gateway address [Default: 10.35.0.1]:
Enter VLAN tag [Default: Untagged]:
Enter DSCP value [Default: Inherited from Grid: 0]
Configure IPv6 network settings? (y or n):y
```

```
Enter IPv6 address [Default: none]: 2620:10A:6000:2400::168
Enter IPv6 Prefix Length [Default: none]: 64
Enter IPv6 gateway [Default: none]: 2620:10A:6000:2400::1
Enter VLAN tag [Default: Untagged]:
Enter DSCP value [Default: 30]:
Become grid member? (y or n): n

New Network Settings:

    IPv4 address: 10.35.1.104
    IPv4 Netmask: 255.255.0.0
    IPv4 Gateway address: 10.35.0.1
    IPv4 VLAN tag: Untagged
    IPv4 DSCP Value: Inherited from Grid: 0

    IPv6 address: 2620:10a:6000:2400::168/64
    IPv6 Gateway address: 2620:10a:6000:2400::1
    IPv6 VLAN tag: Untagged
    DSCP value: 30

Old IPv4 Network Settings:

    IPv4 address: 192.168.1.2
    IPv4 Netmask: 255.255.255.0
    IPv4 Gateway address: 192.168.1.1
    IPv4 VLAN tag: Untagged
    IPv4 DSCP Value: Inherited from Grid: 0
```

Note

After you confirm your network settings, the Infoblox application automatically restarts.

After configuring the network settings, you cannot change the type of network connectivity of the appliance through CLI. For example, if the appliance is configured in IPv4-only mode, then you can change only the IPv4 interface settings through CLI. But the type of network connectivity for the appliance can be changed through GUI.

set nogrid

The **`set nogrid`** command removes the specified member from the current Grid. Execute this command from the Grid member. This command is valid only on a member.

Note

Infoblox recommends that you use this command only in an emergency, such as when the network is down between the master and the member. Otherwise, you should configure the member to leave the Grid using the GUI on the Grid Master.

Syntax

```
set nogrid
```

This command has no arguments.

Example

```
Infoblox > set nogrid
 The normal method to configure a node to leave a Grid is to use the GUI on the Grid Master. This method is only used for emergencies (e.g. network is down from the master to this node).
 Is this such an emergency? y
 The current node will become a standalone machine, with default values for Grid settings.
 Are you sure? (y or n) y
 The network settings have been updated.
```

set nomastergrid

In a Multi-Grid environment, the **`set nomastergrid`** command enables a Grid to leave the current Master Grid. This command is valid only on the Multi-Grid Master.

Syntax

```
set nomastergrid
```

This command has no arguments.

Example

```
Infoblox > set nomastergrid
 This grid is going to leave master grid
      Are you sure? (y or n): y
 Grid is not joined to a master grid. Exiting without making any change
```

set nosafemode

The `set nosafemode` command disables safe mode on the NIOS appliance by re-enabling DNS and DHCP services. For more information, see *set safemode*.

Syntax

```
set nosafemode
```

This command has no arguments.

Example

```
Infoblox > set nosafemode
```

set ocsp

The `set ocsp off` command disables OCSP authentication service configuration and allow you to login without OCSP validation. It also terminate administrative sessions for users who are currently logged in.

Syntax

```
set ocsp off
```

There are no arguments for this command.

Example

```
Infoblox > set ocsp off
```

set ospf

The **set ospf** command writes statistical information to syslog. This command provides informational data that can be helpful for diagnostic purposes. The statistical information is written (dumped) to syslog. When viewing the syslog file, lines with names such as `ospf statistics` are the OSPF statistical information. Use the *show ospf* command to view the OSPF settings.
Syslog level describes the types of messages that are sent to syslog. You can identify the syslog information by using the `level` option.

> **Note**
> To use this command, the NSQ software package must be installed.

Syntax

set ospf log {*level*}

Argument	Description
level	Writes OSPF statistics to syslog with a specific associated level. The supported log levels are: `debugging, informational, notifications, warnings, errors, critical, alerts,` and `emergencies.`

Example

```
Infoblox > set ospf log alerts
```

set overload_bootp

The **`set overload_bootp`** command enables/disables overloading BOOTP packets.

> **Note**
>
> To disable DHCP overload bootp packet control, DHCP force restart service is required in order for the changed value to take effect.

Syntax

```
set overload_bootp
```

There are no arguments for this command.

Example

```
Infoblox > set overload_bootp
```

set pc_domain add

You can use the `set pc_domain add` command to add category overrides for a specified domain. Use category 104 to add domains to the global proxy list. Queries to domains added to the global proxy list are proxied to the Multi-Service Proxy server when the **Enforce the global proxy list** parental control option is selected. For more information, see *Adding Subscriber Sites*.

For information about the status of the command, see *show pc_domain*. You can use the `set pc_domain delete` command to delete a specific domain.

Syntax

```
set pc_domain add <domain> <category 1> <category 2 > <category 3>
```

> **Note**
>
> - Category values must be integers.
> - If the specified domain is cached in a DNS Cache Acceleration server and if you add the same domain to the global proxy list using the `set pc_domain add` command, the domain does not get proxied unless the TTL (Time To Live) setting of the domain in the DNS Cache Acceleration server has expired. For more information about TTL settings, see *Specifying Time To Live Settings*.
> - Domains added to category 104 using the `set pc_domain add` command are not proxied for members until the domains are synchronized with the members, which happens only after the expiry of the time set in the **Update Interval in hours** field in Subscriber Services Properties. By default this is 24 hours. For more information about the setting, see *Enabling Subscriber Parental Control*.

Argument	Description
`domain`	Name of the domain for which the category override is executed.
`category 1`	Category 1 value.
`category 2`	Category 2 value.
`category 3`	Category 3 value.

Examples

```
Infoblox > set pc_domain add bbc.com 10308 0 0
```

```
Successfully added category override for "bbc.com".
```

set pc_domain delete

You can use the `set pc_domain delete` command to delete all category override for the specified domain. For information about the add category override command, see *set pc_domain add*.

Syntax

```
set pc_domain delete <domain>
```

Argument	Description
`domain`	The name of the domain for which the category override will delete.

Example

```
Infoblox > set pc_domain delete  bbc.com
```

```
Successfully deleted category override for "bbc.com".
```

set phonehome

The **`set phonehome`** command enables a Grid Master or an independent appliance to email reports monthly and after each upgrade to Infoblox Technical Support and other specified recipients.
The reports provide status and event information about the Grid or independent appliance and its services. The report is an XML document that includes the following information:

- The phone home feature version.
- The report type, such as periodic and test.
- The time of the report.
- The Infoblox Support ID that was assigned to the account.
- Information about the Grid, such as its NIOS version, name, VIP, Grid Master hostname, LAN IP, and the number of Grid members and appliances in the Grid.
- The upgrade history of the Grid.
- Information about each Grid member, such as the hostname, IP address, status, role (such as standalone, master), and if the member is an HA pair. If the member is a peer in a DHCP failover association, the report also includes the DHCP failover status.
- Hardware information, such as the hardware type, serial number, HA status, and uptime.
- Information about the interfaces, such as the interface name and IP addresses.
- Resource usage information, such as CPU and system temperature, and CPU, database, disk, and memory usage.

Syntax

```
set phonehome {on | off}
```

Argument	Description
`on`	Enables the appliance to send status and event reports to specified recipients.
`off`	Disables the function to send reports.

Examples

Turning on the phone home feature

```
Infoblox > set phonehome on
```

Turning off the phone home feature

```
Infoblox > set phonehome off
```

set promote_master

The `set promote_master` command specifies a NIOS appliance as the new Grid Master in the case of a Grid Master failure. The new Grid Master then alerts all the Grid members to redirect their traffic to it. If you have configured multi-site reporting cluster, you can modify the primary reporting site. For information about reporting clusters, refer to the *Infoblox NIOS Administrator Guide*.
You can do one of the following to promote a master candidate to a Grid Master:

- Immediately notify all Grid members about the promotion.
- Set a sequential notification to provide wait time for Grid members to join the new Grid Master. Staggering the restarts of Grid members can minimize DNS outages. The sequential order for Grid members to join the new Grid Master begins with the old Grid Master and then the Grid members in FQDN order. The default delay time is 120 seconds. You can configure the delay time from a minimum of 30 seconds up to 600 seconds.

For this command to be effective, you must have previously specified an appliance as the Grid Master candidate. Then when you lose the Grid Master, you can remotely (SSH) log in to the Grid Master candidate and execute this command.

> ⚠
>
> **Note**
>
> When the previous Grid Master comes back on line, it automatically joins the Grid as a master candidate.

Syntax

```
set promote_master
```

This command has no arguments.

Examples

```
Infoblox > set promote_master
Do you want a delay between notification to Grid members? (y or n):
```

Enter `n` to promote the master candidate and send notifications to all Grid members immediately. The appliance displays the following:

```
This action will immediately promote master candidate to become the Grid
Master. This feature is designed to be used primarily for disaster recovery.
Are you sure you want to do this? (y or n): y
The current member will become the Grid Master.
Are you really sure you want to do this? (y or n): y
Member promotion beginning on this member.
```

Enter y to promote the master candidate to the Grid Master immediately and specify the delay time for the Grid members to join the new Grid Master. The appliance displays the following:

```
Set delay time for notification to Grid members? [Default: 120s]: 200
This action will immediately promote master candidate to become the Grid
Master. This feature is designed to be used primarily for disaster recovery.
Are you sure you want to do this? (y or n): y
The current member will become the Grid Master. The Grid members will be
notified sequentially with a delay of 200 seconds.
Are you really sure you want to do this? (y or n): y
```

If you have configured multi-site reporting cluster, the appliance displays all the reporting sites in the order of priority you have configured. For example if you have configured the following reporting sites: site 4(priority 1), site 2 (priority 2), site 1(priority 3), and site 3 (priority 4)

```
Infoblox > set promote_master
Do you want a delay between notification to Grid members? (y or n): n
Primary reporting site candidates (in order of priority):
```

1. `site4 (Existing primary reporting site)`
2. site2
3. `site1`
4. site3

```
Please enter new primary reporting site (1-2) or 'c' to continue without
changing primary reporting site: 5
```

The appliance displays the following error when you enter value incorrectly:

```
ERROR: Please enter a valid choice or 'c' to continue without changing the
primary reporting site.
 Please enter new primary reporting site (1-2) or 'c' to continue without
changing primary reporting site: c
 This action will immediately promote this member to become the grid master.
This feature is designed to be used primarily for disaster recovery.
 Are you sure you want to do this? (y or n): y The current member will
become the grid master.
 Are you really sure you want to do this? (y or n): y
```

```
Master promotion beginning on this member
 Good Bye
```

To change the primary reporting site:

```
Infoblox > set promote_master
 Do you want a delay between notification to Grid members? (y or n):n
Primary reporting site candidates (in order of priority):
```

1. `site4 (Existing primary reporting site)`
2. site2
3. `site1`
4. site3

```
Please enter new primary reporting site (1-4) or 'c' to continue without
changing primary reporting site: 2
 Are you sure you want to do this? (y or n): y The current member will
become the grid master.
 Are you really sure you want to do this? (y or n): y Master promotion
beginning on this member
 Good Bye
```

The new priority order of reporting sites will be:

```
site2 (Existing primary reporting site)
site4
site1
site3
```

set gmc_promotion

Use the `set gmc_promotion disable` command to disable the **Activate GMC Group Promotion Schedule** option. Note that, this command can be executed on Grid Master and Grid Master Candidate.
Use the `set gmc_promotion forced_end` command while Grid Master Candidate promotion is in progress, to unset the master promotion status. Note that, this command can be executed only on master Node.

Syntax

`set gmc_promotion <disable` >< `forced_end` >

Argument	Description
`disable`	Disables the **Activate GMC Group Promotion Schedule** option.

Argument	Description
`forced_end`	Resets the Grid Master Candidate promotion flag to reconfigure Grid Master Candidate group promotion.

Examples

Disabling the Grid Master Candidate group promotion

```
Infoblox > set gmc_promotion disable
Feature is disabled.
```

Resetting the flag to reconfigure Grid Master Candidate group promotion

```
Infoblox > set gmc_promotion forced_end
This command will not end GMC promotions but just resetting the flag for end-users to
reconfigure GMC-promotion again.
This command can be executed only on Master node.
```

set prompt

Use the **`set prompt`** command to change the prompt to the host name, user@host name, host IP address, or user@ host IP address. Note that the prompt displayed in the command line interface (CLI) can be set only on the active Grid Master node. Once you execute the **`set prompt`** command, the prompt displayed for all Grid members is set accordingly and you can see the prompt when you log in to the CLI for each Grid member.

Syntax

```
set prompt {hostname / user@hostname / ip / user@ip / default}
```

Argument	Description
`hostname`	Sets the prompt to the host name of the computer from which you access the appliance.
`user@hostname`	Sets the prompt to the user name@ the host name of the computer from which you access the appliance.
`ip`	Sets the prompt to the IP address of the host.
`user@ip`	Sets the prompt to the user name@ the IP address of the host.

Argument	Description
`default`	Sets the prompt to "Infoblox >".

Example

```
Infoblox > set prompt user@hostname
 admin@infoblox >
 admin@infoblox > set prompt user@ip
 admin@172.31.1.254 >
```

set regenerate_anycast_password

The `set regenerate_anycast_password` command regenerates eight-character alphanumeric password for the anycast service and saves it to the NIOS database. The password can then be used across all anycast configuration files (ospf.conf, bgp.conf, bfd.conf) with the following CLI commands:

- show ospf
- show bgp
- show ipv6_ospf
- show ipv6_bgp
- show bfd

When these commands are executed with the configuration argument, the values of the password and enable password fields are shown encrypted. Running `set regenerate_anycast_password` restarts the anycast service on the Grid members that have the anycast service enabled. For information on OSPF commands, see *show ospf* and *show ipv6_ospf*. For information on BGP commands, see *show bgp* and *show ipv6_bgp*. For information on bfd command, see *show bfd*.

> **Note**
>
> Only superusers can use `set regenerate_anycast_password` in maintenance mode.

Syntax

```
set regenerate_anycast_password
```

This command has no arguments.

Example

```
Maintenance Mode > set regenerate_anycast_password
Resetting the password will restart the anycast service.
Do you want to proceed? (y or n):y
```

```
Are you sure? (y or n):y
Anycast password generation is successful.
```

set remote_console

The **set remote_console** command enables and disables access to the NIOS appliance using a remote console. Use the *show remote_console* command to view the remote console settings.

> **Note**
>
> Infoblox recommends that you close any port that is not being used, for security reasons. An open, unused port offers the potential for unwanted access to your network.

Syntax

```
set remote_console
```

This command has no arguments.

Example

```
Infoblox > set remote_console
 Enable remote console access (Grid level)? (y or n): y
 New remote console access settings:
Remote console access enabled: Yes
 Is this correct? (y or n): y
```

set reporting_cert

In a Grid with a reporting server, you can use the **set reporting_cert** command to generate a new set of SSL certificates on all forwarders and the indexer. You can use this command only on the Grid Master.

Syntax

```
set reporting_cert
```

This command has no arguments.

Example

```
Infoblox > set reporting_cert
 Generate new reporting certificate? (y or n): y
 Reporting certificates generated.
```

set reporting_user_capabilities

The **`set reporting_user_capabilities`** command allows you to configure the `delete` permission on reporting data to a local admin user who has superuser permissions. If you enable the `set reporting_user_capabilities` command for a user, the user can use the `delete` command using the *Splunk API* or *reporting GUI* to delete selected events.

To see the list of users configured with the reporting delete permission, see *`show reporting_user_capabilities`*.

> **Notes**
>
> - This command is supported only on the Grid master.
> - You cannot retrieve the data once it is deleted.
> - The deleted data cannot be visualized and does not reduce any disk space.
> - Frequent deletion of data may affect the search performance.

Syntax

```
set reporting_user_capabilities [enable|disable] <super-user>
```

Argument	Description
enable	Enables the reporting delete capability
disable	Disables the reporting delete capability

Example

```
Infoblox > set reporting_user_capabilities enable user1
```

1. `Delete reporting indexed data`

```
Select capability (1) or q to quit: 1
```

```
The reporting Delete capability has been enabled for user user1.
```

```
Infoblox > set reporting_user_capabilities disable user1
```

1. `Delete reporting indexed data`

```
Select capability (1) or q to quit: 1
```

```
The reporting Delete capability has been disabled for user user1.
```

set restart_anycast_with_dns_restart

The **`set restart_anycast_with_dns_restart`** command sets the DNS and anycast start and restart sequence to the appliance. This command stops the anycast service during a restart or stop of the DNS service and redirects the traffic present on the anycast IP address to another site. You can use this command only on Grid Master. To view information about the current status of the command, see *show restart_anycast_with_dns_restart* .

Syntax

```
set restart_anycast_with_dns_restart [ on | off ]
```

Argument	Description
`on`	Restarting the DNS service stops the anycast service followed by a DNS service stop. The anycast service restarts after the DNS service loads all the zones. In case the DNS service stops, anycast service also stops. The DNS service start triggers anycast service start, after the DNS service loads all the zones.
`off`	Restarting the DNS service will not trigger the restart of anycast service. In case of the DNS service stop, anycast service stops after approximately 30-60 seconds of DNS service stop. In case of DNS service start: • If the DNS service takes more than approximately 30 seconds to load all the zones, anycast service starts at approximately 30 seconds after DNS service starts. • If the DNS service loads immediately, anycast service starts immediately after DNS service starts.

Example

The following is an example to restart anycast.

```
Infoblox > set restart_anycast_with_dns_restart on
```

set revert_grid

Use the **`set revert_grid`** command to revert to a version of software that was running previously on a Grid or on an independent appliance or HA pair. Be aware that when you revert to this software, any configurations made to the currently running software are lost. You can back up the current data before you revert so that you can later determine what configuration changes are missing.

Syntax

```
set revert_grid
```

This command has no arguments.

Example

```
Infoblox > set revert_grid
```

set rpz_recursive_only

Use the `set rpz_recursive_only <view_name> [<zone_name>]` command to use NIOS RPZ zones instead of local RPZ zones to block records with private IP addresses from being queried by external users. This command is available only on the Gird Master.

If you do not specify an RPZ zone name after the DNS view name, all RPZ zones that belong to the specified DNS view are used to block records. If you specify an RPZ zone name, only that zone is used to block records.

⚠ Restart the DNS service on the member after running the command.

Syntax

```
set rpz_recursive_only <view_name> [<zone_name>] <none | yes | no>
```

Argument	Description
view_name	DNS view to which the RPZ zones belong.
zone_name	NIOS zone name that must be used to block records with private IP addresses. If you do not specify an RPZ zone, all zones that belong to the DNS view are considered.
none	Uses the existing setting for the command. For example, if the `set rpz_recursive_only view_name` command was set to `yes`, specifying `none` will consider the command enabled because the earlier setting was set to `yes`.
yes	Enables the command.
no	Disables the command.

Example

```
Infoblox > set rpz_recursive_only default rpz1.com yes
Restart the DNS service in order for changes to take effect.
```

set safemode

The **`set safemode`** command disables DNS and DHCP services. Use this command to troubleshoot a NIOS appliance with unreliable services.
This command restarts all the services, including DNS and DHCP. DNS and DHCP remain active only long enough to write `named.conf` and `dhcp.conf` files. These services then shut down. All other services remain functional. This

allows you to review the `named.conf` and `dhcp.conf` files to determine and alleviate the cause of the appliance distress.
Once you have determined the problem, you can reinstate DNS and DHCP services using the *set nosafemode* command.

Syntax

```
set safemode
```

This command has no arguments.

Example

```
Infoblox > set safemode
```

set scheduled

Use the **`set scheduled`** command to specify the number of times per hour the appliance checks if the services need a restart when the task scheduling feature is enabled. You must manually restart services or schedule a restart of services for the scheduled change to take effect.
You can set the value from 0 to 60, and the default value is 60. When you set the value to 0, the appliance turns off the restart feature.
Use the *show scheduled* to view the number of times per hour the appliance checks whether a restart of services is required.

Syntax

```
set scheduled task restarts [0-60]
```

Argument	Description
`0-60`	The number of times per hour the appliance checks if the services need a restart when the task scheduling feature is enabled. You can enter any number from 0 to 60. The default is 60. A value of 0 turns off the restart feature.

Example

Enter the following command to enable the appliance to check 10 times per hour whether the services need a restart:

```
Infoblox > set scheduled task restarts 10
```

The appliance checks 10 times per hour if the services must be restarted, which is every six minutes of the hour. For example, if you enter the command at 3:15 p.m., the appliance checks if the services must be restarted every six minutes starting at the hour (3:00 p.m.). Therefore, the next checks are at 3:18, 3:24, 3:30, 3:36, 3:42, 3:48, 3:54, and 4:00 p.m.

set security

The **`set security`** command allows you to specify IP or network addresses that can access the appliance through the GUI. The appliance denies access to addresses that are not specified. Use the *show security* command to view the security settings.

Syntax

```
set security
```

This command has no arguments.

Example

In the following example, security is enabled to restrict access to the NIOS appliance (through the GUI) to the IP address range 10.1.1.1:

```
Infoblox > set security
 Enable security? (y or n): y
 Enter access IP range: 10.1.1.1
 Enter access netmask (Default: 255.255.255.0): 255.255.255.0
      New security settings:
  Security enabled: Yes
      IP range: 10.1.1.1
   Is this correct? (y or n): y
 Do you wish to enter additional access range? (y or n): n
```

set session_timeout

Use the **`set session_timeout`** command to specify how long a session remains open when there is no user activity. Use the *show session_timeout* command to view the session_timeout setting.

Syntax

```
set session_timeout
```

This command has no arguments.

Example

```
Infoblox > set session_timeout
 Current GUI/CLI timeout is 60000 seconds (16:40:00)

WARNING: Changing the session timeout will cause GUI users to be logged out.
New GUI/CLI session timeout (in seconds, 0 to abort)? 90000
```

set smartnic monitor-mode

The **`set smartnic monitor-mode`** command enables and disables monitor mode for the Threat Protection service. This is disabled by default. When monitor mode is enabled, the appliance logs DNS packets (instead of dropping them) that would have been blocked by threat protection rules. This information is recorded in the audit log. Note that you can enable or disable monitor mode only for individual members. You cannot set this configuration at the Grid level.
To view whether monitor mode is enabled or disabled for the Threat Protection service, see *show smartnic*.

Syntax

```
set smartnic monitor-mode {on|off}
```

Argument	Description
`on`	Enables monitor mode for the Threat Protection service.
`off`	Disables monitor mode for the Threat Protection service.

Examples

Enable debugging

```
Infoblox > set smartnic monitor-mode on
```

Disable debugging

```
Infoblox > set smartnic monitor-mode off
```

set snmptrap

The `set snmptrap` command sends SNMP traps to the trap receiver (SNMP trap server IP address) you specify.

You can use the optional `v3` command to generate SNMPv3 traps. For information about SNMP, see *Monitoring with SNMP*.

Use the *show snmp* command to get information about SNMP objects.

> **Note**
>
> Use the `set snmptrap` command only for test purposes because it uses 0 as the value of the `msgAuthoritativeEngineBoots` and `msgAuthoritativeEngineTime` variables and this may cause the trap receiver to drop traps.

Syntax

```
set snmptrap variable <name of an SNMP variable, in dotted or symbolic format>
address <address of the trap receiver> [v3] [snmpuser][all] [ibNodeName
<value> ] [ibTrapSeverity <value>] [ibOjectName <value>] [ibProbableCause
<value>] [ibSubSystemName <value>]  [ibCurThresholdValue <value>]
[ibThresholdHigh <value>] [ibThresholLow <value>] [ibPreviousState <value>]
[ibCurrentState <value>] [ibTrapDesc <value>]
```

Argument	Description
`<name of an SNMP variable>`	Name or OID (object ID) of the SNMP object. For example, you can enter sysName.0 or .1.3.6.1.4.1.2021.11.53.0.
`<address of the trap receiver>`	IPv4 or IPv6 address of the management system that receives SNMP traps.
`<snmpuser>`	User name of the SNMPv3 user account. This is optional. If you do not provide a user name, the appliance uses the first SNMPv3 user on the list.
`ibNodeName <value>`	IP address of the appliance to which the trap must be sent.
`ibTrapSeverity <value>`	Severity of the trap. For more information, see *Trap Severity (OID 3.1.1.1.2.2.0)*.
`ibObjectName <value>`	Name of the object for which the trap is generated.

Argument	Description
`ibProbableCause <value>`	Value that provides information about events such as hardware, software for process failures that trigger SNMP traps.
`ibSubSystemName <value>`	Value that provides information about the subsystems that trigger the traps.
`ibCurThresholdValue <value>`	Current value of the threshold counter.
`ibThresholdHigh <value>`	For CPU usage, this is the trigger value of the SNMP trap. For DHCP address usage, this is the value of the high watermark.
`ibThresholdLow <value>`	For CPU usage, this is the reset value of the SNMP trap. For DHCP address usage, this is the value for the low watermark.
`ibPreviousState <value>`	Previous state of the appliance.
`ibCurrentState <value>`	Current state of the appliance.
`ibTrapDesc <value>`	Description of the trap.

For more information about the argument descriptions, see *Types of Traps (OID 3.1.1.1.1)*.

Examples

Sending SNMP Traps to a Specific Trap Receiver

Enter the following on the appliance:

```
Infoblox > set snmptrap variable sysName.0 address 10.0.0.11
```

The appliance sends the following acknowledgement to the trap receiver:

```
2011-02-23 23:02:51 10.0.0.11 [UDP: [10.0.0.11]:35597->[10.0.0.11]]:
DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (42) 0:00:00.42
SNMPv2-MIB::snmpTrapOID.0 = OID: SNMPv2-MIB::sysName.0
2011-02-23 23:02:53 10.0.0.11 [UDP: [10.0.0.11]:52367->[10.0.0.11]]:
DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (42) 0:00:00.42
SNMPv2-MIB::snmpTrapOID.0 = OID: SNMPv2-MIB::sysName.0
```

Sending SNMP Traps Using SNMPv3

Enter the following on the appliance:

```
Infoblox >  set snmptrap variable sysName.0 localhost v3 SNMPv3User1
```

The appliance sends the following acknowledgement to the trap receiver:

```
2011-02-07 01:08:19 localhost [UDP: [127.0.0.1]:41884->[127.0.0.1]]:
DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (42) 0:00:00.42
SNMPv2-MIB::snmpTrapOID.0 = OID: DISMAN-EVENT-MIB::sysName.0
```

Enter the following on the appliance:

```
Infoblox >  set snmptrap variable sysName.0 localhost v3 SNMPv3User1
```

The appliance sends the following to the trap receiver in the event of a process failure:

```
SNMPv2-MIB::snmpTrapOID.0 = OID: SNMPv2-SMI::enterprises.7779.3.1.1.1.1.2.0
SNMPv2-SMI::enterprises.7779.3.1.1.1.2.1.0 = STRING: "192.168.1.2"
SNMPv2-SMI::enterprises.7779.3.1.1.1.2.2.0 = INTEGER: 5
SNMPv2-SMI::enterprises.7779.3.1.1.1.2.5.0 = STRING: "named"
SNMPv2-SMI::enterprises.7779.3.1.1.1.2.4.0 = INTEGER: 20
SNMPv2-SMI::enterprises.7779.3.1.1.1.2.11.0 = STRING: "A named daemon
monitoring
failure has occurred."
```

Sending SNMP Traps When the Primary Disk is Full

Enter the following on an appliance of type disk:

```
Infoblox > set snmptrap variable 1.3.6.1.4.1.7779.3.1.1.1.1.3 address
10.35.5.243 ibNodeName "infoblox.localdomain" ibObjectName Disk ibTrapSeverity 3
ibProbableCause 1001 ibTrapDesc '"Primary drive is full."'
```

The appliance sends the following to the trap receiver in the event of the primary disk being full:

```
2020-06-30 12:36:25 member0.g.infoblox.com [UDP: [10.35.5.243]:44807-
>[10.35.5.243]:162]:

DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (10123392) 1 day, 4:07:13.92
SNMPv2-MIB::snmpTrapOID.0 = OID: IB-TRAP-MIB::ibThresholdCrossingEvent  IB-TRAP-
MIB::ibNodeName.0 = STRING: "infoblox.localdomain"   IB-TRAP-
MIB::ibTrapSeverity.0 = INTEGER: minor(3)       IB-TRAP-MIB::ibObjectName.0 =
STRING: Disk  IB-TRAP-MIB::ibCurThresholdValue.0 = INTEGER: 100 IB-TRAP-
```

```
MIB::ibThresholdHigh.0 = INTEGER: 90    IB-TRAP-MIB::ibThresholdLow.0 =
INTEGER: 0      IB-TRAP-MIB::ibTrapDesc.0 = STRING: Primary drive is full.
```

set static_route

Use the `set static_route` command to configure static routes on your appliance. You can create new IPv4 and IPv6 static routes, move static route to a desired position in the list of static routes, move static routes up and down in the list, or move static route at a specific position up or down in the list of static routes. You can also delete an existing static route, delete static routes at a specific position, or delete all existing static routes for IPv4, IPv6 or both protocols. Use the *show static_routes* command to view the current configuration of static routes on your appliance.

Syntax

```
set static_route add network/cidr gateway [position]
set static_route move network/cidr gateway new-position
set static_route move network/cidr gateway (up|down)
set static_route move (v4|v6) old-position new-position
set static_route move (v4|v6) old-position (up|down)
set static_route delete network/cidr gateway
set static_route delete (v4|v6) position
set static_route delete (all|v4|v6)
```

Argument	Description
`add network/cidr gateway [position]`	Creates a new static route and optionally specifies its position in the list of static routes.
`move network/cidr gateway new-position`	Moves a static route to a new position in the list of static routes.
`move` *`network/cidr gateway`* `[up|down]`	Moves a static route up or down in the list of static routes.
`move` *`(v4 | v6)`* `[old-position] [new-position]`	Moves an IPv4 or IPv6 static route from its existing position to a new position in the list of static routes.
`move (v4 |` *`v6)`* `[old-position] (up|down)`	Moves an IPv4 or IPv6 static route up or down from its current position in the list of static routes.
`delete` *`network/cidr gateway`*	Deletes an existing static route.
`delete` *`(v4 | v6)`* `[position]`	Deletes an IPv4 or IPv6 static route, at a specific position, from the list of static routes.
`delete (all |` *`v4 | v6`*`)`	Deletes all static routes, all IPv4 static routes, or all IPv6 static routes.

Examples

Adding a new static route

```
Infoblox > set static_route add 10.6.112.0/24 10.6.42.1
 Infoblox > set static_route add 2001:1234:5678::/112 2001:1234::42
```

Moving a static route to a new position in the list of static routes

```
Infoblox > set static_route move 10.6.112.0/24 10.6.42.1 5
 Infoblox > set static_route move 2001:1234:5678::/112 2001:1234::42 6
```

Moving a static route up or down in the list of static routes

```
Infoblox > set static_route move 10.6.112.0/24 10.6.42.1 up
Infoblox > set static_route move 10.6.112.0/24 10.6.42.1 down
 Infoblox > set static_route move 2001:1234:5678::/112 2001:1234::42 up
Infoblox > set static_route move 2001:1234:5678::/112 2001:1234::42 down
```

Moving an IPv4 or IPv6 static route from its current position to a new position in the list of static routes

```
Infoblox > set static_route move v4 1 12 Infoblox > set static_route move v6
1 12
```

Moving an IPv4 or IPv6 static route up or down from its current position in the list of static routes

```
Infoblox > set static_route move v4 12 up
Infoblox > set static_route move v6 12 up
Infoblox > set static_route move v4 1 down
Infoblox > set static_route move v6 1 down
```

Deleting an existing static route

```
Infoblox > set static_route delete 10.6.112.0/24 10.6.42.1
 Infoblox > set static_route delete 2001:1234:5678::/112 2001:1234::42
```

Deleting an IPv4 or IPv6 static route at a specific position in the list of static routes

```
Infoblox > set static_route delete v4 1
Infoblox > set static_route delete v6 2
```

Deleting all IPv4 static routes

```
Infoblox > set static_route delete v4
```

Deleting all IPv6 static routes

```
Infoblox > set static_route delete v6
```

Deleting all IPv4 and IPv6 static routes

```
Infoblox > set static_route delete all
```

set subscriber_secure_data add

If you have configured Infoblox Subscriber Services, you can use the `set subscriber_secure_data add` command to add a specific subscriber record to the subscriber database. For information about Infoblox Subscriber Services, see *Infoblox Subscriber Services*. You can use `set subscriber_secure_data delete` command to delete a subscriber record.

Syntax

```
set subscriber_secure_data add <ip_addr> <prefix> <local_id> <ip_space_desc>
<data_string> [flags]
```

Argument	Description
`<ip_addr>`	Specify the IPv4 or IPv6 address of the subscriber.
`<prefix>`	Specify the prefix length.
`<local_id>`	Specify the Local ID, which is the MAC address of the subscriber device. To indicate a record without a Local ID, enter N/A.
`<ip_space_desc>`	Specify the IP space discriminator. To indicate a record without an IP space discriminator, enter N/A.
`<data_string>`	The cache data string is a concatenation of “AVPTAG:AVP-NAME=Value” separated by ';'.

Argument	Description
`[flags]`	This is optional. You can specify the following: S - For the non-expiring static record. B - If a blacklist or whitelist domains are configured for the subscriber.

The AVPTAG can include the following tags:

> **Note**
>
> The following tags are for the AVPs available in the list of predefined AVPs. You can also add tags for user-defined AVPs.

- **SUB**: Indicates the subscriber ID AVP, that is configured in the *Subscriber Services Properties* editor of the Grid. Example: `SUB:IMSI=602030100000057`.
- **NAS**: Indicates the NAS contextual information AVP, that is configured in the *Subscriber Services Properties* editor of the Grid. Example: `NAS:NAS-PORT=168496141`.
- **IPS**: Indicates the IP space discriminator AVP, that is configured in the *Subscriber Services Properties* editor of the Grid. Example: `IPS:NAS-IPv6-Address=2620:010a:6000:22f2::006e`.
- **PCP**: Parental-Control-Policy. It is a 128-bit value provided by the Service Providers. Example: `PCP:Parental-Control-Policy=400000`.
- **DCP**: Dynamic-Category-Policy. It is an indication to resolve domains categorized as dynamic. If Dynamic AVP is set, then all domains categorized as dynamic are forwarded to Infoblox Harmony. If Dynamic AVP is not set, then the domains categorized as dynamic would either be blocked or allowed depending on the parental control policy. Example: `DCP` : `Dynamic-Category-Policy=0`.
- **SSP**: Subscriber-Secure-Policy. It is a 32-bit value provided by the Service Providers. Example: `SSP:Subscriber-Secure-Policy=5F`.
- **EXP**: The date and time when the profile expires. Example: `EXP:Expire-Profile=Mon May 29 10\ \:23\\:56 2017`.
- **AN0**: Indicates the AVP configured in ancillary position 0 in the ancillary list, that is configured in the *Subscriber Services Properties* editor of the Grid. Example: `AN0:Class=0x010x000x120x000x12`.
- **AN1**: Indicates the AVP configured in ancillary position 1 in the ancillary list, that is configured in the *Subscriber Services Properties* editor of the Grid. Example: `AN1:IMEI=8635800299072601`.
- **AN2**: Indicates the AVP configured in ancillary position 2 in the ancillary list, that is configured in the *Subscriber Services Properties* editor of the Grid. Example: `AN2:NAS-Port-Identifier=portid-1232`.
- **AN3**: Indicates the AVP configured in ancillary position 3 in the ancillary list, that is configured in the *Subscriber Services Properties* editor of the Grid. Example: `AN3:User-Name=user1`.

Note: The ancillary fields are numbered as AN0, AN1, AN2 etc. You cannot add more than five ancillary AVPs.

- **ACS**: The accounting session ID. Example: `ACS:Acct-Session-Id=29de847acde415ab`.

Example 1

```
set subscriber_secure_data add 2620:10a:6000:7814::50b 128 003048d5d928 N/A
"ACS:Acct-Session-Id=29de847acde415ab;LID:003048d5d928;IPS:NAS-IPv6-
Address=2540:010a:6000:22f2::006e;AN0:APN=corp1;SUB:IMSI=602030100000045;AN3
:User-Name=user1;AN2:NAS-Port-Identifier=portid-1232;NAS:NAS-
PORT=168496141;SSP:Subscriber-Secure-Policy=00000001;DYN:Dynamic-Category-
Policy=0;PCP:Parental-Control-Policy=400000;"
```

Example 2

```
set subscriber_secure_data add 10.32.1.145 32 AABBCC112233 corp1 "ACS:Acct-
Session-
Id=32de327aced215ab;SUB:IMSI=301030100000026;LID:AABBCC112233;NAS:NAS-
PORT=168496141;PCP:Parental-Control-Policy=20001;EXP:Expire-Profile=Mon May
29 10\\:23\\:56 2017;DCP:Dynamic-Category-Policy=0;SSP:Subscriber-Secure-
Policy=5F;"
```

Format of a Subscriber Record

The following is an example of a subscriber record in the subscriber cache:

```
10.32.1.145/32 | IPS:corp1 | ACS:Acct-Session-
Id=32de327aced215ab;SUB:IMSI=301030100000026;LID:003048d5d928;NAS:NAS-
PORT=168496141;PCP:Parental-Control-Policy=20001;EXP:Expire-Profile=Mon May
29 10\\:23\\:56 2017;DCP:Dynamic-Category-Policy=0;SSP:Subscriber-Secure-
Policy=5F | 2017-06-05 21:20:51
```

set subscriber_secure_data bypass

You can use the `set subscriber_secure_data bypass` command to configure bypass subscriber service policies on all members of each site on the entire Grid, all members of the site or on a local member. To view information about the status of the command, see *show subscriber_secure_data bypass*.

Syntax

```
set subscriber_secure_data bypass <on | off > [grid | site][ "site_name" ]
```

Argument	Description
`on`	Enables subscriber service policies bypass.
`off`	Disables subscriber service policies bypass.
`grid`	Enable or disable the subscriber service policies bypass for all members of each site on the entire Grid.
`site`	Enable or disable the subscriber service policies bypass for all members of the site.

Note

- The newly added member do not inherit the bypass settings configured for the site. You must re-execute the bypass on/off CLI command.
- For a member of the group, that is not upgraded, the bypass subscriber service policies are not configured, and the message "Failed to set Subscriber Secure Bypass state for the member dns.com: upgrade is in progress." is displayed.
- The member must be part of a site even if the Subscriber Services are not running in order to configure Bypass Subscriber Service Policies.
- When there is a DNS service restart, if a member is restarting and the `set subscriber_secure_data bypass` command is executed, then the Subscriber Secure Bypass state is not enabled for the member.
- You can execute the `set subscriber_secure_data bypass` command with grid and site arguments only on the Grid Master and not on members.

Examples

```
Infoblox > set subscriber_secure_data bypass on site mobile1
Site: mobile1
            Member: dns1.com
                        Subscriber Secure Bypass enabled for the member dns1.com.
            Member: dns2.com
                        Subscriber Secure Bypass enabled for the member dns2.com .
            Member: dns3.com
                        Subscriber Secure Bypass enabled for the member dns3.com .
Infoblox>  set subscriber_secure_data bypass off site mobile1
```

```
Site: mobile1
            Member: dns1.com
                        Subscriber Secure Bypass enabled for the member
dns1.com.
            Member:  dns2.com
                        Subscriber Secure Bypass disabled for the member
dns2.com .
            Member:  dns3.com
                        Subscriber Secure Bypass disabled for the member
dns3.com .
Infoblox > set subscriber_secure_data bypass off
Member:  dns1.com
            Subscriber Secure Bypass disabled on the member  dns1.com .
```

set subscriber_secure_data delete

If you have configured Infoblox Subscriber Services, you can use the `set subscriber_secure_data delete` command to delete a specific subscriber record from the subscriber cache. For information about Infoblox Subscriber Services, see *Infoblox Subscriber Services*.

Syntax

```
set subscriber_secure_data delete <ip_addr> <prefix> <local_id>
<ip_space_desc>
```

Argument	Description
`< ip_addr >`	Specify the IPv4 or IPv6 address of the subscriber.
`<prefix>`	Specify the prefix length.
`<local_id>`	Local ID present in the incoming EDNS0 packet.
`<ip space desc>`	The IP space discriminator. To indicate a record without an IP space discriminator, enter N/A.

Example

```
Infoblox > set subscriber_secure_data delete 10.32.1.145 32 AABBCC112233 corp1
```

```
10.32.1.145/32|LID:aabbcc112233|IPS:corp1|FLG:|ACS:Acct-Session-Id=32de327aced215ab;SUB:IMSI=301030100000026;LID:AABBCC112233;NAS:NAS-PORT=168496141;PCP:Parental-Control-Policy=20001;EXP:Expire-Profile=Mon May 29 10\\:23\\:56 2017;DCP:Dynamic-Category-Policy=0;SSP:Subscriber-Secure-Policy=5F;|Thu Dec 20 10:53:41 2018
```

```
Record successfully deleted
```

set subscriber_secure_data clear_all

If you have configured Infoblox Subscriber Services, you can use the `set subscriber_secure_data clear_all` command to delete all the subscriber records from the subscriber's cache. Note that only the subscriber records with the K flag are deleted, however the subscriber records with an S flag and without any flag will not be deleted, they remain in the subscriber's cache.

Syntax

```
Infoblox > set subscriber_secure_data clear_all
```

This command has no arguments.

Example

```
Infoblox > set subscriber_secure_data clear_all
```

```
Deleted: 1 record
```

set subscriber_secure_data garbage_collect

You can use the `set subscriber_secure_data garbage collect` command to designate the specific member for garbage collection service. To view information about the status of the command, see *show subscriber_secure_data garbage_collect*.

Syntax

```
set subscriber_secure_data garbage_collect {on | off}
```

Argument	Description
`on`	Enables the member for garbage collection.
`off`	Disables the member for garbage collection.

Examples

```
Infoblox > set subscriber_secure_data garbage_collect on
```

```
This member is now configured for garbage collection at 2 AM everyday. Do you want to change the scheduled time for garbage collection (y or n): y
```

```
Enter garbage collection start time [<1-12> <AM/PM>]: 3 AM
```

```
Garbage collection is scheduled at 3 AM everyday.
```

set subscriber_secure_data never_proxy

If you have configured Infoblox Subscriber Services, use the `set subscriber_secure_data never_proxy` command to set a 32-bit hexadecimal character. This character represents the list of categories to be used in the global list used to resolve DNS queries without proxying to an MSP (Multi-Services Proxy) server.

You can view the hexadecimal value of the never_proxy category using the `show subscriber_secure_data never_proxy` command.

Syntax

```
set subscriber_secure_data never_proxy <category hexadecimal_character>
```

> **Note**
>
> You must restart the DNS service for the hexadecimal character to be set.

For a list of the different types of parental control policies and their hexadecimal values, refer to the supplemental documentation provided by Infoblox or contact your Infoblox representative.

Example

```
Infoblox > set subscriber_secure_data never_proxy
000ffffffffffffffffffffffff01
never_proxy categories are set
!!! A RESTART of the DNS service is required before this change can take effect !!!
```

In this example, the hexadecimal character of 000ffffffffffffffffffffffffff01 represent the category "Alcohol". Therefore, any domain related to alcohol (for example, www.beer.com, www.liquor.com) is not proxied to an MSP server. Instead, it is directly resolved by NIOS.

set subscriber_secure_data persist

If you have configured Infoblox Subscriber Services, you can use the `set subscriber_secure_data persist` command to enable data persistence mode which allows static records to survive restart. For information about Infoblox Subscriber Services, see *Infoblox Subscriber Services*.

Syntax

```
set subscriber_secure_data persist on
```

This command turn on persistence of static subscriber records.

Example

```
Infoblox > set subscriber_secure_data persist on
```

set support_access

The **`set support_access`** command enables and disables support access. This feature is disabled (off) by default. Enabling this feature allows Infoblox Support (Tier 3 access) to perform root level diagnostics on an appliance that is in severe distress. A special key is required to access the appliance at root level, and only Infoblox Support (Tier 3) can generate this key.

Note: Once the problem has been resolved, Infoblox recommends that you turn off this port. Any open port that is not in use can become a security risk.

Syntax

```
set support_access
```

This command has no arguments.

Example

```
Infoblox > set support_access
 Enable support access (Grid level)? (y or n): y
    New support access settings:
```

```
    Support access enabled: Yes
   Is this correct? (y or n): y
```

set support_timeout

The `set support_timeout` command allows you to specifying a custom timeout value for the support bundle download. For information on display of the custom timeout value, see *show support_timeout*.

Syntax

```
set support_timeout [value/off]
```

Argument	Description
value	Specify the timeout value for the support bundle download. The recommended value is between 0 to 86400 seconds, the default value is 1200.
off	The timeout value is set to its default value 1200.

Example

```
Infoblox > set support_timeout 2600
```

set sysName

You can use the **set sysName** command to set the FQDN (fully qualified domain name) of the appliance to allow configured SNMP management system to query the sysName value. If the appliance is an HA pair, you can use the **name2** command to set the FQDN of node 2 of the HA pair.

Syntax

```
set sysName name1 [name2]
```

Argument	Description
`name1`	The FQDN of the appliance.
`name2`	The FQDN of node 2 of an HA pair.

Examples

Setting the FQDN of the appliance

Enter the following on the appliance:

```
Infoblox > set sysName eng.corp100.com
```

Setting the FQDNs of an HA Pair

Enter the following on the appliance:

```
Infoblox > set sysName active.corp100.com passive.corp100.com
```

set tcp_timestamps

The **set tcp_timestamps** command allows you to enable or disable TCP timestamps. You can view these timestamps in the traffic capture file. TCP timestamps are enabled by default. If you disable TCP timestamps, the timestamps are not displayed in the traffic capture file.

You can run the *show tcp_timestamps* command to determine whether the TCP timestamps are enabled or disabled before running `set tcp_timestamps`.

Syntax

```
set tcp_timestamps {enable|disable}
```

Example

```
Infoblox > set tcp_timestamps enable
```

set temp_license

The **`set temp_license`** command generates and installs a temporary 60-day license for a fully functional NIOS appliance and IBOS (Infoblox Orchestration Server). Depending on the appliance model, the list of temporary licenses varies. To view the list of licenses installed on a NIOS appliance, use the *show license* command. For more information about licenses, see *Managing Licenses*.
Infoblox supports cloud API calls to set temporary licenses for **Threat Protection (Software add-on)** and **Threat Protection Update** licenses.

To install temporary license(s) for...	Select...	Remarks
DNS and DHCP services	**DNSone (DNS, DHCP)**	Installs DNS and DHCP licenses.

To install temporary license(s) for...	Select...	Remarks
DNS and DHCP services with Grid	**DNSone with Grid (DNS, DHCP, Grid)**	Installs DNS, DHCP, and Grid licenses.
DHCP services with Grid	**Network Services for Voice (DHCP, Grid)**	Installs DHCP and Grid licenses.
NIOS services	**Add NIOS License**	Installs a NIOS license for Trinzic 2016 hardware appliances.
DNS services	**Add DNS Server license**	Installs a DNS license.
DNS Cache Acceleration	**Add DNS Cache Acceleration**	Installs a DNS Cache Acceleration license.
DHCP services	**Add DHCP Server license**	Installs a DHCP license.
Grid	**Add Grid license**	Installs a Grid license.
Microsoft server management	**Add Microsoft management license**	Installs a Microsoft server management license.
Multi-Grid management	**Add Multi-Grid Management license**	Installs a Multi-Grid license for Multi-Grid management.
Query Redirection	**Add Query Redirection license**	Installs a query redirection license.
Software Advanced DNS Protection (ADP)	**Threat Protection (Software add-on)**	Installs a Software Advanced DNS Protection license for supported platforms.
Threat protection	**Threat Protection Update license**	Installs a Threat Protection Update license.
Response Policy Zones support	**Add Response Policy Zones**	For support of Response Policy Zones.
FireEye integrated RPZ support	**Add FireEye license**	Installs a FireEye license.
DNS Traffic Control	**Add DNS Traffic Control license**	Installs a DNS Traffic Control license.

To install temporary license(s) for...	Select...	Remarks
Cloud Network Automation	**Add Cloud Network Automation license**	Installs a Cloud Network Automation license.
Cloud Platform Appliances	**Add Cloud Platform license**	Installs a Cloud Platform license.
Security Ecosystem	**Add Security Ecosystem license**	Installs a Security Ecosystem license.
Threat Analytics	**Add Threat Analytics license**	Installs a Threat Analytics license.
Flex Grid Activation	**Flex Grid Activation license**	Installs the following licenses: Grid (enterprise), Unbound, DNS Cache Acceleration (DCA), DNS, DHCP, DNS Traffic Control (DTC), Response Policy Zone, Dual Engine DNS (only for recursive DNS), Software Threat Protection (sw_tp), Threat Protection Update (tp_sub), DNSFW (rpz), NXDOMAIN Redirect (qrd), FireEye, Threat Analytics, Microsoft Management, Security Ecosystem, and Cloud Network Automation.
FLEX Grid Activation for Managed Services	**FLEX Grid Activation for Managed Services license**	Installs FLEX Grid Activation for Managed Services license. It includes the same set of licenses that are bundled with the Flex Grid Activation license.
Discovery service	**Add Discovery license**	Installs a network discovery license.
Reporting service	**Add Reporting license**	Installs a license on the reporting server.
Reporting Subscription service	**Reporting Subscription**	Installs a Reporting Subscription license, which is a Grid-wide license.

> ⚠ **Note**
>
> To configure an appliance as an IB-FLEX, use the set hardware-type command. For more information, see *set hardware-type*.

Syntax

```
set temp_license
```

This command has no arguments.

Example

Installing a Temporary License on the NIOS Appliance

```
Infoblox > set temp_license
```

1. DNSone (DNS, DHCP)
2. DNSone with Grid (DNS, DHCP, Grid)
3. Network Services for Voice (DHCP, Grid)
4. Add NIOS license
5. Add DNS Server license
6. Add DHCP Server license
7. Add Grid license
8. Add Microsoft management license
9. Add Multi-Grid Management license
10. Add Query Redirection license
11. Add Threat Protection (Software add-on) license
12. Add Threat Protection Update license
13. Add Response Policy Zones license
14. Add FireEye license
15. Add DNS Traffic Control license
16. Add Cloud Network Automation license
17. Add Security Ecosystem license
18. Add Threat Analytics license
19. Add Flex Grid Activation license
20. Add Flex Grid Activation for Managed Services license

```
Select license (1-20) or q to quit: 4
```

1. IB-V805
2. CP-V805
3. IB-V815
4. IB-V825
5. IB-V1405
6. CP-V1405
7. IB-V1415
8. IB-V1425
9. IB-V2205
10. CP-V2205

11. `IB-V2215`
12. `IB-V2225`
13. `IB-V4005`
14. `IB-V4015`
15. `IB-V4025`
16. `IB-V5005`

```
Enter a number corresponding to a NIOS model (1 - 16) or q to quit:
```

Installing a Temporary License on the Discovery (ND) Appliance

```
Infoblox > set temp_license
```

1. `DNSone (DNS, DHCP)`
2. `DNSone with Grid (DNS, DHCP, Grid)`
3. `Network Services for Voice (DHCP, Grid)`
4. `Add NIOS license`
5. `Add DNS Server license`
6. `Add DHCP Server license`
7. `Add Grid license`
8. `Add Microsoft management license`
9. `Add Multi-Grid Management license`
10. `Add Query Redirection license`
11. `Add Response Policy Zones license`
12. `Add FireEye license`
13. `Add DNS Traffic Control license`
14. `Add cloud Network Automation license`
15. `Add Security Ecosystem license`
16. `Add Threat Analytics license`
17. `Add Flex Grid Activation license`
18. `Add Flex Grid Activation for Managed Services license`

```
Select license (1-18) or q to quit: 4
```

1. `ND-V805`
2. `ND-V1405`
3. `ND-V2205`
4. `ND-V4005`

```
Enter a number corresponding to a NIOS model (1-4) or q to quit:
```

```
Infoblox > set temp_license
```

1. `Add Grid license`
2. `Add Discovery license`

```
Select license (1-2) or q to quit:
```

Installing a Temporary License on the Trinzic IB-V805 Reporting Appliance

```
Infoblox > set temp_license
```

1. `Add NIOS license`
2. `Add Grid license`
3. `Add Reporting license`

```
Select license (1-3) or q to quit:
```

set term

Use the **`set term`** command to set the correct terminal type for future commands in the current session.

Syntax

```
set term
```

This command has no arguments.

Example

```
Infoblox > set term vt100
```

set test_promote_master

Run the **`set test_promote_master`** command before promoting a Grid Master Candidate to Grid Master. The command checks whether the Grid Master Candidate is connected to the rest of the Grid members. It runs a test promotion by sending specifically crafted test packets from the Grid Master Candidate and checking whether the Grid members are able to receive these packets. To view the status of the promotion, run the *show test_promote_master* command.

You can run a test promotion by also using the **GM Test** option on the Grid Manager. For more information, see *Managing a Grid*.

Syntax

```
set test_promote_master <ip_address>
```

Argument	Description
ip_address	IP address of the Grid Master Candidate that you want to promote to Grid Master

Examples

To test the Grid Master Candidate promotion:

```
Infoblox > set test_promote_master 10.33.151.4
```

```
Enter Timeout (>10 secs) for test messages(default 120 sec): 120
```

```
Upgrade/Downgrade is prohibited during the test. Do you want to proceed? (y or n): y
```

Here, test packets are sent every 10 seconds for 120 seconds from the Grid Master Candidate to the Grid members.

To stop a test promotion that is in progress:

```
Infoblox > set test_promote_master stop
```

```
This action will stop the promote master test which is still in progress.
```

```
Do you want to proceed? (y or n): y
```

set thresholdtrap

Use the **`set thresholdtrap`** command to enable the SNMP trap for CPU usage and to configure the trigger and reset values of the trap. The CPU usage trap is disabled by default. When you use this command to change the trigger and reset values, you enable the trap and the appliance sends and resets traps based on the configured values. When CPU usage of an appliance exceeds the trigger threshold for 15 seconds, the appliance sends a "CPU usage above threshold value" trap. After the appliance sends the "CPU usage above threshold value" trap, it sends a "CPU usage OK" trap when the CPU usage dips below the reset threshold.
Use the *show thresholdtrap* command to view the current settings of the CPU usage trap. Note that the CPU usage trap is disabled by default, and the trigger value is set at 100 and reset value at 0. For information about Infoblox SNMP traps, refer to the *Infoblox NIOS Administrator Guide*.

Syntax

```
set thresholdtrap {type} trigger {value} reset {value}
```

`Argument`	Description
`type`	The type of threshold trap. Enter **`CpuUsage`** to enable the CPU usage trap and set the trigger and reset values. Valid values are: NetworkCapacity, DBObjects, Disk, Memory, Rootfs, CpuUsage, Reporting, ReportingVolume, FDUsage
`value (for trigger)`	The trigger value of the SNMP trap. When CPU usage exceeds this value, the appliance sends a "CPU usage above threshold value" trap.

Argument	Description
`value (for reset)`	The reset value of the SNMP trap. When CPU usage dips below this value, the appliance sends a "CPU usage OK" trap. Ensure that the reset value is smaller than the trigger value.

Example

Enabling the CPU usage trap and set the trigger and reset values

```
Infoblox > set thresholdtrap CpuUsage trigger 80 reset 71
Infoblox >
```

When CPU usage exceeds 80% of capacity for 15 seconds, the appliance sends the “CPU usage above threshold value” trap. The appliance sends the “CPU usage OK” trap when CPU usage dips below the reset value of 71.
Following is a sample SNMP output of this example:

```
2011-09-30 04:32:20 ib-10-35-107-9.infoblox.com [UDP: [10.35.107.9]:44183->[10.35.107.9]]:

```

set token

The **set token** command is used to set Token, Grid Masters IP address and Certificate to the token file.

Syntax

```
set token [on|off|join]
```

Argument	Description
on	Sets Token, Grid Masters IP address and Certificate to the token file
off	Removes Token from the file and all corresponding data
join	To join the grid using the existing token file

Example

```
Infoblox > set token on
```

set traffic_capture

The `set traffic_capture` command allows you to capture the traffic for one or all of the ports on a NIOS appliance and save the traffic capture in a file. To capture traffic, the NIOS appliance must have a minimum of 500 MB of free disk space; otherwise, the traffic capture might fail.
The NIOS appliance saves all traffic it captures in a .cap file and compresses it into a .tar.gz file. The size of the .cap file is limited to 4 GB for Infoblox-4030-10GE and the size is limited to 1 GB for all other NIOS appliances. In Grid Manager, you can download the traffic capture file after the traffic capture stops by navigating to the **Grid** tab -> **Grid Manager** tab -> **Members** tab -> and click **Traffic Capture** from the Toolbar. To view information about the traffic capture running on the member, see *show traffic_capture_status*.
You can also transfer the traffic capture file to remote hosts either using FTP or SCP. You cannot transfer the traffic capture files when the traffic capture is in progress. Note that this operation may take a long time to complete.

Syntax

```
set traffic_capture on [port <all|lan1|lan2|mgmt|ha>] [vlan <id>] [duration
<seconds>]
[filter 'valid-tcpdump-filter-expression'] [with-rolling]
set traffic_capture off
set traffic_capture transfer [ftp|scp] <server-ip> <user-name> <user-
password>
[dest <file_name>]
```

Argument	Description
`on`	Starts the traffic capture.
`off`	Stops the traffic capture after you have started it.

`port`
`all`
`lan1`
`lan2`
`mgmt`
`ha`
	Specifies the port for which you want to capture the traffic:
	• Captures traffic on all ports.
	• Captures traffic on the LAN1 port.
	• Captures traffic on the LAN2 port.
	• Captures traffic on the MGMT port.
	• Captures traffic on the HA port.
	The default is LAN1. Note that if you have enabled the LAN2 failoverfeature, the LAN1 and LAN2 ports generate the same output. (For information about the LAN2 failover feature, see the *About Port Redundancy* section in the *Infoblox NIOS Administrator Guide*.)

`vlan <id>`	Captures traffic for the vLAN interface on LAN1 or LAN2
`duration <seconds>`	Specifies the duration in seconds for which you want the traffic capture to run. The default is 1800 seconds.
`filter 'valid-tcpdump-filter-expression'`	Allows you to set the “tcpdump” filter for traffic capture.
`with-rolling`	Enables rolling of traffic capture file. When the traffic capture file reaches the maximum size limit, the appliance automatically saves the file into a new file and continues capturing the traffic. The appliance can save up to 4 traffic capture files.
`transfer`	Allows you to transfer the traffic capture file to an FTP server or a SCP server.
`ftp`	Transfers the traffic capture file to an FTP server.
`scp`	Transfers the traffic capture file to an SCP server.

Example

Start the traffic capture

```
Infoblox > set traffic_capture on
 Traffic capture started successfully.
```

Stop the traffic capture

```
Infoblox > set traffic_capture off
 Traffic capture stopped successfully.
```

Start the traffic capture on a specific port

```
Infoblox > set traffic_capture on port lan1
 Traffic capture started successfully.
```

Specify the traffic capture filter

```
Infoblox > set traffic_capture on port lan1 filter 'host 10.32.2.34'
 Traffic capture started successfully.
 Infoblox > set traffic_capture on port lan1 filter 'net 192.168.0.0/24'
 Traffic capture started successfully.
 For information about valid tcpdump filter expressions, refer to https://wiki.wireshark.org/CaptureFilters.
```

Transfer traffic capture file to an FTP server

```
Infoblox > set traffic_capture transfer ftp 10.120.20.239 frtest Infoblox123 dest
 /home/rpadasalagi/ftp_back.tar.gz
 WARNING: This operation may take a long time to complete
Do you want to proceed? (y or n):y
```

Transfer traffic capture file to an SCP server

```
set traffic_capture transfer scp 10.120.20.239 frtest - dest /home/test/scp_back.tar.gz
Enter password:
 WARNING: This operation may take a long time to complete
Do you want to proceed? (y or n):y
```

WARNING: When you use the `set traffic_capture transfer` command, the user password is logged in the history. In order to avoid exposure of the user password, you can enter dash (-) instead of the actual

password in the `<user-password>` field. You can enter the password when the appliance prompts for the password.

---

set txn_trace

The **`set txn_trace`** command enables/disables tracing of DB transaction.

Syntax

```
set txn_trace [on|off]
```

Argument	Description
on	Enable tracing for DB transactions
off	Disable tracing for DB transactions

Example

```
Infoblox > set txn_trace
```

set update_rabbitmq_password

The **`set update_rabbitmq_password`** command updates the RabbitMQ password from the unsecure to the secure mode. When you perform a staged upgrade of NIOS from any source version to version 8.6.2 or later, Infoblox recommends that you run this command to make the password secure.

> ⚠ **Note**
>
> Running the `set update_rabbitmq_password` command restarts the Grid Manager. Therefore, Infoblox recommends that you run the command within the maintenance window.

Syntax

```
set update_rabbitmq_password
```

This command has no arguments.

Example

```
Infoblox > set update_rabbitmq_password
```

```
Switching RabbitMQ password to secure mode requires a product restart.
Are you sure you want to proceed? (y or n): y
RabbitMQ password updated.
```

set upgrade_dist rsync_batch disable

The set upgrade_dist rsync_batch disable command disables the resync-batch mode for all members on the Grid.

Syntax

```
set upgrade_dist rsync_batch disable
```

Examples

```
Infoblox > set upgrade_dist rsync_batch disable
```

set wins_forwarding

Use the `set wins_fowarding` command to configure the appliance to forward WINS packets to Microsoft DNS and DHCP servers. You can enable or disable this feature for the entire Grid or override Grid-level settings for specific Grid members. To configure Grid level setting, you must execute this command on the Grid Master.
To view information about the current packet forwarding configuration, see *show wins_forwarding*.

Syntax

```
set wins_forwarding grid|member
```

Argument	Description
`grid`	Configures all members in the Grid to enable or disable the forwarding of WINS packets to Microsoft DNS and DHCP servers. Grid-level setting can be set only on the Grid Master.
`member`	Overrides the Grid settings to enable or disable packet forwarding for a specific Grid member.

Examples

Enable packet forwarding for the Grid

```
Infoblox > set wins_forwarding grid
 This command will change default settings for WINS packets forwarding (will
```

```
affect members inheriting grid settings). Continue? (y or n): y
 Enable WINS packets forwarding? (y or n): y Enter default WINS server IP:
1.0.0.123 Select output interface from the list:
```

a. `MGMT`
b. `LAN`
c. `LAN2`
d. `VIP`

```
WINS packets forwarding is enabled. WINS packets will be forwarded to
"1.0.0.123".
```

Override Grid-level packet forwarding configuration for a specific Grid member

```
Infoblox > set wins_forwarding member
 WINS forwarding on grid level is enabled. WINS server IP is 1.0.0.123.
Override grid level settings? (y or n): y
```

```
Enable WINS packets forwarding on this member? (y or n): y Enter WINS
server IP: 1.0.0.321
 Select output interface from the list:
```

1. `MGMT`
2. `LAN`
3. `LAN2`
4. `VIP`

```
WINS packets forwarding is enabled. WINS packets will be forwarded to
"1.0.0.321".
```

Disable packet forwarding for the Grid

```
Infoblox > set wins_forwarding grid
 This command will change default settings for WINS packets forwarding (will
affect members inheriting grid settings). Continue? (y or n): y
```

```
Enable WINS packets forwarding? (y or n): n
```

```
WINS packets forwarding was disabled on grid level.
```

Overriding Grid-level configuration and disable packet forwarding for a specific Grid member

```
Infoblox > set wins_forwarding member
 WINS forwarding on grid level is enabled. WINS server IP is 1.0.0.123.

    Override grid level settings? (y or n): y
     Enable WINS packets forwarding on this member? (y or n): n
    WINS packets forwarding is disabled for this member.
```

show admin_group_acl

The `show admin_group_acl` command displays admin groups that have ACL settings.

Syntax

```
show admin_group_acl
```

This command has no arguments.

Example

The following example shows the response when none of the admin groups have enabled ACL settings.

```
Infoblox > show admin_group_acl
 None of Admin Groups have enabled ACL settings.
```

show allow_query_domain

The `show allow_query_domain` command displays the list of all domain names in the DNS view specified or its default DNS view. For information about adding, updating, or deleting the allow query domain ACLs, see *set allow_query_domain*. To view the list of all DNS views that have the allow query domain ACLs, see *show allow_query_domain_views*.

Syntax

```
show allow_query_domain [view-name]
```

```
show allow_query_domain <view-name> [domain-name]
```

Arguments	Description
`view-name`	Displays the named ACLs configured under the view name.
`domain-name`	Displays the domains in which the named ACLs are configured.

Example

```
Infoblox > show allow_query_domain
DNS View: default
Domain Name : foo.com
Named ACL : Named_ACL

Domain Name : abc.com
Named ACL : Named_ACL2
```

show allow_query_domain_views

The **`show allow_query_domain_views`** command displays the list of all DNS views that have the allow query domain ACLs configured. For information about adding, updating, or deleting the allow query domain ACLs, see *set allow_query_domain*. To view the list of all domains that have allow query domain ACLs, see *show allow_query_domain*.

Syntax

```
show allow_query_domain_views
```

This command has no arguments.

Example

```
Infoblox > show allow_query_domain_views

DNS views that have domain ACL associations:
1. default
2. dns_view
```

show analytics_parameter

The **`show analytics_parameter`** command displays configuration of Analytics service.

Syntax

```
show analytics_parameter [grid|member]
```

Argument	Description
grid	Displays configuration of Grid Analytics service
member	Displays configuration of member Analytics service

Example

```
Infoblox > show analytics_parameter
```

show adp

The **show adp** command displays ADP (Advanced Threat Protection) details on the supported platform. You can use this command only if **Threat Protection** (hardware based) or **Threat Protection (Software add-on)** licenses are installed on the platform.

Syntax

```
show adp
```

This command has no arguments.

Example

```
Infoblox > show adp
 Threat Protection:                  Enabled
Threat Protection monitor mode:    Disabled
 Threat Protection event stats:     CRITICAL=0 MAJOR=0 WARNING=0
INFORMATIONAL=2
Log level:                         6(Info)
```

show arp

The **show arp** command displays ARP (Address Resolution Protocol) data to view mappings. This allows you to see if the current state matches the mappings. If the mappings are out of date, use the *reset arp* command. This command is also useful for troubleshooting network connectivity issues.

Syntax

```
show arp
```

This command has no arguments.

Example

The following example shows the IP address (10.1.1.1), MAC address (`00:04:96:1D:19:80`), and type of connection (ethernet).

```
Infoblox > show arp
? (10.1.1.1) at 00:04:96:1D:19:80 [ether] or LAN
```

show action_to_activate_hotfix

The `show action_to_activate_hotfix` command displays the best action recommended to be performed for activating the latest installed hotfix changes. Note that this can be used only on Grid Master.

Syntax

```
show action_to_activate_hotfix <host_name> [<nios_version>] [resync]
```

Argument	Description
host_name	Enter the hostname. Note this is mandatory.
nios_version	Enter the NIOS version. Note this is optional.
resync	This option is used to re-synchronize to the hotfix manifest file from the Grid member. Note this is optional.

Example

```
Infoblox > show action_to_activate_hotfix infoblox.localdomain

Hotfix generic name               : CHF-8.6.3.1-J90002-apply-1681369836
Hotfix time                       : 15-06-23 07:10:36 UTC
Suggested best action to activate : Node restart required
Member status                     : ONLINE

Note: This action is to be performed after applying the hotfix, if already done
please ignore.
```

show auto_provision

The **`show auto_provision`** command shows the state of auto-provisioning for an appliance. It displays whether auto-provisioning is enabled or disabled for an appliance.

Syntax

```
show auto_provision
```

This command has no arguments.

Example

```
Infoblox > show auto_provision
 Auto Provision is enabled

Infoblox > show auto_provision
 Auto Provision is disabled
```

show bfd

The `show bfd` command displays the detailed BFD information, session details, and configuration information. For information about how to set the logging level, see *set bfd*.

Syntax

```
show bfd [ summary | details | config ]
```

Argument	Description
`summary`	Displays the BFD neighbor information.
`details`	Displays the BFD neighbor detailed information.
`config`	Displays the running BFD configuration file.

Example

```
Infoblox > show bfd details
 OutAddr              NeighAddr         LD/RD           Holdown(mult)

 Min tx interval: 100000- Min rx interval: 100000 Min Echo interval: 100000
```

show bgp

The **show bgp** command displays information about the BGP configuration on the appliance, reachability information about neighbors, and BGP routes to destinations. You can specify the command with or without an argument. A command without an argument defaults to **show bgp route**.
For information about how to write statistical information to syslog, see *set bgp log*.

Syntax

```
show bgp {route | neighbor | summary | config}
```

Argument	Description
route	Displays the BGP routing table.
summary	Displays the BGP protocol summary.
neighbor	Displays information about all known BGP neighbors.

Argument	Description
config	Displays the running BGP configuration file.

Example

```
The following examples are for illustration only. The actual output varies based on the Quagga version.
```

```
Infoblox > show bgp route
 BGP table version is 0, local router ID is 50.0.1.2
 Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, r RIB-failure, S Stale, R Removed
 Origin codes: i - IGP, e - EGP, ? - incomplete

Total number of neighbors 2
```

show bloxtools

The **show bloxtools** command displays the operational status of the bloxTools service and the usage percentage for the CPU, memory and disk resources.

Syntax

```
show bloxtools
```

This command has no arguments.

Example

Following is an example of the output displayed when you execute the command and bloxTools is enabled and its services are running:

```
Infoblox > show bloxtools
bloxTools status: enabled(GREEN)
CPU: 1%, Memory: 21%, Hard Disk: 0%
```

show capacity

The **show capacity** command displays database capacity limits for your NIOS appliance. This allows you to see the object counts and types on a member. This command is useful to see the amount of data is assigned to a member and how that relates to the member's specified capacity.

Syntax

```
show capacity
```

This command has no arguments.

Example

```
Infoblox > show capacity
 Hardware Type = IB-2000
 Database Capacity = 1200000 "objects"
Objects Present = 112466 (9 percent used)
```

```
 Count   Area         Type
 16638   dns          bind_a
 15000   dns          bind_cname
 1000   dns          bind_mx
 19392   dns          bind_ns
 15501   dns          bind_ptr
  836   dns          bind_soa
  500   dns          bulk_host
 5000   dns          dhcp_host
  385   dns          dhcp_member
  322   dns          dhcp_range
 1538   dns          fixed_address
 5000   dns          host
 5000   dns          host_address
 5000   dns          host_alias
  265   dns          network
  263   dns          shared_network_item
  500   dns          srg_zone_linking
  840   dns          zone
 18018   dns          zone_cluster_secondary_server
  537   dns          zone_ext_secondary_server
  208   Grid         product_license
 Note: Counts per object type not displayed unless at least 100 of that type
exist.
```

show cc_mode

The **show** **cc_mode** command displays the Common Criteria settings.

Syntax

```
show cc_mode
```

This command has no arguments.

Example

```
Infoblox > show cc_mode
 Common Criteria Mode Setting:
 Common Criteria Mode Enabled (grid-level): Yes
```

show certificate_auth_admins

The `show certificate_auth_admins` command displays whether the certificate authentication service is enabled for admins.

Syntax

```
show certificate_auth_admins
```

This command has no arguments.

Example

```
Infoblox > show certificate_auth_admins
Certificate authentication is enabled for next admins:
   admin
   ...
   [username]
```

show certificate_auth_services

The `show certificate_auth_services` command displays the list of certificate authentication services that are used as effective authorization policies.

Syntax

```
show certificate_auth_services
```

This command has no arguments.

Example

```
Infoblox > show certificate_auth_services
Effective Certificate Authentication Services:
```

```
   DoD CaC
  [service name]
```

show check_auth_ns

The **`show check_auth_ns`** command displays check authoritative NS RRset setting.

Syntax

```
show check_auth_ns
```

This command has no arguments.

Example

```
Infoblox > show check_auth_ns
Check authoritative NS RRset is disabled
```

show clusterd_info

The **`show clusterd_info`** command displays clusterd run-time information.

Syntax

```
show clusterd_info
```

This command has no arguments.

Example

```
Infoblox > show check_auth_ns

Waiting 5 sec while clusterd is creating dump file...
g_am_master_vnode: true (configured as a master node)
g_clusterd_max_nodes: 350
g_active_GM_openvpn_serv_cnt (actual count of OpenVPN servers to run): 1
g_first_join_attempt: false
g_using_conn_config_file (using conn info sent by grid master): false
g_delay_master_run (postpone starting master): false
g_dirty_shutdown: false
g_running_one (are the ONE services running?): true
g_is_real_unit (true for real HW): true
```

```
g_power_down_if (power-down unused interfaces): true
g_is_vnios (true for vNIOS): false
g_udp_vrrp (true for Platforms that use UDP based VRRP): false
g_am_active_master (am I the current grid master?): true
g_am_master_vnode (am I part of grid master vnode?): true
g_was_master: true
g_ha_enabled (is HA enabled?): false
g_active (am I the active node in an HA pair?): true
g_vpn_server_setup (is the VPN server setting up): false
g_directing_upgrade (are we directing the upgrade of the grid?): false
g_reverted (a flag indicating that the member just reverted): false
g_need_grid_upgrade_state_update: false
g_upgrade_lite (lite upgrade in progress): false
g_partner_upgrade_mode: UPGRADE_NONE
g_db_locked_for_snapshot: false
g_rollback_failed (meaningul only if g_db_locked_for_snapshot is set): false
g_removing (am I being removed?): false
g_start_proxyd (should proxyd be running?): false
g_partial_replication_disabled (last known state): false
g_am_logging_member: false
g_failover_syncing: false
g_tftp_limit (grid-wide tftp storage limit, in MB): 500
g_subgrid_cnt (number of subgrids): 0
g_using_external_time_servers (is using external NTP time servers): false
```

show config

The **`show config`** command displays the DNS, DHCP, DHCPv6, or DTC configuration files, named.conf, dhcp.conf, dhcpv6.conf, dtc.conf, and healthd.conf.

Syntax

```
show config { dns | dhcp | dhcpv6 | dtc | healthd }
```

`show config` displays the contents of named.conf, dhcp.conf, dhcpv6.conf, dtc.conf, and healthd.conf files. You can page through the output 10 lines at a time.

Argument	Description
dns	Displays the named.conf file.
dhcp	Displays the dhcp.conf file.
dhcpv6	Displays the dhcpv6.conf file.
dtc	Displays the dtc.conf file at /Infoblox/var/idns_conf/dtc.conf
healthd	Displays the healthd.conf file at /Infoblox/var/idns_conf/healthd.conf

Example

```
Infoblox > show config dns
   include "/infoblox/var/named_conf";
   options {
           zone-statistics yes;
           directory "/infoblox/var/named_conf"; version "";
           recursion no;
           listen-on {127.0.0.1; 10.0.0.0;}
           query-source address 10.0.0.0;
   Enter <return> to continue with More lines or enter q<return> to go back
to the command line.

Infoblox > show config dhcp
   local-address 10.0.0.0.;
   server-identifier 10.0.0.0;
   ddns-update-style interim;
   authoritative;
   option domain-name "corp100.com";
   mini-lease-time 43200;
   max-lease-time 43200; ping-check false;
   log-facility daemon;
   Enter <return> to continue with More lines or enter q<return> to go back
to the command line.

Infoblox > show config healthd
# AUTO GENERATED FILE, DO NOT EDIT
{
```

```
 'servers': [],
 'monitors': [],
'checks': [],
 'options': {
 'source': 'VIP',
'log_idns_health': False,
'log_facility': 29,
'source_ip': '10.120.21.129'
'socket_limit': 9000
}
}
```

show connections

The **`show connections`** command shows the active Internet connections for the NIOS appliance. Use this command to investigate connectivity issues or processes that may have stopped running.

Syntax

```
show connections
```

This command has no arguments.

Example

The following example provides information on:

- **Proto:** Active protocol, TCP or UDP
- **Recev-Q:** Packets received
- **Send-Q:** Packets sent
- **LocalAddress:** Host name and type of connection
- **ForeignAddress:** IP address of the system connected to the appliance
- **State:** State of the connection

```
Infoblox > show connections

Active Internet connections (servers and established)
Proto Recv-Q Send-Q Local Address Foreign Address State
 tcp 0    0    localhost:kdm*:*LISTEN
tcp 0    0    localhost:cluster-disk*:*LISTEN
tcp 0    0    localhost:localdo:domain*:*LISTEN
tcp 0    0    localhost:domain*:*LISTEN
tcp 0    0    localhost:rndc*:*LISTEN
tcp 0    0    infoblox:localdom:https*:*LISTEN
```

```
tcp 0    0    localhost:https*:*LISTEN
tcp 0    0    infobloxlocaldom:https10.1.1.1:arbotext-lm ESTABLISHED
 Enter <return> to continue with More lines or enter q<return> to go back to
the command line.
```

show connection_limit

You can use the **show connection_limit** command to display the per client IP address maximum connection limit for the following protocols: HTTP and HTTPS. Note that maximum connections here refer to the network level connections, not application level connections. For example, an HTTPS connection limit of 4 means that there can be a maximum of four TCP connections between any given client IP address and the appliance that are concerned using the HTTPS protocol.
To set the maximum connection limit, see *set connection_limit*.

Syntax

```
show connection_limit {http | https}
```

Argument	Description
`http`	The maximum connection limit for the HTTP protocol.
`https`	The maximum connection limit for the HTTPS protocol.

Examples

Showing the Per Client Address Maximum Connection Limit for the HTTP Protocol

```
Infoblox > show connection_limit http
 Current http connection limit: 150
```

show cpu

The **show cpu** command displays the processor and memory statistics for the NIOS appliance. This command tells you how busy the appliance is and indicates if an appliance is not performing properly.

Syntax

```
show cpu
```

This command has no arguments.

Example

The following example provides information on:

- **swpd:** Amount of virtual memory (swap space) used
- **free:** Amount of available memory
- **idle:** Amount of idle memory
- **buff:** Amount of memory used as buffers (I/O)
- **cache:** Amount of memory used as cache (kernel used memory)
- **swap**
  - **si:** Amount of memory paged in (per/sec) from swap or the file system
  - **so:** Amount of memory swapped out
- **io:** Disk input/output
  - **bi:** Blocks (4K each) received from a block appliance
  - **bo:** Blocks sent to a block appliance
- **system**
  - **in:** Number of hardware interrupts per second—measures how busy the CPU is
  - **cs:** Number of context switches per second—measures how busy the CPU is
- **cpu:** Measures (%) of CPU used in each of these areas—the total equals 100%
  - **us:** Percentage of CPU used running the Infoblox product and other non-kernel processes
  - **sy:** Percentage of CPU used running kernel processes
  - **id:** Percentage of CPU that is currently idle
  - **wa:** Percentage of CPU spent waiting for disk I/O

Note: If the combined io (bi and bo) and cpu wa values are high, it is a sign that the system is overloaded.

```
 Infoblox > showcpu
 ---------memory------------------- -swap-- --io--- --system- -----cpu-------
swpd   free    idle   buff   cache  si  so bi bo in cs us sy id wa st
0      984024  15432  51932  916660 0   0  0  42 61 94 3  2  95 0  0
```

show date

The **`show date`** command displays the current date, time zone, and time of a NIOS appliance. Use this command if you log in to an appliance from a different time zone. This command is helpful when dealing with a Grid that comprises multiple appliances in multiple time zones.

Syntax

```
show date
```

This command has no arguments.

Example

```
Infoblox > show date
 Tue Aug 16:24:19 EDT 2006
```

show debug

The **`show debug`** command shows whether debug logging is on or off. When on, debug logging captures all traffic and processes on the NIOS appliance. Due to the verbose nature and the extent of the information captured, these log files grow at a rapid rate. For information on how to turn on or off the debug logging, see *set debug*.

> **Note**
>
> Infoblox recommends that you turn off debug logging unless Infoblox Support specifically directs you to turn on this feature. If left on, debug logging can cause performance issues.

Syntax

```
show debug
```

This command has no arguments.

Example

```
Infoblox > show debug
 Debug logging status : enabled
```

```
Infoblox > show debug
 Debug logging status : disabled
```

For information on viewing the output of the debug log file, see *show log*.

show debug_analytics

The **`show debug_analytics`** command shows the status of Analytics service debugging.

Syntax

```
show debug_analytics
```

This command has no arguments.

Example

```
Infoblox > show debug_analytics
show debug_analytics
off
```

show delete_tasks_interval

The **show delete_tasks_interval** command shows the time interval the appliance waits until it deletes the completed and rejected tasks from the system. Once the tasks are removed, they are no longer displayed in the **Task Manager** tab of **Grid Manager**. The default interval is 14 days. For information about how to configure this time interval, see *set delete_tasks_interval*.

Syntax

```
show delete_tasks_interval
```

This command has no arguments.

Example

```
Infoblox > show delete_tasks_interval
 show delete_tasks_interval
 Current delete tasks interval is 25 days
```

show dhcp_gss_tsig

The `show dhcp_gss_tsig` commands provide information about an Infoblox DHCP server that is configured to send GSS-TSIG authenticated DDNS updates to an AD integrated DNS server. You can use these commands to verify your configuration and troubleshoot potential issues. You can also test whether the appliance can communicate with the Key Distribution Center (KDC) and the DNS server.

Syntax

```
show dhcp_gss_tsig config show dhcp_gss_tsig keytab
 show dhcp_gss_tsig test dns {ns-ip}
 show dhcp_gss_tsig test kdc {kdc-ip} {principal}
```

Argument	Description
`config`	Displays configuration information and runs tests to verify the configuration.

Argument	Description
`keytab`	Displays information about the keytab file that is in use by the appliance.
`test dns`	Tests the configuration by verifying that the destination DNS server is reachable. You must enter the IP address of the destination DNS server.

`test kdc`	Tests the configuration by obtaining a test Ticket Granting Ticket (TGT)) from the configured KDC.
	You must specify the following:
	• IP address of the AD domain controller that hosts the KDC for the domain
	• The Kerberos principal you specified when you generated the keytab file, in the following format: *username/instance@REALM*
	  • *username/instance*: The AD user name for the NIOS appliance and the FQDN of the appliance. This entry must be the same on the AD domain controller and the Infoblox appliance.
	  • *REALM*: The Kerberos realm in uppercase.

Examples

Displaying GSS-TSIG configuration information and run a test

The `show dhcp_gss_tsig config` command displays the following information:

- Whether DHCP and GSS-TSIG dynamic DNS updates are enabled on the appliance
- The system time in UTC
- Information about the KDC, principal, and domain

After it displays information, the appliance can test if it can obtain a TGT from the KDC and provides information about that transaction. Note that the TGT is for test purposes only and does not affect the data used by DHCP and DNS.
It can also test the external zones that are supposed to receive the DDNS updates as follows:

- Verify if the external zones specified in the member's network view match the member's domain
- Query the name server IP address for the address of the FQDN from the DNS principal
- Query the name server for the SOA of the zone. It displays a warning if the name server does not respond or if the result does not list the FQDN from the DNS principal as authoritative.

```
Infoblox > show dhcp_gss_tsig config
 System time: Tue Oct 21 16:01:43 UTC 2008
 D

HCP GSS-TSIG configuration for this member:

KDC address                  10.34.123.4
 KDC IP                       10.34.123.4
 Member principal         jdoe/anywhere@CORP100.LOCAL
Member domain                CORP100.LOCAL
 GSS-TSIG                     enabled
 DDNS updates                 enabled
```

```
 DHCP service                  enabled

Test KDC using member configuration? (y or n): y
 Requesting TGT for jdoe/anywhere@CORP100.LOCAL from KDC 10.34.123.4...
Successfully obtained test TGT.
 Credentials cache: FILE:/tmp/krb5_cache.18338
      Principal: jdoe/anywhere@CORP100.LOCAL
   Cache version: 4
 Server: krbtgt/CORP100.LOCAL@CORP100.LOCAL Client: jdoe/
anywhere@CORP100.LOCAL
 Ticket etype: arcfour-hmac-md5, kvno 2
Ticket length: 957
 Auth time: Oct 21 12:00:52 2008
 End time:Oct 21 13:00:52 2008
 Ticket flags: initial, pre-authenticated
Addresses: addressless
 Successful test. Test TGT destroyed.

This member is configured to update the following zones:
corp100 on 10.34.123.4 as dns/ns-corp100.CORP100.local

Test configured zones? (y or n): y

Next zone is corp100 on 10.34.123.4.
Test this zone? (y or n): y
 Testing external zone corp100 on NS 10.34.123.4...
DNS principal is dns/ns-corp100.corp100.local.
 Derived FQDN is ns-corp100.corp100.local.
FQDN resolves to nameserver IP.
 SOA for corp100 has MNAME ns-corp100.corp100.local.
Nameserver is authoritative for zone.
 Zone corp100 appears valid.
```

Displaying information about the keytab

The `show dhcp_gss_tsig keytab` command displays the current keytab.

```
Infoblox > show dhcp_gss_tsig keytab
 Vno Type Principal
 7 des-cbc-md5 jdoe/instance@CORP100.LOCAL
```

Verifying the DNS server

The `show dhcp_gss_tsig test dns` command verifies the destination DNS server by performing a reverse lookup of the IP address.

```
Infoblox > show dhcp_gss_tsig test dns 10.34.123.4
 Querying DNS server 10.34.123.4...
Server responded.

Probable DNS principal: dns/ns-corp100.corp100.local
```

Obtaining a test TGT from the KDC

When you use the show dhcp_gss_tsig test kdc command, the appliance tries to obtain a TGT from the KDC using the specified principal. It provides information about the transaction and upon successful completion, deletes the test TGT.

```
Infoblox > show dhcp_gss_tsig test kdc 10.34.123.4 jdoe/
instance@CORP100.LOCAL
 Requesting TGT for jdoe/instance@CORP100.LOCAL from KDC 10.34.123.4...
 Successfully obtained test TGT.

Credentials cache: FILE:/tmp/krb5_cache.12000
      Principal: jdoe/instance@CORP100.LOCAL
     Cache version: 4

 Server: krbtgt/CORP100.LOCAL@CORP100.LOCAL Client: jdoe/
instance@CORP100.LOCAL
 Ticket etype: arcfour-hmac-md5, kvno 2
Ticket length: 957
 Auth time: Oct 21 12:30:01 2008
 End time:Oct 21 13:30:01 2008
 Ticket flags: initial, pre-authenticated
Addresses: addressless

Successful test. Test TGT destroyed.
```

show dhcpd_recv_sock_buf_size

The **`show dhcpd_recv_sock_buf_size`** displays the current DHCP receive socket buffer size. The default is 1,536 kilobytes. For information about how to set the receive socket buffer size, see *set dhcpd_recv_sock_buf_size*.

Syntax

```
show dhcpd_recv_sock_buf_size
```

This command has no arguments.

Examples

For NIOS Appliances

```
Infoblox > show dhcpd_recv_sock_buf_size
 DHCP 'dhcpd' UDP receive socket buffer size: 1500 KB
```

show dhcpv6_gss_tsig

The `show dhcpv6_gss_tsig` commands provide information about an Infoblox DHCP server for IPv6 that is configured to send GSS-TSIG authenticated DDNS updates to an AD integrated DNS server. You can use these commands to verify your configuration and troubleshoot potential issues. You can also test whether the appliance can communicate with the Key Distribution Center (KDC) and the DNS server.

Syntax

```
show dhcpv6_gss_tsig config show dhcpv6_gss_tsig keytab
 show dhcpv6_gss_tsig test dns {ns-ip}
 show dhcpv6_gss_tsig test kdc {kdc-ip} {principal}
```

Argument	Description
`config`	Displays configuration information and runs tests to verify the configuration.
`keytab`	Displays information about the keytab file that is in use by the appliance.
`dns`	Tests the configuration by verifying that the destination DNS server is reachable. You must enter the IP address of the destination DNS server.

Argument	Description

`kdc`	Tests the configuration by obtaining a test Ticket Granting Ticket (TGT)) from the configured KDC. You must specify the following:
	• IP address of the AD domain controller that hosts the KDC for the domain
	• The Kerberos principal you specified when you generated the keytab file, in the following format: *username/instance@REALM*
	  • *username/instance*: The AD user name for the NIOS appliance and the FQDN of the appliance. This entry must be the same on the AD domain controller and the Infoblox appliance.
	  • *REALM*: The Kerberos realm in uppercase.

show disk

The **`show disk`** command displays the disk space that is used. Use this command to verify the amount of free disk space on the NIOS and vNIOS virtual appliances. Infoblox recommends that you regularly check the available disk space. Clear off outdated logs to maintain maximum available disk space. You should not allow the disk to become completely full because this can be detrimental to the performance of the appliance.

Syntax

```
show disk
```

This command has no arguments.

Examples

For NIOS Appliances

```
Infoblox > show disk
Available disk space: 207G
Disk space used: 4%
Infoblox >
```

For vNIOS Virtual Appliances

```
Infoblox > show disk
Available disk space: 53G
Disk space used: 5%
 Overall disk capacity: 120G
Infoblox >
```

show dns

The **show dns** command displays DNS query statistics for all DNS views. It also displays the recursive cache for the specified DNS views. This command displays IDN data in punycode.

Syntax

```
show dns {stats | cache [wait_time ntime][dns_view...]}
```

Argument	Description
stats	Displays DNS query statistics for all DNS views. You can also use this command to display DNS query statistics for all the DNS views of DNS cache acceleration on IB-FLEX.
ntime	The maximum time (from 1 to 600 seconds) to wait for the cache file to be ready.
cache dns_view	Specifies the DNS views for which you want to display the recursive cache.

Example

```
Infoblox > show dns stats
 success 10
 referral 0
 nxrrset 0
 nxdomain 0
 recursion 0
 failure 10
```

show dns-accel

The **show dns-accel** command displays DNS Cache Acceleration information. This command is available for:

- IB-FLEX only if the **Flex Grid Activation** license is present in the Grid.

Syntax

```
show dns-accel
```

Example

```
Infoblox > show dns-accel
```

```
Log level: 2(Critical)
Cache: Enabled
Minimum cached TTL: 1
Maximum cached lifetime: 86400
Cache hit count: 0
Cache miss count: 0
DNS query stats: SUCCESS=0 NXDOMAIN=0 NXRRSET=0 FAILURE=0 REFERR
AL=0
System UDP DNS query count: LAN1=0 LAN2=0 MGMT=0 HA=0
System UDP DNS response count: 0
```

```
Infoblox > show dns-accel
```

```
Log level: 5(Notice)
Cache: Enabled
Minimum cached TTL: 1
Maximum cached lifetime: 86400
Cache hit count: 0
Cache miss count: 0
DNS query stats: SUCCESS=0 NXDOMAIN=0 NXRRSET=0 FAILURE=0 REFERRAL=0
System UDP DNS query count: LAN1=0 LAN2=0 MGMT=0 HA=0
System UDP DNS response count: 0
```

show dns-accel-cache

The **`show dns-accel-cache`** command enables you to view the cache for DNS Cache Acceleration. It fetches and displays new acceleration cache data. For existing files, it displays data from the previous collection, if present. This command is available for:

- IB-FLEX only if the **Flex Grid Activation** license is present in the Grid.

Syntax

```
show dns-accel-cache
```

Example

```
Infoblox > show dns-accel-cache
```

```
Cache is empty
```

```
Infoblox > show dns-accel-cache

Warning: This operation will temporarily disable the acceleration cache to obtain the latest cached data.

The operation should take about 15 seconds to complete.

During this period, this member's DNS query performance may be significantly reduced, and changes to the member's DNS configuration will not be permitted.

Are you sure you want to proceed with this operation (y/n): y

Cache data obtained at 2018-12-14-06:22:51

Note: In case of multiple RR's, they will be printed on their own line after the first one, aligned with commas to match correct column.

show dns_gss_tsig

The **show dns_gss_tsig** commands provide information about an Infoblox DNS server that is configured to receive GSS-TSIG authenticated DDNS updates from a DHCP server. You can use these commands for diagnostic purposes and to troubleshoot issues.

Syntax

```
show dns_gss_tsig counters [crypto]| keytab
```

Argument	Description
`counters`	Displays information from the internal counters, which are non-persistent and reset to zero when services are restarted. It displays the number of TKEY (transaction key) requests the Infoblox DNS server has accepted and the number of GSS-TSIG authenticated DDNS updates received. If you specify **crypto,** the display includes the number of successful and failed attempts to establish a security by context, by encryption type.

Argument	Description
`keytab`	Displays information about the DNS keytab files that are in use by the appliance.

Example

```
Infoblox > show dns_gss_tsig keytab

    Vno Type Principal
     4 des-cbc-md5 DNS/ns1.local.test@TEST.LOCAL
```

show dns-over-tls-config

The `show dns-over-tls-config` command displays the DNS over TLS configuration and includes DNS over TLS servers that are listening on port 853.

Syntax

```
show dns-over-tls-config
```

This command has no arguments.

Example

```
Infoblox > show dns-over-tls-config
DoT listen on v4 addresses:
  10.39.51.58
DoT listen on v6 addresses:
  2620:10a:6000:2745::1011
DoT listen on port: 853
```

show dns-over-tls-stats

The `show dns-over-tls-stats` command displays the statistics of DNS over TLS sessions. Statistics displayed include but are not limited to:

- Active TLS sessions
- Total number of queries received over TLS
- Total number of responses sent over TLS

Syntax

```
show dns-over-tls-stats
```

This command has no arguments.

Example

```
Infoblox > show dns-over-tls-stats
IP 10.39.51.58 (TLS):
  rx_packets:                   0
  tx_packets:                   0
  dropped_packets:              0
  max_qry_overflow_sess_drop:   0
  opened_sessions:              0
  closed_sessions:              0
  curr_sessions:                0
IP 2620:010a:6000:2745::1011 (TLS):
  rx_packets:                   0
  tx_packets:                   0
  dropped_packets:              0
  max_qry_overflow_sess_drop:   0
  opened_sessions:              0
  closed_sessions:              0
  curr_sessions:                0
```

show dns-over-tls-status

The `show dns-over-tls-status` command displays the status of DNS over TLS service. Use this command to verify whether the feature is enabled. For steps to enable DNS over TLS, see *Configuring DNS over TLS*.

Syntax

```
show dns-over-tls-status
```

This command has no arguments.

Example

```
Infoblox > show dns-over-tls-status
DoT is enabled
DoT trace is off
DoT key logging is off
Max server sockets: 128
curr server sockets: 4
curr client sockets: 0
```

show dns_rrl

The **show dns_rrl** command provides information about the Grid or member DNS RRL (Response Rate Limiting) settings. You can use the **set dns_rrl** command to configure the DNS RRL settings. For more information, see *set dns_rrl*.

Syntax

```
show dns_rrl [member <hostname> | view <viewname> | grid]
```

> **Note**
> The show dns_rrl command accepts the member option only on the Grid Master.

Argument	Description
member *<hostname>*	The FQDN of the Grid member.
view *<viewname>*	The name of the DNS view.
grid	Show RRL settings for the Grid.

Examples

```
Infoblox > show dns_rrl grid
 Grid RRL configuration:
  responses_per_second: 200
  window: 15 (default)
  slip: 3
```

```
  log_only: false (default)

Grid logging configuration:
  log rate-limit: true (default)
```

show dnstap-stats

The `show dnstap-stats` command displays the number of queries and responses sent to the destination when the dnstap log format is enabled for high performance query logging. To configure dnstap in Grid Manager, see *Capturing DNS Queries and Responses*. To enable the dnstap log format, see *set enable_dnstap*.

Syntax

```
show dnstap-stats
```

This command has no arguments.

Example

```
Infoblox > show dnstap-stats
Packed queries: 1
Packed responses: 1
Total records: 2
Duration connected(s): 423
Total bytes sent: 286
```

show dnstap-status

Use the show dnstap-status command to view the status of the dnstap configuration. The CLI displays the status of the all the fields in the **Toggle Advanced Mode** > **Logging** tab. To enable or disable the dnstap status use the *set enable_dnstap* command.

Syntax

```
show dnstap-status
```

Example

```
Infoblox > show dnstap-status
DNSTAP is on
DNSTAP configuration overridden on a Member level.
Enable forwarding queries category of log messages using DNSTAP: Yes
```

```
Enable forwarding DNS responses category of log messages using DNSTAP: No
IP address of DNSTAP receiver to transfer captured DNS queries/responses:
7.29.121.1
DNSTAP receiver port number: 7000
```

show docker_bridge

The **`show docker_bridge`** command displays the IP address of the current Docker bridge. You can then choose to reset the IP address by running the *set docker_bridge* command.

Syntax

```
show docker_bridge
```

This command has no arguments.

Example

```
Infoblox > show docker_bridge
Current Docker Bridge settings:
Bridge Gateway/CIDR: 172.17.0.1/16
```

show doh-config

The **`show doh-config`** command displays the DNS over HTTPS configuration and includes DNS over HTTPS servers that are listening on port 443.

Syntax

```
show doh-config
```

This command has no arguments.

Example

```
Infoblox > show doh-config
DoH listen on v4 addresses:
  10.39.51.58
DoH listen on v6 addresses:
  2620:10a:6000:2745::1011
DoH listen on port: 443
```

show doh-stats

The `show doh-stats` command displays the statistics of DNS over HTTPS sessions. Statistics displayed include but are not limited to:

- Active HTTPS sessions
- Total number of queries received over HTTPS
- Total number of responses sent over HTTPS

Syntax

```
show doh-stats
```

This command has no arguments.

Example

```
Infoblox > show doh-stats
IP 10.39.51.58
  rx_queries:                  0
  tx_queries:                  0
  dropped_packets:             0
  max_qry_overflow_sess_drop:  0
  opened_sessions:             11
  closed_sessions:             11
  curr_sessions:               0
IP 2620:010a:6000:2745::1011
  rx_queries:                  0
  tx_queries:                  0
  dropped_packets:             0
  max_qry_overflow_sess_drop:  0
  opened_sessions:             0
  closed_sessions:             0
  curr_sessions:               0
```

show doh-status

The `show doh-status` command displays the status of the DNS over HTTPS service. Use this command to verify whether the feature is enabled. For steps to enable DNS over TLS, see *Configuring DNS over HTTPS*.

Syntax

```
show doh-status
```

This command has no arguments.

Example

```
Infoblox > show doh-status
DoH is enabled
DoH trace is off
DoH key logging is off
Max server sockets: 128
curr server sockets: 2
curr client sockets: 0
```

show dscp

The **show dscp** command provides information about the Grid and member DSCP values in both decimal and hexadecimal formats. You can use the **set dscp** command to configure the DSCP value. For more information, see *set dscp*.

Syntax

```
show dscp
```

This command has no arguments.

Examples

For a Grid:

```
Infoblox > show dscp
 Grid Level: 30 (Ox1e)
 Member Level:Override grid setting
            20 (Ox14)

Infoblox > show dscp
 Grid Level: 30 (Ox1e)
Member Level:Use grid setting
```

For an independent appliance:

```
Infoblox > show dscp
DSCP:       28 (0x1c)
```

show dtc_geoip

The `show dtc_geoip` command provides information about the GeoIP labels that are available in the current MaxMind location database for the respective IP address. You can run this command only if you have installed the DNS Traffic Control license. For more information about DNS Traffic Control, refer to the *Infoblox NIOS Administrator Guide*.

Syntax

```
show dtc_geoip <ip-address>
```

Argument	Description
ip-address	Valid IPv4/IPv6 address of the host.

Examples

```
Infoblox > show dtc_geoip 54.243.36.49
 Continent = North America
Country = United States
Subdivision = Virginia
```

```
Infoblox > show dtc_geoip 2607:f8b0:400a:804::1012
 Continent = North America
Country = United States
Subdivision = Atlanta
```

show enable_match_recursive_only

Use the `show enable_match_recursive_only` command to view the status of the match-recursive-only option for all DNS views on a specific Grid member. For information about how to use the match-recursive-only feature, see *set enable_match_recursive_only,* and also refer to the *Infoblox NIOS Administrator Guide*.

The `show enable_match_recursive_only` command reports one of three possible states:

- `True:` The DNS view is set to use the match-recursive-only setting to restrict and filter client access for the view.
- `False:` The DNS view does not use the match-recursive-only setting.
- `Inherit:` The default, where the DNS view inherits its match-recursive-only setting from the Grid.

Syntax

```
show enable_match_recursive_only
```

This command has no arguments.

Example

```
Infoblox > show enable_match_recursive_only
   View 'default': false
   View 'dnsview1': true
   View 'external': inherit
```

show extra_dns_name_validations

The `show extra_dns_name_validations` command displays the status of the additional validation that takes place on host names when creating or modifying zones, subzones, and records of type A, AAAA, host record, ALIAS, CAA, MX, and NS. You can use the `set extra_dns_name_validations` command to enable or disable the additional validation on host names. For more information, see *set extra_dns_name_validations*.

Syntax

```
show extra_dns_name_validations
```

This command has no arguments.

Example

```
Infoblox > show extra_dns_name_validations
```

```
extra_dns_name_validations option is turned off
```

show file

The **`show file`** command displays specified groups and files that you can access for diagnostic purposes. You can page through the display 10 lines at a time. Use this command to view files after you enable the bloxTools Environment service.

Syntax

```
show file {groups | group}
show file group file1 [file2 ...] [follow]
```

If you use the **`show file`** command without any arguments, it displays all the files that you can manage with this command. If you use the groups argument, a list of all groups is shown.
If you use the `show file` command with a *`group`* argument but no `file ,` it displays a list of all the files in the specified group. If you use the **`show file`** command with `group` and *`file`* arguments, you can specify a real-time (live) view of the file—the same as the using tail -f arguments. You can interrupt the display by pressing **`Enter.`**

Argument	Description
`groups`	Displays a list of available groups.
`group`	Displays a list of files for the specified group.
`group file1 [file2 ...]`	Displays the specified (group) files.
`follow`	Displays the contents of the file live, in real-time.

Examples

Viewing bloxTools Files

```
Infoblox > show file bloxtools portal_access
Showing file /storage/web-portal/udata/logs/access.log
Infoblox > show file bloxtools portal_error
Showing file /storage/web-portal/udata/logs/error.log

file
```

show fips_mode

The **show fips _mode** command displays settings of the FIPS mode.

Syntax

```
show fips_mode
```

This command has no arguments.

Example

```
Infoblox > show fips_mode
 FIPS Mode Setting:
 FIPS Mode Enabled (grid-level): Yes
```

show hardware_status

The **show hardware_status** command displays information about the various hardware components of a NIOS appliance. It displays the power supply status, fan speed, the CPU temperature, and status of the RAID array (for the Infoblox-2000 only).

Syntax

```
show hardware_status
```

This command has no arguments.

Example

The following example displays the status of an Infoblox-2000.

```
Infoblox > show hardware_status

 POWER:Power OK
 Fan1:5075 RPM
 Fan2:4927 RPM
 Fan3:4787 RPM
 CPU1_TEMP: +42.0 C
 CPU2_TEMP: +48.0 C
 SYS_TEMP: +49 C
```

```
RAID_ARRAY: OPTIMAL
RAID_BATTERY: OK READY Yes 103 HOURS
```

The following are notes about the output:

- POWER: Displays the status of the power supply. The Infoblox-1552, -1552-A and -2000 have redundant power supplies. If one power supply fails, the line displays POWER FAIL. To find out which power supply failed, check the LEDs of the power supplies.
- Fan1, Fan2, Fan3: Displays the fan speed. The Infoblox-2000 has three fans, therefore the sample output displays the speed of each fan. If a fan is not functioning, the output displays 0 RPM.
- CPU1 TEMP, CPU2 TEMP: Displays the CPU temperature.
- SYS TEMP: Displays the operating temperature of the appliance.
- RAID ARRAY: Displays the status of the RAID array of an Infoblox-2000. If at least one disk is not functioning properly, this line indicates that the RAID array is degraded and lists the disks which are online. It also indicates when the RAID array is rebuilding. If there is a disk mismatch, this line indicates so and lists all the RAID disks and their disk types.
- RAID BATTERY: This line reports the status of the disk controller backup battery. It includes the following information:
  - Charge status: Displays either OK or CHARGING.
  - Ready status: Displays either READY YES or READY NO.
  - Hours: Displays the estimated number of hours remaining on the battery.

> **Note**
>
> This command is not supported on vNIOS appliances on VMware. The vNIOS appliance displays No sensors present when you enter this command.

show hardware-type

Use the **`show hardware-type`** command to display the current hardware type, member host platform, and hypervisor details for your appliance.

For IB-FLEX only, you can set the hardware type on an appliance and configure it as an IB-FLEX. For more information, see *set hardware-type*. For information about IB-FLEX, see *About IB-FLEX*.

Syntax

```
show hardware-type
```

This command has no arguments.

Example

To display the hardware type of an appliance:

```
Infoblox > show hardware-type
```

```
Member hardware type: IB-V825
```

```
Member host platform = Openstack
```

```
Member hypervisor = KVM
```

> **Note**
>
> The `Member hypervisor` value differs based on the underlying hypervisor. For example, in Nutanix host platforms, the `Member hypervisor` value is displayed as `HYPERV` or `KVM`. This is because Nutanix AHV supports different types of hypervisors in Windows and Linux platforms.

show hwid

The **`show hwid`** command displays the hardware ID. The information provided by this command is required for acquiring a new license.

Syntax

```
show hwid
```

This command has no arguments.

Example

```
Infoblox > show hwid
 Hardware ID: 4dcef037e91a403fe05e10ecd241
```

show ibtrap

The **`show ibtrap`** command displays whether SNMP traps and email notifications are enabled for the specified event category.

Syntax

```
show ibtrap [category]
```

Argument	Description
category	Valid values are: `Fan, Bloxtools, Disk, Memory, CPU, MGM, HSM, Login, PowerSupply, FTP, TFTP, HTTP, NTP, DNS, DHCP, RootFS, Database,R AID, HA, MSServer, Backup, Clear, SNMP, LCD, SSH, SerialConsole, ENAT, Network, Cluster, Controld, OSPF, IFMAP, BGP, CaptivePortal, DuplicateIP, License, System, Syslog, DiscoveryConflict, ReportingVolume, DisconnectedGrid`

Example

```
Infoblox > show ibtrap Fan
 Trap Category: Fan snmp: true
 email: false
```

show interface

The **show interface** command displays network interface details. The information reveals how the NIOS appliance is connected to the network. It shows line rate, broadcast address, and whether packets are being dropped. This information allows you to check the status, find the MAC address of an appliance, and provides statistics on the quality of the network signal. This command also displays whether IPv6 is enabled. On the Infoblox-250, -550-A, -1050-A, -1550-A, -1552-A, -2000, and -2000-A appliances, the appliance displays information about the LAN2 port as well. It also displays the bonded interface information when NIC bonding is enabled in the NIOS appliance.
For information about how to change your interface settings, see *set interface*.

Syntax

```
show interface [name | all]
```

Argument	Description
name	Displays information about a specific interface. Enter one of the following: lan, lan2, ha, mgmt, or loopback.
all	Displays information about all interfaces.

Example

The following example illustrates how you can use the **show interface** command to view the IP address and MAC address of an appliance, and its network connection details. Note that when you manually configure the speed and duplex of an interface, the appliance communicates only the settings. When you configure the Speed/Duplex settings at 1000M/Full, auto-negotiating is required and the appliance displays `Enabled (Speed/Duplex configured by user)` instead of `Enabled` in the **Negotiation** field, as shown in the following example.
Statistical information is also provided on the packets received and transmitted, as well as any errors that have occurred. Lack of packet activity can be a sign of connectivity problems, dropped packages, overruns, or collisions.

```
Infoblox > show interface
 LAN:

        IP Address: 10.34.33.11          MAC Address: 00:30:48:98:63:AD
        Mask:255.255.255.0               Broadcast:   10.34.33.255
        MTU: 1500                        Metric:      1
```

```
 IPv6 Link:          fe80::230:48ff:fe98:63ad/64
IPv6 Status:        Enabled
 Negotiation: Enabled
 Speed:       1000M               Duplex:Full
DSCP Value:     30
 Status:  UP BROADCAST RUNNING MULTICAST

Statistics Information
Received

    packets:  24812        bytes:   11660993 (11.1 Mb)
    errors:   0            dropped: 0
    overruns: 0            frame:   0

Transmitted

```

```
Enter <return> to continue with More lines or enter q<return> to go back
to command line
```

show ip_rate_limit

The **`show ip_rate_limit`** command displays the current rate limiting rules. You configure rate limiting rules to limit access or block connections from external sources. The rules take effect immediately when you enable rate limiting. For information on rate limiting and on how to configure rate limiting rules, see *set ip_rate_limit*.

Syntax

```
show ip_rate_limit
```

This command has no arguments.

Example

Viewing the current rate limiting rules

```
IP rate limiting is enabled.
 Source            Limit               Burst
 ========================================
10.10.1.1        0 packets/minute     0 packets
10.10.1.2        5 packets/minute     5 packets
10.10.2.1/24     5 packets/minute     10 packets
all              5000 packets/minute  5000 packets
```

show ipv6_bgp

The **`show ipv6_bgp`** command displays the local NIOS appliance's IPv6 BGP configuration, reachability information about neighbors, and BGP routes to destinations. You can specify the command with or without an argument. A command without an argument defaults to **`show bgp route`** .

For information about how to write statistical information to syslog, see *set bgp log*.

Syntax

```
show ipv6_bgp {route | neighbor | summary | config}
```

Argument	Description
`route`	Displays the BGP routing table.
`summary`	Displays the BGP protocol summary.
`neighbor`	Displays information about all known BGP neighbors. If only IPv4 BGP information is available, this command option displays IPv4 information.
`config`	Displays the running BGP configuration file, including all IPv4 and IPv6 configuration, prefix lists and access-lists.

If no applicable information is available (for example, the current device has no IPv6 BGP configuration and hence no IPv6 BGP neighbor information), you are returned to the NIOS CLI prompt.

Example

```
Infoblox > show ipv6_bgp summary
 BGP router identifier 10.34.1.179, local AS number 1 RIB entries 3, using
288 bytes of memory
 Peers 1, using 4560 bytes of memory

BGP connection: non shared network
 Read thread: on Write thread: off
```

show ipv6_disable_on_dad

The **`show ipv6_disable_on_dad`** command displays whether IPv6 is disabled, when a duplicate IPv6 address is detected, on the corresponding interface.

Syntax

```
show ipv6_disable_on_dad
```

Examples

```
Infoblox > show ipv6_disable_on_dad
 Disable IPv6 if duplicate IPv6 address detected: off
```

```
Infoblox > show ipv6_disable_on_dad
 Disable IPv6 if duplicate IPv6 address detected: on
```

show ipv6_neighbor

The **`show ipv6_neighbor`** command displays the status, IPv6 address and link-local address (normally, the MAC address of the neighboring port) of the IPv6 neighbor for the specified NIOS appliance interface–LAN, LAN2 or MGMT.

Syntax

```
show ipv6_neighbor <lan|lan2|mgmt>
```

If no applicable information is available (for example, the current device has no IPv6 configuration and hence no IPv6 neighbor information), you are returned to the NIOS CLI prompt.

Example

```
Infoblox > show ipv6_neighbor lan
 fe80::204:96ff:fe1d:1980 lladdr 00:04:96:1d:19:80 router STALE
```

show ipv6_ospf

The **`show ipv6_ospf`** command displays configuration and statistical information about the OSPFv3 protocol (if any) running on the NIOS appliance. For information on changing OSPF log settings, see *set ipv6_ospf*.

Syntax

```
show ipv6_ospf {route | interface | database | neighbor | configuration}
```

Argument	Description
`route`	Displays the OSPF routing table, as determined by the most recent SPF calculation.
`interface`	Displays the state and configuration on all interfaces configured with OSPF.
`database`	Displays all OSPF database information.
`neighbor`	Displays the OSPF neighbor information.
`configuration`	Displays the running OSPF configuration file.

Examples

```
Infoblox > show ipv6_ospf
OSPFv3 Routing Process (0) with Router-ID 10.34.1.179
 Running 11d03:14:41
 Number of AS scoped LSAs is 2
 Number of areas in this router is 1
 Area 0.0.0.61
    Number of Area scoped LSAs is 4
    Interface attached to this area: eth1
```

```
Infoblox > show ipv6_ospf interface
eth1 is up, type BROADCAST
 Interface ID: 11
 Internet Address:
    inet : 10.34.1.179/29

 DR: 255.1.1.1 BDR: 10.34.1.179
 Number of I/F scoped LSAs is 2
  0 Pending LSAs for LSUpdate in Time 00:00:00 [thread off]
  0 Pending LSAs for LSAck in Time 00:00:00 [thread off]
eth2 is down, type BROADCAST
```

show lcd

The **`show lcd`** command displays whether the LCD keys are turned on or off.

Syntax

```
show lcd
```

This command has no arguments.

Example

```
Infoblox > show lcd
No LCD present
```

show lcd_info

The **`show lcd_info`** command displays status, CPU temperature, network settings, version, hardware ID, and licensing information. It also displays the bonded interface information when NIC bonding is enabled in the NIOS appliance. This command combines the output of the following CLI commands: **`show status`**, **`show temperature`**, **`show network`**, and **`show license`**.

Syntax

```
show lcd_info
```

This command has no arguments.

Example

```
Infoblox > show lcd_info
 Grid Status: ID Grid Master
HA Status:   Not Configured

CPU_TEMP: +45.5 C

Current network settings:

```

> **Note**
> This command is not supported on vNIOS appliances on VMware.

show lcd_settings

The **`show lcd_settings`** command displays the value of these fields: lcd_autodim/lcd_brightness/lcd_hwident.

Syntax

```
show lcd_settings
```

This command has no arguments.

Example

```
Infoblox > show lcd_settings
 LCD settings can not be configured.
```

show license

The **`show license`** command displays information about the licenses installed on NIOS appliances, vNIOS appliances, and Orchestration Servers. For information, refer to the *Infoblox NIOS Administrator Guide*. You can use this command to view licenses that were transferred from one vNIOS on VMware appliance to another. For information on how to set your licenses, see *set license*.
This command displays Grid-wide licenses when you specify gridwide or all arguments. Without any arguments, the static licenses for the member are displayed.

Syntax

```
show license [all | csv | gridwide | revoked]
```

Argument	Description
all	Displays all product licenses in a Grid.
csv	Displays all product licenses in a Grid in csv format.

Argument	Description
gridwide	Displays Grid-wide licenses in a Grid.
revoked	Displays vNIOS licenses that were transferred from one vNIOS appliance to another.

Examples

Showing product licenses installed on a NIOS appliance

```
Infoblox > show license

```

show license_uid

The `show license_uid` command displays the license UID of the Grid. The UID is required when requesting Grid-wide licenses. The UID that the appliance returns is the same as the **License Pool Container UID** that is used for obtaining dynamic licenses.

Syntax

```
show license_uid
```

This command has no arguments.

Examples

```
Infoblox > show license_uid
 The grid-wide license unique ID (same as LPC_UID):
e51f90527dce4708bc1ada576286d26a
```

show license_pool_container

The `show license_pool_container` command displays the license UID that is required when obtaining dynamic licenses for vNIOS virtual appliances.

Syntax

```
show license_pool_container
```

This command has no arguments.

Examples

```
Infoblox > show license_pool_container
 The Unique ID of the License Pool Container (LPC_UID):
e51f90527dce4708bc1ada576286d26a
```

show log_guest_lookups

Use the `show log_guest_lookups` CLI command to disable the logging of guest lookups. That is, this command is used to enable or disable the logging of DNS lookup requests by guest devices behind a home router.

Syntax

```
set log_guest_lookups [on|off]
```

show log_txn_id

The **`show log_txn_id`** command displays whether DHCP transaction ID logging is on or off. By default, DHCP transaction ID logging is enabled. Use the *set log_txn_id* to enable or disable logging of DHCP transaction IDs.

Syntax

```
show log_txn_id
```

This command has no arguments.

Example

```
Infoblox > show log_txn_id
 DHCP Transaction id logging turned OFF
```

show lom

The **`show lom`** command displays the LOM (Lights Out Management) settings for the IPMI interface. To configure the network settings for the IPMI interface, use the *set lom* command.

Syntax

```
show lom
```

This command has no arguments.

Example

```
Infoblox > show lom
 LOM for Grid: enabled
 LOM for member: enabled (inherit)

Network settings:
 IP Address: 10.34.10.42
 Subnet Mask: 255.255.255.0 Default Gateway IP: 10.34.10.1

Users:
```

show max_recursion_depth

The **`show max_recursion_depth`** command displays the maximum recursion depth value.

Syntax

```
show max_recursion_depth
```

This command has no arguments.

Example

```
Infoblox > show max_recursion_depth
Recursion depth limit: 7
```

show max_recursion_queries

The **`show max_recursion_queries`** command displays the maximum recursion queries value.

Syntax

```
show max_recursion_queries
```

This command has no arguments.

Example

```
Infoblox > show max_recursion_queries
```

```
show max_recursion_queries
Recursion queries limit: 150
```

show memory

The **`show memory`** command displays memory statistics on used and available buffers and cache. Poor performance can be an indicator that the memory is full. If your NIOS appliance is not performing as it should, use this command to verify whether or not the appliance is experiencing a memory problem. If so, Infoblox recommends that you call Infoblox Support.

Syntax

```
show memory
```

This command has no arguments.

Example

```
Infoblox > show memory
```

```
             total      used      free      buffers     cached
Mem:         1032852    309904    722948    32864       242060
Swap:        2047992    0         2047992
Total:       3080844    309904    2770940
```

show mld_version

The `show mld_version` command displays the version of the MLD (Multicast Listener Discovery) protocol that is running on the appliance. The appliance runs MLD version2 by default, but you can enable it to run MLD version 1 instead. For information, see *set mld_version_1*. Note that MLDv2 is interoperable with MLDv1.

Syntax

```
show mld_version
```

This command has no arguments.

Example

```
Infoblox > show mld_version
 Current Multicast Listener Discovery Setting:
  MLD Version: 2
```

show monitor

The **`show monitor`** command displays current network monitoring data, when network monitoring for DNS is turned on. This command also provides information on the average latency of authoritative and non-authoritative replies to DNS queries. Latency is the time it takes for a packet to cross a network connection, from sender to receiver.

> **Note**
>
> You must turn on network monitoring for DNS to view this data. For more information, see *set monitor dns*.

Syntax

```
show monitor
```

This command has no arguments.

Examples

The following example for Network Monitoring for DNS shows information on the interval times in minutes, the latency (in milliseconds), and the number of queries.

Viewing network monitoring for DNS data

```
Infoblox > show monitor
 Network Monitoring for DNS is ON
 Data last updated: Tue Sep 12 19:05:51 2006
 Authoritative        Interval (min)       Latency (usec)      Number of
queries

                          1                    2                    3
                          5                    3                   20
                          15                   3                   65
                          60                   3                  300

Non Authoritative    Interval (min)       Latency (usec)      Number of
queries

                          1                    2                    2
                          5                    3                   10
                          15                   3                   55
                          60                   3                  150
```

When network monitoring for DNS is off

```
Infoblox > show monitor
 Network Monitoring for DNS is OFF
```

show monitor dns alert

The **`show monitor dns alert`** command displays the current DNS alert thresholds. The appliance displays the default thresholds (50% for both invalid ports and invalid TXIDs) if you have not configured new thresholds for the DNS alerts.

Syntax

```
show monitor dns alert
```

This command has no arguments.

Example

Viewing DNS alert thresholds

```
Infoblox > show monitor dns alert
DNS Network Monitoring is enabled.
Alerting is enabled.
 DNS Alert      Threshold (per minute)
 ========================================
 port           over 70% of packets
 txid           over 100 packets
```

show monitor dns alert status

The **show monitor dns alert status** command displays the current status of invalid DNS responses that arrive on DNS ports that are not open and have mismatched TXIDs (DNS transaction ID). You can view the alert status to identify the primary source of invalid DNS responses. The appliance displays historical alert counts and up to five primary sources that generate invalid DNS responses.

Syntax

```
show monitor dns alert status
```

This command has no arguments.

Example

Viewing DNS alert status

```
Infoblox > show monitor dns alert status
Data last updated: Mon Oct 6 14:47:12 2008
DNS Alert   1m   5m   15m   60m   24h   Ever
 ============================================
port        8    12   12    12    12    12
txid        8    12   12    12    12    12

 There were 80 DNS responses seen in the last minute.
10% were to an invalid port.
```

```
 10% had an invalid TXID.

Primary sources of invalid responses:
 4.4.4.4 (unknown) sent 4
 2.2.2.2 (unknown) sent 3
 7.7.7.7 (unknown) sent 1
```

show ms_sticky_ip

The **`show ms_sticky_ip`** command displays whether the ms_sticky_ip is turned on or off.

Syntax

```
show ms_sticky_ip
```

This command has no arguments.

Example

```
Infoblox > show ms_sticky_ip
```

```
show ms_sticky_ip
ms_sticky_ip is off
```

show named_recv_sock_buf_size

The **`show named_recv_sock_buf_size`** command displays the current BIND receive socket buffer size. The default is 1,536 kilobytes. For information about how to set the receive socket buffer size, see *set named_recv_sock_buf_size*.

Syntax

```
show named_recv_sock_buf_size
```

This command has no arguments.

Example

```
Infoblox > show named_recv_sock_buf_size
 DNS 'named' UDP receive socket buffer size: 5000
```

show network

The **`show network`** command displays the current network settings for the NIOS appliance and status with respect to a Grid. For information on how to change your network settings, see *set network*.

Syntax

```
show network
```

This command has no arguments.

Example

```
Infoblox > show network
Current LAN1 network settings:
IP Address: 10.34.33.11
  Network Mask: 255.255.255.0
  Gateway Address: 10.34.33.1
  VLAN Tag: 110
  DSCP Value: 23
  IPv6 Address: 2620:010A:6000:2400:0000:0000:0000:6508/64
  IPv6 Gateway Address: 2620:010A:6000:2400:0000:0000:0000:0001
  IPv6 VLAN Tag: Untagged
IPv6 DSCP Value: Inherited

HA enabled: false
  Grid Status: Member of Infoblox Grid

Current LAN2 Port Settings:
LAN2 Port enabled: true
  NIC failover for LAN1 and LAN2 enabled: false
LAN2 IP Address: 10.1.1.35
  LAN2 Netmask: 255.255.255.0
  LAN2 Gateway: 10.1.1.1
```

show ntp

The `show ntp` command displays a list of the peers of the NTP server, along with status information about each peer.

Syntax

```
show ntp
```

This command has no arguments.

Example

```
Infoblox > show ntp

 remote      refid   st t   when   poll  reach  delay  offset   jitter
 ==============================================================================
 *LOCAL(1)   LOCAL(1) 12 l   47     64    377   +0.000  0.000    0.008
```

When you execute the `show ntp` command, the NIOS appliance displays the following information:

- **remote**: The IP address of the remote peer.
- **refid**: Identifies the reference clock.
- **st**: The stratum of the remote peer.
- **t**: The type of the peer, such as local, unicast or broadcast.
- **when**: When the last packet was received.
- **poll**: The polling interval, in seconds.
- **reach**: The reachability register, in octal numerals.
- **delay**: The current estimated delay, in seconds.
- **offset**: The offset of the peer clock relative to the local clock, in milliseconds.
- **jitter**: The estimated time error of the system clock.

The following special characters may be seen on a peer:

- *****: The NTP server is synchronized to this peer.
- **#**: The NTP server is almost synchronized to this peer.
- +: This peer is selected for possible synchronization.
- –: This peer is a candidate for selection.
- ~: This Peer is statically configured.

show ospf

The **`show ospf`** command displays configuration and statistical information about the OSPF protocol that is running on the NIOS appliance. For information on how to change your OSPF settings, see *set ospf*.

Syntax

```
show ospf {route | interface | database | neighbor | configuration}
```

The `show ospf` command displays information about the OSPF configuration on the appliance, reachability information about neighbors, and OSPF routes to destinations. You can specify the command with or without arguments.

Argument	Description
`route`	Displays the OSPF routing table, as determined by the most recent SPF calculation.
`interface`	Displays the state and configuration on all interfaces configured with OSPF.
`database`	Displays all OSPF database information.
`neighbor`	Displays the OSPF neighbor information.
`configuration`	Displays the running OSPF configuration file.

Examples

```
Infoblox > show ospf interface
 eth0 is down
  OSPF not enabled on this interface
eth1 is up
  Internet Address 172.32.0.61/24, Broadcast 172.32.0.255, Area 0.0.0.0
  Router ID 172.32.0.61, Network Type BROADCAST, Cost: 100
  Transmit Delay is 1 sec, State DROther, Priority 0
  Designated Router (ID) 172.32.0.110, Interface Address 172.32.0.254
  No backup designated router on this network
  Timer intervals configured, Hello 10, Dead 40, Wait 3, Retransmit 5
   Hello due in 00:00:01
  Neighbor Count is 1, Adjacent neighbor count is 1
lo is up
  Internet Address 172.16.10.10/32, Area 0.0.0.0
  Router ID 172.32.0.61, Network Type LOOPBACK, Cost: 100
  Transmit Delay is 1 sec, State Loopback, Priority 0
  No designated router on this network
  No backup designated router on this network
```

```
  Timer intervals configured, Hello 10, Dead 40, Wait 3, Retransmit 5
   Hello due in inactive
  Neighbor Count is 0, Adjacent neighbor count is 0
 Infoblox > show ospf route
 ============ OSPF network routing table ============
N 172.16.10.10/32   [100] area: 0.0.0.0
                    directly attached to lo
N 172.32.0.0/24     [100] area: 0.0.0.0
                    directly attached to eth1

============ OSPF router routing table =============
 ============ OSPF external routing table ===========
```

show overload_bootp

The **`show overload_bootp`** command displays whether the overload BOOTP functionality is turned on or off.

Syntax

```
show overload_bootp
```

This command has no arguments.

Example

```
Infoblox > show overload_bootp
```

```
Overload BOOTP option turned OFF
```

show pc_domain

The **`show pc_domain`** command displays the entries of the domains for which the category is overridden. For information about the add category command, see *set pc_domain add*. To see information about the delete category command, see *set pc_domain delete*.

Syntax

```
show pc_domain
```

This command has no arguments.

Example

```
Infoblox > show pc_domain
bbc.com 10308,0,0,0,0,
```

show phonehome

The **show phonehome** command displays the settings of the phone home feature on the appliance.

Syntax

```
show phonehome
```

This command has no arguments.

Example

```
Infoblox > show phonehome
 Phone home enabled <Grid wide>:   Yes
Send to Infoblox Support:         Yes
 Support ID:                       8561
 Address to send to:
     support@infoblox.com
```

show query_capture

The `show query_capture` displays the captured DNS queries that are stored locally on the appliance. You can use filters to restrict the DNS queries to specific time and date range, client FQDNs, and IP addresses. Note that the time zone in the CLI console is the time zone of the Grid member.

Note: Using multiple CLI commands to filter data for the appliances with large number of captured DNS queries and responses can significantly affect the system performance, protocol performance, and CLI command performance.

Syntax

```
show query_capture tail [<num>]
                   follow [[fqdn /regex/] [ip /regex/ | grep /regex/]]
                   [[fqdn /regex/] [ip /regex/ | grep /regex/]] [after
```

`[date] time]`
`[before [date] time]`

You can specify the command with or without arguments. If you use the `show query_capture` command without any arguments, it displays queries from the current capture file.
If you use the `show query_capture` command with `follow, tail, before, after, fqdn`, and `ip arguments ,` you can view queries for a specific data and time range, queries sent from the client FQDNs, and IP addresses.

Note: A capture file for logging DNS queries and responses is compressed every 10 minutes or when it reaches 100 MB in size, whichever comes sooner. A new current file is created when a capture file is compressed. If you are running the `show query_capture` command with `follow` or `tail` when a new capture file is created, the CLI console may return an error indicating that `captured-dns-xxxxxx has become inaccessible: No such file or directory`. In these situations, you must execute the CLI command again.

Argument	Description
`tail <num>`	Shows the last num lines from the capture file. If you do not specify a number, only the last ten lines are displayed.
`follow`	Displays continuously the lines till the end of the capture file as lines are appended. In addition, you can use 'follow' with '/regex/' to search for FQDNs, IP addresses, and regular expressions.
`before [date] time`	Displays captured DNS queries before the specified date time starting with the oldest saved log file. Make sure that you specify the date (optional for today's date) in the day-month-year format (example: 25-oct-2014), and time in hour:minutes:seconds format (example: 10:09:30).
`after [date] time`	Displays captured DNS queries after the specified date time until the end of the current log file. The CLI console will not display DNS queries when you specify the current date and time or a future date and time. Make sure that you specify the date (optional for today's date) in the day-month-year format (example: 02-aug-2014), and time in hour:minutes:seconds format (example: 10:09:30).
`/regex/`	Matches the pattern specified in regex and displays the matched lines from the capture file. To insert "/" in the search pattern, use escape sequence \/. The search string starts at the first forward slash (/) ends at the second forward slash (/), and ignores the remaining. For information about regular expressions, see Appendix D Regular Expressions, in the *Infoblox Administrator Guide*.
`fqdn /regex/`	Displays queries sent from the client FQDN. You can combine this option with 'ip /regex/' as well.
`ip /regex/`	Displays queries sent from the client IP address. You can combine this option with 'fqdn /regex/' as well.
`grep /regex/`	Displays queries by the regular expressions.

Examples

```
Infoblox > show query_capture
```

```

show remote_console

The **show remote_console** command displays remote console access settings. This command allows you to see if remote console access is enabled without accessing the GUI. You can set this option at the member level and the Grid level. For information on how to change your remote_console, see *set remote_console*.

Syntax

```
show remote_console
```

This command has no arguments.

Example

```
Infoblox > show remote_console
 current remote console access settings:
 Remote console access enabled (Grid-level): true
```

show reporting_user_capabilities

The **show reporting_user_capabilities** command displays information about users who have the `delete` permission for reporting data. To set the `delete` permission on reporting data for a local admin who has superuser permissions, see *set reporting_user_capabilities*.

> **Note**
> This command is supported only on the Grid Master.

Syntax

```
show reporting_user_capabilities
```

Example

```
Infoblox > show reporting_user_capabilities
User : user1
Capabilities: Delete reporting indexed data

User : user2
Capabilities: Delete reporting indexed data
```

show restart_anycast_with_dns_restart

The `show restart_anycast_with_dns_restart` command displays the status of the `set restart_anycast_with_dns_restart` command. For information about how to set restart anycast command, see *set restart_anycast_with_dns_restart* .

Syntax

```
show restart_anycast_with_dns_restart
```

This command has no arguments.

Example

The following is an example of the output displayed when you execute the `show restart_anycast_with_dns_restart` command:

```
Infoblox > show restart_anycast_with_dns_restart

restart_anycast_with_dns_restart is set to "on" (default value).

Therefore, when the DNS service restarts, the anycast service also restarts.
```

show routes

The **show routes** command displays the current IPv4 and IPv6 routing information on the NIOS appliance and organizes the information according to the interface. This command is a valuable diagnostic tool for connectivity issues.

If you had selected the **Enable default route redundancy on LAN1/LAN2** checkbox, then output of this command displays two default routes each having a different metric number. For more information about the checkbox, see *About Route Redundancy*.

Syntax

```
show routes
```

This command has no arguments.

Example

In the following example, `default` specifies the direct connection to the interface and the static routes are represented (in this example) in bold. You specify static routes by manually entering them through the GUI.

```
Infoblox > show routes
 From LAN:
 10.34.33.0/24 dev eth1 scope link default via 10.34.33.1 dev eth1

From LAN2:
 10.1.1.0/24 dev eth3 scope link default via 10.1.1.1 dev eth3

From IPv4 main route table:
 10.34.33.0/24 dev eth1 proto kernel scope link src 10.34.33.11 10.1.1.0/24
dev eth3 proto kernel scope link src 10.1.1.35 default via 10.34.33.1 dev
eth1
 From IPv6 main route table:
 fe80::/64 dev eth1 metric 256 expires 21257697sec mtu 1500 advmss 1440
metric10 4294967295
 fe80::/64 dev eth3 metric 256 expires 21334065sec mtu 1500 advmss 1440
metric10 4294967295
 ff00::/8 dev eth1 metric 256 expires 21257697sec mtu 1500 advmss 1440
metric10 4294967295
 ff00::/8 dev eth3 metric 256 expires 21334065sec mtu 1500 advmss 1440
metric10 4294967295
 default via fe80::204:96ff:fe1d:1980 dev eth1 proto kernel metric 1024
expires 1661sec mtu 1500 advmss 1440 metric10 64
 default via fe80::204:96ff:fe1d:1980 dev eth3 proto kernel metric 1024
expires 1661sec mtu 1500 advmss 1440 metric10 64
 unreachable default dev lo proto none metric -1 error -101 metric10 255
```

The following example shows the output when the **Enable default route redundancy on LAN1/LAN2** checkbox is selected. It displays two default routes each having a different metric number. For IPv4 networks, the primary default route has a metric value of 0 and the secondary default route has a metric value of 10. For IPv6 networks, the primary default route has a metric value of 1024 and the secondary default route has a metric value of 1124.

```
Infoblox > show routes
From LAN1:
IPv4 route table:
10.33.55.0/24 dev oct1 scope link
default via 10.33.55.1 dev oct1

IPv6 route table:
2620:10a:6000:2290::/64 dev oct1 metric 1024
default via 2620:10a:6000:2290::1 dev oct1 metric 1024
```

```
From IPv4 main route table:
default via 10.34.1.17 dev oct3 proto ifplugd
default via 10.34.52.1 dev oct1 proto ifplugd metric 10
10.33.7.11/29 dev oct3 proto kernel scope link src 10.33.7.11
10.33.7.11/29 dev oct3.103 proto kernel scope link src 10.33.7.11
10.33.55.0/24 dev oct1 proto kernel scope link src 10.33.55.19
10.33.55.0/24 dev oct1.245 proto kernel scope link src 10.33.55.19
10.33.0.0/16 dev oct0 proto kernel scope link src 10.33.1.111
From IPv6 main route table:
2620:10a:6000:2203::/64 dev oct3 proto kernel metric 256
2620:10a:6000:2203::/64 dev oct3.103 proto kernel metric 256
2620:10a:6000:2290::/64 dev oct1 proto kernel metric 256
2620:10a:6000:2290::/64 dev oct1.245 proto kernel metric 256
2620:10a:6000:2500::/64 dev oct0 proto kernel metric 256
fe80::/64 dev oct4 proto kernel metric 256
fe80::/64 dev oct1 proto kernel metric 256
fe80::/64 dev oct1.245 proto kernel metric 256
fe80::/64 dev oct3 proto kernel metric 256
fe80::/64 dev oct3.103 proto kernel metric 256
fe80::/64 dev oct0 proto kernel metric 256
default via 2620:10a:6000:2203::1 dev oct3 proto ifplugd metric 1024
default via 2620:10a:6000:2290::1 dev oct1 proto ifplugd metric 1124
```

show rpz_recursive_only

Use the `show rpz_recursive_only` < `view_name>` command to view whether NIOS RPZ zones are used instead of local RPZ zones to block records with private IP addresses from being queried by external users. This command is available only on the Gird Master.

For information about changing the setting, run the *`set rpz_recursive_only`* command.

Syntax

```
show rpz_recursive_only <view_name> [zone_name]
```

Argument	Description
view_name	DNS view to which the RPZ zones belong.
zone_name	NIOS RPZ zone name to be used

The command can return the following output values:

- `none` : Denotes that the setting applied earlier will continue to apply.
- `yes` : Denotes that NIOS RPZ zones are used instead of local RPZ zones to block records with private IP addresses from being queried by external users.
- `no` : Denotes that local RPZ zones are used to block records with private IP addresses from being queried by external users.

If you do not specify the zone name, the command displays the output for the DNS view only.

Example

```
Infoblox > show rpz_recursive_only default
default: recursive-only none
```

show scheduled

Use the **`show scheduled`** command to view the number of times per hour the appliance checks if the services need a restart when the scheduling task feature is enabled. The appliance restarts services only when the execution of a scheduled task requires a service restart.
Use the *set scheduled* command to configure the value. You can set the value from 0 to 60, and the default value is 60. A value of 0 turns off the restart feature.

Syntax

```
show scheduled task restarts
```

This command has no argument.

Example

```
Infoblox > show scheduled task restarts
 Number of restarts per hour: 4
```

show security

The **`show security`** command shows the current security settings and whether access to the NIOS appliance through the GUI is restricted. For more information, see *set security*.

Syntax

```
show security
```

This command has no arguments.

Example

```
Infoblox > show security
 current security settings:
Access restricted: false
```

show session_timeout

The **show session_timeout** command shows how long a session remains open when there is no user activity. For more information, see *set session_timeout*.

Syntax

```
show session_timeout
```

This command has no arguments.

Example

```
Infoblox > show session_timeout
 Current GUI/CLI timeout is 31536000 seconds (8760:00:00)
```

show smartnic

The **show smartnic** command shows whether monitor mode for the Threat Protection service is on or off. When on, monitor mode for the Threat Protection service is enabled and the appliance logs DNS packets (instead of dropping them) that would have been blocked by threat protection rules. This information is recorded in the audit log.
For information on how to disable monitor mode for the Threat Protection service, see *set smartnic monitor-mode*.

Syntax

```
show smartnic
```

This command has no arguments.

Example

```
Infoblox > show smartnic
 Firmware version:                3.8.1 Jul 21, 2014,
 Log level:                       6
 Failed cores:                    None
 Threat Protection:               Enabled
```

```
 Threat Protection monitor mode:    Disabled
 Threat Protection event stats:     CRITICAL=0 MAJOR=0 WARNING=0
INFORMATIONAL=575349
```

show snmp

The **show snmp** command shows information about the SNMP object that you specify. You can enter the SNMP object name or OID. This command is similar to the SNMP "get" operation. You can use the optional **v3** command to get the information using SNMPv3. For information about SNMP, see *Monitoring with SNMP* in the *Infoblox NIOS Administrator Guide*.
Use the *set snmptrap* command to send SNMP traps to management systems you specify.

Syntax

```
show snmp variable {name of an SNMP variable, in dotted or symbolic format}
v3 {snmpuser}
```

Argument	Description
name of an SNMP variable	The name or OID (object ID) of the SNMP object you want to retrieve. For example, you can enter sysName.0 or .1.3.6.1.4.1.2021.11.53.0.
snmpuser	The user name of the SNMPv3 user account. This is optional. If you do not provide a user name, the appliance uses the first SNMPv3 user on the list.

Examples

Displaying the host name

```
Infoblox > show snmp variable sysName.0
 SNMPv2-MIB::sysName.0 = STRING: ib-10-34-61-253.infoblox.com
```

Displaying the CPU temperature

```
Infoblox > show snmp variable .1.3.6.1.4.1.7779.3.1.1.2.1.1.0
 IB-PLATFORMONE-MIB::ibCPUTemperature.0 = STRING: +40.75 C
```

Displaying the host name using SNMPv3

```
Infoblox > show snmp variable sysName.0 v3 SNMPv3User1
 SNMPv2-MIB::sysName.0 = STRING: ib-10-34-10.42.infoblox.com
```

show static_routes

Use the `show static_routes` command to display the current static route configuration on your appliance. To configure static routes, use the *set static_route* command.
You can also use the *show routes* command to view the current IPv4 and IPv6 routing information on the NIOS appliance and how the information is organized according to the interfaces.

Syntax

show static_routes [v4|v6]

Argument	Description
`v4|v6`	Shows IPv4 or IPv6 static routes. If this is not specified, static routes for both IPv4 and IPv6 are displayed.

Examples

Displaying IPv4 Static Routes

`Infoblox > show static_routes v4`

Position	Destination	Gateway
1	1.1.1.1/32	192.168.1.11
2	1.1.1.2/32	192.168.1.12
3	1.1.1.11/32	192.168.1.21
4	1.1.1.3/32	192.168.1.13
5	1.1.1.4/32	192.168.1.14
6	1.1.1.5/32	192.168.1.15
7	1.1.1.6/32	192.168.1.16
8	1.1.1.7/32	192.168.1.17
9	1.1.1.8/32	192.168.1.18

10	1.1.1.9/32	192.168.1.19
11	1.1.1.10/32	192.168.1.20

Displaying IPv6 Static Routes

```
Infoblox > show static_routes v6
```

Position	Destination	Gateway
1	1111:2222:3333:4444:5555:	1111:2222:3333:4444:5555:6666:7777:9999
	6666:7777:1000/125	
2	1111:2222:3333:4444:5555:	1111:2222:3333:4444:5555:6666:7777:bbbb
	6666:7777:2000/125	

show status

The `show status` command shows the Grid and HA status. For a Grid member, the command also shows the host name and the Grid Master IP address. You can use this command to gather information about the current state of a Grid.

Syntax

```
show status
```

This command has no arguments.

Examples

Status of Grid Master

```
Infoblox > show status

 Grid Status: ID Grid Master
HA Status: Not Configured
```

Status of Grid Member

```
Infoblox > show status
Grid Status: ID Grid Member
HA Status: Not Configured
 Hostname: member1.infoblox.local
Grid Master IP: 10.64.40.31
```

Status of HA member

```
Infoblox > show status
Grid Status: ID Grid Member
HA Status: Active
 Hostname: member1.infoblox.com
Grid Master IP: 10.35.113.15
```

Note:

- If the Grid member uses IPv6 communication protocol to join a dual mode Grid, then IPv6 address of the Grid Master is displayed.
- If a Grid Master has a Management Interface set up, then the `show status` output of its Grid Member shows the Management interface IP address as the Grid Master IP address.

---

show subscriber_secure_data

If you have configured Infoblox Subscriber Services, the command `show subscriber_secure_data` enables you to view information about the subscriber data cached by the collector member. For information about Infoblox Subscriber Services, see *Infoblox Subscriber Services*.

Syntax

```
  show subscriber_secure_data
```

```
  show subscriber_secure_data cache_usage
```

```
  show subscriber_secure_data persist
```

```
  show subscriber_secure_data never_proxy
```

```
  show subscriber_secure_data list_ip_space_desc
```

```
  show subscriber_secure_data find <subscriber_id>
```

```
  show subscriber_secure_data find <ip_addr> <prefix> <local_id>
<ip_space_desc>
```

```
  show subscriber_secure_data search <regex>
```

Argument	Description
`cache_usage`	Displays the number of subscriber records in the cache.
`persist`	Displays the data persistence mode of static subscriber records.
`never_proxy`	Displays the hexadecimal character of the never_proxy setting.
`list_ip_space_desc`	Displays the list of all configured IP space discriminators.
`find` `<subscriber_id>`	Displays the subscriber record for the matching subscriber client ID. You must specify the subscriber client ID (MSISDN).
`find` `<ip_addr>` `<prefix>` `<local_id>` `<ip_space_desc>`	Displays the subscriber record for the matching subscriber client IP address. Enter the subscriber client IP address. Enter the prefix length. Enter the local ID. Enter the IP space discriminator.
`search <regex>`	Displays the cached subscriber records for the matching regular expressions.

Example

Displaying the subscriber cached entries

```
Infoblox > show subscriber_secure_data
```

```
111.111.111.111/32|IPS:10.35.120.10|ACS:Acct-Session-

```

If the `Proxy-All` setting is set to `1` and the `Subscriber-Secure-Policy` and `Parental-Control-Policy` settings do not block this query, then NIOS proxies these queries to the MSP server for further processing. NIOS first sends the query to the primary MSP server (denoted by the PXY_PRI parameter) and if the primary MSP server is not available, NIOS sends the query to the secondary MSP server (denoted by the PXY_SEC parameter). If you want all the queries in a specific category to be resolved directly by NIOS without proxying to an MSP server, use the `set subscriber_secure_data never_proxy <category hexadecimal_character>` command. The hexadecimal character represents the category that is not proxied to an MSP server. For more information see *set subscriber_secure_data never_proxy*.

For example, if you have configured an Internet Off policy for a subscriber during a particular timeframe, then if the `Proxy-All` setting is set to `1`, the MPS server processes and blocks all live video streams by terminating the connections during that timeframe.

If you want all sporting videos except videos about tennis to be blocked, run the `set subscriber_secure_data never_proxy <category hexadecimal_character>` command, where <category hexadecimal_character> is the category related to tennis videos. Here, only videos about tennis are allowed to be streamed on NIOS systems; all other videos are blocked.

Displaying the number of subscriber entries in cache

```
Infoblox > show subscriber_secure_data cache_usage
122798 accounting records in the cache.
```

Displaying the list of IP Space Discriminators

```
Infoblox > show subscriber_secure_data list_ip_space_desc

show subscriber_secure_data bypass

If you have configured Infoblox Subscriber Services, the `show subscriber_secure_data bypass` command allows you to view the status of the subscriber data bypass for the member, all members of each site on the entire Grid, or all members of the site. For information about how to set data bypass, see *set subscriber_secure_data bypass*. For information about Infoblox Subscriber Services, see *Infoblox Subscriber Services*.

Syntax

```
show subscriber_secure_data bypass [ grid | site ] [ "site_name" ]
```

Argument	Description
`grid`	Display the status of the subscriber service policies bypass for all members of each site on the entire Grid.
`site`	Display the status of the subscriber service policies bypass for all members of the site.

Examples

```
Infoblox > show subscriber_secure_data bypass site mobile1
```

```
Site: Site1
          Member:  dns1.com
                        Subscriber Secure Bypass disabled for the member  dns1
.com .
          Member:  dns2.com
                        Subscriber Secure Bypass enabled for the member  dns2.
com .
          Member:   dns3.com
                        Subscriber Secure Bypass disabled for the member  dns3
.com .
```

```
Infoblox> show subscriber_secure_data bypass
```

```
Member:  dns3.com
          Subscriber Secure Bypass disabled on the member  dns3.com .
```

show subscriber_secure_data garbage_collect

If you have configured Infoblox Subscriber Services, use the `show subscriber_secure_data garbage_collect` command to display the status of garbage collection for the specific member. For information about how to set the garbage collect command, see *set subscriber_secure_data garbage_collect*.

Syntax

```
show subscriber_secure_data garbage_collect
```

This command has no arguments.

Example

```
Infoblox > show subscriber_secure_data garbage_collect
```

```
This member is configured for garbage collection scheduled at 3 AM everyday.
```

show subscriber_secure_data cache_usage_stats

If you have configured Infoblox Subscriber Services, the `show subscriber_secure_data cache_usage_stats` command displays the statistics for subscriber static, provisioned, and non-provisioned devices based on the flag you used in subscriber data.

Non-provisioned devices display the count of all the devices you set without a K flag, provisioned devices display the count of all devices you set with a K flag, and static devices display the count of all the devices you set with an S flag.

Syntax

```
Infoblox > show subscriber_secure_data cache_usage_stats
```

This command has no arguments.

Example

```
Infoblox > show subscriber_secure_data
10.120.20.94/32|LID:N/A|IPS:N/A|FLG:BK|ACS:Acct-Session-Id=9999732d-34590e08;NAS:NAS-

Infoblox > show subscriber_secure_data cache_usage_stats
Getting cache usage details may take some time.
Static devices          : 1
Provisioned devices     : 1
Non-provisioned devices : 2
```

show subscriber_secure_data never_proxy

If you have configured Infoblox Subscriber Services, use the `show subscriber_secure_data never_proxy` command to view the hexadecimal character of the never_proxy setting.

To set the hexadecimal value of the never_proxy category, see the `set subscriber_secure_data never_proxy` command.

Syntax

```
show subscriber_secure_data never_proxy
```

Example

```
Infoblox > show subscriber_secure_data never_proxy
never_proxy category set is 000ffffffffffffffffffffffff01
```

show subscriber_secure_data persist

If you have configured Infoblox Subscriber Services, you can use the `show subscriber_secure_data persist` command to view the information about the enabled data persistence mode which allows static records to survive restart. For information about Infoblox Subscriber Services, see *Infoblox Subscriber Services*.

Syntax

```
show subscriber_secure_data persist
```

Example

```
Infoblox > show subscriber_secure_data persist
1.2.3.4/32|IPS:N/A|FLG:S||Mon Oct 30 10:55:50 2017 Persistent Subscriber Secure Data last modified at Mon Oct 30 15:12:07 2017
```

show support_access

The **`show support_access`** command shows whether the support_access function is enabled. By default, the support_access function is disabled. For more information on the support_access function, see *set support_access*.

Syntax

```
show support_access
```

This command has no arguments.

Example

```
Infoblox > show support_access
 current support access settings:
  Support access enabled (Grid-level):  true
```

show support_timeout

The `show support_timeout` command displays the custom timeout value set for the support bundle download. For information about how to set the timeout value, see *set support_timeout*.

Syntax

```
show support_timeout
```

This command has no arguments.

Example

```
Infoblox > show support_timeout
```

```
Support timeout is 2600
```

show tcp_timestamps

The **show tcp_timestamps** command shows whether TCP timestamps are enabled or disabled. If timestamps are enabled, you can view them in the traffic capture file.

Typically, you run the `show tcp_timestamps` command before running the *set tcp_timestamps* command to determine the status of the TCP timestamps. Based on the status (enabled or disabled), you can run `set tcp_timestamps` to enable or disable the timestamps.

Syntax

```
show tcp_timestamps
```

Example

When TCP timestamps are enabled:

```
Infoblox > show tcp_timestamps
```

```
TCP timestamps are enabled.
```

When TCP timestamps are disabled:

```
Infoblox > show tcp_timestamps
```

```
TCP timestamps are disabled.
```

show tech-support

The **show tech-support** command displays output for all show commands. It is a labor saving command that allows you to view the information provided by all the **show** commands. Using the log argument allows you to save the output to a log file that is included in the support bundle.

Syntax

```
show tech-support [log]
```

Argument	Description
log	Saves the output to a log file that is included in the support bundle.

Example

```
Infoblox > show tech-support
 Current date and time: Thu Aug 24 14:06:01 EDT 2008
Up time : 19:29
 Version : 4.3r2

 REVERT version is: N/A
 No upgrade history found for this box.
```

show temperature

The **`show temperature`** command displays the temperature.

Syntax

```
show temperature
```

This command has no arguments.

Example

```
Infoblox > show temperature

show temperature
CPU_TEMP: 25 C

```

show test_promote_master

Use the **`show test_promote_master`** command to view the results of the test promotion of a Grid Master Candidate to Grid Master. You can run a test promotion by running the *set test_promote_master* command.

Syntax

show test_promote_master <ip_address>

Argument	Description
<ip_address>	IP address of the Grid Master Candidate to be promoted to Grid Master

Examples

To see the results of the latest run:

```
Infoblox > show test_promote_master status
[Mon Sep 23 10:37:34 2019] - [10.39.166.9]: Test state is STARTED
a1.com              IRDP port (:2114): Message is sent from GMC [Mon Sep 23
10:37:34 2019]
                    VPN port (:1194): Message is sent from GMC  [Mon Sep 23
10:37:34 2019]
vm-09-75.com IRDP port (:2114): Connected                       [Mon Sep 23
10:37:35 2019]
                    VPN port (:1194): Connected                 [Mon Sep 23
10:37:35 2019]
```

To see the test results for a specific Grid Master Candidate:

```
Infoblox > show test_promote_master 10.39.166.9
[Wed Sep 25 05:51:24 2019] - [10.35.191.9]: Test state is FINISHED

```

```
vm-11-77.com IRDP port (:2114): Connected [Wed Sep 25 05:49:21 2019]
                          VPN port (:1194): Connected [Wed Sep 25 05:49:21 2019]
```

show thresholdtrap

The **`show thresholdtrap`** command displays the trigger and reset values of the SNMP trap for CPU usage. The CPU usage trap is disabled by default, and the trigger value is set at 100 and reset value at 0. For information about how to configure the trigger and reset values, see *set thresholdtrap*.

Syntax

```
show thresholdtrap {type}
```

Argument	Description
`type`	The type of threshold trap. Enter **CpuUsage** to display the trigger and reset values of the CPU usage trap. The trap is disabled by default, and the trigger value is set at 100 and reset value at 0.

Example

```
Infoblox > show thresholdtrap CpuUsage
 Trap type: CpuUsage
trigger: 80
 reset: 71
```

show token

The **`show token`** command displays token settings.

Syntax

```
show token
```

This command has no arguments.

Example

```
Infoblox > show token
```

```
show token
The token is not configured
```

show traffic_capture_status

The **show traffic_capture_status** command displays the status of traffic capture on the NIOS appliance. You can use the set traffic_capture command to start or stop the traffic capture on a NIOS appliance. For more information, see *set traffic_capture*.

Syntax

```
show traffic_capture_status
```

This command has no arguments.

Example

```
Infoblox > show traffic_capture_status
 Traffic capture is stopped.
3277072 bytes captured.
```

show upgrade_history

The **show upgrade_history** command displays the upgrade history of the NIOS appliance, showing how many times the appliance has been upgraded and the versions for each upgrade. It also shows the revert version—the version that you can go back to—which is the version of the software the appliance was (last) running prior to the most recent upgrade.

Syntax

```
show upgrade_history
```

This command has no arguments.

Example

```
Infoblox > show upgrade_history
REVERT version is: 4.0r1
[2006/08/14 19:05:48] Upgraded to: 4.0r2-4-06070517
```

show uptime

The **show uptime** command displays the uptime (hours and minutes) of the NIOS appliance since the last reboot. In a test environment, this command can be used as a metric. In a production environment, this command is of less use since the appliance remains continually functional.

Syntax

```
show uptime
```

This command has no arguments.

Example

```
Infoblox > show uptime
 Up time : 19:33
```

show version

The **`show version`** command displays the current version of the NIOS software that is installed on the NIOS appliance. You can use this information when performing an upgrade to determine what version of the software to upgrade to.

Syntax

```
show version
```

This command has no arguments.

Example

```
Infoblox > show version
 Version : 4.0r2
 SN: 000100e081277a69
 Hotfix : N/A
```

show vpn_cert_dates

Use the **`show vpn_cert_dates`** command to display the start and end dates of the Infoblox appliance certificate. This information is also included in the Support Bundle.

Syntax

```
show vpn_cert_dates
```

This command has no arguments.

Example

The following is an example of the command:

```
Infoblox > show vpn_cert_dates
Start Date=Dec 13 11:00:00 2003 GMT
 End Date=May 20 11:00:00 2019 GMT
```

show wins_forwarding

Use the **`show wins_forwarding`** command to display the current configuration for WINS packet forwarding for the Grid or a specific Grid member.
For information about how to configure WINS packet forwarding to Microsoft servers, see *set wins_forwarding*.

Syntax

```
show wins_forwaring
```

This command has no arguments.

Examples

Execute the command on the Grid member that inherited the Grid settings

```
Infoblox > show wins_forwarding
     Grid level WINS forwarding: enabled
     Grid level WINS default server IP: 10.35.0.123
     Member level WINS forwarding: Use grid setting
```

Execute the command on the Grid member that overrode the Grid settings

```
Infoblox > show wins_forwarding
     Grid level WINS forwarding: Enabled
     Grid level WINS default server IP: 10.35.0.123
    Member level output interface: LAN2
     Member level WINS forwarding: Override grid setting
    Member level forwarding: Enabled
     Member level WINS server IP: 10.35.0.321
    Member level output interface: MGMT
```

Execute the command on the Grid member that overrode the Grid settings and packet forwarding was disabled

```
Infoblox > show wins_forwarding
     Grid level WINS forwarding: Enabled
     Grid level WINS default server IP: 10.35.0.123
    Member level output interface: LAN

     Member level WINS forwarding: Override grid setting
    Member level forwarding: Disabled
```

shutdown

The **shutdown** command halts the NIOS appliance. The appliance is designed to operate continuously. However, if you want to halt the appliance you can do so with the **shutdown** command.

> **Note**
> Once you shutdown the appliance using this command, you must manually bring it back up.

Syntax

```
shutdown
```

This command has no arguments.

Example

The following example uses the `shutdown` command.

```
Infoblox >
shutdown
```

```
    SHUT DOWN THE SYSTEM? [y or n]
 y
```

snmpget

Fetches the information from a discovered device's SNMP data. You specify the IP address or hostname and the SNMP Object ID (also often referred to as an SNMP variable) or its dotted numeric equivalent as defined in the device MIB.

Syntax

```
snmpget <hostname or IP address> <SNMP OID>
```

Example

The following example uses the `snmpget` command, specifying the IP address of a device discovered by NIOS, along with the standard Object ID `sysName.0` to look up the hostname string for a device. You will need the community string or privacy key to fetch the information.

```
Infoblox > snmpget 172.22.53.5 sysName.0
 Enter SNMP Version (1, 2c or 3): 2c
 Enter SNMP community string: *********
Created directory: /var/lib/net-snmp/cert_indexes
 Created directory: /var/lib/net-snmp/mib_indexes
SNMPv2-MIB::sysName.0 = STRING: DEVsw08
```

snmpwalk

Obtain a tree of information from a network device, using automatic SNMP GETNEXT commands. In the NIOS administrative shell version of the **snmpwalk** command, you can specify the SNMP version, the community string, and the desired Root Object ID (OID).

Syntax

```
snmpwalk <hostname or IP address> <SNMP OID>
```

Example

The following example lists a partial output from querying the root Object ID for a Cisco Nexus 5K switch (this technique is also useful for looking up other Object IDs within a particular device):

```
Infoblox > snmpwalk 172.22.33.5 1.3
Enter SNMP Version (1, 2c or 3): 2c
```

```
Enter SNMP community string: *********
 SNMPv2-MIB::sysDescr.0 = STRING: Cisco NX-OS(tm) n5000, Software (n5000-
uk9), Version 5.1(3)N2(1b), RELEASE SOFTWARE Copyright (c) 2002-2011 by

SNMPv2-MIB::sysORDescr.3 = STRING: The SNMP Management Architecture MIB.
 ...
```

traceroute

The **`traceroute`** command displays information on the route IPv4/IPv6 packets. You can use this command to determine the path of an IPv4/IPv6 query. This command provides information on the path packets travel and the time it takes to reach the IPv4/IPv6 destination address.

Syntax

```
traceroute {hostname | ip_address} [ opt ]
```

Argument	Description
hostname	Fully qualified domain name
ip_address	Valid IPv4/IPv6 address of the host

Argument	Description
`opt`	Can be any of the following: • *`numerical`* (specifies to not interpret the IP address as a DNS name) • *`src_addr`* (specifies the starting or "from" address) • `ICMP` (specifies to use `ping`) • *`v6`* (specifies IPv6 hostname)

Example

The following example shows you how to use the traceroute command.

```
Infoblox > traceroute 10.1.1.1
 traceroute to 10.1.1.1 (10.1.1.1), 30 hops max, 40 byte packets
 1 10.1.1.5 (10.1.1.5) 1.951 ms 1.637 ms 1.734 ms
 2 10.1.1.1 (10.1.1.1) 0.248 ms 0.284 ms 0.239 ms
```

show rabbitmq_queues

The `show rabbitmq_queues` command checks the status of the RabbitMQ queue. This command only checks the status of the queue, but does not increase the count.

Use this command mainly as a diagnostic command to be used when you encounter problems related to RabbitMQ. Typically, the queue length must be close to 0; big numbers (in thousands or millions) indicate RabbitMQ issues.

Use the `show rabbitmq_queues` command to check the status of the RabbitMQ queue in the following scenarios:

- When you install or remove the Threat Analytics license
- When Threat Analytics is running
- When you start or stop the threat analytics service
- When a large number of domains is queried
- When the Outbound service is running
- When you add or remove an endpoint
- When an HA failover occurs
- When you add a member to a Grid Master
- During a Grid Master promotion
- When you add or remove a reporting member to or from a Grid
- When you install or remove an RPZ license
- When you install or remove a Threat Protection license
- On an IB-FLEX appliance
- When you perform an Amazon Web Services (AWS) Route 53 synchronization for zones and records
- When you restore or back up the database
- After an auto-synchronization of an ND member
- When you restore a Grid

Syntax

```
show rabbitmq_queues
```

This command has no arguments.

Example

```
Infoblox > show rabbitmq_queues
Listing queues....
analytics_dnst_blacklist_queue 0
aws_route53_q 0
sddc_gm 0
sddc_vnode 0
Grid information (OID, host name, virtual IP): 0
infoblox.localdomain "IP of the VM"
Total no. nodes
```

Using NIOS APIs

Infoblox provides a Perl API (application programming interface) to help facilitate the integration of the Infoblox device into network environments. The Infoblox DMAPI (Data and Management API) is a set of packages delivered with the Infoblox device to install the package. Use the usual Perl module installation tools on your management system to install the package. For Windows systems using the ActiveState build of Perl, the package is called PPM ("Perl Package Manager" or "Programmer's Package Manager"). For UNIX systems, the package is called CPAN, a global archive of Perl resources.

You can make REST API calls using Java version 1.7 and later. For detailed information about these APIs, see the Infoblox API Documentation (in PDF format), at *docs.infoblox.com*.

Reference Information

This section provides reference information in the following sections:

Configurations Requiring Service Restart

This topic includes a list of objects that require service restart after you make configuration changes to them. For more information about restarting services, see *Restarting Services*.

Object	Service	Action	Comment
Grid Security Properties	DNS	Update	
Member Security Properties	DNS	Update	
Authoritative Zone	DNS	Insert, update, delete	If the "Restart if needed" option is enabled, restart is triggered immediately.
DNS Traffic Control Monitor	DNS	Update	All functions
Network Container	DHCP	Insert, update, delete	
Shared Network	DHCP	Insert, delete	
Blacklist Rule	DNS	Insert, update, delete	
Bulk Host	DNS	Insert, update, delete

GNU General Public License

GNU GENERAL PUBLIC LICENSE
Version 2, June 1991

Copyright (C) 1989, 1991 Free Software Foundation, Inc.

59 Temple Place, Suite 330, Boston, MA 02111-1307 USA

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General PublicLicense is intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundations software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each authors protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyones free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

GNU GENERAL PUBLIC LICENSE
TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Programs source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.
   You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.
2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:
   a. You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.
   b. You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.
   c. If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

   These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.
   Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program. In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.
3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:
   a. Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,
   b. Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be 11 distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

c. Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.
If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.
5. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.
6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.
7. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.
   If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.
   It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.
   This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.
8. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.
9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.
   Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.
10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.
12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

END OF TERMS AND CONDITIONS

PCRE - Perl Compatible Regular Expressions

PCRE2 LICENCE

PCRE2 is a library of functions to support regular expressions whose syntax and semantics are as close as possible to those of the Perl 5 language.
Release 10 of PCRE2 is distributed under the terms of the "BSD" licence, as specified below. The documentation for PCRE2, supplied in the "doc"
directory, is distributed under the same terms as the software itself. The data in the testdata directory is not copyrighted and is in the public domain.
The basic library functions are written in C and are freestanding. Also included in the distribution is a just-in-time compiler that can be used to optimize pattern matching. This is an optional feature that can be omitted when the library is built.

GNU General Public License 2.0 for Suricata, Netfilter and IPTables

GNU General Public License
Version 2, June 1991 Copyright © 1989, 1991 Free Software Foundation, Inc. 51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software–to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Lesser General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".
Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.
   You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.
2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:
   a. You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.
   b. You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

c. If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program. In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:
    a. Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,
    b. Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,
    c. Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

    The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

    If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.
4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.
5. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.
6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.
7. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

    If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.
This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

8. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.
9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.
   Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.
10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

    NO WARRANTY

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.
12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

END OF TERMS AND CONDITIONS

How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.
<one line to give the program's name and a brief idea of what it does.> Copyright (C)
<year> <name of author>

This program is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 2 of the License, or (at your option) any later version.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program; if not, write to the Free Software Foundation, Inc., 51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA.

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

Gnomovision version 69, Copyright (C) year name of author Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type `show w'. This is free software, and you are welcome to redistribute it under certain conditions; type `show c' for details.

The hypothetical commands `show w` and `show c` should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than `show w' and `show c`; they could even be mouse-clicks or menu items–whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

Yoyodyne, Inc., hereby disclaims all copyright interest in the program `Gnomovision' (which makes passes at compilers) written by James Hacker.
<signature of Ty Coon>, 1 April 1989 Ty Coon, President of Vice

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Lesser General Public License instead of this License.

PSF License Agreement for Python 3.5.0

1. This LICENSE AGREEMENT is between the Python Software Foundation ("PSF"), and the Individual or Organization ("Licensee") accessing and otherwise using Python 3.5.0 software in source or binary form and its associated documentation.
2. Subject to the terms and conditions of this License Agreement, PSF hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python 3.5.0 alone or in any derivative version, provided, however, that PSF's License Agreement and PSF's notice of copyright, i.e., "Copyright © 2001-2015 Python Software Foundation; All Rights Reserved" are retained in Python 3.5.0 alone or in any derivative version prepared by Licensee.
3. In the event Licensee prepares a derivative work that is based on or incorporates Python 3.5.0 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python 3.5.0.
4. PSF is making Python 3.5.0 available to Licensee on an "AS IS" basis. PSF MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, PSF MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON 3.5.0 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
5. PSF SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 3.5.0 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 3.5.0, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.
6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
7. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between PSF and Licensee. This License Agreement does not grant permission to use PSF trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.
8. By copying, installing or otherwise using Python 3.5.0, Licensee agrees to be bound by the terms and conditions of this License Agreement.

PSF License Agreement for Python 2.6

1. This LICENSE AGREEMENT is between the Python Software Foundation ("PSF"), and the Individual or Organization ("Licensee") accessing and otherwise using this software ("Python") in source or binary form and its associated documentation.
2. Subject to the terms and conditions of this License Agreement, PSF hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python alone or in any derivative version, provided, however, that PSF's License Agreement and PSF's notice of copyright, i.e., "Copyright (c) 2001, 2002, 2003, 2004, 2005, 2006 Python Software Foundation; All Rights Reserved" are retained in Python alone or in any derivative version prepared by Licensee.
3. In the event Licensee prepares a derivative work that is based on or incorporates Python or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python.
4. PSF is making Python available to Licensee on an "AS IS" basis. PSF MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, PSF MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
5. PSF SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.
6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
7. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between PSF and Licensee. This License Agreement does not grant permission to use PSF trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.
8. By copying, installing or otherwise using Python, Licensee agrees to be bound by the terms and conditions of this License Agreement.

Importlib

(No license included in the package, this is in the readme)

Purpose
========

This package contains the code from importlib as found in Python 2.7. It is provided so that people who wish to use "importlib.import_module()" with a version of Python prior to 2.7 or in 3.0 have the function readily available. The code in no way deviates from what can be found in the Python 2.7 standard library.

For documentation, see the `importlib docs`_ for Python 2.7.

Dateutil

dateutil - Extensions to the standard Python datetime module.

Cybox

(INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

INFO-ZIP

This is version 2007-Mar-4 of the Info-ZIP license.
The definitive version of this document should be available at *ftp://ftp.info-zip.org/pub/infozip/license.html* indefinitely and a copy at *http://www.info-zip.org/pub/infozip/license.html.*

Copyright (c) 1990-2007 Info-ZIP.All rights reserved.

For the purposes of this copyright and license, "Info-ZIP" is defined as the following set of individuals:

> Mark Adler, John Bush, Karl Davis, Harald Denker, Jean-Michel Dubois, Jean-loup Gailly, Hunter Goatley, Ed Gordon, Ian Gorman, Chris Herborth, Dirk Haase, Greg Hartwig, Robert Heath, Jonathan Hudson, Paul Kienitz, David Kirschbaum, Johnny Lee, Onno van der Linden, Igor Mandrichenko, Steve P. Miller, Sergio Monesi, Keith Owens, George Petrov, Greg Roelofs, Kai Uwe Rommel, Steve Salisbury, Dave Smith, Steven M. Schweda, Christian Spieler, Cosmin Truta, Antoine Verheijen, Paul von Behren, Rich Wales, Mike White.

This software is provided "as is," without warranty of any kind, express or implied.In no event shall Info-ZIP or its contributors be held liable for any direct, indirect, incidental, special or consequential damages arising out of the use of or inability to use this software.

Permission is granted to anyone to use this software for any purpose, including commercial applications, and to alter it and redistribute it freely, subject to the above disclaimer and the following restrictions:

1. Redistributions of source code (in whole or in part) must retain the above copyright notice, definition, disclaimer, and this list of conditions.

2. Redistributions in binary form (compiled executables and libraries) must reproduce the above copyright notice, definition, disclaimer, and this list of conditions in documentation and/or other materials provided with the distribution. The sole exception to this condition is redistribution of a standard UnZipSFX binary (including SFXWiz) as part of a self-extracting archive; that is permitted without inclusion of this license, as long as the normal SFX banner has not been removed from the binary or disabled.

3. Altered versions-including, but not limited to, ports to new operating systems, existing ports with new graphical interfaces, versions with modified or added functionality, and dynamic, shared, or static library versions not from Info-ZIPmust be plainly marked as such and must not be misrepresented as being the original source or, if binaries, compiled from the original source.Such altered versions also must not be misrepresented as being Info-ZIP releases-including, but not limited to, labeling of the altered versions with the names "Info-ZIP" (or any variation thereof, including, but not limited to, different capitalizations), "Pocket UnZip," "WiZ" or "MacZip" without the explicit permission of Info-ZIP.Such altered versions are further prohibited from misrepresentative use of the Zip-Bugs or Info-ZIP e-mail addresses or the Info-ZIP URL(s), such as to imply Info-ZIP will provide support for the altered versions.

4. Info-ZIP retains the right to use the names "Info-ZIP," "Zip," "UnZip," "UnZipSFX," "WiZ," "Pocket UnZip," "Pocket Zip," and "MacZip" for its own source and binary releases.

The PHP License, version 3.01

Copyright (c) 1999 - 2006 The PHP Group. All rights reserved. Redistribution and use in source and binary forms, with or without modification, is permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.

2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.

3. The name "PHP" must not be used to endorse or promote products derived from this software without prior written permission. For written permission, please contact *group@php.net.*

4. Products derived from this software may not be called "PHP", nor may "PHP" appear in their name, without prior written permission from *group@php.net.*You may indicate that your software works in conjunction with PHP by saying "Foo for PHP" instead of calling it "PHP Foo" or "phpfoo"

5. The PHP Group may publish revised and/or new versions of the license from time to time. Each version will be given a distinguishing version number.
   Once covered code has been published under a particular version of the license, you may always continue to use it under the terms of that version. You may also choose to use such covered code under the terms of any subsequent version of the license published by the PHP Group. No one other than the PHP Group has the right to modify the terms applicable to covered code created under this License.

6. Redistributions of any form whatsoever must retain the following acknowledgment:
   "This product includes PHP software, freely available from *<http://www.php.net/software/>"*.

THIS SOFTWARE IS PROVIDED BY THE PHP DEVELOPMENT TEAM ``AS IS'' AND ANY EXPRESSED OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE PHP DEVELOPMENT TEAM OR ITS CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR

SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

This software consists of voluntary contributions made by many individuals on behalf of the PHP Group.

The PHP Group can be contacted via Email at *group@php.net.*

For more information on the PHP Group and the PHP project,

please see *<http://www.php.net>.*

PHP includes the Zend Engine, freely available at
<http://www.zend.com>.

Net-SNMP

Various copyrights apply to this package, listed in various separate parts below.Please make sure that you read all the parts. Up until 2001,
the project was based at UC Davis, and the first part covers all code written during this time. From 2001 onwards, the project has been based at SourceForge, and Networks Associates Technology, Inc hold the copyright on behalf of the wider Net-SNMP community, covering all derivative work done since then. An additional copyright section has been added as Part 3 below also under a BSD license for the work contributed by Cambridge Broadband Ltd. to the project since 2001.
An additional copyright section has been added as Part 4 below also under a BSD license for the work contributed by Sun Microsystems, Inc. to the project since 2003.
Code has been contributed to this project by many people over
the years it has been in development, and a full list of contributors can be found in the README file under the THANKS section.

The Independent JPEG Group's JPEG software

In plain English:

1. We don't promise that this software works. (But if you find any bugs, please let us know!)

2. You can use this software for whatever you want.You don't have to pay us.
3. You may not pretend that you wrote this software. If you use it in a program, you must acknowledge somewhere in your documentation that you've used the IJG code.

In legalese:

The authors make NO WARRANTY or representation, either express or implied, with respect to this software, its quality, accuracy, merchantability, or fitness for a particular purpose.This software is provided "AS IS", and you, its user, assume the entire risk as to its quality and accuracy.

This software is copyright (C) 1991-1998, Thomas G. Lane. All Rights Reserved except as specified below.

Permission is hereby granted to use, copy, modify, and distribute this software (or portions thereof) for any purpose, without fee, subject to these conditions:

(1) If any part of the source code for this software is distributed, then this README file must be included, with this copyright and no-warranty notice unaltered; and any additions, deletions, or changes to the original files must be clearly indicated in accompanying documentation.

(2) If only executable code is distributed, then the accompanying documentation must state that "this software is based in part on the work of the Independent JPEG Group".

(3) Permission for use of this software is granted only if the user accepts full responsibility for any undesirable consequences; the authors accept NO LIABILITY for damages of any kind.

These conditions apply to any software derived from or based on the IJG code, not just to the unmodified library. If you use our work, you ought to acknowledge us.

Permission is NOT granted for the use of any IJG author's name or company name in advertising or publicity relating to this software or products derived from it.This software may be referred to only as "the Independent JPEG Group's software".

We specifically permit and encourage the use of this software as the basis of commercial products, provided that all warranty or liability claims are assumed by the product vendor.

ansi2knr.c is included in this distribution by permission of L. Peter Deutsch, sole proprietor of its copyright holder, Aladdin Enterprises of Menlo Park, CA. ansi2knr.c is NOT covered by the above copyright and conditions, but instead by the usual distribution terms of the Free Software Foundation; principally, that you must include source code if you redistribute it. (See the file ansi2knr.c for full details.)However, since ansi2knr.c is not needed as part of any program generated from the IJG code, this does not limit you more than the foregoing paragraphs do.

The Unix configuration script "configure" was produced with GNU Autoconf.
It is copyright by the Free Software Foundation but is freely distributable. The same holds for its supporting scripts (config.guess, config.sub, ltconfig, ltmain.sh).Another support script, install-sh, is copyright
by M.I.T. but is also freely distributable.

It appears that the arithmetic coding option of the JPEG spec is covered by patents owned by IBM, AT&T, and Mitsubishi. Hence arithmetic coding cannot legally be used without obtaining one or more licenses. For this reason, support for arithmetic coding has been removed from the free JPEG software. (Since arithmetic coding provides only a marginal gain over the unpatented Huffman mode, it is unlikely that very many implementations will support it.) So far as we are aware, there are no patent restrictions on the remaining code.

The IJG distribution formerly included code to read and write GIF files. To avoid entanglement with the Unisys LZW patent, GIF reading support has been removed altogether, and the GIF writer has been simplified to produce "uncompressed GIFs". This technique does not use the LZW algorithm; the resulting GIF files are larger than usual, but are readable by all standard GIF decoders.

We are required to state that

> "The Graphics Interchange Format(c) is the Copyright property of CompuServe Incorporated.GIF(sm) is a Service Mark property of CompuServe Incorporated."

The FreeType Project LICENSE

2002-Apr-11

Introduction
==========

The FreeType Project is distributed in several archive packages; some of them may contain, in addition to the FreeType font engine, various tools and contributions which rely on, or relate to, the FreeType Project.

This license applies to all files found in such packages, and which do not fall under their own explicit license. The license affects thus the FreeType font engine, the test programs, documentation and makefiles, at the very least.

This license was inspired by the BSD, Artistic, and IJG (Independent JPEG Group) licenses, which all encourage inclusion and use of free software in commercial and freeware products alike. As a consequence, its main points are that:

- We don't promise that this software works. However, we will be interested in any kind of bug reports. (`as is' distribution)
- You can use this software for whatever you want, in parts or full form, without having to pay us. (`royalty-free' usage)
- You may not pretend that you wrote this software. If you use it, or only parts of it, in a program, you must acknowledge somewhere in your documentation that you have used the FreeType code. (`credits')

We specifically permit and encourage the inclusion of this software, with or without modifications, in commercial products. We disclaim all warranties covering The FreeType Project and assume no liability related to The FreeType Project.

Finally, many people asked us for a preferred form for a credit/disclaimer to use in compliance with this license. We thus encourage you to use the following text:
" " "
Portions of this software are copyright © 1996-2002 The FreeType Project (www.freetype.org). All rights reserved.
" " "

Legal Terms
==========

0. Definitions

Throughout this license, the terms `package', `FreeType Project', and `FreeType archive' refer to the set of files originally distributed by the authors (David Turner, Robert Wilhelm, and Werner Lemberg) as the `FreeType Project', be they named as alpha, beta or final release.
`You' refers to the licensee, or person using the project, where
`using' is a generic term including compiling the project's source code as well as linking it to form a `program' or `executable'. This program is referred to as `a program using the FreeType engine'.
This license applies to all files distributed in the original FreeType Project, including all source code, binaries and documentation, unless otherwise stated in the file in its original, unmodified form as distributed in the original archive. If you are unsure whether or not a particular file is covered by this license, you must contact us to verify this.
The FreeType Project is copyright (C) 1996-2000 by David Turner, Robert Wilhelm, and Werner Lemberg. All rights reserved except as specified below.

1. No Warranty

THE FREETYPE PROJECT IS PROVIDED `AS IS' WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT WILL ANY OF THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY DAMAGES CAUSED BY THE USE OR THE INABILITY TO USE, OF THE FREETYPE PROJECT.

2. Redistribution

This license grants a worldwide, royalty-free, perpetual and irrevocable right and license to use, execute, perform, compile, display, copy, create derivative works of, distribute and sublicense the FreeType Project (in both source and object code forms) and derivative works thereof for any purpose; and to authorize others to exercise some or all of the rights granted herein, subject to the following conditions:

- Redistribution of source code must retain this license file (`FTL.TXT') unaltered; any additions, deletions or changes to the original files must be clearly indicated in accompanying documentation. The copyright notices of the unaltered, original files must be preserved in all copies of source files.

- Redistribution in binary form must provide a disclaimer that states that the software is based in part of the work of the FreeType Team, in the distribution documentation. We also encourage you to put an URL to the FreeType web page in your documentation, though this isn't mandatory.

These conditions apply to any software derived from or based on the FreeType Project, not just the unmodified files. If you use our work, you must acknowledge us. However, no fee need be paid to us.

3. Advertising

Neither the FreeType authors and contributors nor you shall use the name of the other for commercial, advertising, or promotional purposes without specific prior written permission.

We suggest, but do not require, that you use one or more of the following phrases to refer to this software in your documentation or advertising materials: `FreeType Project', `FreeType Engine', `FreeType library', or `FreeType Distribution'.

As you have not signed this license, you are not required to accept it. However, as the FreeType Project is copyrighted material, only this license, or another one contracted with the authors, grants you the right to use, distribute, and modify it. Therefore, by using, distributing, or modifying the FreeType Project, you indicate that you understand and accept all the terms of this license.

4. Contacts

There are two mailing lists related to FreeType:

- *freetype@freetype.org*

  Discusses general use and applications of FreeType, as well as future and wanted additions to the library and distribution. If you are looking for support, start in this list if you haven't found anything to help you in the documentation.

- *devel@freetype.org*

  Discusses bugs, as well as engine internals, design issues, specific licenses, porting, etc.

- *http://www.freetype.org*

  Holds the current FreeType web page, which will allow you to download our latest development version and read online documentation.

You can also contact us individually at:

David Turner *<david.turner@freetype.org>*

Robert Wilhelm *<robert.wilhelm@freetype.org>*

Werner Lemberg *<werner.lemberg@freetype.org>*

COMMON DEVELOPMENT AND DISTRIBUTION LICENSE (CDDL)

Version 1.0

1. Definitions.

1.1. Contributor means each individual or entity that creates or contributes to the creation of Modifications.

1.2. Contributor Version means the combination of the Original Software, prior Modifications used by a Contributor (if any), and the Modifications made by that particular Contributor.

1.3. Covered Software means (a) the Original Software, or (b) Modifications, or (c) the combination of files containing Original Software with files containing Modifications, in each case including portions thereof.

1.4. Executable means the Covered Software in any form other than Source Code.

1.5. Initial Developer means the individual or entity that first makes Original Software available under this License.

1.6. Larger Work means a work which combines Covered Software or portions thereof with code not governed by the terms of this License.

1.7. License means this document.

1.8. Licensable means having the right to grant, to the maximum extent possible, whether at the time of the initial grant or subsequently acquired, any and all of the rights conveyed herein.

1.9. Modifications means the Source Code and Executable form of any of the following:

A. Any file that results from an addition to, deletion from or modification of the contents of a file containing Original Software or previous Modifications;

B. Any new file that contains any part of the Original Software or previous Modification; or

C. Any new file that is contributed or otherwise made available under the terms of this License.

1.10. Original Software means the Source Code and Executable form of computer software code that is originally released under this License.

1.11. Patent Claims means any patent claim(s), now owned or hereafter acquired, including without limitation, method, process, and apparatus claims, in any patent Licensable by grantor.

1.12. Source Code means (a) the common form of computer software code in which 1.13. You (or Your) means an individual or a legal entity exercising rights under, and complying with all of the terms of, this License. For legal entities, You includes any entity which controls, is controlled by, or is under common control with You. For purposes of this definition, control means (a) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (b) ownership of more than fifty percent (50%) of the outstanding shares or beneficial ownership of such entity.

2. License Grants.

2.1. The Initial Developer Grant.

Conditioned upon Your compliance with Section 3.1 below and subject to third party intellectual property claims, the Initial Developer hereby grants You a world-wide, royalty-free, non-exclusive license:

(a) under intellectual property rights (other than patent or trademark) Licensable by Initial Developer, to use, reproduce, modify, display, perform, sublicense and distribute the Original Software (or portions thereof), with or without Modifications, and/or as part of a Larger Work; and

(b) under Patent Claims infringed by the making, using or selling of Original Software, to make, have made, use, practice, sell, and offer for sale, and/or otherwise dispose of the Original Software (or portions thereof).

(c) The licenses granted in Sections 2.1(a) and (b) are effective on the dateInitial Developer first distributes or otherwise makes the Original Software available to a third party under the terms of this License.

(d) Notwithstanding Section 2.1(b) above, no patent license is granted: (1) for code that You delete from the Original Software, or (2) for infringements caused by: (i) the modification of the Original Software, or (ii) the combination of the Original Software with other software or devices.

2.2. Contributor Grant.

Conditioned upon Your compliance with Section 3.1 below and subject to third party intellectual property claims, each Contributor hereby grants You a world-wide, royalty-free, non-exclusive license:

(a) under intellectual property rights (other than patent or trademark) Licensable by Contributor to use, reproduce, modify, display, perform, sublicense and distribute the Modifications created by such Contributor (or portions thereof), either on an unmodified basis, with other Modifications, as Covered Software and/or as part of a Larger Work; and

(b) under Patent Claims infringed by the making, using, or selling of Modifications made by that Contributor either alone and/or in combination with its Contributor Version (or portions of such combination), to make, use, sell, offer for sale, have made, and/or otherwise dispose of: (1) Modifications made by that Contributor (or portions thereof); and (2) the combination of Modifications made by that Contributor with its Contributor Version (or portions of such combination).

(c) The licenses granted in Sections 2.2(a) and 2.2(b) are effective on the date Contributor first distributes or otherwise makes the Modifications available to a third party.

(d) Notwithstanding Section 2.2(b) above, no patent license is granted: (1) for any code that Contributor has deleted from the Contributor Version; (2) for infringements caused by: (i) third party modifications of Contributor Version, or (ii) the combination of Modifications made by that Contributor with other software (except as part of the Contributor Version) or other devices; or (3) under Patent Claims infringed by Covered Software in the absence of Modifications made by that Contributor.

3. Distribution Obligations.

3.1. Availability of Source Code.

Any Covered Software that You distribute or otherwise make available in Executable form must also be made available in Source Code form and that Source Code form must be distributed only under the terms of this License.
You must include a copy of this License with every copy of the Source Code form of the Covered Software You distribute or otherwise make available. You must inform recipients of any such Covered Software in Executable form as to how they can obtain such Covered Software in Source Code form in a reasonable manner on or through a medium customarily used for software exchange.

3.2. Modifications.

The Modifications that You create or to which You contribute are governed by the terms of this License. You represent that You believe Your Modifications are Your original creation(s) and/or You have sufficient rights to grant the rights conveyed by this License.

3.3. Required Notices.

You must include a notice in each of Your Modifications that identifies You as the Contributor of the Modification. You may not remove or alter any copyright, patent or trademark notices contained within the Covered Software, or any notices of licensing or any descriptive text giving attribution to any Contributor or the Initial Developer.

3.4. Application of Additional Terms.

You may not offer or impose any terms on any Covered Software in Source Code form that alters or restricts the applicable version of this License or the recipients rights hereunder. You may choose to offer, and to charge a fee for, warranty, support, indemnity or liability obligations to one or more recipients of Covered Software. However, you may do so only on Your own behalf, and not on behalf of the Initial Developer or any Contributor. You must make it absolutely clear that any such warranty, support, indemnity or liability obligation is offered by You alone, and You hereby agree to indemnify the Initial Developer and every Contributor for any liability incurred by the Initial Developer or such Contributor as a result of warranty, support, indemnity or liability terms You offer.

3.5. Distribution of Executable Versions.

You may distribute the Executable form of the Covered Software under the terms of this License or under the terms of a license of Your choice, which may contain terms different from this License, provided that You are in compliance with the terms of this License and that the license for the Executable form does not attempt to limit or alter the recipients rights in the Source Code form from the rights set forth in this License. If You distribute the Covered Software in Executable form under a different license, You must make it absolutely clear that any terms which differ from this License are offered by You alone, not by the Initial Developer or Contributor. You hereby agree to indemnify the Initial Developer and every Contributor for any liability incurred by the Initial Developer or such Contributor as a result of any such terms You offer.

3.6. Larger Works.

You may create a Larger Work by combining Covered Software with other code not governed by the terms of this License and distribute the Larger Work as a single product. In such a case, You must make sure the requirements of this License are fulfilled for the Covered Software.

4. Versions of the License.

4.1. New Versions.

Sun Microsystems, Inc. is the initial license steward and may publish revised and/or new versions of this License from time to time. Each version will be given a distinguishing version number. Except as provided in Section 4.3, no one other than the license steward has the right to modify this License.

4.2. Effect of New Versions.

You may always continue to use, distribute or otherwise make the Covered Software available under the terms of the version of the License under which You originally received the Covered Software. If the Initial Developer includes a notice in the Original Software prohibiting it from being distributed or otherwise made available under any subsequent version of the License, You must distribute and make the Covered Software available under the terms of the version of the License under which You originally received the Covered Software. Otherwise, You may also choose to use, distribute or otherwise make the Covered Software available under the terms of any subsequent version of the License published by the license steward.

4.3. Modified Versions.

When You are an Initial Developer and You want to create a new license for Your Original Software, You may create and use a modified version of this License if You: (a) rename the license and remove any references to the name of the license steward (except to note that the license differs from this License); and (b) otherwise make it clear that the license contains terms which differ from this License.

5. DISCLAIMER OF WARRANTY.

COVERED SOFTWARE IS PROVIDED UNDER THIS LICENSE ON AN AS IS BASIS, WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, WITHOUT LIMITATION, WARRANTIES THAT THE COVERED SOFTWARE IS FREE OF DEFECTS, MERCHANTABLE, FIT FOR A PARTICULAR PURPOSE OR NON-INFRINGING. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE COVERED SOFTWARE IS WITH YOU. SHOULD ANY COVERED SOFTWARE PROVE DEFECTIVE IN ANY RESPECT, YOU (NOT THE INITIAL DEVELOPER OR ANY OTHER CONTRIBUTOR) ASSUME THE COST OF ANY NECESSARY SERVICING, REPAIR OR CORRECTION. THIS DISCLAIMER OF WARRANTY CONSTITUTES AN ESSENTIAL PART OF THIS LICENSE. NO USE OF ANY COVERED SOFTWARE IS AUTHORIZED HEREUNDER EXCEPT UNDER THIS DISCLAIMER.

6. TERMINATION.

6.1. This License and the rights granted hereunder will terminate automatically if You fail to comply with terms herein and fail to cure such breach within 30 days of becoming aware of the breach. Provisions which, by their nature, must remain in effect beyond the termination of this License shall survive.

6.2. If You assert a patent infringement claim (excluding declaratory judgment actions) against Initial Developer or a Contributor (the Initial Developer or Contributor against whom You assert such claim is referred to as Participant) alleging that the Participant Software (meaning the Contributor Version where the Participant is a Contributor or the Original Software where the Participant is the Initial Developer) directly or indirectly infringes any patent, then any and all rights granted directly or indirectly to You by such Participant, the Initial Developer (if the Initial Developer is not the Participant) and all Contributors under Sections 2.1 and/or 2.2 of this License shall, upon 60 days notice from Participant terminate prospectively and automatically at the expiration of such 60 day notice period, unless if within such 60 day period You withdraw Your claim with respect to the Participant Software against such Participant either unilaterally or pursuant to a written agreement with Participant.

6.3. In the event of termination under Sections 6.1 or 6.2 above, all end user licenses that have been validly granted by You or any distributor hereunder prior to termination (excluding licenses granted to You by any distributor) shall survive termination.

7. LIMITATION OF LIABILITY.

UNDER NO CIRCUMSTANCES AND UNDER NO LEGAL THEORY, WHETHER TORT (INCLUDING NEGLIGENCE), CONTRACT, OR OTHERWISE, SHALL YOU, THE INITIAL DEVELOPER, ANY OTHER CONTRIBUTOR, OR ANY DISTRIBUTOR OF COVERED SOFTWARE, OR ANY SUPPLIER OF ANY OF SUCH PARTIES, BE LIABLE TO ANY PERSON FOR ANY INDIRECT, SPECIAL, INCIDENTAL, OR CONSEQUENTIAL DAMAGES OF ANY CHARACTER INCLUDING, WITHOUT LIMITATION, DAMAGES FOR LOST PROFITS, LOSS OF GOODWILL, WORK STOPPAGE, COMPUTER FAILURE OR MALFUNCTION, OR ANY AND ALL OTHER COMMERCIAL DAMAGES OR LOSSES, EVEN IF SUCH PARTY SHALL HAVE BEEN INFORMED OF THE POSSIBILITY OF SUCH DAMAGES. THIS LIMITATION OF LIABILITY SHALL NOT APPLY TO LIABILITY FOR DEATH OR PERSONAL INJURY RESULTING FROM SUCH PARTYS NEGLIGENCE TO THE EXTENT APPLICABLE LAW PROHIBITS SUCH LIMITATION. SOME JURISDICTIONS DO NOT ALLOW THE EXCLUSION OR LIMITATION OF INCIDENTAL OR CONSEQUENTIAL DAMAGES, SO THIS EXCLUSION AND LIMITATION MAY NOT APPLY TO YOU.

8. U.S. GOVERNMENT END USERS.

The Covered Software is a commercial item, as that term is defined in 48 C.F.R. 2.101 (Oct. 1995), consisting of commercial computer software (as that term is defined at 48
C.F.R. 252.227-7014(a)(1)) and commercial computer software documentation as such terms are used in 48 C.F.R. 12.212 (Sept. 1995). Consistent with 48 C.F.R. 12.212 and 48 C.F.R. 227.7202-1 through 227.7202-4 (June 1995), all U.S. Government End Users acquire Covered Software with only those rights set forth herein. This U.S. Government Rights clause is in lieu of, and supersedes, any other FAR, DFAR, or other clause or provision that addresses Government rights in computer software under this License.

9. MISCELLANEOUS.

This License represents the complete agreement concerning subject matter hereof. If any provision of this License is held to be unenforceable, such provision shall be reformed only to the extent necessary to make it enforceable. This License shall be governed by the law of the jurisdiction specified in a notice contained within the Original Software (except to the extent applicable law, if any, provides otherwise), excluding such jurisdictions conflict-of-law provisions. Any litigation relating to this License shall be subject to the jurisdiction of the courts located in the jurisdiction and venue specified in a notice contained within the Original Software, with the losing party responsible for costs, including, without limitation, court costs and reasonable attorneys fees and expenses. The application of the United Nations Convention on Contracts for the International Sale of Goods is expressly excluded. Any law or regulation which provides that the language of a contract shall be construed against the drafter shall not apply to this License. You agree that You alone are responsible for compliance with the United States export administration regulations (and the export control laws and regulation of any other countries) when You use, distribute or otherwise make available any Covered Software.

10. RESPONSIBILITY FOR CLAIMS.

As between Initial Developer and the Contributors, each party is responsible for claims and damages arising, directly or indirectly, out of its utilization of rights under this License and You agree to work with Initial Developer and Contributors to distribute such responsibility on an equitable basis. Nothing herein is intended or shall be deemed to constitute any admission of liability.

OpenJDK

GNU General Public License, version 2, with the Classpath Exception

The GNU General Public License (GPL) Version 2, June 1991

Copyright (C) 1989, 1991 Free Software Foundation, Inc.
59 Temple Place, Suite 330, Boston, MA 02111-1307 USA

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

Preamble

The licenses for most software are designed to take away your freedom to share and change it.By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users.This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it.(Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.
When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.
To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights.These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.
We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.
Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.
Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.
The precise terms and conditions for copying, distribution and modification follow.

TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License.The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language.(Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".
Activities other than copying, distribution and modification are not covered by this License; they are outside its scope.The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program).Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

   You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:
   a. You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.
   b. You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.
   c. If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License.(Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

   These requirements apply to the modified work as a whole.If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

   Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

   In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:
   a. Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,
   b. Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,
   c. Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License.However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

5. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works.These actions are prohibited by law if you do not accept this License.Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

7. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License.If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

   If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

   It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.

   This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

8. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

   Each version is given a distinguishing version number. If the Program specifies a version number of this License

which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

    NO WARRANTY

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW.EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU.SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

    END OF TERMS AND CONDITIONS

How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

> One line to give the program's name and a brief idea of what it does.
>
> Copyright (C) <year> <name of author>
>
> This program is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 2 of the License, or (at your option) any later version.
>
> This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.
>
> You should have received a copy of the GNU General Public License along with this program; if not, write to the Free Software Foundation, Inc., 59 Temple Place, Suite 330, Boston, MA 02111-1307 USA

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

> Gnomovision version 69, Copyright (C) year name of author Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type 'show w'.This is free software, and you are welcome to redistribute it under certain conditions; type 'show c' for details.

The hypothetical commands 'show w' and 'show c' should show the appropriate parts of the General Public License.Of course, the commands you use may be called something other than 'show w' and 'show c'; they could even be mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

> Yoyodyne, Inc., hereby disclaims all copyright interest in the program 'Gnomovision' (which makes passes at compilers) written by James Hacker.
>
> signature of Ty Coon, 1 April 1989
>
> Ty Coon, President of Vice

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library.If this is what you want to do, use the GNU Library General Public License instead of this License.

"CLASSPATH" EXCEPTION TO THE GPL

Certain source files distributed by Oracle America and/or its affiliates are subject to the following clarification and special exception to the GPL, but only where Oracle has expressly included in the particular source file's header the words "Oracle designates this particular file as subject to the "Classpath" exception as provided by Oracle in the LICENSE file that accompanied this code."

> Linking this library statically or dynamically with other modules is making a combined work based on this library. Thus, the terms and conditions of the GNU General Public License cover the whole combination.
>
> As a special exception, the copyright holders of this library give you permission to link this library with independent modules to produce an executable, regardless of the license terms of these independent modules, and to copy and distribute the resulting executable under terms of your choice, provided that you also meet, for each linked independent module, the terms and conditions of the license of that module.An independent module is a module which is not derived from or based on this library.If you modify this library, you may extend this exception to your version of the library, but you are not obligated to do so. If you do not wish to do so, delete this exception statement from your version.

AOP Alliance (Java/J2EE AOP standards)

LICENSE: all the source code provided by AOP Alliance is Public Domain.

Eclipse Public License - v 1.0

THE ACCOMPANYING PROGRAM IS PROVIDED UNDER THE TERMS OF THIS ECLIPSE PUBLIC LICENSE ("AGREEMENT"). ANY USE, REPRODUCTION OR DISTRIBUTION OF THE PROGRAM CONSTITUTES RECIPIENT'S ACCEPTANCE OF THIS AGREEMENT.

1. DEFINITIONS
"Contribution" means:

> a) in the case of the initial Contributor, the initial code and documentation distributed under this Agreement, and
>
> b) in the case of each subsequent Contributor:
>
> i)changes to the Program, and
>
> ii)additions to the Program;

where such changes and/or additions to the Program originate from and are distributed by that particular Contributor. A Contribution 'originates' from a Contributor if it was added to the Program by such Contributor itself or anyone acting on such Contributor's behalf. Contributions do not include additions to the Program which: (i) are separate modules of software distributed in conjunction with the Program under their own license agreement, and (ii) are not derivative works of the Program.

"Contributor" means any person or entity that distributes the Program.

"Licensed Patents " mean patent claims licensable by a Contributor which are necessarily infringed by the use or sale of its Contribution alone or when combined with the Program.

"Program" means the Contributions distributed in accordance with this Agreement.

"Recipient" means anyone who receives the Program under this Agreement, including all Contributors.

2. GRANT OF RIGHTS

a) Subject to the terms of this Agreement, each Contributor hereby grants Recipient a non-exclusive, worldwide, royalty-free copyright license to reproduce, prepare derivative works of, publicly display, publicly perform, distribute and sublicense the Contribution of such Contributor, if any, and such derivative works, in source code and object code form.

b) Subject to the terms of this Agreement, each Contributor hereby grants Recipient a non-exclusive, worldwide, royalty-free patent license under Licensed Patents to make, use, sell, offer to sell, import and otherwise transfer the Contribution of such Contributor, if any, in source code and object code form. This patent license shall apply to the combination of the Contribution and the Program if, at the time the Contribution is added by the Contributor, such addition of the Contribution causes such combination to be covered by the Licensed Patents. The patent license shall not apply to any other combinations which include the Contribution. No hardware per se is licensed hereunder.

c) Recipient understands that although each Contributor grants the licenses to its Contributions set forth herein, no assurances are provided by any Contributor that the Program does not infringe the patent or other intellectual property rights of any other entity. Each Contributor disclaims any liability to Recipient for claims brought by any other entity based on infringement of intellectual property rights or otherwise. As a condition to exercising the rights and licenses granted hereunder, each Recipient hereby assumes sole responsibility to secure any other intellectual property rights needed, if any. For example, if a third party patent license is required to allow Recipient to distribute the Program, it is Recipient's responsibility to acquire that license before distributing the Program.

d) Each Contributor represents that to its knowledge it has sufficient copyright rights in its Contribution, if any, to grant the copyright license set forth in this Agreement.

3. REQUIREMENTS

A Contributor may choose to distribute the Program in object code form under its own license agreement, provided that:

a) it complies with the terms and conditions of this Agreement; and

b) its license agreement:

i) effectively disclaims on behalf of all Contributors all warranties and conditions, express and implied, including warranties or conditions of title and non-infringement, and implied warranties or conditions of merchantability and fitness for a particular purpose;

ii) effectively excludes on behalf of all Contributors all liability for damages, including direct, indirect, special, incidental and consequential damages, such as lost profits;

iii) states that any provisions which differ from this Agreement are offered by that Contributor alone and not by any other party; and

iv) states that source code for the Program is available from such Contributor, and informs licensees how to obtain it in a reasonable manner on or through a medium customarily used for software exchange.

When the Program is made available in source code form:

a) it must be made available under this Agreement; and

b) a copy of this Agreement must be included with each copy of the Program.

Contributors may not remove or alter any copyright notices contained within the Program.

Each Contributor must identify itself as the originator of its Contribution, if any, in a manner that reasonably allows subsequent Recipients to identify the originator of the Contribution.

4. COMMERCIAL DISTRIBUTION

Commercial distributors of software may accept certain responsibilities with respect to end users, business partners and the like. While this license is intended to facilitate the commercial use of the Program, the Contributor who includes the Program in a commercial product offering should do so in a manner which does not create potential liability for other Contributors. Therefore, if a Contributor includes the Program in a commercial product offering, such Contributor ("Commercial Contributor") hereby agrees to defend and indemnify every other Contributor ("Indemnified Contributor") against any losses, damages and costs (collectively "Losses") arising from claims, lawsuits and other legal actions brought by a third party against the Indemnified Contributor to the extent caused by the acts or omissions of such Commercial Contributor in connection with its distribution of the Program in a commercial product offering. The obligations in this section do not apply to any claims or Losses relating to any actual or alleged intellectual property infringement. In order to qualify, an Indemnified Contributor must:
a) promptly notify the Commercial Contributor in writing of such claim, and b) allow the Commercial Contributor to control, and cooperate with the Commercial Contributor in, the defense and any related settlement negotiations. The Indemnified Contributor may participate in any such claim at its own expense.

For example, a Contributor might include the Program in a commercial product offering, Product X. That Contributor is then a Commercial Contributor. If that Commercial Contributor then makes performance claims, or offers warranties related to Product X, those performance claims and warranties are such Commercial Contributor's responsibility alone. Under this section, the Commercial Contributor would have to defend claims against the other Contributors related to those performance claims and warranties, and if a court requires any other Contributor to pay any damages as a result, the Commercial Contributor must pay those damages.

5. NO WARRANTY

EXCEPT AS EXPRESSLY SET FORTH IN THIS AGREEMENT, THE PROGRAM IS PROVIDED ON AN "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, EITHER EXPRESS OR IMPLIED INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OR CONDITIONS OF TITLE, NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Each Recipient is solely responsible for determining the appropriateness of using and distributing the Program and assumes all risks associated with its exercise of rights under this Agreement , including but not limited to the risks and costs of program errors, compliance with applicable laws, damage to or loss of data, programs or equipment, and unavailability or interruption of operations.

6. DISCLAIMER OF LIABILITY

EXCEPT AS EXPRESSLY SET FORTH IN THIS AGREEMENT, NEITHER RECIPIENT NOR ANY CONTRIBUTORS SHALL HAVE ANY LIABILITY FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING WITHOUT LIMITATION LOST PROFITS), HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OR DISTRIBUTION OF THE PROGRAM OR THE EXERCISE OF ANY RIGHTS GRANTED HEREUNDER, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

7. GENERAL

If any provision of this Agreement is invalid or unenforceable under applicable law, it shall not affect the validity or enforceability of the remainder of the terms of this Agreement, and without further action by the parties hereto, such provision shall be reformed to the minimum extent necessary to make such provision valid and enforceable.

If Recipient institutes patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Program itself (excluding combinations of the Program with other software or hardware) infringes such Recipient's patent(s), then such Recipient's rights granted under Section 2(b) shall terminate as of the date such litigation is filed.

All Recipient's rights under this Agreement shall terminate if it fails to comply with any of the material terms or conditions of this Agreement and does not cure such failure in a reasonable period of time after becoming aware of such noncompliance. If all Recipient's rights under this Agreement terminate, Recipient agrees to cease use and distribution of the Program as soon as reasonably practicable. However, Recipient's obligations under this Agreement and any licenses granted by Recipient relating to the Program shall continue and survive.

Everyone is permitted to copy and distribute copies of this Agreement, but in order to avoid inconsistency the Agreement is copyrighted and may only be modified in the following manner. The Agreement Steward reserves the right to publish new versions (including revisions) of this Agreement from time to time. No one other than the Agreement Steward has the right to modify this Agreement. The Eclipse Foundation is the initial Agreement Steward. The Eclipse Foundation may assign the responsibility to serve as the Agreement Steward to a suitable separate entity. Each new version of the Agreement will be given a distinguishing version number. The Program (including Contributions) may always be distributed subject to the version of the Agreement under which it was received. In addition, after a new version of the Agreement is published, Contributor may elect to distribute the Program (including its Contributions) under the new version. Except as expressly stated in Sections 2(a) and 2(b) above, Recipient receives no rights or licenses to the intellectual property of any Contributor under this Agreement, whether expressly, by implication, estoppel or otherwise. All rights in the Program not expressly granted under this Agreement are reserved.

This Agreement is governed by the laws of the State of New York and the intellectual property laws of the United States of America. No party to this Agreement will bring a legal action under this Agreement more than one year after the cause of action arose. Each party waives its rights to a jury trial in any resulting litigation.

ZLIB License

(C) 1995-2002 Jean-loupGailly and Mark Adler
This software is provided as-is, without any express or implied warranty. In no event will the authors be held liable for any damages arising from the use of this software.

Permission is granted to anyone to use this software for any purpose, including commercial applications, and to alter it and redistribute it freely, subject to the following restrictions:
The origin of this software must not be misrepresented; you must not claim that you wrote the original software. If you use this software in a product, an acknowledgment in the product documentation would be appreciated but is not required.
Altered source versions must be plainly marked as such, and must not be misrepresented as being the original software.
This notice may not be removed or altered from any source distribution.
Jean-loup Gailly Mark Adler *jloup@gzip.org madler@alumni.caltech.edu*
If you use the zlib library in a product, we would appreciate **not** receiving lengthy legal documents to sign. The sources are provided for free but without warranty of any kind. The library has been entirely written by Jean-loup Gailly and Mark Adler; it does not include third-party code.
If you redistribute modified sources, we would appreciate that you include in the file ChangeLog history information documenting your changes.

VIM License

COPYING
Vim is Charityware. You can use and copy it as much as you like, but you are encouraged to make a donation to orphans in Uganda. Please read the file "runtime/doc/uganda.txt" for details.
There are no restrictions on distributing an unmodified copy of Vim. Parts of Vim may also be distributed, but this text must always be included. You are allowed to include executables that you made from the unmodified Vim sources, your own usage examples and Vim scripts.
If you distribute a modified version of Vim, you are encouraged to send the maintainer a copy, including the source code. Or make it available to the maintainer through ftp; let him know where it can be found. If the number of changes is small (e.g., a modified Makefile) e-mailing the diffs will do. When the maintainer asks for it (in any way) you must make your changes, including source code, available to him.
The maintainer reserves the right to include any changes in the official version of Vim. This is negotiable. You are not allowed to distribute a modified version of Vim when you are not willing to make the source code available to the maintainer.
The current maintainer is Bram Moolenaar *<Bram@vim.org>.* If this changes, it will be announced in appropriate places (most likely *www.vim.org* and comp.editors). When it is completely impossible to contact the maintainer, the obligation to send him modified source code ceases.
It is not allowed to remove these restrictions from the distribution of the Vim sources or parts of it. These restrictions may also be used for previous Vim releases instead of the text that was included with it.
Vim is Charityware. You can use and copy it as much as you like, but you are encouraged to make a donation for needy children in Uganda. Please see |kcc| below or visit the ICCF web site, available at these mirrors:
http://iccf-holland.org/ http://www.vim.org/iccf/ http://www.iccf.nl/
The Open Publication License applies to the Vim documentation, see | manual - copyright |.

=== begin of license ===

VIM LICENSE
There are no restrictions on distributing unmodified copies of Vim except that they must include this license text. You can also distribute unmodified parts of Vim, likewise unrestricted except that they must include this license text. You are also allowed to include executables that you made from the unmodified Vim sources, plus your own usage examples and Vim scripts.
It is allowed to distribute a modified (or extended) version of Vim, including executables and/or source code, when the following four conditions are met:

1. This license text must be included unmodified.
2. The modified Vim must be distributed in one of the following five ways:
    a. If you make changes to Vim yourself, you must clearly describe in the distribution how to contact you. When the maintainer asks you (in any way) for a copy of the modified Vim you distributed, you must make your changes, including source code, available to the maintainer without fee. The maintainer reserves the right to include your changes in the official version of Vim. What the maintainer will do with your changes and under what license they will be distributed is negotiable. If there has been no negotiation then this license, or a later version, also applies to your changes. The current maintainer is Bram Moolenaar <*Bram@vim.org>.* If this changes it will be announced in appropriate places (most likely vim.sf.net, *www.vim.org* and/or comp.editors). When it is completely impossible to contact the maintainer, the

obligation to send him your changes ceases. Once the maintainer has confirmed that he has received your changes they will not have to be sent again.

b. If you have received a modified Vim that was distributed as mentioned under a) you are allowed to further distribute it unmodified, as mentioned at I). If you make additional changes the text under a) applies to those changes.
c. Provide all the changes, including source code, with every copy of the modified Vim you distribute. This may be done in the form of a context diff. You can choose what license to use for new code you add. The changes and their license must not restrict others from making their own changes to the official version of Vim.
d. When you have a modified Vim which includes changes as mentioned under c), you can distribute it without the source code for the changes if the following three conditions are met:
   - The license that applies to the changes permits you to distribute the changes to the Vim maintainer without fee or restriction, and permits the Vim maintainer to include the changes in the official version of Vim without fee or restriction.
   - You keep the changes for at least three years after last distributing the corresponding modified Vim. When the maintainer or someone who you distributed the modified Vim to asks you (in any way) for the changes within this period, you must make them available to him.
   - You clearly describe in the distribution how to contact you. This contact information must remain valid for at least three years after last distributing the corresponding modified Vim, or as long as possible.
e. When the GNU General Public License (GPL) applies to the changes, you can distribute the modified Vim under the GNU GPL version 2 or any later version.

3. A message must be added, at least in the output of the ":version" command and in the intro screen, such that the user of the modified Vim is able to see that it was modified. When distributing as mentioned under 2)e) adding the message is only required for as far as this does not conflict with the license used for the changes.
4. The contact information as required under 2)a) and 2)d) must not be removed or changed, except that the person himself can make corrections.

If you distribute a modified version of Vim, you are encouraged to use the Vim license for your changes and make them available to the maintainer, including the source code.
The preferred way to do this is by e-mail or by uploading the files to a server and
e-mailing the URL. If the number of changes is small (e.g., a modified Makefile) e-mailing a context diff will do. The e-mail address to be used is *<maintainer@vim.org>*
It is not allowed to remove this license from the distribution of the Vim sources, parts of it or from a modified version. You may use this license for previous Vim releases instead of the license that they came with, at your option.

archive site such as uunet.uu.net, or by allowing the Copyright Holder to include your modifications in the Standard Version of the Package.
    b. use the modified Package only within your corporation or organization.
    c. rename any non-standard executables so the names do not conflict with standard executables, which must also be provided, and provide a separate manual page for each non-standard executable that clearly documents how it differs from the Standard Version.
    d. make other distribution arrangements with the Copyright Holder.
4. You may distribute the programs of this Package in object code or executable form, provided that you do at least ONE of the following:
    a. distribute a Standard Version of the executables and library files, together with instructions (in the manual page or equivalent) on where to get the Standard Version.
    b. accompany the distribution with the machine-readable source of the Package with your modifications.
    c. give non-standard executables non-standard names, and clearly document the differences in manual pages (or equivalent), together with instructions on where to get the Standard Version.
    d. make other distribution arrangements with the Copyright Holder.
5. You may charge a reasonable copying fee for any distribution of this Package. You may charge any fee you choose for support of this Package. You may not charge a fee for this Package itself. However, you may distribute this Package in aggregate with other (possibly commercial) programs as part of a larger (possibly commercial) software distribution provided that you do not advertise this Package as a product of your own. You may embed this Packages interpreter within an executable of yours (by linking); this shall be construed as a mere form of aggregation, provided that the complete Standard Version of the interpreter is so embedded.
6. The scripts and library files supplied as input to or produced as output from the programs of this Package do not automatically fall under the copyright of this Package, but belong to whoever generated them, and may be sold commercially, and may be aggregated with this Package. If such scripts or library files are aggregated with this Package via the so-called "undump" or "unexec" methods of producing a binary executable image, then distribution of such an image shall neither be construed as a distribution of this Package nor shall it fall under the restrictions of Paragraphs 3 and 4, provided that you do not represent such an executable image as a Standard Version of this Package.
7. C subroutines (or comparably compiled subroutines in other languages) supplied by you and linked into this Package in order to emulate subroutines and variables of the language defined by this Package shall not be considered part of this Package, but are the equivalent of input as in Paragraph 6, provided these subroutines do not change the language in any way that would cause it to fail the regression tests for the language.
8. Aggregation of this Package with a commercial distribution is always permitted provided that the use of this Package is embedded; that is, when no overt attempt is made to make this Packages interfaces visible to the end user of the commercial distribution. Such use shall not be construed as a distribution of this Package.
9. The name of the Copyright Holder may not be used to endorse or promote products derived from this software without specific prior written permission.
10. THIS PACKAGE IS PROVIDED "AS IS" AND WITHOUT ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTIBILITY AND FITNESS FOR A PARTICULAR PURPOSE.

    The End

Apache Software License, Version 2.0

Copyright (c) 2004 The Apache Software Foundation. All rights reserved. TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions.

    "License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

    "Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

    "Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership

of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

    a. You must give any other recipients of the Work or Derivative Works a copy of this License; and

    b. You must cause any modified files to carry prominent notices stating that You changed the files; and

    c. You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

d. If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

APPENDIX: How to apply the Apache License to your work.

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets "[]" replaced with your own identifying information. (Don't include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.

Copyright [yyyy] [name of copyright owner]

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.

GNU Lesser General Public License

GNU LESSER GENERAL PUBLIC LICENSE
Version 2.1, February 1999

59 Temple Place, Suite 330, Boston, MA 02111-1307 USA

[This is the first released version of the Lesser GPL. It also counts as the successor of the GNU Library Public License, version 2, hence the version number 2.1.]

Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public Licenses are intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users.

This license, the Lesser General Public License, applies to some specially designated software packages-typically libraries-of the Free Software Foundation and other authors who decide to use it. You can use it too, but we suggest you first think carefully about whether this license or the ordinary General Public License is the better strategy to use in any particular case, based on the explanations below.

When we speak of free software, we are referring to freedom of use, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish); that you receive source code or can get it if you want it; that you can change the software and use pieces of it in new free programs; and that you are informed that you can do these things.

To protect your rights, we need to make restrictions that forbid distributors to deny you these rights or to ask you to surrender these rights. These restrictions translate to certain responsibilities for you if you distribute copies of the library or if you modify it.

For example, if you distribute copies of the library, whether gratis or for a fee, you must give the recipients all the rights that we gave you. You must make sure that they, too, receive or can get the source code. If you link other code with the library, you must provide complete object files to the recipients, so that they can relink them with the library after making changes to the library and recompiling it. And you must show them these terms so they know their rights.

We protect your rights with a two-step method: (1) we copyright the library, and (2) we offer you this license, which gives you legal permission to copy, distribute and/or modify the library.

To protect each distributor, we want to make it very clear that there is no warranty for the free library. Also, if the library is modified by someone else and passed on, the recipients should know that what they have is not the original version, so that the original authors reputation will not be affected by problems that might be introduced by others.

Finally, software patents pose a constant threat to the existence of any free program. We wish to make sure that a company cannot effectively restrict the users of a free program by obtaining a restrictive license from a patent holder. Therefore, we insist that any patent license obtained for a version of the library must be consistent with the full freedom of use specified in this license.

Most GNU software, including some libraries, is covered by the ordinary GNU General Public License. This license, the GNU Lesser General Public License, applies to certain designated libraries, and is quite different from the ordinary

General Public License. We use this license for certain libraries in order to permit linking those libraries into non-free programs.

When a program is linked with a library, whether statically or using a shared library, the combination of the two is legally speaking a combined work, a derivative of the original library. The ordinary General Public License therefore permits such linking only if the entire combination fits its criteria of freedom. The Lesser General Public License permits more lax criteria for linking other code with the library.

We call this license the "Lesser" General Public License because it does Less to protect the users freedom than the ordinary General Public License. It also provides other free software developers Less of an advantage over competing non-free programs. These disadvantages are the reason we use the ordinary General Public License for many libraries. However, the Lesser license provides advantages in certain special circumstances.

For example, on rare occasions, there may be a special need to encourage the widest possible use of a certain library, so that it becomes a de-facto standard. To achieve this, non-free programs must be allowed to use the library. A more frequent case is that a free library does the same job as widely used non-free libraries. In this case, there is little to gain by limiting the free library to free software only, so we use the Lesser General Public License.

In other cases, permission to use a particular library in non-free programs enables a greater number of people to use a large body of free software. For example, permission to use the GNU C Library in non-free programs enables many more people to use the whole GNU operating system, as well as its variant, the GNU/Linux operating system.

Although the Lesser General Public License is Less protective of the users freedom, it does ensure that the user of a program that is linked with the Library has the freedom and the wherewithal to run that program using a modified version of the Library.

The precise terms and conditions for copying, distribution and modification follow. Pay close attention to the difference between a "work based on the library" and a "work that uses the library". The former contains code derived from the library, whereas the latter must be combined with the library in order to run.

GNU LESSER GENERAL PUBLIC LICENSE

TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License Agreement applies to any software library or other program which contains a notice placed by the copyright holder or other authorized party saying it may be distributed under the terms of this Lesser General Public License (also called "this License"). Each licensee is addressed as "you".

A "library" means a collection of software functions and/or data prepared so as to be conveniently linked with application programs (which use some of those functions and data) to form executables.

The "Library", below, refers to any such software library or work which has been distributed under these terms. A "work based on the Library" means either the Library or any derivative work under copyright law: that is to say, a work containing the Library or a portion of it, either verbatim or with modifications and/or translated straightforwardly into another language. (Hereinafter, translation is included without limitation in the term "modification".)

"Source code" for a work means the preferred form of the work for making modifications to it. For a library, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the library.

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running a program using the Library is not restricted, and output from such a program is covered only if its contents constitute a work based on the Library (independent of the use of the Library in a tool for writing it). Whether that is true depends on what the Library does and what the program that uses the Library does.

1. You may copy and distribute verbatim copies of the Librarys complete source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and distribute a copy of this License along with the Library.
   You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.
2. You may modify your copy or copies of the Library or any portion of it, thus forming a work based on the Library, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions
   a. The modified work must itself be a software library.

b. You must cause the files modified to carry prominent notices stating that you changed the files and the date of any change.
c. You must cause the whole of the work to be licensed at nocharge to all third parties under the terms of this License.
d. If a facility in the modified Library refers to a function or a table of data to be supplied by an appropriate program that uses the facility, other than as an argument passed when the facility is invoked, then you must make a good faith effort to ensure that, in the event an application does not supply such function or table, the facility still operates, and performs whatever part of its purpose remains meaningful.

(For example, a function in a library to compute square roots has a purpose that is entirely well-defined independent of the application. Therefore, Subsection 2d requires that any application-supplied function or table used by this function must be optional: if the application does not supply it, the square root function must still compute square roots.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Library, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Library, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Library.

In addition, mere aggregation of another work not based on the Library with the Library (or with a work based on the Library) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may opt to apply the terms of the ordinary GNU General Public License instead of this License to a given copy of the Library. To do this, you must alter all the notices that refer to this License, so that they refer to the ordinary GNU General Public License, version 2, instead of to this License. (If a newer version than version 2 of the ordinary GNU General Public License has appeared, then you can specify that version instead if you wish.) Do not make any other change in these notices.

   Once this change is made in a given copy, it is irreversible for that copy, so the ordinary GNU General Public License applies to all subsequent copies and derivative works made from that copy.

   This option is useful when you wish to copy part of the code of the Library into a program that is not a library.
4. You may copy and distribute the Library (or a portion or derivative of it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange.

   If distribution of object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place satisfies the requirement to distribute the source code, even though third parties are not compelled to copy the source along with the object code.
5. A program that contains no derivative of any portion of the Library, but is designed to work with the Library by being compiled or linked with it, is called a "work that uses the Library". Such a work, in isolation, is not a derivative work of the Library, and therefore falls outside the scope of this License.

   However, linking a "work that uses the Library" with the Library creates an executable that is a derivative of the Library (because it contains portions of the Library), rather than a "work that uses the library". The executable is therefore covered by this License. Section 6 states terms for distribution of such executables.

   When a "work that uses the Library" uses material from a header file that is part of the Library, the object code for the work may be a derivative work of the Library even though the source code is not. Whether this is true is especially significant if the work can be linked without the Library, or if the work is itself a library. The threshold for this to be true is not precisely defined by law.

   If such an object file uses only numerical parameters, data structure layouts and accessors, and small macros and small inline functions (ten lines or less in length), then the use of the object file is unrestricted, regardless of whether it is legally a derivative work. (Executables containing this object code plus portions of the Library will still fall under Section 6.)

   Otherwise, if the work is a derivative of the Library, you may distribute the object code for the work under the terms of Section 6. Any executables containing that work also fall under Section 6, whether or not they are linked directly with the Library itself.
6. As an exception to the Sections above, you may also combine or link a "work that uses the Library" with the Library to produce a work containing portions of the Library, and distribute that work under terms of your choice, provided that the terms permit modification of the work for the customers own use and reverse engineering for debugging such modifications.

You must give prominent notice with each copy of the work that the Library is used in it and that the Library and its use are covered by this License. You must supply a copy of this License. If the work during execution displays copyright notices, you must include the copyright notice for the Library among them, as well as a reference directing the user to the copy of this License. Also, you must do one of these things:

a. Accompany the work with the complete corresponding machine-readable source code for the Library including whatever changes were used in the work (which must be distributed under Sections 1 and 2 above); and, if the work is an executable linked with the Library, with the complete machine-readable "work that uses the Library", as object code and/or source code, so that the user can modify the Library and then relink to produce a modified executable containing the modified Library. (It is understood that the user who changes the contents of definitions files in the Library will not necessarily be able to recompile the application to use the modified definitions.)
b. Use a suitable shared library mechanism for linking with the Library. A suitable mechanism is one that (1) uses at run time a copy of the library already present on the users computer system, rather than copying library functions into the executable, and (2) will operate properly with a modified version of the library, if the user installs one, as long as the modified version is interface-compatible with the version that the work was made with.
c. Accompany the work with a written offer, valid for at least three years, to give the same user the materials specified in Subsection 6a, above, for a charge no more than the cost of performing this distribution.
d. If distribution of the work is made by offering access to copy from a designated place, offer equivalent access to copy the above specified materials from the same place.
e. Verify that the user has already received a copy of these materials or that you have already sent this user a copy.

For an executable, the required form of the "work that uses the Library" must include any data and utility programs needed for reproducing the executable from it. However, as a special exception, the materials to be distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

It may happen that this requirement contradicts the license restrictions of other proprietary libraries that do not normally accompany the operating system. Such a contradiction means you cannot use both them and the Library together in an executable that you distribute.

7. You may place library facilities that are a work based on the Library side-by-side in a single library together with other library facilities not covered by this License, and distribute such a combined library, provided that the separate distribution of the work based on the Library and of the other library facilities is otherwise permitted, and provided that you do these two things:
    a. Accompany the combined library with a copy of the same work based on the Library, uncombined with any other library facilities. This must be distributed under the terms of the Sections above.
    b. Give prominent notice with the combined library of the fact that part of it is a work based on the Library, and explaining where to find the accompanying uncombined form of the same work.
8. You may not copy, modify, sublicense, link with, or distribute the Library except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense, link with, or distribute the Library is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.
9. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Library or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Library (or any work based on the Library), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Library or works based on it.
10. Each time you redistribute the Library (or any work based on the Library), the recipient automatically receives a license from the original licensor to copy, distribute, link with or modify the Library subject to these terms and conditions. You may not impose any further restrictions on the recipients exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties with this License.
11. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Library at all. For example, if a patent license would not permit royalty-free redistribution of the Library by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Library.

    If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the

section is intended to apply, and the section as a whole is intended to apply in other circumstances.
It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.
This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

12. If the distribution and/or use of the Library is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Library under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.
13. The Free Software Foundation may publish revised and/or new versions of the Lesser General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.
    Each version is given a distinguishing version number. If the Library specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Library does not specify a license version number, you may choose any version ever published by the Free Software Foundation.
14. If you wish to incorporate parts of the Library into other free programs whose distribution conditions are incompatible with these, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

    NO WARRANTY

15. BECAUSE THE LIBRARY IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE LIBRARY, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE LIBRARY "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE LIBRARY IS WITH YOU. SHOULD THE LIBRARY PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.
16. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE LIBRARY AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE LIBRARY (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE LIBRARY TO OPERATE WITH ANY OTHER SOFTWARE), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

    END OF TERMS AND CONDITIONS

Product Compliance

This section describes the hardware components, requirements, and specifications, plus agency and RFC (Request for Comments) compliance for the Infoblox appliance. Topics in this section include:

Power Safety Information

The main external power connector for the Infoblox appliance is located on the back of the system. Ensure power to the system is off before connecting the power cord into the power connector. Please read the following power safety statements for your AC- or DC-powered appliance:

RFC Compliance

The NIOS appliance is compliant with the following:

- Qualys and Nessus security requirements
- Joint Interoperability Test Command (JITC) certification for Internet Protocol version 6 capability
- RFCs (Request for Comments)

The list of RFCs are:

- *DNS RFC Compliance*
- *DHCP RFC Compliance*
- *DHCPv6 RFC Compliance*
- *IDN (Internationalized Domain Names) RFC Compliance*

DNS RFC Compliance

The NIOS appliance complies with the following DNS RFCs:

RFCs for DNS

RFC Number	RFC Title
805	Computer Mail Meeting Notes
811	Hostnames Server
819	The Domain Naming Convention for Internet User Applications
881	The Domain Names Plan and Schedule
882	Domain Names: Concepts and Facilities

5893	Right-to-left scripts for IDNA
5894	Internationalized Domain Names in Applications (IDNA): Protocol
5895	Mapping Characters in IDNA2008
6452	The Unicode Code Points and Internationalized Domain Names for Applications (IDNA) - Unicode 6.0

Agency Compliance

The Infoblox appliance is compliant with these EMI and safety agency regulations:
Agency Regulation Compliance

Standard	Agency	Marks
FCC Part 15	FCC	FCC
EN55022, EN55024, EN61000-3-2, EN61000-3-3	TUV	CE
UL60950/CSA60950	UL	cULus
EN60950	TUV	GS

Standard	Agency	Marks
CB Scheme	IECEE	Report and Certificate IEC 60950-1:2001
VCCI-A	VCCI	VCCI
AS/NZS 3548	ACMA	C-Tick

FCC

The FCC label on the back of the system indicates this network appliance is compliant with limits for a Class A digital device in accordance with Part 15 of the FCC Rules. These limits are designed to provide reasonable protection against harmful interference when this equipment is operated in a commercial environment. Operation is subject to the following two conditions:

- This device might not cause harmful interference.
- This device must accept any interference received, including interference that may cause undesired operation.

This device generates, uses, and can radiate radio frequency energy if not installed and used in accordance with the instructions in this manual. Operating this equipment in a residential area is likely to cause harmful interference, and the customer will be required to rectify the interference at his or her own expense. This product requires the use of external shielded cables to maintain compliance pursuant to Part 15 of the FCC Rules.

Canadian Compliance

English

This Class A digital apparatus complies with Canadian ICES-003.

French

Cet appareil numérique de la classe A est conforme à la norme NMB-003 du Canada.

VCCI

The Infoblox appliance complies with this VCCI regulation (compliance statement follow by its translation):

この装置は、情報処理装置等電波障害自主規制協議会（ＶＣＣＩ）の基準
に基づくクラスＡ情報技術装置です。この装置を家庭環境で使用すると電波
妨害を引き起こすことがあります。この場合には使用者が適切な対策を講ず
るよう要求されることがあります。

This is a Class A product based on the Technical Requirements of the Voluntary Control Council for Interference Technology (VCCI). In a domestic environment this product may cause radio interference, in which case the user may be required to take corrective action.

Caution

Lithium battery included with this board. Do not puncture, mutilate, or dispose of battery in fire. Danger of explosion if battery is incorrectly replaced. Replace only with the same or equivalent type recommended by manufacturer. Dispose of used battery according to manufacturer instructions and in accordance with your local regulations.

DC

English

When stranded wiring is required, use approved wiring terminations, such as closed-loop or spade-type with upturned lugs. These terminations should be the appropriate size for the wires and should clamp both the insulation and conductor.

AC

English

Warning

This product relies on the building's installation for short-circuit (overcurrent) protection.
Ensure that a fuse or circuit breaker no larger than 120VAC, 15AU.S. (240VAC, 10A international) is used on the phase conductors (all current-carrying conductors)

French

Warning

Pour ce qui est de la protection contre les courts-circuits (surtension), ce produit dépend de l'installation électrique du local. Vérifier qu'un fusible ou qu'un disjoncteur de 120V alt., 15A
U.S. maximum (240V alt., 10A international) est utilisé sur les conducteurs de phase (conducteurs de charge).

German

Warning

Dieses Produkt ist darauf angewiesen, daß im Gebäude ein Kurzschluß - bzw. Überstromschutz installiert ist. Stellen Sie sicher, daß eine Sicherung oder ein Unterbrecher von nicht mehr als 240V Wechselstrom, 10A (bzw. in den USA120V Wechselstrom, 15A) an den Phasenleitern (allen stromf¸ hrenden Leitern) verwendet wird.

vNIOS Appliances

vNIOS appliances support most of the features of the Infoblox NIOS software, with some limitations. The subtopics in this section describe these limitations.

- *vNIOS for Appliances Limitations*

> ⚠
>
> ## Notes
>
> - VMware Tools are automatically installed for each vNIOS appliance. Infoblox supports the control functions in Hyper-V Manager and VMware Tools. For example, through the vSphere client, you can shut down the virtual appliance.
> - The VMXNET virtual network adapter for vNIOS is not supported from NIOS 8.4.x onwards.

Infoblox NIOS virtual appliances support any hardware that provides the required Hypervisor version, memory, CPU, and disk resources. To maintain high performance on your NIOS virtual appliances and to avoid not having enough resources to service all the NIOS virtual appliances, do not oversubscribe physical resources on the virtualization host. Required memory, CPU, and disk resources must be adequately allocated for each virtual appliance that is running on the virtualization host. For information about the required specification for each NIOS virtual appliance model, see the following table:

Supported vNIOS Appliance Models and Specifications

NIOS Virtual Appliances	Overall Disk (GB)	# of CPU Cores	Memory Allocation (GB)	Recommended CPU Per Core Clock Rate	NIOS for VMware	NIOS for MS Hyper-V*	NIOS for KVM	NIOS for AWS, Azure and GCP	NIOS for Nutanix AHV	NIOS for Red Hat Open Shift	Supported as Grid Master and Grid Master Candidate
IB-V815**	250	2	16	1100 MHz	✓	✓	✓1	X	✓	X	Yes
IB-V825**	250	2	16	1600 MHz	✓	✓	✓1	✓	✓	X	Yes
IB-V1415**	250	4	32	1200 MHz	✓	✓	✓1	X	✓	X	Yes
IB-V1425**	250	4	32	1800 MHz	✓	✓	✓1	✓	✓	X	Yes
IB-V2215**	250	8	64	2100 MHz	✓	✓	✓1	X	✓	X	Yes
IB-V2225**	250	8	64	2100 MHz	✓	✓	✓1	✓	✓	✓	Yes
IB-V4015**	250	14	128	2400 MHz	✓	✓	✓1	✓2	X	✓	Yes
IB-V4025**	250	16	122	2400 MHz	✓	✓	✓1	✓2	X	X	Yes

NIOS Reporting Virtual Appliances	Overall Disk (GB)	# of CPU Cores	Memory Allocation (GB)	Recommended CPU Per Core Clock Rate	NIOS for VMware	NIOS for MS Hyper-V*	NIOS for KVM	NIOS for AWS, Azure	NIOS for GCP	NIOS for Nutanix AHV	Supported as Grid Master and Grid Master Candidate

CP-V1405	250	4	32	6000 MHz	✓	✓	✓	✓	✓	X	No
CP-V2205	250	8	64	12000 MHz	✓	✓	✓	✓	✓	✓	No

* When running NIOS in MS Hyper-V with dynamic memory allocation enabled, your system might experience high memory usage. To avoid this issue, Infoblox recommends that you disable dynamic memory allocation.
* For optimal performance, vNIOS for Hyper-V is not recommended as a Grid Master or Grid Master Candidate.
* Specifications of vNIOS for Microsoft Azure Stack Hub are different from the other vNIOS for Microsoft Azure flavors. For the exact specifications, see *Infoblox Installation Guide vNIOS for Microsoft Azure*.
** To achieve best performance on your virtual appliances, follow the recommended specifications and allocate your resources within the limits of the licenses being installed on the appliances.
** Specifications of Network Insight appliances for vNIOS for AWS and vNIOS for Azure are different from other vNIOS products. For detailed specifications, see the *Infoblox Installation Guide for vNIOS for AWS* and *Infoblox Installation Guide vNIOS for Microsoft Azure* respectively.

[1] NIOS for KVM is supported in the following environments: Red Hat OpenStack and Ubuntu. Note that only IB-V1405 as a reporting server has been qualified for Red Hat OpenStack.
[2] vNIOS for AWS is supported on the IB-V4025 appliance running NIOS 8.5.2 or later, and IB-V4015 appliance running NIOS 8.6.2 or later. vNIOS for Azure and vNIOS for GCP instances are supported on IB-V4015 and IB-V4025 appliances running NIOS 8.6.2 or later.
[3] vNIOS for AWS and vNIOS for Azure instances are supported only on the IB-V5005 appliance running NIOS 8.6.2 or later. For detailed specifications, see the *Infoblox Installation Guide for vNIOS for AWS* and *Infoblox Installation Guide vNIOS for Microsoft Azure*.

For information about the limitations on each vNIOS appliance, see *vNIOS for VMware Limitations*.

NIOS 8.6.1 is not supported on the following appliances:

IB-250, IB-250-A, IB-500, IB-550, IB-550-A, IB-1000, IB-1050, IB-1050-A, IB-1550, IB-1550-A, IB-1552, IB-1552-A, IB-1852-A, IB-2000, IB-2000-A, IB-VM-250, IB-VM-550, IB-VM-1050, IB-VM-1550, IB-VM-1850, IB-VM-2000, PT-1400, PT-2200, PT-4000, PT-4000-10GE, ND-800, ND-1400, ND-2200, TE-100, TE-810, TE-820, TE-1410, TE-1420, TE-2210, TE-2220, TR-800, TR-1400, TR-2200, IB-4010, IB-4020, TR-4000, IB-4030, ND-V800, ND-V1400, ND-V2200, TE-V810, TE-V820, TE-V1410, TE-V1420, TE-V2210, TE-V2220, TR-V2200, IB-V4010, IB-V4020, TE-V800, TE-V1400, TE-V2200, CP-V800, CP-V1400, CP-V2200, and Trinzic Reporting TR-2000 and TR-2000-A series appliances.

Because these appliances are not supported, Infoblox recommends that you do not upgrade to NIOS 8.6.1 on these appliances.

⚠

Note

- TE appliances are also known as the IB appliances.

- You can freely assign resources to these virtual appliances to suit your business needs, as long as the resources are within the limits of the licenses being installed on the appliances.
- For the latest and most complete list of supported platforms, see the 8.6.1 Release Notes.

vNIOS for Appliances Limitations

This topic lists the limitations on each vNIOS appliance:

- *vNIOS for VMWare Limitations*
- *vNIOS for Hyper-V Limitations*

vNIOS for VMWare Limitations

The Infoblox vNIOS for VMware can also run on Cisco SRE-V (Services Ready Engine Virtualization), which is part of the Cisco UCS (Unified Computing System) Express. For more information about vNIOS for VMware, refer to the *Infoblox Installation Guide for vNIOS Software on VMware*.
vNIOS for VMware appliances support most of the features of the Infoblox NIOS appliances, with the following limitations:

- You must have a vNIOS license installed on the appliance before you can access the Infoblox GUI.
- vNIOS appliances do not support the following features:
  - Configuration of port settings for MGMT, LAN, LAN2, and HA ports
  - The bloxTools environment
- The IB-BOB virtual appliance is supported on Cisco SRE-V and can function as a Grid member only. It does not support configuration as an independent appliance, an HA pair, a Grid Master, or a Grid Master candidate. It also does not support access to the Infoblox GUI.
- The IB-VM-250 virtual appliance supports all the services provided by vNIOS virtual appliances, but it is not recommended as a Grid Master or Grid Master candidate.
- If you are using NIOS versions earlier than 8.6.*x*, if you configure an HA pair, both nodes in the HA pair must be NIOS virtual instances. You cannot configure a physical NIOS appliance and a NIOS virtual instance in an HA pair in versions earlier than 8.6.*x*.
- vNIOS appliances run on virtual hardware. They do not have sensors to monitor the physical CPU temperature, fan speed, and system temperature.
- Changing the vNIOS appliance settings through the VMware vSphere or vCenter console may violate the terms of the vNIOS licensing and support models. The vNIOS appliance may not join the Grid or function properly.

vNIOS for Hyper-V Limitations

vNIOS for Microsoft Windows 2008 R2 and 2012 R2 server appliances support most of the features of the Infoblox NIOS appliances, with the following limitations:

- You must have a vNIOS license installed on the appliance before you can access the Infoblox GUI.
- vNIOS appliances do not support the following features:
  - Configuration of port settings for MGMT, LAN, LAN2, and HA ports
  - The bloxTools environment
- All the IB-VM appliance models support all the services provided by vNIOS virtual appliances, but Grid Master or Grid Master Candidate is not supported.
- The Captive Portal is supported only on IB-VM-1410 virtual appliances.
- vNIOS appliances run on virtual hardware. They do not have sensors to monitor the physical CPU temperature, fan speed, and system temperature.
- Changing the vNIOS appliance settings through the Hyper-V Manager or Virtual Machine Manager Administrator console may violate the terms of the vNIOS licensing and support models. The vNIOS appliance may not join the Grid or function properly.

Guidance Documentation

Common Criteria provides an independent and objective evaluation of the security of Information Technology (IT) products. It gives assurance that the product satisfies a set of internationally recognized security standards.

This section provides additional guidance on the secure installation of the Target of Evaluation (TOE) for Common Criteria Evaluation Assurance Level (EAL) 2. To ensure that your appliance is Common Criteria compliant, make sure that your hardware and software settings match the evaluated configuration that was certified for Common Criteria.

This section should be used as the guiding document for installation of the TOE in the Common Criteria evaluated configuration.

> **Note**
>
> Standalone NIOS is the Common Criteria compliant configuration for the TOE, which does not support Grid configuration.

This section contains the following topics:

Secure Syslog Transport

The TOE provides the secure syslog transport feature using the TLS protocol. This allows secure transmission of messages between the syslog client, i.e. your NIOS appliance, and an external syslog server. You must use this feature to be Common Criteria compliant.
To ensure secure syslog transport, you add a trusted CA certificate of the server to your NIOS appliance. The certificate is then used to establish a secure connection to the server before transmitting data. For more information, see *Specifying Syslog Servers*.

Audit Log

The audit log contains a record of all TOE administrative activities. The stored audit records in the audit trail are protected from unauthorized modifications and deletion. For more information about the audit log, see *Using the Audit Log*.
Following are the events that are logged and examples of their corresponding audit log messages:

Identification and Authentication

Event: Invalid password when logging in to the WebUI.
Message: "2011-10-19 14:02:32.750Z [admin]: Login_Denied - - to=Serial\040Console apparently_via=Directerror=invalid\040login\040or\040password"

Event: Number of attempts exceeds the limit when logging in to the WebUI.
Message: "2011-10-19 14:05:23.217Z [admin]: Login_Denied - - to=Serial\040Console apparently_via=Directerror=failed\040logins\040exceed\040limit"

Event: Invalid password when logging in to the CLI.
Message: "2011-10-19 14:02:32.750Z [admin]: Login_Denied - - to=Serial\040Console apparently_via=Directerror=invalid\040login\040or\040password"

Event: Number of attempts exceeds the limit when logging in to the CLI.
Message: "2011-10-19 14:05:23.217Z [admin]: Login_Denied - - to=Serial\040Console apparently_via=Directerror=failed\040logins\040exceed\040limit"

Event: Enable Common Criteria mode:
Message: 2011-10-19 19:48:37.299Z [admin]: Login_Allowed - - to=Serial\040Console apparently_via=Directauth=Local group=.admin-group

Message: 2011-10-19 19:48:48.705Z [admin]: Called - set_cc_mode: Args cc_mode_enabled="true"
Event: Disable Common Criteria mode:
Message: 2011-10-19 19:48:37.299Z [admin]: Login_Allowed - - to=Serial\040Console apparently_via=Directauth=Local group=.admin-group
Message: 2011-10-19 19:48:48.705Z [admin]: Called - set_cc_mode: Args cc_mode_enabled="false"

Event: Login successful
Message: 2011-10-19 19:48:48.706Z [USER\040admin]: rebooted the system
2011-11-01 17:09:21.696Z [admin]: Login_Allowed - - to=Serial\040Console apparently_via=Direct auth=Localgroup=.admin-group

Event: First login
Message: 2011-10-19 12:43:47.375Z [user]: First_Login - - to=AdminConnector ip=127.0.0.1 auth=LOCALgroup=admin-group apparently_via=GUI first login

Event: Password expired

WAPI Detailed

You can view detailed WAPI session information logs in the audit log for successful WAPI calls such as PUT, POST, and DELETE. For more information, see *Monitoring Tools*.

Event: Member restart or reboot service
Message: [2018-07-10 16:23:08.112Z] [admin]: Called(POST) v2.9/member {“_function”:”restartservices”, “restart_option": "FORCE_RESTART","service_option": "ALL"} 3.081 MemberRestartServices: Args service_option="ALL",grid_member=Member:infoblox.localdomain,restart_option="FORCE_RESTART"

Event: All succeeded function calls

Message: [2018-07-28 08:56:44.399Z] [admin]: Called(POST) v2.9/network {"_function":"next_available_ip"} 0.034 NextAvailableIp: Args parent=Network:2.2.2.0/24\054network_view\075default

Event: Enhanced audit log for POST method

Message: [2018-05-29 09:20:12.026Z] [admin]: Created(POST) v2.9/zone_auth {"fqdn":"foo.com"} 2.233 AuthZone foo.com DnsView=default: Set fqdn="foo.com"

Event: Enhanced audit log for PUT method

Message: 2018-06-07 08:45:25.681Z [admin]: Modified(PUT) v2.2/zone_auth {"comment":"testing auditlogs"} 1.930 AuthZone foo.com DnsView=default: Changed comment:NULL->"testing auditlogs"

Event: Enhanced audit log for DELETE method:

Message: 2018-07-24 13:11:26.614Z [admin]: Deleted(DELETE) v2.6/zone_auth {} 0.356 AuthZone foo.com DnsView=default exclude_subobj=False

Host Record Logging

NIOS inserts two records for each host record object and the audit log displays the URI, InData and response time twice, that is, one for the host record and the other one for the host address/host alias records.

Example of Host Record logging: curl -H "Content-Type: application/json" -k -u admin:infoblox -X POST https://10.120.20.129/wapi/v2.0/record:host -d '{ "ipv4addrs":[{"ipv4addr" : "1.1.1.0","configure_for_dhcp" : false, "mac" : "aa:0:0:0:1:cc" }], "comment":"this is my one.perfusera comment","view":"default","name":"perfusera.test.com"}'

Message: 2018-07-24 12:27:40.375Z [admin]: Created(POST) v2.0/record:host {"ipv4addrs":[{"ipv4addr" : "1.1.1.0","configure_for_dhcp" : false, "mac" : "aa:0:0:0:1:cc" }],"comment":"this is my one.perfusera comment","view":"default","name":"perfusera.test.com"} 0.236 HostAddress 1.1.1.0 network_view=default: Set address="1.1.1.0",configure_for_dhcp=False,mac_address="aa:0:0:0:1:cc",match_option="MAC_ADDRESS",parent=HostRecord:._default.com.foo.perfusera

Message: 2018-07-24 12:27:40.375Z [admin]: Created(POST) v2.0/record:host {"ipv4addrs":[{"ipv4addr" : "1.1.1.0","configure_for_dhcp" : false, "mac" : "aa:0:0:0:1:cc" }],"comment":"this is my one.perfusera comment","view":"default","name":"perfusera.test.com"} 0.236 HostRecord perfusera.foo.com DnsView=default address=1.1.1.0: Set addresses=[address="1.1.1.0"],comment="this is my one.perfusera comment",fqdn="perfusera.foo.com",view=DnsView:default

Requesting an Object

Each WAPI call for a request object shows the timestamp, user, operation, URI, InData, and the response time.

Example of Request object: https://10.35.120.1/wapi/v2.9/request body : [{ "method": "POST", "object": "network", "data": {"network": "22.2.2.0/24"} }, { "method": "POST", "object": "network", "data": {"network": "111.1.111.0/24"} }]

Message: 2018-10-24 11:18:18.828Z [admin]: Created(POST) v2.9/request [{'object': 'network', 'data': {'network': '22.2.2.0/24'}, 'method': 'POST'}, {'object': 'network', 'data': {'network': '111.1.111.0/24'}, 'method': 'POST'}] 5.5867

Message: 2018-10-24 11:18:18.828Z [admin]: Created Network 22.2.2.0/24 network_view=default: Set address="22.2.2.0",cidr=24

Message: 2018-10-24 11:18:18.828Z [admin]: Created Network 111.1.111.0/24 network_view=default: Set address="111.1.111.0",cidr=24

Scheduling an Object

For a schedule object, PUT/POST/DELETE calls and WAPI session log information, such as URI, InData, and response time, are added only in the first line.

Example of Schedule object: curl -k1 -u admin:infoblox -X POST https://10.35.120.1/wapi/v2.9/network -d network=3.3.8.0/24 -d _schedinfo.scheduled_time=1540386870

Message: 2018-10-24 11:22:01.998Z [admin]: Sched:3 Created(POST) v2.9/network {'_schedinfo.scheduled_time': '1540380251', 'network': '3.3.8.0/24'} 1.7615 Network 3.3.8.0/24 network_view=default: Set address="3.3.8.0",cidr=24

Message: 2018-10-24 11:22:01.998Z [admin]: Sched:3 Created ScheduledTask 3: Set scheduled_time=2018-10-24 11:24:11.000Z,submit_time=2018-10-24 11:22:01.983Z,submitter="admin",type="SCHEDULED

Database Backup

NIOS logs information about who started the database backup and where the database backup file is stored.

Event: Successful database backup
Message: 2020-06-03 10:15:28.634Z [admin]: Called - GetGridData message=backed\040up\040database\040at\040scp\072//root:****@10.120.20.38/tmp/adf: Args message="backed up database at scp://root:****@10.120.20.38/tmp/adf" 2020-06-03 10:15:28.852Z [admin]: Called - DataGetComplete message=data\040get\040completed: Args message="data get completed

Backing Up and Restoring the Database

You must log in with a superuser account to back up files. The administrator must back up system files to the local appliance.
You can restore a backup up file to an appliance running the same NIOS version as that of the appliance from which the

backup file originates. You can also restore a backup file from an appliance running a NIOS version to an appliance running a later NIOS version as long as the upgrade from the earlier NIOS version to the later version is supported. Note that if you need to restore a backup file to an appliance, ensure that the backup file that you are restoring is from an appliance that was Common Criteria compliant as well. NIOS stores information such as who started the database backup and where the backup file is stored in the audit log. For more information see *Audit Log*.

For more information about backing up and restoring the database, see *Backing Up and Restoring Configuration Files*.

About DNS

The TOE provides DNS service. There are two basic methods used to protect DNS communication: TSIG and GSS-TSIG. The TSIG (transaction signature) method signs communications using either HMAC-MD5 or HMAC-SHA25. Both end points must be configured with the key. The GSS-TSIG method (based on the GSS API) uses a Kerberos server to retrieve the key, and is only available in Microsoft environments.
When you configure the TOE to use TSIG and GSS-TSIG keys, you must select HMAC-SHA256 as the key algorithm. For information about using TSIG keys to ensure security in several DNS operations, see the following:

- To control access to DNS views. For more information, see *Defining Match Clients Lists* and *Configuration Example: Configuring a DNS View*.
- To control to which recursive and non-recursive queriers the TOE is allowed to respond. For more information, see *Specifying Queries* and *Enabling Recursion*.
- To authenticate zone transfer requests and replies. For more information, see *Configuring Zone Transfers*.
- To authenticate and verify dynamic DNS updates from DHCP servers. For more information, see *Enabling DNS Servers to Accept DDNS Updates*.
- When a secondary DNS server receives DDNS updates, it must forward the updates to the primary server because it cannot update zone data itself. To specify the source of DDNS updates. For more information, see *Forwarding Updates*.

For information about using GSS-TSIG, see *About GSS-TSIG*.

WebUI Settings

This section describes the properties that you can set to ensure the security of the Grid Manager web interface.

Creating a Login Banner

Before establishing a user session via the WebUI, the TOE displays an initial banner regarding unauthorized use. The message is displayed before the session is established. You can change this message to your organization's specific advisory notice and warning message regarding unauthorized use of the system. For information about defining the login banner, see *Creating a Login Banner*.

Modifying the Session Timeout Setting

You can set the length of idle time before an administrative session to the WebUI times out. The default timeout value is 600 seconds (10 minutes). If an admin does not interact with the application for the specified time, the TOE displays a message that a timeout has occurred. The admin is then required to lag back in to Grid Manager. For information about setting the session timeout, see *Modifying the Session Timeout Setting*.

Managing Certificates

The TOE generates a self-signed certificate when it first starts. Because the default certificate is self-signed, your browser does not have a trusted CA certificate or a cached NIOS appliance server certificate (saved from an earlier connection) to authenticate the NIOS appliance certificate. Also, the hostname in the default certificate

is[www.infoblox.com,|http://www.infoblox.com/] which is unlikely to match the hostname of your NIOS appliance. Consequently, a message appears warning that the certificate is not from a trusted certifying authority and that the hostname on the certificate is either invalid or does not match the name of the site that sent the certificate. To eliminate certificate warnings, you can replace the default self-signed certificate with a different certificate.
After the initial login, you can do one of the following:

- Generate another self-signed certificate with the correct hostname and save it to the certificate store of your browser.
- Request a CA-signed certificate with the correct hostname by generating a Certificate Signing Request (CSR) and sending it to your trusted Certificate Authority (CA). Then when you receive the certificate from the CA, import it to the appliance.

For information about these tasks, see *Managing Certificates*.
For Common Criteria compliance, superusers must not use CSRs or certificates with keys smaller than 2048 bits. Limited access users are not allowed to upload a certificate with a key that is smaller than 2048 bits, or create a certificate signing request or self-signed certificate with a key size that is smaller than 2048 bits.

Licenses and Services

The TOE does not have general computing capabilities, other than the services required for the operation, administration and support of the TOE. In the evaluated configuration, the TOE has only the following licenses installed: DNS, DHCP, Microsoft Management, DNS Cache Acceleration and Query Redirection. It does not have the Multi-Grid Management license installed. For more information about licenses, see *Managing Licenses*.
The following services are disabled by default in the Common Criteria evaluated configuration and no claims are made regarding their function:

- bloxTools
- MGM (Multi-Grid Management)
- HSM (Hardware Security Module) Signing
- Support access
- Remote console access
- Remote authentication using RADIUS and TACACS+

Installing additional licenses or enabling any of the listed services may result in a non-compliant system.

Enabling / Disabling Common Criteria Mode

⚠ Infoblox recommends that you do not change the Common Criteria setting of a NIOS appliance that is in a production environment.

Before you enable Common Criteria mode, you must reset a NIOS appliance to its original factory settings. This removes the database, network settings, logs, and configuration files. Then, it reboots with its factory settings, which are the default user name and password, and default network settings. If you do not reset the appliance to its original factory settings, the appliance will not be Common Criteria compliant, even if you enable Common Criteria mode.

To reset the NIOS appliance to its factory settings:

1. Log in to the Infoblox CLI using a superuser account.
2. Enter the following CLI command:
   `reset all`

You can enable and disable Common Criteria mode from the Infoblox CLI only. Do the following to set Common Criteria mode on the appliance:

1. Log in to the Infoblox CLI. After executing the `resetall` command, you can log in to the TOE only by using the default superuser admin name `admin` and password `infoblox`.

2. Type the following command:
   `set cc_mode`

The TOE reboots and goes through boot time self tests. If the test fails, the TOE goes into a loop and displays an error message on the serial console and the LCD. Otherwise, it displays the Login prompt after the self tests.

To clear Common Criteria mode on an appliance, log in to the Infoblox CLI and execute the command: `reset all`.

Using the CLI

Only superusers can access the CLI. To ensure security, access to the CLI is permitted through a direct console connection only. Note that activating the option **Enable Remote Console Access** in the Grid or Member Properties editor will result in a non-compliant system.
To access the Infoblox CLI through the console port:

1. Connect a serial cable from the console port on your management system to the console port on the appliance. The appliance has a male DB-9 console port on its front panel.
2. Use the following connection settings to launch an emulation session through a serial terminal emulation program such as Hilgraeve Hyperterminal® (provided with the Windows® operating systems):
   - Bits per second: 9600
   - Data bits: 8
   - Parity: None
   - Stop bits: 1
   - Flow control: Xon/Xoff
3. Use the following default user name and password to log in to the Infoblox appliance:
   `admin`
   `infoblox`

> **Note**
>
> After you log in, change the default user name and password of the default superuser admin to prevent unauthorized access to the TOE. For more information on changing passwords, see *Changing the Password and Email Address*.

For more information about the Infoblox CLI, refer to the *Infoblox CLI Guide*.

Administration

A user must have an admin account to log in to the TOE. Each admin account belongs to an admin group, which contains roles and permissions that determine the tasks a user can perform.
The TOE provides a default superuser admin group, called **admin-group**, with one superuser administrator, **admin**. The default superuser admin can log in to the TOE, using the default user name **admin** and password **infoblox**.
Superuser admins are the security admins and have full access and control of all the operations of a TOE. Note that you must change the default user name and password of the default superuser admin to prevent unauthorized access to the TOE.
Only superusers can do the following:

- Create admin accounts and groups. For more information, see *Managing Administrators*.
- Set password parameters. For more information, see *Managing Passwords*.
- Create the login banner. For more information, see *Creating a Login Banner*.
- Set the session timeout. For more information, see *Modifying the Session Timeout Setting*.

Limited-access admin groups provide their members with read-only or read/write access to specific resources. These admin groups can access the appliance through the GUI, API, or both. They cannot access the appliance through the console. In addition, limited-access admins are not allowed to perform the following tasks:

- Download the support bundle.
- Enable SNMP on the appliance.
- Upload files that are larger than 100 MB. If the file size is greater than the maximum size allowed, the **Upload** dialog box closes and an error message is displayed in the feedback panel. The attempt to upload a file that exceeded the maximum will be logged to syslog. Non-superusers only are able to upload files for file distribution and do CSV import.

Setting Password Restrictions for Local Admins

All admins are required to enter a username and password when they log in to Grid Manager or the CLI. The password is always obscured when an admin logs in. The TOE defaults to locking out the user after three consecutive failed logins. A superuser must define a password policy that is consistent with the security policy of the organization. The password policy specifies the minimum password length and character types, such as lowercase or uppercase characters, that are allowed in the password. In addition, the policy specifies the number of required character changes from the previous password, whether passwords expire and their duration. Additionally, you can require admins to change their passwords when they first log in or after their passwords are reset. For information about defining the password policy, see *Managing Passwords*.

Local admins must change their passwords according to the defined password policy. A password can be changed as follows:

- By the local admin in the User Profile page. For more information, see *Changing the Password and Email Address*.
- By the local admin when a password expires or when the admin first logs in. Note that this applies to logging in to the CLI or WebUI.
- By a superuser admin.

Security Guidelines

Following are security assumptions to ensure that the TOE is administered in a secure manner after it is delivered:

- The environment ensures the physical security of the TOE, commensurate with its value and the value of the data that it contains.
- Administrators are non-hostile, properly trained and trusted to apply all administrator guidance.
- Administrators will take appropriate measures to prevent unauthorized individuals from accessing the TOE.

Installation and Configuration

To ensure the security of the installation and configuration of the TOE:

- Administrators must install the appliance according to the procedures in the installation guides.
- The TOE contains an option for upgrading the system. This is available only for security administrators. The security administrator will be able to upgrade to a validated release package only. The security administrator can verify the TOE by the version number included in the file name as well as through the administrative interface before and after the upgrade.
  When upgrading, ensure that the .bin2 file is uploaded, and not the .bin file. Refer to the Release Notes of the NIOS version to which the TOE is upgrading for additional upgrade instructions.
- Users' access to the TOE is controlled by security mechanisms and unauthorized users are denied access to the TOE. For more information, see *Administration*.
- The TOE provides external authentication mechanisms for remote users using SSL with Active Directory. For more information, see *Authenticating Admins Using Active Directory*.

Syslog

NIOS `appliances` generate syslog messages that you can view through the Syslog viewer and download to a directory on your management station. For more information about syslog, see *Using a Syslog Server*.

Following are the events that are logged and examples of their corresponding syslog messages:

```
\\
*Establishment/Termination* *of* *an* *HTTPS* *Session*
*Event:* Generation of RSA key failed.
*Message:* "Oct 19 09:15:01 EPBYMINW0065T1 httpd\[2115\]: cryptographic key generation
failed"
\\
*Cluster logout*
*Event:* Cluster logout.
*Message:* "2020-06-03T12:58:13+00:00 daemon infoblox.localdomain INFOBLOX-Grid[]: notice
Cluster logout for node <node_name>, for node clean restart.
\\
*Event:* Session is terminated.
*Message:* "Oct 19 09:15:01 EPBYMINW0065T1 httpd\[2115\]: Session terminated (remote
address: 10.6.11.249)"

CSV Import Reference

This section provides reference information during a CSV import. It contains the following topics:

Documentation Conventions

The text in this guide uses the following style conventions:

Style	Usage
bold	Indicates examples of the field names.
`data`	Signifies the data in a CSV file.

Customer Care

This section addresses user accounts, software upgrades, licenses and warranties, and technical support.

User Accounts

The Infoblox appliance ships with a default user name and password. Change the default admin account password immediately after the system is installed to safeguard its use. Make sure that the NIOS appliance has at least one administrator account with superuser privileges at all times, and keep a record of your account information in a safe place. If you lose the `admin` account password, and did not already create another superuser account, the system will need to be reset to factory defaults, causing you to lose all existing data on the NIOS appliance. You can create new administrator accounts, with or without superuser privileges. For more information, refer to the *Infoblox Administrator Guide*.

Software Upgrades

Software upgrades are available according to the Terms of Sale for your system. Infoblox notifies you when an upgrade is available. Register immediately with Infoblox Technical Support at *http://www.infoblox.com/support/customer/evaluation-and-registration* to maximize your Technical Support.

Technical Support

Infoblox Technical Support provides assistance via the Web, e-mail, and telephone. The Infoblox Support web site at *https://support.infoblox.com* provides access to product documentation and release notes, but requires the user ID and password you receive when you register your product online at: *http://www.infoblox.com/support/customer/evaluation-and-registration.*

Guidelines for CSV Import

This section provides general guidelines and file format information about each supported object type for CSV import. You must follow the format and syntax described in this section to ensure a successful data import.

You can create a data file using a text editor, such as Microsoft Notepad, or an application that supports CSV file format, such as Microsoft Excel. You can also import data using Infoblox Migration Wizard, which is a standalone software tool that facilitates the migration of DNS and DHCP data from Microsoft servers to the Infoblox Grid. This tool synchronizes DNS and DHCP data from Microsoft servers and generates a CSV file based on conversion rules you set up through the tool. You can then import the CSV data to the Infoblox Grid through CSV import. For more information, refer to the *Infoblox Administrator Guide for Infoblox Migration Wizard*.

CSV imports and operations that involve massive data, such as deleting large zones and recursive deletion of networks and all child objects, will significantly affect member performance, resulting in service outage.

General Guidelines

Follow these rules to start a data file:

- Do not use UTF-8 characters in the CSV file name, but the contents of a CSV file must be encoded in UTF-8 characters. Note that Microsoft Excel imports data in the default code page, either in ISO-8859-1 or WINDOWS-1252. You must not import a CSV file that is encoded in Windows 1252 or ISO-8859-1 formats.
- Use a new line to enter data for each row. Separate each data field with a supported separator, such as a comma, semicolon, space, or tab.
- Do not include blank lines in the data file.
- Field names: Specify the field names in the second line. You can include multiple rows of field names as long as you define the fields before the data. The first column in the field name row must be defined as "Header." The rest of the columns are field names of the data. Columns without a field name are ignored. If multiple field names are specified, the latest field names are used to import the data.
- It may take longer than expected to import a large number of DHCP ranges that are associated with a single MAC address filter.
- When a CSV import starts, the appliance validates the first 100,000 rows of data in the CSV file. If the file contains more than 100,000 rows of data, the appliance validates the rest of the data as the import progresses.
- The appliance supports up to one million rows of data in each CSV import.
- Use the add function to add new rows from the imported CSV file to the database.
- Use the **Override** function, not the merge function, to overwrite existing data. When you use the merge function, the appliance does not overwrite existing data, even if the data file contains new data.
- Use the **Delete** function to delete import jobs that are uploaded. You can delete the content of a CSV file that you have imported to the database. Note that you cannot delete jobs that are already imported.
- Use the **Replace** operation to replace current data in the database with data in the imported file. You can use the replace function for authoritative zone data only. The replace operation might affect system performance if you try to replace a zone with a lot of changes. Infoblox recommends that you perform the replace operation for large import files (more than 10,000 rows of changes) during non-peak hours. This operation does not support DNS records that are automatically generated or exported, but it supports NS records that are created manually.
- When you import CSV files for NS record updates, you must specify a value for **zone_nameservers**. NIOS displays an error message if you do not specify a value for this field when you import the CSV file.
- When you perform a CSV export of automatically created NS records using Infoblox API, the **zone_nameservers** field will have an empty value. Therefore, if you import the previously exported CSV file that includes automatically created NS records through the Infoblox GUI, then the CSV import fails and Grid Manager displays an error message.
- When you perform a CSV import that includes objects that have scheduled changes or updates associated with them, the import fails. Only superusers can cancel the scheduled changes.
- When you stop an import, the appliance completes the import of the data row it is currently processing before it stops the import. You cannot resume the import from where it stopped.
- You can download uploaded or error files, snapshots, and results file. For more information, see *Infoblox NIOS Administrator Guide.*

- When you import a small file, the appliance processes the import quickly. Under this circumstance, the appliance may generate an error message when you try to stop the import because the import is completed before you can stop it.
- The error files of the last two imports are stored on the appliance. You can download these files using the APIimport_id method. For information, refer to the *Infoblox API Documentation*.
- When you use Microsoft Excel to create or view a data file, ensure that you review the settings of the file. Some data, such as dates, may show up in a different format depending on your settings.
- All operations triggered by a CSV import are recorded in the audit log.

Data Specific Guidelines

Follow these guidelines to enter data:

- The appliance uses double quotes (") as the escape characters in CSV import. If you want to include supported separators in a field, you must enclose the data in a pair of double quotes (" "). This applies to the field names and data. For example, if you want to use the field name **ADMGRP-CSV,;Import**, you must enter **"ADMGRP-CSV,;Import"** as the value. Otherwise, the import fails. When you enter "123""123", the imported data is 123""123, and when you enter "\ \ ", the imported data is \ \.
- If you have an empty value in the last field, you must still include the separator at the end of the data row. Otherwise, the corresponding column and all its data are not imported, and the appliance generates an error.
- For each supported object type, you must include all the required fields in the data file. For information, see *Supported Object Types*. All required fields are marked with an asterisk (*) in an exported file.
  Note that if you want to modify a required field XXX (for either the overwrite or merge function), you must add a corresponding field, *new_XXX, to include the new value. For example, "fqdn" is a required field in an A record. If you want to update this field, you must include a new field "_new_fqdn" and define the new value here. The appliance overwrites the existing data in the required field using the values you specify in the new field. Note that the replace function ignores __new_XXX* fields in the imported CSV files.
- When you perform an overwrite function, you must define all boolean and integer data types in each supported object type in order for the appliance to overwrite existing data.
- Inherited fields: The appliance uses the following conventions to override inherited fields:
  - When a value is specified in a field, the appliance overrides the inherited value with the new value.
  - When a value is set to " " or an empty value, the appliance does not override the inherited value.
  - When a value is set to a string with a value of <empty>, the appliance overrides the inherited value with an empty value.
- Extensible attributes: A field name of EA-XXX indicates an extensible attribute, where XXX is the attribute name. The value of an extensible attribute can be a string, a list, an integer, an email address, a URL, or a date in YYYY-MM-DD format. Note that extensible attributes do not support time zones. Following are some examples:
- "EA-Site" is a predefined string type for locations. It can have a value of "Santa Clara".
- "EA-User" is a user defined list type for employee types. It can have a list of values, such as "Local,Remote,Temp". Note that only one value can be specified when importing the extensible attribute.
- "EA-Building" is a predefined integer type for building numbers. It can have a value of "5".
- "EA-TechPubs" is a user defined email address type. It can have a value of "techpubs@infoblox.com".
- "EA-IB" is a user defined URL type. It can have a value of "*www.infoblox.com*".
- "EA-Date" is a user defined date type attribute. It can have a value of "2010-11-20".
- Admin permissions: A field name of ADMGRP-XXX indicates the admin permission of a specific admin group, where XXX is the name of the admin group. The value of an admin permission can be a string or a list of strings with subtypes. If there is a single value in the permission, use RW, RO, or DENY. If there is a subtype in the permission, use a list format, such as "RW, ARecord/RO".
- DHCP options: A field name of OPTION-XXX-nn indicates a DHCP option, where XXX is the vendor name of the option and nn is the option number. If the option is of the DHCP vendor class, you can omit -XXX in the field name. For example, OPTION-1 implies vendor class = DHCP and option number = 1, and OPTION-CISCO-122 implies vendor class = CISCO and option number = 122.
- Named ACLs (access control lists): When you import a named ACL or ACEs (access control entries) to a named ACL, ensure that you validate the named ACLs to avoid conflicts and unexpected results. When adding ACEs to a named ACL, all entries are appended to the end of the list. To reorder ACEs in a named ACL through CSV import, you must first export the ACEs, delete all the ACEs in the current ACL, reorder the ACES in the exported .csv file, and than re-import the ACEs to the named ACL. For more information about access control and named ACLs, refer to the *Infoblox NIOS Administrator Guide*.

CSV Import Limitations

Ensure that you understand the following limitations before you start an import:

- You can import multiple CSV files at a time, but at any given time you can execute only one single task. The import tasks are queued. Note that only one task at a time will be in the **Import in progress** state, while the others are in the **Import pending** state.
- You cannot roll back to previous data.
- The following data cannot be imported: Microsoft management, DNSSEC, and GSS-TSIG data.
- You cannot export or import zone configuration for DNSSEC signed zones, although resource records added for a signed zone are supported.
- Only editable data can be imported. Discovered data cannot be imported or manipulated.
- If you upload a file and preview the file using the **Preview** option, and later update the content of the same CSV file, and then try to view the edited file using the same *Preview* wizard, you may not be able to see the changes. Infoblox recommends that you start a fresh CSV import to upload the edited file and navigate to the *Preview* wizard to preview the file.
- You cannot perform the CSV import operation on a Microsoft Server zone object, but NIOS allows you to perform the CSV import operation on records within a Microsoft Server zone. You may not see an error message when you perform a CSV import using the replace operation on an Microsoft Server zone.
- When you promote a new Grid Master during an import, the import stops; and it does not restart on the new Grid Master. When a failover occurs during an import, the import stops on the old active node, and it does not restart on the new active node.
- When you configure Unbound as the DNS resolver, NIOS does not support certain features and they are not displayed in Grid Manager. However, fields related to these unsupported features will appear in CSV export files. Although these fields are only relevant to the IB-4030-10GE appliance and might not apply to the appliances in your Grid, you can still perform CSV imports using these CSV export files without any issues.

Limitations for CSV Import and Export

Ensure that you understand the following limitations before you start an import:

- You can import multiple CSV files at a time, but at any given time you can execute only one single task. The import tasks are queued. Note that only one task at a time will be in the **Import in progress** state, while the others are in the **Import pending** state.
- You cannot roll back to previous data.
- You cannot import network containers.
- The following data cannot be imported: Microsoft management, DNSSEC, and GSS-TSIG data.
- You cannot export or import zone configuration for DNSSEC signed zones, although resource records added for a signed zone are supported.
- Only editable data can be imported. Discovered data cannot be imported or manipulated.
- If you upload a file and preview the file using the **Preview** option, and later update the content of the same CSV file, and then try to view the edited file using the same *Preview* wizard, you may not be able to see the changes. Infoblox recommends that you start a fresh CSV import to upload the edited file and navigate to the *Preview* wizard to preview the file.
- You cannot perform the CSV import operation on a Microsoft Server zone object, but NIOS allows you to perform the CSV import operation on records within a Microsoft Server zone. You may not see an error message when you perform a CSV import using the replace operation on an Microsoft Server zone.
- When you promote a new Grid Master during an import, the import stops; and it does not restart on the new Grid Master. When a failover occurs during an import, the import stops on the old active node, and it does not restart on the new active node.
- When you configure Unbound as the DNS resolver, NIOS does not support certain features and they are not displayed in Grid Manager. However, fields related to these unsupported features will appear in CSV export files. Although these fields are only relevant to the IB-4030-10GE appliance and might not apply to the appliances in your Grid, you can still perform CSV imports using these CSV export files without any issues.
- During the start of the CSV export, only the approximate number of objects to be exported is displayed on Grid Manager. You can get the total exported object count only after the CSV export is complete.

CSV File Format

A CSV file is typically created and edited using a spreadsheet, though you can create a CSV file in a text editor using any supported separator. You can include more than one object type in a single CSV file when you add or modify data. For information, see *Supported Object Types*. You can also organize field names and data in a CSV file using different formats, as shown in the following examples. For additional information about how to create a CSV file, see *Guidelines for CSV Import*.

You can create one CSV file to update data of multiple object types (Network and Host Record), as illustrated in *CSV File Example 1*. In this example, you define the field names you want to modify for the two object types in rows 1 and 2. You then include the corresponding data as shown in rows 3 to 6.

CSV File Example 1

	A	B	C	D	E
1	**HEADER-NETWORK**	**ADDRESS***	**NETMASK***	**EA-Gateway**	**EA-Secondary Address**
2	**HEADER-HostRecord**	**configure_for_dns***	**FQDN***	**ADDRESSES**	
3	NETWORK	10.251.133.128	255.255.255.192	10.251.133.129	
4	NETWORK	10.176.80.255	255.255.252.0	10.176.80.1	172.16.213.0
5	HostRecord	TRUE	host1.dhcp.corp100.com	172.20.2.21	
6	HostRecord	TRUE	host2.dhcp.corp100.com	172.20.2.22	

In the above example the field name HEADER-NETWORK identifies the first row as a header row for the Network objects. The field names ADDRESS, NETMASK, EA-Gateway, and EA-Secondary Address (in rows B1 to E1) tell NIOS how to interpret a row of network data in the CSV file. Each row of data that begins with "Network" in column A is identified as a network data row. Therefore, NIOS interprets rows 3 and 4 as network data rows, in which column B contains the network addresses, column C contains the network masks, and columns D and E contain extensible attribute values for gateway and secondary address.

Similarly, the field name HEADER-HostRecord identifies the second row as a header row for the Host Record objects. This header declaration tells NIOS that for each subsequent row of data that begins with "HostRecord" in column A, column C contains the FQDN of the host, and column D contains the host address. Therefore, NIOS interprets rows 5 and 6 as host record data rows that contain the FQDNs of the hosts in column C and the host addresses in column D. Alternatively, you can organize the information in the table above so that the data rows immediately follow the header rows, as shown in *CSV File Example 2*.

CSV File Example 2

	A	B	C	D	E
1	**HEADER-NETWORK**	**ADDRESS***	**NETMASK***	**EA-Gateway**	**EA-Secondary Address**

2	NETWORK	10.251.133.128	255.255.255.192	10.251.133.129	
3	NETWORK	10.176.80.255	255.255.252.0	10.176.80.1	172.16.213.0
4	**HEADER-HostRecord**	**configure_for_dns***	**FQDN***	**ADDRESSES**	
5	HostRecord	TRUE	host1.dhcp.corp100.com	172.20.2.21	
6	HostRecord	TRUE	host2.dhcp.corp100.com	172.20.2.22	

You can also specify multiple header declarations for the same object type, as shown in *CSV File Example 3*. In this example, you specify the field names (in row 1) and data (in rows 2 and 3) to modify the extensible attributes (EA-Gateway and EA-Secondary Address) of two network addresses. You then specify the field names (in row 4) and data (in rows 5 and 6) to add new extensible attributes (EA-Gateway and EA-Host Range) of two other network addresses.

CSV File Example 3

	A	B	C	D	E
1	**HEADER-NETWORK**	**ADDRESS***	**NETMASK***	**EA-Gateway**	**EA-Secondary Address**
2	NETWORK	10.251.133.128	255.255.255.192	10.251.133.129	
3	NETWORK	10.176.80.255	255.255.252.0	10.176.80.1	172.16.213.0
4	**HEADER-NETWORK**	**ADDRESS***	**NETMASK***	**EA-Gateway**	**EA-Host Range**
5	NETWORK	10.176.90.0	255.255.255.128	10.176.90.1	10.176.90.4-126
6	NETWORK	10.176.90.128	255.255.255.128	10.176.90.129	10.176.90.132-254

The examples in this section are illustrated using tables that resemble spreadsheet layouts. However, all other examples in this appendix use the comma separated value text file format. For example, the following is the CSV file notation equivalent of *CSV File Example 2*.

```
HEADER-NETWORK,ADDRESS*,NETMASK*,EA-Gateway,EA-Secondary Address
NETWORK,10.251.133.128,255.255.255.192,10.251.133.129
NETWORK,10.176.80.255,255.255.252.0,10.176.80.1,172.16.213.0 HEADER-
HostRecord,FQDN*,ADDRESSES
 HostRecord,host1.dhcp.corp100.com,172.20.2.21
HostRecord,host2.dhcp.corp100.com,172.20.2.22
```

IDN Support for CSV Import

The appliance supports IDNs (Internationalized Domain Names) and punycode for most of the DNS object types in a CSV file. An IDN is a domain name that contains a language-specific script or alphabet, such as Arabic, Chinese, Russian, Devanagari, or the Latin alphabet-based characters with diacritics, such as French. IDNs are encoded in multi-byte Unicode and are decoded into ASCII strings using a standardized mechanism known as Punycode transcription. For example, DNS Zone 'инфоблокс.рф' (IDN in Russian) can be written as 'xn-90anhdigczv.xn-p1ai' in the punycode representation. For information about IDNs, refer to the Infoblox NIOS Administrator Guide.
You can use either IDNs or punycode to create DNS zones. Even if you use punycode to create a zone, the appliance automatically generates the corresponding IDN and displays the zone name in its native characters. Note that the appliance does not perform any conversion (IDN to punycode and vice versa) for DNS records, but preserves the data in the original characters. In other words, if a DNS object or a field name contains IDN, the appliance imports the data in IDN. If a DNS object or a field name is in punycode, the appliance imports the data in punycode. For more information about supported objects for CSV import, see *Supported Object Types*.

CSV Import for Response Policy Zones

You can import local RPZs (Response Policy Zones) and their rulesets using the **CSV Import** feature. When you import local RPZs using this feature, you must specify three new columns, **priority, rpz_policy,** and **substitute_name** with relevant values, whereas importing an RPZ ruleset requires specifying the value for parent RPZ in the **parent_zone** column, as mentioned in the following tables. For a local RPZ, CSV import supports all the values that are listed in *Authoritative Zone* along with the three new columns. However, for RPZ rulesets it supports the values that are listed in *CNAME Record* along with a new column **parent_zone**.
For example, if you want to add a new local RPZ, **JKL.INFO** and substitute this domain with **JKI.NET**, then you must mention the priority, rpz_policy, and substitute name as follows:

A	B	C	D	E	F	G	H	I
HEADER-RESPONSEPOLICYZONE	**FQDN***	**ZONE_FORMAT***	**ALLOW_UPDATE**	**PRIORITY**	**RPZ_POLICY**	**SUBSTITUTE_NAME**	**VIEW**	**ZONE_TYPE**
RESPONSEPOLICYZONE	ABC.NET	FORWARD	TSIG-RPZ_LOCAL_UPDATER_KEY._default. abc.net/kA36uJeavmhrH2Yqx8hEDPC6okSFcsOb2evyWVAO5f M=/ALLOW/HMAC-S HA256	1001	GIVEN		DEFAULT	RESPONSE POLICY
RESPONSEPOLICYZONE	XYZ.IN	FORWARD	TSIG-RPZ_LOCAL_UPDATER_KEY._default. xyz.in/kA36uJeavmhrH2Yqx8hEDPC6okSFcsOb2evyWVAO5f M=/ALLOW/HMAC-SHA2 56	1002	NXDOMAIN		DEFAULT	RESPONSE POLICY

A	B	C	D	E	F	G	H	I
RESPONSEPOLICYZONE	AIM.EDU	FORWARD	TSIG-RPZ_LOCAL_UPDATER_KEY._default. aim.edu/ vIeLOfean4 YZUMOzGIvWnxhtOP XWM5QfJwxfHJbDXjQ =/ALLOW/HMAC-SHA 256	1003	NODATA		DEFAULT	RESPONSE POLICY
RESPONSEPOLICYZONE	PQDR.COM	FORWARD	TSIG-RPZ_LOCAL_UPDATER_KEY._default. pqdr.com/ R9TDpx8N +cBs0W32hEDzk5M wRjPuH%2FeYJsSgUk sX8SM=/ ALLOW/HM AC-SHA256	1004	PASSTHRU		DEFAULT	RESPONSE POLICY
RESPONSEPOLICYZONE	JKL.INFO	FORWARD	TSIG-RPZ_LOCAL_UPDATER_KEY._default.j kl.info/ rLopR5+Sf4M pcfYpDJV+KWAdtTXA U5kFTFWFWuLV2Rw= /ALLOW/HMAC-SHA2 56	1005	SUBSTITUTE	JKI.NET	DEFAULT	RESPONSE POLICY
RESPONSEPOLICYZONE	ASAC.COM	FORWARD	TSIG-RPZ_LOCAL_UPDATER_KEY._default. asac.com/ kA36uJeav mhrH2Yqx8hEDPC6o kSFcsOb2evyWVAO5 fM=/ALLOW/ HMAC-S HA256	1006	DISABLED		DEFAULT	RESPONSE POLICY

Examples of Substitute and Block Domain Names:
The following example shows a new column, **parent_zone,** which is added to the spreadsheet while importing an RPZ ruleset to a local RPZ **abc.net**:

A	B	C	D	E	F
HEADER- RESPONSEPOLICYCNAMERECORD	**FQDN***	**CANONICAL_NAME**	**DISABLED**	**PARENT_ZONE**	**VIEW**
RESPONSEPOLICYCNAMERECORD	CLARITY.ABC.NET	CLEAR.IN	FALSE	NET.ABC	DEFAULT
RESPONSEPOLICYCNAMERECORD	ARM.ABC.NET		FALSE	NET.ABC	DEFAULT

Example of an A Record CSV format:

A	B	C	D	E	F
HEADER- RESPONSEPOLICYARECORD	**ADDRESS***	**FQDN***	**DISABLED**	**PARENT_ZONE**	**VIEW**
RESPONSEPOLICYCNAMERECORD	10.32.2.1	PQR.ABC.NET	FALSE	NET.ABC	DEFAULT

Example of an RPZ Policy IP Address:

A	B	C	D	E	F
HEADER- RESPONSEPOLICYIPADDRESS	**FQDN***	**CANONICAL_NAME**	**DISABLED**	**PARENT_ZONE**	**VIEW**
RESPONSEPOLICYIPADDRESS	10.1.2.3.ABC.NET	10.1.2.3	FALSE	NET.ABC	DEFAULT

Example of an RPZ Policy Client IP Address:

A	B	C	D	E	F
HEADER-RESPONSEPOLICYCLIENTIPADDRESS	**FQDN***	**CANONICAL_NAME**	**DISABLED**	**PARENT_ZONE**	**VIEW**
RESPONSEPOLICYCLIENTIPADDRESS	10.1.2.1.ABC.NET	10.1.2.1	FALSE	NET.ABC	DEFAULT

Note the following:

- You must specify the name of the parent zone when you import RPZ rules to a local zone. For example, **clarity.abc.net** where **abc.net** is the local RPZ.
- In the above example, the domain name **clarity.abc.net** is substituted with the domain name **clear.in** because **clear.in** is specified as the canonical name.
- The domain **arm.abc.net** is blocked and the DNS client receives a message that the domain does not exist. For more information about RPZ rules, refer to the *Infoblox NIOS Administrator Guide*.

CSV Format for Inheritable Extensible Attributes

Exporting Inheritable Extensible Attributes

When you export data, if an object has inheritable extensible attributes associated with it, then an additional column **EAInherited-XXX** is displayed in the spreadsheet, where XXX is the name of the inheritable extensible attribute. Note that the column **EA-XXX** displays the name of the inheritable extensible attribute and its value whereas **EAInherited-XXX** displays the inheritance state, which is either **Inherit** or **Override**. Extensible attributes with the following inheritance states will be exported: **Inherited**, **Native**, and **Overridden**.
Note the following about inheritable extensible attributes:

- By default, the value is displayed as **Override** for inheritable extensible attributes, which are at the top of the inheritance chain or if the value of the inherited extensible attribute is overridden at the descendant level.
- If the value is inherited by the descendants of the parent object, then the inheritance state is set to **Inherit.**
- If an extensible attribute is not inheritable or if the status is set to **Not Inherited**, then the **EAInherited-XXX** column will not be displayed for these attributes.

- NIOS does not support EA inheritance for DNS objects, but you might see the **EAInherited-XXX** column in the CSV file when you export data through Grid Manager. Note that NIOS treats these objects as normal extensible attributes even when you enable inheritance for extensible attributes.

Importing Inheritable Extensible Attributes

You can specify new inheritable extensible attributes in the spreadsheet and import this file using the CSV Import feature. When you import inheritable extensible attributes using the CSV Import feature, you must specify two new columns, **EA-XXX** and **EAInherited-XXX**, with relevant values as mentioned in the following tables. Note that *XXX* is the name of the inheritable extensible attribute.
For example, if you want to update the value of an existing inheritable extensible attribute **Building**, you must set the inheritance state to **OVERRIDE** in the spreadsheet. The following example shows that the original value of attribute **Building**, which is replaced by **Millennium Tower**.

A	B	C	D	E
HEADER-NETWORK	**ADDRESS***	**NETMASK***	**EA-Building**	**EAInherited-Building**
NETWORK	10.251.133.128	255.255.255.192	Millennium Tower	OVERRIDE

The following example shows two new columns, **EA-Region** and **EAInherited-Region,** which are added to the spreadsheet to associate a new inheritable extensible attribute with an existing object:

A	B	C		
HEADER-NETWORK	**ADDRESS***	**NETMASK***	**EA-Region**	**EAInherited-Region**
NETWORK	10.251.133.128	255.255.255.192	San Pablo	INHERIT

Note the following about inheritance states:

- When you import attributes for a parent object, the inheritance state must be set to **OVERRIDE**.
- For descendants, the inheritance state can be set to **OVERRIDE** or **INHERIT**. If you specify **INHERIT**, the attribute value will be inherited from the parent object. If you specify **OVERRIDE**, the original value of the attribute will be replaced with the value specified in the spreadsheet.
  This is valid for Network related objects only. The supported inheritance chain is: **Network View -> Network Container -> Network -> Range -> Host/Fixed Address/Reservation**.

Importing Active Directory Domains and Sites

The Infoblox CSV format does not support extensible attributes that contain information about Active Directory domains and sites or objects that represent Active Directory domains or sites. The appliance displays an error message when you define values for such extensible attributes in the imported CSV file.
When you export networks, the appliance does not include extensible attributes that contain information about Active Directory domains or sites in the generated .CSV file.

CSV Import for Topology Rulesets and Rules in DNS Traffic Control

You can import DNS Traffic Control topology rulesets and their rules using the **CSV Import** feature. You must specify the topology rulesets and rules separated by commas in the CSV file:

```
header-dtctopology,name*,comment
header-dtctopologyrule,dest_link*,dest_type*,name*,parent*,sources*,position
dtctopology,topo_server11,TopologyRule
dtctopologyrule,dtc_s11,Server,Rule11,topo_server11,SUBNET/IS_NOT/
172.31.0.0/16,1 dtctopologyrule,pool12,Server,Rule12,topo_server11,"COUNTRY/IS/
Canada",2
```

Importing Topology Rulesets and Rules

To import topology rulesets, you must specify the **header-topology**, **name** and **comment** columns in the spreadsheet. The **name** column indicates the name of the topology ruleset. To import topology rules, specify the following in the spreadsheet:

A	B	C				
HEADER-DTCTOPOL OGY	**NAME***	**COMMENT**				
HEADER-DTCTOPOL OGYRULE	**DEST_LINK***	**DEST_TYPE***	**NAME***	**PARENT***	**SOURCES***	**POSITION**
DTCTOPOL OGY	topo_server1	Topology Server 1				
DTCTOPOL OGYRULE	dtc_s1	SERVER	RULE1	topo_server1	SUBNET/IS/10.0.0.0/8	1
DTCTOPOL OGYRULE	dtc_s2	SERVER	RULE2	topo_server1	SUBNET/IS/10.120.0.0/16	2
DTCTOPOL OGY	topo_pool1	Topology Pool 3				
DTCTOPOL OGYRULE	pool1	POOL	RULE3	topo_pool1	COUNTRY/IS/Antarctica,CONTINENT/IS/Africa,SUBDIVISION/IS/Aden	1

You must specify the **dest_link, dest_type, name, parent, sources,** and **position** columns when you import a CSV file with topology rules. Note that the **dest_link** indicates the name of the destination, which is either a pool or server and **position** indicates the order of rules in a topology ruleset. The values that you specify for **dest_link** must exist in the database. The **dest_type** indicates the destination type, which can either be a server or a pool. Specify a name for the topology rule in the **name** column. In the **parent** column, you can specify the name of the DTC topology ruleset. The **sources** column must contain either a subnet IP address or a geographic location. The appliance displays an error message if you do not specify valid GeoIP labels when you import a CSV file.

Supported Object Types

This section describes the supported object types and their corresponding fields for CSV import and export. It also includes examples of how to create data files. Ensure that you review this information before you import or export a data file.

> **Note**
>
> All inherited fields follow the override conventions described in *Data Specific Guidelines*.

Supported DNS Object Types

DNS Object Type	Required Fields & Syntax	IDN Supported (Yes/No)
Grid DNS Objects	*Grid DNS Objects*	Yes
Member DNS Objects	*Member DNS Objects*	Yes
Authoritative Zone	*Authoritative Zone*	Yes
Forward-Mapping Zone	*Forward-Mapping Zone*	Yes
Stub Zone	*Stub Zone*	Yes
Delegated Zone	*Delegated Zone*	Yes
Authoritative Name Server Group	*Authoritative Name Server Group*	Yes
Forwarding Member Name Server Group	*Forwarding Member Name Server Group*	Yes
Stub Member Name Server Group	*Stub Member Name Server Group*	Yes
Forward/Stub Server Name Server Group	*Forward/Stub Server Name Server Group*	Yes
A Record	*A Record*	Yes
AAAA Record	*AAAA Record*	Yes
CNAME Record	*CNAME Record*	Yes
DNAME Record	*DNAME Record*	Yes
MX Record	*MX Record*	Yes
NAPTR Record	*NAPTR Record*	Yes
NS Record	*NS Record*	Yes (supports only FQDN)
PTR Record	*PTR Record*	Yes

DNS Object Type	Required Fields & Syntax	IDN Supported (Yes/No)
SRV Record	*SRV Record*	Yes
TXT Record	*TXT Record*	Yes
TLSA Record	*TLSA Record*	No
CAA Record	*CAA Record*	Yes
Host Record	*Host Record*	Yes
IPv4 Host Address	*IPv4 Host Address*	No
IPv6 Host Address	*IPv6 Host Address*	No
Bulk Host	*Bulk Host*	No
Rulesets	*NXDOMAIN and Blacklist Rulesets*	No
NXDOMAIN Rule	*NXDOMAIN Rule*	No
Blacklist Rule	*Blacklist Rule*	No
Whitelist Rule	*Whitelist Rule*	No
DNS64 Synthesis Group	*DNS64 Synthesis Group*	No
Response Policy Zone	*Response Policy Zone*	No
Response Policy A Record	*Response Policy A Record*	No
Response Policy AAAA Record	*Response Policy AAAA Record*	No
Response Policy IP A Record	*Response Policy IP A Record*	No
Response Policy IP AAAA Record	*Response Policy IP AAAA Record*	No
Response Policy MX Record	*Response Policy MX Record*	No
Response Policy NAPTR Record	*Response Policy NAPTR Record*	No
Response Policy PTR Record	*Response Policy PTR Record*	No

DNS Object Type	Required Fields & Syntax	IDN Supported (Yes/No)
Response Policy SRV Record	*Response Policy SRV Record*	No
Response Policy TXT Record	*Response Policy TXT Record*	No
Response Policy CNAME Record	*Response Policy CNAME Record*	No
Response Policy IP Address	*Response Policy IP Address*	No
Response Policy Client IP Address	*Response Policy Client IP Address*	No
Response Policy IP Address CNAME	*Response Policy IP Address CNAME*	No
Response Policy Client IP Address CNAME	*Response Policy Client IP Address CNAME*	No
Dynamic Update Group	*Dynamic Update Group*	No
Dynamic Update Cluster Group	*Dynamic Update Cluster Group*	No

Supported DHCP Object Types

> **Note**
> IDN is not supported for DHCP object types.

DHCP Object Type	Required Fields & Syntax
Grid DHCP	*Grid DHCP Objects*
Member DHCP	*Member DHCP Objects*
Network View	*Network View*
DNS View	*DNS View*
IPv4 Network Container	*IPv4 Network Container*
IPv4 Network	*IPv4 Network*
IPv6 Network Container	*IPv6 Network Container*
IPv6 Network	*IPv6 Network*

DHCP Object Type	Required Fields & Syntax
IPv4 Shared Network	*IPv4 Shared Network*
IPv6 Shared Network	*IPv6 Shared Network*
IPv4 DHCP Range	*IPv4 DHCP Range*
IPv6 DHCP Range	*IPv6 DHCP Range*
IPv4 Fixed Address and Reservation	*IPv4 Fixed Address/Reservation*
IPv6 Fixed Address	*IPv6 Fixed Address*
DHCP Fingerprint	*DHCP Fingerprint*
DHCP MAC Filter	*DHCP MAC Filter*
MAC Filter Address Item	*MAC Filter Address*

Other Supported Objects

Other Supported Objects	Required Fields and Syntax
Grid Member	For more information on Grid member section, see *DHCP Failover Association*.
Upgrade Groups Distribution Schedules Upgrade Schedules	*Upgrade Groups and Schedules*
Named ACLs (access control lists)	*Named ACLs* *ACES in Named ACLs*
Infoblox Network Insight	*Discovery Credentials*

Grid DNS Objects

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-GridDNS	String	Yes			Identifies the first row as a header row for the Grid DNS objects. Example: GridDNS
refresh	Unsigned integer	No			Indicates the refresh time in seconds. Example: 10800
retry	Unsigned integer	No			Indicates the retry time in seconds. Example: 3600
expire	Unsigned integer	No			Indicates the expiration time in seconds. Example: 2419200
default_ttl	Unsigned integer	No			Indicates the default TTL value in seconds. Example: 28800
negative_ttl	Unsigned integer	No			Indicates the negative TTL value in seconds. Example: 900
lame_ttl	Unsigned integer	No			Indicates the lame TTL value in seconds. Example: 600
email	String	No			Indicates the email address. Example: admin@xyz.com
enable_secondary_notify	Boolean	No			Enable Grid secondaries to send notification. Example: False
enable_notify_source_port	Boolean	No			Enable notification source port Example: False

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
notify_source_port	Unsigned integer	No			Indicates notify-source port number.
enable_query_source_port	Boolean	No			Enable query source port. Example: False
query_source_port	Unsigned integer	No			Indicates query-source port number.
allow_transfer	ACL	No	Allow zone transfers to	allow_transfer	List of **address_tsig_ac** items. Example: NACL1or "12.0.0.12/Deny,1234::/64/Allow". Note that you can import the name of a named ACL in this field.
excluded_servers	IP address list	No			List of excluded servers for zone transfers.
zone_transfer_format_option	String	No			Indicates the zone transfer format. Example: MANY_ANSWERS
allow_query	ACL	No	Allow queries from	allow_query	List of **address_tsig_ac** items. It can be an IP address, a network entry, Any or a TSIG-/permission. If the first value is not **Any** or **TSIG-**, it is assumed to be an IP address or a network entry. Example: 10.0.0.10/Allow, 11.0.0.0/16/Deny, TSIG-foo/xyz/Allow. It can also be a named ACL. Example: NACL1.
recursion_enabled	Boolean	No			Indicates the flag to respond to recursive queries. Example: False
recursive_query_list	ACL	No			It can be an IP address, a network entry, Any or a TSIG-/permission. If the first value is not **Any** or **TSIG-**, it is assumed to be an IP address or a network entry. Example: 10.0.0.10/Allow, 11.0.0.0/16/Deny,TSIG-foo/xyz/Allow. It can also be a named ACL. Example: NACL1.
allow_update	ACL	No	Allow updates from	allow_update	List of **address_tsig_ac** items. It can be an IP address, a network entry, Any or a TSIG-/permission. If the first value is not **Any** or **TSIG-**, it is assumed to be an IP address or a network entry. Example: 10.0.0.10/Allow, 11.0.0.0/16/Deny, TSIG-foo/xyz/Allow. It can also be a named ACL. Example: NACL1.
allow_update_forwarding	Boolean	No	Allow updates from	forward_to	Enable update forwarding for secondary zones. Example: False
allow_bulkhost_ddns	String	No			Enable updates to PTR records sourced from a bulkhost. Example: Refuse

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
forwarders_only	Boolean	No	Use Forwarders Only		Enable use of forwarders only. Example: False
allow_forwarder	IP address list	No			Indicates the list of forwarders.
enable_custom_root_server	Boolean	No			Indicates the flag to enable custom root servers. Example: False
root_name_servers	Root nameserver list	No			Indicates the list of custom root servers. Example: rnm1.test.com/1.1.1.1/,... The appliance displays an error message if the **root_name_servers** column has an empty value when the **enable_custom_root_server** field is set to **True** in the imported CSV file.
enable_blackhole	Boolean	No			Enable blackhole setting. Example: False
blackhole	ACL	No			Indicates the list of banned addresses. Example: "NACL" or "12.0.0.12/Deny,1234::/64/Allow,.."
notify_delay	Unsigned integer	No		notify_delay	This field specifies the seconds of delay the notify messages are sent to the secondaries. The valid value is between 5 and 86400 seconds. Example: 5
enable_nxdomain_redirect	Boolean	No			Enable intercept and redirect nxdomain responses. Example: False
nxdomain_redirect_addresses	IP address list	No			Indicates the list of IPv4 addresses to redirect to for nxdomain responses. Example: "1.1.1.1,2.2.2.2,..."
nxdomain_redirect_ttl	Unsigned integer	No			Indicates the NXDOMAIN redirect ttl in seconds. Example: 60
nxdomain_log_query	Boolean	No			If you set this to **True**, the appliance logs the NXDOMAIN redirections. Example: False
nxdomain_rulesets	Pattern list	No			Indicates the list of ruleset objects that are used for NXDOMAIN redirection. Example: pattern1/MODIFY, pattern2/PASS, ...
enable_blacklist	Boolean	No		enable_blacklist	Enable or disable blacklist redirection at the Grid level. Example: False

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
blacklist_redirect_addresses	IP address list	No		blacklist_ redirect_ addresses	Indicates the list of IPv4 addresses to which the blacklisted queries are redirected. Example: 1.1.1.1,2.2.2.2
blacklist_action	String	No	Action	blacklist_action	Indicates the action to be performed when a domain name matches the pattern defined in an assigned rule. Example: Refuse
blacklist_redirect_ttl	Unsigned integer	No		blacklist_ redirect_ttl	Indicates the blacklist redirect TTL value in seconds. Example: 60
blacklist_log_query	Boolean	No		blacklist_log_ query	When this is set to **True**, blacklisted queries are logged. Example: False
blacklist_rulesets	List of domain names	No		blacklist_ rulesets	List of ruleset objects that are used for blacklist redirection. Example: list1.com, list2.com, ...
enable_dns64	Boolean	No			Enable DNS64 synthesis. Example: False
dns64_groups	List of Dns64 groups	No			List of SynthesisGroup objects. Example: dns64_groupA, dns64_groupB, ...
host_rrset_order	Boolean	No			Specify **True** to set the **enable_host_rrset_order** flag or **False** to deactivate **enable_host_rrset_order** value at the Grid level. Example: False
preserve_host_rrset_order_on_ secondaries	Boolean	No			Specify **True** to set the **preserve_host_rrset_order_on_secondaries** flag or **False** to deactivate **preserve_host_rrset_order_on_secondaries** value at the Grid level. The default value is **False**. Example: False
filter_aaaa	String	No			Indicates the type of AAAA filtering for this Grid DNS object. The default value is **No**. Example: Yes
filter_aaaa_list	ACL	No			Indicates the list of IPv4 addresses and networks from which queries are received. Note that the AAAA filtering is applied to these addresses. Example: "12.0.0.12/Deny,13.0.0.0/8/Allow,.." or "NACL1"
copy_xfer_to_notify	Boolean	No			Enable or disable copying of the allowed IP addresses from zone transfer list into also-notify statement in named.conf. Example: False

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
transfers_in	Unsigned integer	No			Indicates the number of maximum concurrent transfers for the Grid. You can specify unsigned integers between 10 and 100. The default value is 10. Example: 10
transfers_out	Unsigned integer	No			Indicates the number of maximum outbound concurrent zone transfers for the Grid. You can specify unsigned integers between 10 and 100. The default value is 10. Example: 10
transfers_per_ns	Unsigned integer	No			Indicates the number of maximum concurrent transfers per member for the Grid. You can specify unsigned integers between two and 100. The default value is two. Example: 2
serial_query_rate	Unsigned integer	No			Indicates the number of maximum concurrent SOA queries per second for the Grid. You can specify unsigned integers between 20 and 100. The default value is 20. Example: 20
max_cache_ttl	Unsigned integer	No			Indicates the maximum time (in seconds) for which the server will cache positive answers. The default value is 604800.
max_ncache_ttl	Unsigned integer	No			Indicates the maximum time (in seconds) for which the server will cache negative (NXDOMAIN) responses. The default value is 10800. The maximum allowed value is 604800.
disable_edns	Boolean	No			Enable or disable EDNS0 support for queries that require recursive resolution. The default value is **False**.
query_rewrite_enabled	Boolean	No			When this is set to **True**, query rewrite is enabled at the Grid level. Example: False
query_rewrite_domain_names	List of domain names	No			Indicates the list of domain names that trigger DNS query rewrite.Example: "aa.com, bb.com."
query_rewrite_prefix	String	No			Indicates the domain name prefix for DNS query rewrite. The default value is **undefined**.
rpz_drop_ip_rule_enabled	Boolean	No	Ignore RPZ-IP triggers with too smallprefix lengths		When this is set to **True**, DNS server ignores RPZ-IP rules with prefix lengths that are less than the specified prefix length limit. Example: TRUE

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
rpz_drop_ip_rule_min_prefix_leng th_ipv4	Unsigned Integer	No	Minimum IPv4 Prefix Length		Indicates the minimum IPv4 prefix length for RPZ-IP triggers. The default value is 29.
rpz_drop_ip_rule_min_prefix_leng th_ipv6	Unsigned Integer	No	Minimum IPv6 Prefix Length		Indicates the minimum IPv6 prefix length for RPZ-IP triggers. The default value is 112.
rpz_hit_rate_interval	Unsigned Integer	No	Interval		Indicates the minimum time interval in seconds between RPZ hit rate checks. The default interval is 10 seconds.
rpz_hit_rate_min_query	Unsigned Integer	No	Minimum query		Indicates the minimum number of queries between RPZ hit rate checks. The default value is 1000.
rpz_hit_rate_max_query	Unsigned Integer	No	Maximum query		Indicates the maximum number of queries between RPZ hit rate checks. The default value is 100000.

Authoritative Zone

You can import the name of a named ACL in the fields that support named ACLs, such as allow_transfer, allow_query, and allow_update.

> ⚠ Note
>
> IDN is supported for object types: fqdn, soa_mname, and soa_email. You can use punycode or IDNs while importing these objects.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-AuthZone	String	Yes			
fqdn	FQDN	Yes	Name	name	Example: test.com
zone_format	String	Yes			Valid values are FORWARD, IPV4,and IPV6
view	String	No			If no view is specified, the Default view is used.
prefix	String	No			Prefix is used for reverse-mapping RFC2317 zones only. If you include a prefix in a forward-mapping zone, the appliance ignores the prefix. No error message is generated.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
_new_prefix	String	No			Add this field to overwrite the prefix field when you select the overwrite or merge option.Use the hostname of the grid member in this field. Example: infoblox.localdomain
is_multimaster	Boolean	No	Multi-master	is_multimaster	Indicates whether the zone has multiple primary servers. Example: True
grid_primaries	Grid member list and stealth state	No	Grid Primary/Stealth	primary stealth	Data must be in the following format: "hostname/stealth" Example: "foo.localadmin/ False,corp1.com/True,..."
external_primaries	Server list	No	External Primary	primary	Data must be in the following format: "name/ip/stealth/ use_2x_tsig/ use_tsig/ tsig_name/tsig_key/ tsig_key_algorithm". Only name and ip are required fields. If no value is specified for stealth, use_2x_tsig, and use_tsig, the default value FALSE is used. If either use_2x_tsig or use_tsig is TRUE, tsig_name and tsig_key are required. If no value is specified for tsig_key_algorithm, the default value is HMAC-MD5. If both use_2x_tsig and use_tsig are TRUE, only use_tsig = TRUE and the tsig key name and key are imported. Example: "ext1.test.com/ 1.1.1.1/FALSE"
grid_secondaries	Member server list	No	Grid Secondary	secondaries	Data must be in the following format: "hostname/stealth/ lead/grid_ replicate". Only hostname is required. If you do not specify values for stealth, lead, and grid_replicate, the default value FALSE is used. Example: "member1.localdomain/ FALSE/TRUE/FALSE"

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
external_secondaries	Server list	No	External Secondary	secondaries	Data must be in the following format: "name/ip/stealth/ use_2x_tsig/use_tsig/ tsig_name/tsig_key/ tsig_key_algorithm". Only name and ip are required fields. If no value is specified for stealth, use_2x_tsig, and use_tsig, the default value FALSE is used. If either use_2x_tsig or use_tsig is TRUE, tsig_name and tsig_key are equired. If no value is specified for tsig_key_algorithm, the default value is HMAC-MD5. If both use_2x_tsig and use_tsig are TRUE, only use_tsig = TRUE and the tsig key name and key are imported. Example: "sec1.com/1.1.1.1/FALSE/ FALSE/FALSE/foo/ sdfssdf86ew"
ns_group	String	No	Name server group	ns_group	Authoritative name server group name. Example: name-ns-group1
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable	disable	Example: FALSE
create_underscore_zones	Boolean	No	Automatically create underscore zones	create_underscore_zones	Example: FALSE
allow_active_dir	List of IP addresses	No	Allow unsigned updates from these domain controllers	enable_ad_server	The Valid value is a list of IP addresses. Example: “1.1.1.1, 10.0.0.1
soa_refresh	Unsigned integer	No	Refresh	soa_refresh	When you modify this field to override an inherited value, you must include values for all SOA timer fields. The appliance updates all the SOA timers when you update any of them.
soa_retry	Unsigned integer	No	Retry	soa_retry	Ensure that you include this field when you override the soa_refresh field.
soa_expire	Unsigned integer	No	Expire	soa_expire	Ensure that you include this field when you override the soa_refresh field.
soa_default_ttl	Unsigned integer	No	Default TTL	soa_default_ttl	Ensure that you include this field when you override the soa_refresh field.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
soa_negative_ttl	Unsigned integer	No	Negative-caching TTL	soa_negative_ttl	Ensure that you include this field when you override the soa_refresh field.
soa_mnames	FQDN list	No	List of SOA MNAME fields	soa_mname	Data must include the FQDN and hostname Example: “foo.localdomain/ foobar.localadmin,...”
soa_email	Email address	No	Email address for SOA MNAME field	soa_email	Example: root@
soa_serial_number	Unsigned integer	No	Serial Number	soa_serial_number	
disable_forwarding	Boolean	No	Don’t use forwarders...	disable_forwarding	Example: TRUE
allow_update_forwarding	Boolean	No	Allow updates from	forward_to	Example: FALSE
update_forwarding	ACL	No	Allow updates from... Permission table	forward_to	Data must be in the following formats: ip address/ permissionnetwork/network cidr/permissionANY/ permissionTSIG-XXX/ permission Permission can be ALLOW or DENY If the first value is not Any or TSIG-, it is assumed to be an IP or network address. Example: "10.0.0.10/ Allow,11.0.0.0/16/ Deny,TSIG-foo/ sdfdsfwhsdgfsw8sdf/Allow
allow_transfer	ACL	No	Allow zone transfers to	allow_transfer	Example: "12.0.0.12/ Deny,1234::/64/Allow" Note that you can import the name of a named ACL in this field.
allow_update	ACL	No	Allow updates from	allow_update	Example: “13.0.0.0/8/Allow” Note that you can import the name of a named ACL in this field.
allow_query	ACL	No	Allow queries from	allow_query	Example: “127.0.0.1/Allow” Note that you can import the name of a named ACL in this field.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
notify_delay	Unsigned integer	No		notify_delay	This field specifies the seconds of delay the notify messages are sent to the secondaries. The valid value is between 5 and 86400 seconds.Example: 10
EA-Site	String	No	Extensible attribute	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	List	No	Extensible attribute	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role		ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for DNS zones. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding DNS Zones

This example shows how to add a forward mapping zone, corp100.com, with a Grid primary and a Grid secondary, where the grid secondary = hostname/stealth/lead/grid_replicate.

```
header-authzone,fqdn*,zone_format*,comment,grid_secondaries
authzone,corp100.com,FORWARD,USA,member.infoblox.com/False/ False3
```

This example shows how to create a data file to add an IPv4 reverse mapping zone, 100.0.0.0/8, with a Grid primary and an external secondary, where the external secondary = name/ip/stealth/use_2x_tsig/use_tsig/ tsig_name/tsig_key.

```
header-authzone,fqdn*,zone_format*,external_secondaries
authzone,100.0.0.0/8,IPV4,ns2.com/2.2.2.2/False/False/False/None/None
```

This example shows how to create a data file to add an IPv6 reverse-mapping zone, 1234::/64, with an external primary and a Grid secondary, where the external primary = name/ip/stealth/use_2x_tsig/use_tsig/ tsig_name/tsig_key.

```
header-authzone,fqdn*,zone_format*,external_primaries,grid_secondaries
authzone,1234::/64,IPV6,ns1.com/1.1.1.1/False/False/False/None/None,
member.infoblox.com/False/False/False
```

Overwriting DNS Zone Data

This example shows how to overwrite a comment from "USA" to "Japan" and remove the Grid secondary.

```
header-authzone,fqdn*,zone_format*,comment,grid_secondaries
authzone,corp100.com,FORWARD,Japan
```

Merging DNS Zone Data

This example shows how to merge the extensible attribute "Site" = "HQ" and add the RW permission to an admin group "DNS_admins".

```
header-authzone,fqdn*,zone_format*,ADMGRP-DNS_admins,EA-site
authzone,corp100.com,FORWARD,RW,HQ
```

This example shows how to add an external secondary with these values: "ns3.com/2.2.2.2/False/False/False/None/None".

```
header-authzone,fqdn*,zone_format*,external_secondaries
authzone,100.0.0.0/8,IPV4,ns2.com/2.2.2.2/False/False/False/None/None,ns3.com/
2.2.2.2/ False/False/False/None/None
```

Adding Named ACL Data

This example shows how to import the names of named ACLs in supported fields, such as allow_transfer, allow-query, and allow_update:

```
Header-
authzone,fqdn*,grid_primary,view,external_secondaries,allow_transfer,allow_quer
y,zone_type,allow_active_dir,allow_update,zone_format,notify_delay,disabled,grid
_prima
ry_stealth,soa_negative_ttl,soa_mname,soa_default_ttl,soa_retry,,create_undersco
re_zon es,soa_serial_number,soa_email,comment,soa_expire,soa_refresh

authzone,test_data_export.com,infoblox.localdomain,default,test_data.infoblox.co
m/1.1. 1.1/TRUE,"12.0.0.12/Deny,1234::/64/
Allow",My_Named_ACL,Authoritative,1.2.3.4,"1234::/6 4/
Allow",FORWARD,100,FALSE,FALSE,100,mname2,300,600,FALSE,FALSE,1,soaemail@infoblo
x.c (mailto:

2Csoaemail@infoblox.co)o m,Authzone2,200,500

```

```
authzone,test_csv_export.com,infoblox.localdomain,default,test_csv.infoblox.com
/1.1.1. 1/TRUE,My_Named_ACL,"12.0.0.12/Deny,1234::/64/
Allow",,2.3.4.5,"4321::/64/Allow",FORWAR

D,100,FALSE,FALSE,400,mname1,900,800,FALSE,FALSE,1,tel@infoblox.com,Authzone1,10
0,200
```

Delegated Zone

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-DelegatedZone	String	Yes			Identifies the first row as a header row for delegated zones. Example: DelegatedZone
fqdn	FQDN	Yes	Name	zone	This field combines the AAAA record name and the zone name to form the FQDN. Example: aaaa1.corp100.com
view	String	No	DNS View	views	If no view is specified, the default view is used. Example: Default
zone_format	String	Yes	Type		Valid values are **FORWARD**, **IPV4**,and **IPV6**.
prefix	String	No	RFC 2317 Prefix	prefix	Prefix is used for reverse-mapping RFC2317 zones only. If you include a prefix in a forward-mapping zone, the appliance ignores the prefix. No error message is generated.
disabled	Boolean	No	Disable	disable	Enable or disable the zone. Example: FALSE
comment	String	No	Comment	comment	Example: Delegated zone header.
delegate_to	Delegated Servers list	Yes			Example: delegate_server1.test.com/1.1.1.1/,
delegated_ttl	Unsigned integer	No			This is an inherited field. Example: 28800
EA-Site	String	No	Extensible attribute	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. Example: California.
EA-Users	List	No	Extensible attribute	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: ['Annie', 'John'].
ADMGRP-XXXX	String	No	Permissions Admin Group/Role	permission	ADMGRP-JimSmith is an example of an admin permission of a specific admin group. Example: RW

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ns_group	String	No	Name server group	ns_group	Authoritative name server group name. Example: name-ns-group1
_new_prefix	String	No			Add this field to overwrite the prefix field when you select the Overwrite or Merge option. Use the host name of the Grid member in this field. Example: infoblox.localdomain
ddns_protected	Boolean	No	Protected		Add this field in order to restrict DDNS updates to record.
ddns_principal	String	No	Principal		Displays the principal name for dynamic records with the GSS-TSIG principal authentication enabled in the advanced updates properties of the Grid, view, zone, or Standalone.

Delegation Name Server Group

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-delegationnsgroup	String	Yes			Identifies the first row as a header row for the delegation name server group objects. Example: DelegationNsGroup.
group_name	String	Yes	Name		Indicates the name of the delegation name server group. Example: ns_group1
_new_group_name	String	No			You can overwrite the group name.
delegate_to	String/IP Address	Yes	Name Server/ Address		List of name servers with valid IP address. Example: “foo.com/1.1.1.1”
comment	String	No	Comment	Comment	Example: This is a delegation name server group.

Forwarding Member Name Server Group

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-ForwardingMemberNsGroup	String	Yes			Identifies the first row as a header row for the forwarding member name server group objects. Example: ForwardingMemberNsGroup.
group_name	String	Yes	Name	name	Indicates the name of the forwarding member name server group. Example: fwd_ns_group1
_new_group_name	String	No			You can overwrite the group name.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
comment	String	No	Comment	comment	Example: This is a forwarding member name server group.
forwarding_servers	Forwarding members list	Yes	Edit-Per-Member Forwarders Editor	forwarding_servers	List of forwarding servers per Grid member. Example: False/True/infoblox.localdomain/[test/2.2.2.2], where: - False indicates the **Use Forwarders Only** checkbox is not selected. - True indicates the **Override Default Forwarders** checkbox is selected. - test/2.2.2.2 - Custom forwarders **Note**: You cannot clear the custom forwarders using the CSV import operation.
EA-XXX	String	No	Extensible attribute	extensible_attributes	EA-XXX is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: John.

Forward or Stub Server Name Server Group

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-ForwardStubServerNsGroup	String	Yes			Identifies the first row as a header row for the forward/stub server name server group objects. Example: ForwardStubServerNsGroup.
group_name	String	Yes	Name	name	Indicates the name of the forward/stub server name server group. Example: ext_ns_group1
_new_group_name	String	No			You can overwrite the group name.
comment	String	No	Comment	comment	Example: This is a forward/stub server name server group.
external_servers	External server list	Yes		external_servers	List of external servers.
EA-XXX	String	No	Extensible attribute	extensible_attributes	EA-XXX is an example of a user defined attribute. You can ad

Stub Member Name Server Group

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-StubMember NsGroup	String	Yes			Identifies the first row as a header row for the stub member name server group objects. Example: StubMemberNsGroup.
group_name	String	Yes	Name	name	Indicates the name of the stub member name server group. Example: stub_ns_group1
_new_group_name	String	No			You can overwrite the group name.
comment	String	No	Comment	comment	Example: This is a stub member name server group.
stub_members	Member server list	Yes		stub_members	List of stub Grid members.
EA-XXX	String	No	Extensible attribute	extensible_attributes	EA-XXX is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: John.

A Record

> **Note**
> IDN is supported for object type: fqdn. You can use IDN or punycode while importing this object.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-ARecord	String	Yes			Example: ARecord
fqdn	FQDN	Yes	Name	name	This field combines the A record name and the zone name to form the FQDN. Example: a1.corp100.com
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used.
address	IP address	Yes	IP Address	ipv4addrss	Example: 192.138.1.1
_new_address	IP address	No			Add this field to overwrite the address field when you select the overwrite or merge option.
comment	String	No	Comment	comment	

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
disabled	Boolean	No	Disable	disable	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 7200
EA-Site	String	No	Extensible attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	List	No	Extensible attribute Users	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for A records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an A Record

This example shows how to add an A record, bind_a.corp100.com, with the extensible attribute Site = Infoblox, and the permission, DNS_Admins = RO.

```
header-arecord,address*,fqdn*,ADMGRP-DNS_Admins,EA-Site
arecord,100.0.0.1,bind_a.corp100.com,RO,Infoblox
```

Overwriting A Record Data

This example shows how to modify the permission of the admin group DNS_Admins from RO to DENY in an existing A record, bind_a.corp100.com.

```
header-arecord,address*,fqdn*,ADMGRP-DNS_Admins
arecord,100.0.0.1,bind_a.corp100.com,DENY
```

Merging DNS Zone Data

This example shows how to merge the TTL value = 1280 to an existing A record, bind_a.corp100.com.

```
header-arecord,address*,fqdn*,ttl
arecord,100.0.0.1,bind_a.corp100.com,1280
```

AAAA Record

> **Note**
>
> IDN is supported for object type: `fqdn.` You can use IDN or punycode while importing this object.

Field Name	Data Type	Required (Yes/No)	Associated GUI field	Associated PAPI Method	Usage and Guidelines
Header-AaaaRecord	String	Yes			Example: AaaaRecord
fqdn	FQDN	Yes	Name	zone	This field combines the AAAA record name and the zone name to form the FQDN. Example: aaaa1.corp100.com
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
address	IPv6 address	Yes	IP Address	ipv6addrss	Example: 100::10
_new_address	IPv6 address	No			Add this field to overwrite the address field when you select the overwrite or merge option.
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable	disabled	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 7200
EA-Site	String	No	Extensible attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	List	No	Extensible attribute Users	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.

Field Name	Data Type	Required (Yes/No)	Associated GUI field	Associated PAPI Method	Usage and Guidelines
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for AAAA records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an AAAA Record

This example shows how to add an AAAA record, bind_aaaa.corp100.com, with a comment = add by superuser, and TTL = 3600.

```
header-aaaarecord,address*,fqdn*,comment,ttl
aaaarecord,1234:1234::1,bind_aaaa.corp100.co,add by superuser,3600
```

Overwriting AAAA Record Data

This example shows how to modify an existing AAAA record from address 1234:1234::1 to 1234:1234::2, and TTL from 3600 to 3800.

```
header-aaaarecord,address*,_new_address,fqdn*,ttl
aaaarecord,1234:1234::1,1234:1234:2,bind_aaaa.corp100.com,3800
```

Merging AAAA Record Data

This example shows how to disable an existing AAAA record.

```
header-aaaarecord,address*,fqdn*,disabled
aaaarecord,1234:1234::2,bind_aaaa.corp100.com,TRUE
```

Alias Records

> **Note**
>
> IDN is supported for object type: `fqdn.` You can use IDN or punycode while importing this object.

Field Name	Data Type	Required (Yes/No)	Associated GUI field	Associated PAPI Method	Usage and Guidelines
Header-aliasrecord	String	Yes	NA	NA	Example: Alias Record

Field Name	Data Type	Required (Yes/No)	Associated GUI field	Associated PAPI Method	Usage and Guidelines
fqdn	FQDN	Yes	Name	name	This field combines the Alias record name and the zone name to form the FQDN. Example: aaaa1.corp100.com
new_fqdn	FQDN	No	NA	dns_name	
target_name	String	Yes	Target Name	target_name	You can type the domain name for the resource. Examples: • CloudFront distribution domain name: d111111abcdef8.cloudfront.net • Elastic Beanstalk environment CNAME: example.elasticbeanstalk.com • ELB load balancer DNS name: example-1.us-east-1.elb.amazonaws.com • S3 website endpoint: s3-website.us-east-2.amazonaws.com • Resource record set in this hosted zone: www.example.com
new_target_name	String	No	NA	dns_target_name	
target_type	String	Yes	Target Type	target_type	Type of the aliased resource record, can be one of: A, AAAA, MX, NAPTR, PTR, SPF, SRV, TXT.
_new_target_type	String	No	NA	NA	
comment	String	No	Comment	comment	Additional Information
ttl	Boolean	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 7200
disabled	Boolean	No	Disable	disabled	Example: FALSE
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
Creator	String	No	NA	creator	

CNAME Record

> **Note**
>
> IDN is supported for object types: fqdn and canonical_name. You can use punycode or IDNs while importing these objects.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-CnameRecord	String	Yes			Example: CnameRecord
fqdn	FQDN	Yes	Alias	zone	This field combines the CNAME record name and the zone name to form the FQDN. Example: c1.corp100.com
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
canonical_name	Domain name	Yes	Canonical Name	canonical	Example: www.corp100.com
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable	disabled	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 28800
EA-Site	String	No	Extensible attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for CNAME records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a CNAME Record

This example shows how to add a CNAME record, bind_cname.corp100.com, to the Default DNS view.

```
header-cnamerecord,fqdn*,canonical_name*,view
cnamerecord,bind_cname.corp100.com,somewhere.corp100.com,default
```

Overwriting CNAME Record Data

This example shows how to override a canonical name from somewhere.corp100.com to somewhere2.corp100.com.

```
header-cnamerecord,fqdn*,canonical_name*
cnamerecord,bind_cname.corp100.com,somewhere2.corp100.com
```

Merging CNAME Record Data

This example shows how to merge the following data: admin group DNS_Admins with RW permission and extensible attribute Site = New York.

```
header-cnamerecord,fqdn*,ADMGRPDNS_Admins,EA-Site
cnamerecord,bind_cname.corp100.com,RW,New York
```

DNAME Record

> **Note**
>
> IDN is supported for object types: fqdn and target. You can use punycode or IDNs while importing these objects.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-DnameRecord	String	Yes			Example: DnameRecord
fqdn	FQDN	Yes	Alias	zone	This field combines the DNAME record name and the zone name to form the FQDN. Example: d1.corp100.com
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
target	Domain name	Yes	Target	target	Example: d1.foo.com
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable	disabled	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 28800
EA-Site	String	No	Extensible attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines.*
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for DNAME records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a DNAME Record

This example shows how to add a DNAME record, bind_dname.corp100.com, with target = bind_dname.corp200.com, extensible attribute Site = HQ, and disabled = TRUE.

```
header-dnamerecord,fqdn*,target*,disabled,EA-Site
dnamerecord,bind_dname.corp100.com,bind_dname.corp200.com,TRUE,HQ
```

Overwriting DNAME Record Data

This example shows how to enable the existing DNAME record, bind_dname.corp100.com, and add admin group DNS_Admins with RO permission.

```
header-dnamerecord,fqdn*,target*,disabled,ADMGRPDNS_Admins
dnamerecord,bind_dname.corp100.com,bind_dname.corp200.com,FALSE,RO
```

Merging DNAME Record Data

This example shows how to add a comment to the existing DNAME record, bind_dname.corp100.com, and change the TTL to 3860.

```
header-dnamerecord,fqdn,target*,comment,ttl
dnamerecord,bind_dname.corp100.com,bind_dname.corp200.com,Add by DNS admin,3860
```

MX Record

> **Note**
> IDN is supported for object types: fqdn and mx. You can use punycode or IDNs while importing these objects.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-MxRecord	String	Yes			Example: MxRecord
fqdn	FQDN	Yes	Mail Destination	zone	This field combines the MX record name and the zone name to form the FQDN. Example: MX1.corp100.com
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
mx	Domain name	Yes	Mail Exchange	exchanger	Example: mailer.foo.com
_new_mx	Domain name	No			Add this field to overwrite the mx field when you select the overwrite or merge option.
priority	Unsigned integer	Yes	Preference	pref	Example: 10
_new_priority	Unsigned integer	No			Add this field to overwrite the priority field when you select the overwrite or merge option.
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable	disable	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 28800
EA-Site	String	No	Extensible attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines.*
EA-Users	String	No	Extensible attribute Country	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for MX records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an MX Record

This example shows how to add an MX record, bind_mx.corp100.com, with a mail exchanger, exchange.corp100.com and priority = 20.

```
header-mxrecord,fqdn*,mx*,priority*
mxrecord,bind_mx.corp100.com,exchange.corp100.com,20
```

Overwriting MX Record Data

This example shows how to overwrite an existing MX record with a new fqdn, bind_mx2.corp100.com, and a new mail exchanger, new_exchange.corp100.com.

```
header-mxrecord,fqdn*,_new_fqdn,mx*,_new_mx

mxrecord,bind_mx.corp100.com,bind_mx2.corp100.com,exchange.corp100.com,new_excha
nge.co rp100.com
```

Merging MX Record Data

This example shows how to merge data to the existing MX record, bind_mx2.corp100.com, by adding inherited TTL value and extensible attributes Site = USA.

```
header-mxrecord,fqdn*,mx*,priority*,ttl,EA-Site
mxrecord,bind_mx2.corp100.com,new_exchange.corp100.com,20,USA
```

NAPTR Record

> **Note**
>
> IDN is supported for object types: fqdn and replacement. You can use punycode or IDNs while importing these objects.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-NaptrRecord	String	Yes			Example: NaptrRecord
fqdn	FQDN	Yes	Domain	name	This field combines the domain name and the zone name to form the FQDN. Example: aptr1.corp100.com
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
order	Unsigned integer	Yes	Order	order	Example: 10
_new_order	Unsigned integer	No			Add this field to overwrite the order field when you select the overwrite or merge option.
preference	Unsigned integer	Yes	Preference	preference	Example: 20

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
_new_preference	Unsigned integer	No			Add this field to overwrite the preference field when you select the overwrite or merge option.
flags	String	No	Flags	flags	You can leave this field empty. Example: U
_new_flags	String	No			Add this field to overwrite the flags field when you select the overwrite or merge option.
services	String	No	Service	services	You can leave this field empty. Example: SIP+D2U
_new_services	String	No			Add this field to overwrite the services field when you select the overwrite or merge option.
regexp	String	No	REGEX	regexp	You can leave this field empty. Example: http://([^/:]+)!\1!i
_new_regexp	String	No			Add this field to overwrite the regexp field when you select the overwrite or merge option.
replacement	String	Yes	Replacement	replacement	Example: corp100.com
_new_replacement	String	No			Add this field to overwrite the replacement field when you select the overwrite or merge option.
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable	disable	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 28800
EA-Site	String	No	Extensible attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible attribute Country	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for NPATR records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a NAPTR Record

This example shows how to add a NAPTR record, bind_naptr.corp100.com, with order = 10, preference = 20, and replacement = corp200.com.

```
header-naptrrecord,fqdn*,order*,preference*,replacement*
naptrrecord,bind_naptr.corp100.com,10,20,corp200.com
```

Overwriting NAPTR Record Data

This example shows how to overwrite the FQDN of an existing NAPTR record from bind_naptr.corp100.com to bind_naptr2.corp100.com.

```
header-naptrrecord,fqdn*,_new_fqdn order*,preference*,replacement*
naptrrecord,bind_naptr.corp100.com,bind_naptr2.corp100.com,10,20,corp200.com
```

This example shows how to override the preference of an existing NAPTR record from 20 to 25 and replacement from corp200.com to corp300.com.

```
header-
naptrrecord,fqdn*,order*,preference*,_new_preference,replacement*,_new_replacem
ent
 naptrrecord,bind_naptr.corp100.com,10 20 25,corp200.com,corp300.com
```

Merging NAPTR Record Data

This example shows how to merge Service = http+E2U and TTL = 3600 seconds to an existing NAPTR record.

```
header-naptrrecord,fqdn*,order*,preference*,replacement*,services,ttl
naptrrecord,bind_naptr.corp100.com,10,25,Corp300.com,http+E2U,3600
```

NS Record

> **Note**
>
> IDN is supported for object type: fqdn. You can use IDN or punycode while importing this object.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-NsRecord	String	Yes			Example: NsRecord
fqdn	FQDN	Yes	Zone	name	This field combines the domain name and the zone name to form the FQDN. Example: test.corp100.com

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
dname	Domain name	Yes	Name Server	nameserver	Example: ns1.corp100.com
_new_dname	Domain name	No			Add this field to overwrite the dname field when you select the overwrite or merge option.
zone_nameservers	Server list	Yes	Name server list	addresses	Data must be in the following format: "IPAddress1/auto_create_ptr1, IPAddress2/auto_create_ptr2" Example: "10.0.0.4/TRUE, 10.0.0.44/FALSE, 10.0.0.55/TRUE"

Note

When you perform a CSV export of automatically created NS records using Infoblox API, the **zone_nameservers** field will have an empty value. Therefore, if you import the previously exported CSV file that includes automatically created NS records through the Infoblox GUI, then the CSV import fails and Grid Manager displays an error message.

Examples

This section contains examples of how to create data files for NS records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an NS Record

This example shows how to add an NS record corp100.com in the Default DNS view with DNAME (name server) = ns1.corp100.com, name server address = 100.0.0.101, and TRUE for adding a PTR Record.

```
header-nsrecord,fqdn*,view,dname*,zone_nameservers*
nsrecord,corp100.com,default,ns1.corp100.com,"100.0.0.101/TRUE"
```

This example shows how to add an NS record corp200.com in the Internal DNS view with DNAME (name server) = ns1.corp200.com and two name server addresses: 200.0.0.101 with TRUE for adding a PTR Record and 200.0.0.102 with TRUE for adding a PTR record.

```
header-nsrecord,fqdn*,view,dname*,zone_nameservers*
nsrecord,corp200.com,Internal,ns1.corp200.com,"200.0.0.101/TRUE,200.0.0.102/
TRUE"
```

Overwriting NS Record Data

This example shows how to overwrite the DNAME of an existing NS record from ns1.corp100.com to ns2.corp100.com.

```
header-nsrecord,fqdn*,dname*,_new_dname,zone_nameservers*
nsrecord,corp100.com,ns1.corp100.com,ns2.corp100.com,"100.0.0.101/TRUE"
```

This example shows how to overwrite the zone name servers of an existing NS record to 100.0.0.101/TRUE and 100.0.0.102/TRUE.

```
header-nsrecord,fqdn*,dname*,zone_nameservers*
nsrecord,corp100.com,ns2.corp100.com,"100.0.0.101/TRUE,100.0.0.102/TRUE"
```

Merging NS Record Data

This example shows how to merge zone name servers 100.0.0.101/TRUE and 100.0.0.102/TRUE to an NS record.

```
header-nsrecord,fqdn*,dname*,zone_nameservers*
nsrecord,corp200.com,ns1.corp200.com,"100.0.0.101/TRUE,100.0.0.102/TRUE"
```

PTR Record

> **Note**
>
> IDN is supported for object type: fqdn and dname. You can use punycode or IDNs while importing these objects.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-PtrRecord	String	Yes			Example: PtrRecord
fqdn	FQDN	No	Name	name zone	This field is required if you do not use the address field. Either the IP address or FQDN is required. Example: 10.0.0.10.in.addr.arpa
_new_fqdn	Reverse FQDN	No			Add this field to overwrite the fqdn field when you use the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
address	IP address	No	IP Address	ipv4addrss ipv6addrss	This field is required if you do not use the fqdn field. Either the IP address or FQDN is required. Example: 10.0.0.11 If the PTR record belongs to a forward-mapping zone, this field is empty.
_new_address	IP address	No			Add this field to overwrite the address field when you use the overwrite or merge option.
dname	FQDN	Yes	Domain Name	ptrdname	Example: ss.dd.ff
_new_dname	FQDN	No			Add this field to overwrite the dname field when you select the overwrite or merge option.
comment	String	No		Comment comment	
disabled	Boolean	No	Disable	disable	Example: FALSE

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. Example: 28800
EA-Site	String	No	Extensible attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for PTR records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a PTR Record

This example shows how to add a PTR record.

```
header-ptrrecord,dname*,fqdn ptrrecord,ptr.corp100.com,1.0.0.100.in-addr.arpa
```

Overwriting PTR Record Data

This example shows how to overwrite an existing PTR record with a new FQDN, 2.0.0.100.in-addr.arpa.

```
header-ptrrecord,dname*,fqdn ptrrecord,ptr.corp100.com,2.0.0.100.in-addr.arpa
```

This example shows how to overwrite an existing PTR record with a new IP address, 100.0.0.3.

```
header-ptrrecord,dname*,address ptrrecord,ptr.corp100.com,100.0.0.3
```

Merging PTR Record Data

This example shows how to change the DNAME of a PTR record from ptr.corp100.com to ptr2.corp100.com, and to add comment = East Asia.

```
header-ptrrecord,dname*,_new_dname,comment
ptrrecord,ptr.corp100.com,ptr2.corp100.com,East Asia
```

TXT Record

> **Note**
>
> IDN is supported for object type: fqdn. You can use IDN or punycode while importing this object.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-TxtRecord	String	Yes			Example: TxtRecord
fqdn	FQDN	Yes	Name	name zone	This field combines the record name and the zone name to form the FQDN. Example: t1.corp100.com
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
text	String	No	Text	text	You can leave this field empty.
_new_txt	String	No			Add this field to overwrite the txt field when you select the overwrite or merge option.
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable	disable	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 28800
EA-Site	String	No	Extensible attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for TXT record data import. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a TXT Record

This example shows how to add a TXT record, bind_txt.corp100.com, with text = this is a TXT record and TTL set to 3600 seconds.

```
header-txtrecord,fqdn*,text,ttl
txtrecord,bind_txt.corp100.com,this is a TXT record,3600
```

Overwriting TXT Record Data

This example shows how to overwrite the text field of a TXT record.

```
header-txtrecord,fqdn*,text,_new_text
txtrecord,bind_txt.corp100.com,this is a TXT record,this is a new TXT record
```

Merging TXT Record Data

This example shows how to add comment = USA and disabled = TRUE to an existing TXT record.

```
header-txtrecord,fqdn*,text,comment,disabled
txtrecord,bind_txt.corp100.com,this is a TXT record,USA,TRUE
```

SRV Record

> **Note**
>
> IDN is supported for object types: fqdn and target. You can use punycode or IDNs while importing these objects.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-SrvRecord	String	Yes			Example: SrvRecord
fqdn	FQDN	Yes	Service	name	This field combines the service name and the zone zone name to form the FQDN. Example: *_http._tcp.corp100.com*
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default priority
priority	Unsigned integer	Yes	Priority	priority	Example: 10
_new_priority	Unsigned integer	No			Add this field to overwrite the priority field when you select the overwrite or merge option.
weight	Unsigned integer	Yes	Weight	weight	Example: 20
_new_weight	Unsigned integer	No			Add this field to overwrite the weight field when you select the overwrite or merge option.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
port	Unsigned integer	Yes	Port	port	Example: 80
_new_port	Unsigned integer	No			Add this field to overwrite the port field when you select the overwrite or merge option.
target	Domain name	Yes	Target	target	Example: foo.test.com
_new_target	Domain name	No			Add this field to overwrite the target field when you select the overwrite or merge option.
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable		disable Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 28800
EA-Site	String	No	Extensible attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for SRV records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a SRV Record

This example shows how to add a new SRV record.

```
header-srvrecord,fqdn*,port*,priority*,target*,weight*
srvrecord,bind_srv.corp100.com,80,10,srv.corp100.com,20
```

Overwriting SRV Record Data

This example shows how to overwrite the following data of a SRV record: port from 80 to 88 and priority from 10 to 20.

```
header-srvrecord,fqdn*,port*,_new_port,priority*,_new_priority,target*,weight*
srvrecord,bind_srv.corp100.com,80,88,10,20,srv.corp100.com,20
```

This example shows how to overwrite the following data of a SRV record: target from srv.corp100.com to srv2corp100.com and weight from 20 to 30.

```
header-srvrecord,fqdn*,port*,priority*,target*,_new_target,weight*,_new_weight
srvrecord,bind_srv.corp100.com,88,20,srv.corp100.com,sv2.corp100.com,20,30
```

Merging SRV Record Data

This example shows how to merge the following data to a SRV record: comment = USA and disabled = TRUE.

```
header-srvrecord,fqdn*,port*,priority*,target*,weight*,comment,disabled
srvrecord,bind_srv.corp100.com,80,10,srv.corp100.com,20,USA,TRUE
```

TLSA Record

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-TlsaRecord	String	Yes			Identifies the first row as a header row for the TLSA record objects. Example: TlsaRecord.
name	String	Yes	Name	name	This field indicates the name of the TLSA resource record. Example: _123._tcp.
certificate_usage	Unsigned integer	Yes	Certificate Usage	certificate_usage	Indicates the data that is used to match the certificate presented in the TLS handshake. Example: 0.
selector	Unsigned integer	Yes	Selector	selector	Specifies which part of the TLS certificate presented by the server is matched with the data during TLS handshake. Example: 1.
matched_type	Unsigned integer	Yes	Matched Type	matched_type	Specifies how the certificate association is presented. Example: 2.
certificate_data	String	Yes	Certificate Data	certificate_data	Either raw data for matching type No hash, or the hash of the raw data for matching types SHA 256 bit and SHA 512 bit. Example: d2abde240d7cd3ee6b4b28c54df034b979 83a1d16e8a410e4561cb106618e971.
_new_certificate data	String	No	Certificate Data	certificate_data	Add this field to overwrite the certificate_data field when you select the overwrite or merge option.
comment	String	No	Comment	comment	

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ttl	Boolean	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*.
fqdn	String	Yes	FQDN	name zone	This field combines the service name and the zone name to form the FQDN. Example: _http._tcp.corp100.com
_new_fqdn	String	No		zone	Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
disabled	Boolean	No	Disable	disable	Example: FALSE
creator	String	No		creator	Example: STATIC

Examples

This section contains examples of how to create data files for TLSA records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a TLSA Record

This example shows how to add a new TLSA record.

```
header-
tlsarecord,certificate_data*,certificate_usage*,fqdn*,matched_type*,selector*,
creator,disabled,name,view,ADMGRP-cloud-api-only,EA-Site
tlsarecord,2D2D2D2D2D424547494E204345525449464943415445205245515545535 42D2D2D2D
2D0A4D4
9494335444343416377434151417767 5A347,0,_443._tcp.doctest,0,0,STATIC,FALSE,_tcp._
443,
 default,RO,Boston
```

Overwriting TLSA Record Data

This example shows how to overwrite the following data of a TLSA record. Consider an example where certificate_usage* is 0 as in the following example:

```
header-
tlsarecord,certificate_data*,certificate_usage*,fqdn*,matched_type*,selector*,
creator,disabled,name,view,ADMGRP-cloud-api-only,EA-Site
tlsarecord,2D2D2D2D2D424547494E204345525449464943415445205245515545535 42D2D2D2D
2D0A4D4
```

```
949433544434341637743415141776 75A347,0,_443._tcp.doctest,0,0,STATIC,FALSE,_tcp._443,
 default,RO,Boston
```

Note that `certificate_usage*` is changed from 0 to 1:

```
header-tlsarecord,certificate_data*,certificate_usage*,fqdn*,matched_type*,selector*,creator,disabled,name,view,ADMGRP-cloud-api-only,EA-Site
tlsarecord,2D2D2D2D2D424547494E2043455254494649434154452052455155455354 2D2D2D2D2D0A4D4
949433544434341637743415141776 75A347,1,_443._tcp.doctest,0,0,STATIC,FALSE,_tcp._443,
 default,RO,Boston
```

Merging TLSA Record Data

This example shows how to disable an existing TLSA record.

```
header-tlsarecord,certificate_data*,certificate_usage*,fqdn*,matched_type*,selector*,creator,disabled,name,view,ADMGRP-cloud-api-only,EA-Site
tlsarecord,2D2D2D2D2D424547494E2043455254494649434154452052455155455354 2D2D2D2D2D0A4D4
949433544434341637743415141776 75A347,0,_443._tcp.doctest,0,0,STATIC,TRUE,_tcp._443,
 default,RO,Boston
```

This example shows how to add new FQDN to a TLSA record.

```
header-tlsarecord,certificate_data*,certificate_usage*,fqdn*,_new_fqdn,matched_type*,selector*,creator,disabled,name,view,ADMGRP-cloud-api-only,EA-Site
tlsarecord,2D2D2D2D2D424547494E2043455254494649434154452052455155455354 2D2D2D2D2D0A4D4
949433544434341637743415141776 75A347,0,_443._tcp.doctest,_443._udp.doctest,0,0,STATIC,
 FALSE,_tcp._443,default,RO,Boston
```

CAA Record

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-CAARecord	String	Yes			Identifies the first row as a header row for the CAA record objects. Example: CAARecord.
flag	Int	Yes			Indicates critical or default CAA record.Example: 0
type	String	Yes			Specifies the type of CAA record. Example: issue
CA	String	No			Indicates the name of the certificate authority. Example: certissues.example.com.
ca_details	String	No			Specifies additional details about the CA requests. Example: policy=ev
comment	String	No	Comment	comment	
ttl	Boolean	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 28800
fqdn	String	Yes	FQDN	name zone	This field combines the service name and the zone name to form the FQDN. Example: _http._tcp.corp100.com
_new_fqdn	String	No		zone	Add this field to overwrite the fqdn field when you select the overwrite or merge option.
disabled	Boolean	No	Disable	disable	Example: FALSE
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
creator	String	No		creator	Example: STATIC

Examples

This section contains examples of how to create data files for CAA records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab. You can add new rows, update existing CAA resource record values or delete an existing CAA resource record.

Adding a CAA Record

This example shows how to add a new CAA record.

```
header-caarecord,ca_value*,_new_ca,ca_flag*,ca_tag*,fqdn*,_new_fqdn,ca_details,_new_ca_details,comment,creator,disabled,name,ttl,view
```

```
caarecord,abc.com,0,default,issue,xyz.com,0,caa record,new caa record,caa record information,static,false,0,3600,default
```

Overwriting CAA Record Data

This example shows how to overwrite the following data of a CAA record. Consider an example where `ca_tag*` is `issue` as in the following example:

```
header-caarecord,ca_value*,_new_ca,ca_flag*,ca_tag*,fqdn*,_new_fqdn,ca_details,_new_ca_details,comment,creator,disabled,name,ttl,view
caarecord,abc.com,0,default,issue,xyz.com,0,caa record,new caa record,caa record information,static,false,0,3600,default
```

Note that `ca_tag*` is changed from `issue` to `issuewild`:

```
header-caarecord,ca_value*,_new_ca,ca_flag*,ca_tag*,fqdn*,_new_fqdn,ca_details,_new_ca_details,comment,creator,disabled,name,ttl,view
caarecord,abc.com,0,default,issuewild,xyz.com,0,caa record,new caa record,caa record information,static,false,0,3600,default
```

IPv4 Host Address

Use this object type to define parameters for each IP address in an IPv4 host record. The appliance updates an existing host address when you use the "add" mode in an import. For information about host records, refer to the *Infoblox Administrator Guide*.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-HostAddress	String	Yes			Example: HostAddress
parent	FQDN	Yes			Example: h1.corp100.com
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
network_view	String	No	Network View	network_view	If no network view is specified, the Default view is used. Example: Default
address	IP address	Yes	IP Address	ipv4addrss	Example: 10.0.0.11

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
_new_address	IP address	No			Add this field to overwrite the address field when you select the overwrite or merge option.
mac_address	MAC address	No	MAC Address	mac_address	This is required if the IP address is configured for DHCP. Example: aA:Bb:c2:DD:E1:FF
configure_for_dhcp	Boolean	No	DHCP checkbox	configure_for_dhcp	Example: TRUE
configure_for_dns	integer	No	Enable in DNS	configure for dns	This field is used to specify the parent host record. If not value is specified, TRUE is used. Example: TRUE
deny_bootp	Boolean	No	Deny BOOTP Requests	deny_bootp	Example: FALSE
broadcast_address	String	No	Broadcast Address		
option_logic_filters	List of IPv4 logic filter rules		Filter Type/Action		Examples: .com.infoblox.dns.dhcp_mac_filter$mac_filter_name, .com.infoblox.dns.nac_filter$nac_filter_name, .com.infoblox.dns.dhcp_option_filters$opt_filter_name
boot_file	String	No	Boot File	boot_file	
boot_server	String	No	Boot Server	boot_server	
next_server	String	No	Next Server	next_server	
lease_time	Unsigned integer	No	Lease Time	lease_time	
pxe_lease_time_enabled	Boolean	No	Enable PXE Lease Time		Example: TRUE
pxe_lease_time	Unsigned integer	No	PXE Lease Time	pxe_lease_time	
domain_name	FQDN	No	Domain Name	domain_name	

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
domain_name_servers	IP list	No	Name Server		Example: [5.6.7.8,1.2.3.4]
routers	IP list	No	Router		Example: [2.0.0.2,1.2.3.4]
match_option	String	No		match_client	Data must be in the following format: MAC_ADDRESS/ CLIENT_IDENTIFIER/RESERVED
ignore_dhcp_param_request_list	Boolean	No	Ignore Optionlist	ignore-dhcp_option_list_request	
OPTION-1	String	No	Custom DHC Options		This is an example of a DHCP option. For information, see *Data Specific Guidelines* . Example: '255.0.0.0' implies vendor_class='DHCP' (default)
OPTION-XXXX-200	Option information	No	Custom DHC Options		P options This is an example of a DHCP option. For information, see *Data Specific Guidelines* . Example: 'dfdfdfd' name implies vendor_class='XXXX', optioncode/number 200

Examples

This section contains examples of how to create data files for host addresses. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an IPv4 Host Address

This example shows how to import the host address 100.0.0.1 in host record h1.corp100.com with a MAC address, enabled DHCP, and a domain name.

```
header-hostaddress,parent*,address*,mac_address,configure_for_dhcp,domain_name
hostaddres,h1.corp100.com,100.0.0.1,aa:aa:aa:aa:aa:aa,TRUE,corp200.com
```

This example shows how to import the host address 100.0.0.2 in host record h2.corp100.com with a MAC address, and two routers with addresses 1.1.1.1 and 2.2.2.2.

```
header-hostaddress,parent*,address*,mac_address,configure_for_dhcp,routers
hostaddress,h2.corp100.com,100.0.0.2,bb:aa:aa:aa:aa:aa,False,1.1.1.1,2.2.2.2
```

Overwriting IPv4 Host Address Data

This example shows how to overwrite the MAC address and domain name of a host address, and to set configure DHCP to TRUE.

```
header-hostaddress,parent*,address*,mac_address,configure_for_dhcp,domain_name
hostaddress,h1.corp100.com,100.0.0.1,cc:aa:aa:aa:aa:aa,FALSE,corp300.com
```

This example shows how to overwrite the router address of a host address from 1.1.1.1,2.2.2.2 to 1.1.1.1.

```
header-hostaddress,parent*,address*,routers
hostaddress,h2.corp100.com,100.0.0.2,1.1.1.1
```

Merging IPv4 Host Address Data

This example shows how to merge the following data of a host address: change a new address from 100.0.0.1 to 100.0.0.10, change bootp to DENY, and add lease time.

```
header-hostaddress,parent*,address*,_new_address,deny_bootp,lease_time
hostaddress,h1.corp100.com,100.0.0.1,100.0.0.10,FALSE,3600
```

This example shows how to merge the broadcast address, PXE lease time, and enabled ignore option list to an IPv4 host address.

```
header-
hostaddress,parent*,address*,broadcast_address,pxe_lease_time,ignore_dhcp_param
 _request_list hostaddress,h2.corp100.com,100.0.0.2,6.6.6.6,1280,TRUE
```

IPv6 Host Address

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-IPv6HostAddress	String	Yes			Example: IPv6hostaddress
view	String	No	DNS View	view	If no view is specified, the Default view is used. Example: Default
network_view	String	No	Network View	network_view	If no network view is specified, the Default view is used. Example: Default
parent	FQDN	Yes			Example: h1.corp100.com
address_type	Enumeration	No		address_type	Valid values are ADDRESS, PREFIX, or BOTH. If no value is specified, 'ADDRESS' (default) is used. Example: PREFIX
address	IPv6 address	Yes	IPv6 Address	ipv6addrs	Example: 1001::001
_new_address	IPv6 address	No			Add this field to overwrite the address field when you select the overwrite or merge option.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ipv6_prefix	IPv6 prefix	No		ipv6prefix	This field is required if address_type is 'ADDRESS' or 'BOTH'. Example: 2000:1111::
_new_ipv6_prefix	IPv6 prefix	No			Add this field to overwrite the ipv6_prefix field when you select the overwrite or merge option.
ipv6_prefix_bits	Integer	No		IPv6_prefix_bits	This field is required if address_type is 'ADDRESS' or 'BOTH'. Example: 32
configure_for_dhcp	Boolean	No	DHCP checkbox	configure_for_dhcp	Example: TRUE
configure_for_dns	Boolean	No	Enable in DNS	configure for dns	This field is used to specify the parent host record. If not value is specified, TRUE is used. Example: TRUE
match_option	String	No		match_client	Only 'DUID' is allowed. Example: DUID
duid	String	No	DUID	duid	Example: 0001
domain_name	FQDN	No	Domain Name		
domain_name_servers	IPv6 address list	No	Name Server		Example: '2000::10,3000::10'
valid_lifetime	Unsigned integer	No	Valid Lifetime	valid_lifetime	Example: 43200
preferred_lifetime	Unsigned integer	No	Preferred Lifetime	preferred_lifetime	Example: 604800
OPTION-7	Integer	No	Custom DHCP Options	override_options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: '12' name implies option space = 'DHCPv6', option code/number 7
OPTION-XXXX-200	Option information	No	Custom DHCP Options	override_options	This is an example of a DHCP option. For information, see . Example: 'dfdfdfd' name implies vendor_class='XXXX', option code/ number 200

Examples

This section contains examples of how to create data files for IPv6 host addresses. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an IPv6 Host Address

This example shows how to import an IPv6 host address to a host record in the Default DNS view.

```
header-IPv6hostaddress,parent*,address*,view
IPv6hostaddress,h1.corp100.com,1001::001,Default
```

Overwriting IPv6 Host Address Data

This example shows how to overwrite an IPv6 host address.

```
header-IPv6hostaddress,parent*,address*,_new_address
IPv6hostaddress,h1.corp100.com,1001::001,2000::10
```

Merging IPv6 Host Address Data

This example shows how to merge a DUID to an IPv6 host address.

```
header-IPv6hostaddress,parent*,address*,duid IPv6hostaddress,h1.corp100.com,2000::10,0001
```

Bulk Host

Field Name	Data Type	Required (Yes/N0)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-BulkHost	String	Yes			Identifies the first row as a header row for the bulk host objects. Example: BulkHost
parentfqdn	FQDN	Yes	Name	zone	Indicates the FQDN of the zone to which bulk host will be added.
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
prefix	String	No	RFC 2317 Prefix	prefix	Prefix is used for reverse-mapping zones only. The characters must be prepended to the host in the bulk host. If you include a prefix in a forward-mapping zone, the appliance ignores the prefix. No error message is generated.
_new_prefix	String	No			Add this field to overwrite the prefix field when you select the **Overwrite** or **Merge** option.Use the hostname of the Grid member in this field. Example: infoblox.localdomain
start_address	IP address	Yes	Start	start_addr	Indicates the starting IP address. Example: 10.0.0.11
_new_start_address	IP address	No			Add this field to overwrite the **start_address** field when you select the **Overwrite** or **Merge** option. Example: 10.0.0.55
end_address	IP address	Yes	End	end_addr	Indicates the last IP address. Example: 10.0.0.22

Field Name	Data Type	Required (Yes/N0)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
_new_end_address	IP address	No			Add this field to overwrite the **end_address** field when you select the **Overwrite** or **Merge** option. Example: 10.0.0.66
reverse	Boolean	No			Example: True
comment	String	No	Comment	comment	Example: This is a Bulk Host.
disabled	Boolean	No	Disable	disable	Enable or disable the bulk host. Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. Example: 7200
EA-Site	String	No	Extensible attribute	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. Example: California.
EA-Users	List	No	Extensible attribute	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: ['Annie', 'John'].
ADMGRP-XXXX	String	No	Permissions Admin Group/ Role	permission	ADMGRP-JimSmith is an example of an admin permission of a specific admin group. Example: RW

NXDOMAIN and Blacklist Rulesets

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-Ruleset	String	Yes			Example: Ruleset
name	String	Yes	Name	name	Example: ruleset1
_new_name	String	No			Example: ruleset1-new
type	String	Yes		type	You can use this field for NXDOMAIN rules or blacklist rules. Valid value is NXDOMAIN or BLACKLIST. Example: NXDOMAIN
disabled	Boolean	No	Disable	disabled	Example: FALSE
comment	String	No	Comment	comment	
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for NXDOMAIN and blacklist rulesets. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an NXDOMAIN Ruleset

This example shows how to import an NXDOMAIN ruleset.

```
header-Ruleset,name*,type*,comment,disabled ruleset,NXD,NXDOMAIN,This is an NXDOMAIN ruleset,FALSE
```

Adding a Blacklist Ruleset

This example shows how to import a blacklist ruleset.

```
header-Ruleset,name*,type*,disabled,comment
ruleset,blacklistrule1,BLACKLIST,FALSE,This is a blackset ruleset
```

Overwriting Blacklist Ruleset Data

This example shows how to overwrite the name of a blacklist ruleset.

```
header-Ruleset,name*,_new_name,type*
ruleSet,blacklistrule1,blacklistrule2,BLACKLIST
```

Merging NXDOMAIN Ruleset Data

This example shows how to merge an admin permission to a NXDOMAIN ruleset.

```
header-Ruleset,name*,type*,ADMGRP-JoeSmith ruleSet,NXD,NXDOMAIN,RW
```

NXDOMAIN Rule

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-nxdomainrule	String	Yes			Example: NxdomainRule
parent	String	Yes	Name	nxdomain_rules	This field indicates the ruleset to which the NXDOMAIN rule belongs. Example: nxdomain-ruleset1
pattern	String	Yes	Pattern	pattern	Use this to match domain names. You cannot use the characters * and ,, in the domain name. Example: foo
_new_pattern	String	No			Example: foo-new

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
action	String	Yes	Action	action	The valid value is PASS, MODIFY or REDIRECT. Example: PASS

Examples

This section contains examples of how to create data files for NXDOMAIN rules. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an NXDOMAIN Rule

This example shows how to import an NXDOMAIN rule.

```
header-nxdomainrule,action*,parent*,pattern* nxdomainrule,REDIRECT,NXD,*foo.com
```

Overwriting NXDOMAIN Rule Data

This example shows how to overwrite the action of an NXDOMAIN rule.

```
header-nxdomainrule,action*,parent*,pattern* nxdomainRule,REDIRCT,NXD,*bar.com
```

Blacklist Rule

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-blacklistrule	String	Yes			Example: BlacklistRule
parent	String	Yes	Name	blacklist_rulesets	Example: blacklist-ruleset1
domain_name	String	Yes	Domain Name		Use this to match domain names. You cannot use the characters * and ,, in the domain name. The domain name cannot exceed 255 characters. Example: www.foo.com
_new_domain_name	String	No			Example: www.bar.com
action	String	Yes	Action	blacklist_action	The valid value is PASS or REDIRECT. Example: PASS

Examples

This section contains examples of how to create data files for blacklist rules. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a Blacklist Rule

This example shows how to import a blacklist rule.

```
header-blacklistrule,parent*,domain_name*,action*
```

```
BlacklistRule,BlackList,foobar.com,REDIRECT
```

Overwriting Blacklist Rule Data

This example shows how to overwrite the action of a blacklist rule.

```
header-blacklistrule,parent*,domain_name*,action*
```

```
BlacklistRule,BlackList,foobar.com,PASS
```

Whitelist Rule

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
header-analyticsdomain whitelist	String	Yes			Example: analyticsdomainwhitelist
fqdn	String	Yes	Domain Name		Use this to match domain names. You cannot use the characters * and ,, in the domain name. The domain name cannot exceed 255 characters. Example: www.test.com
comment	String	No	Comment		Enter additional information about this domain.
disabled	String	Yes	Disable		The valid value is TRUE or FALSE. Example: FALSE
type	CUSTOM	Yes			Example: CUSTOM

Example

This section contains an example of how to create data file for whitelist rules. The example uses comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a Whitelist Rule

This example shows how to import a whitelist rule.

```
header-analyticsdomainwhitelist, fqdn*, disabled, type
BlacklistRule,BlackList,foobar.com,FALSE,CUSTOM
```

DNS64 Synthesis Group

You can import the name of a named ACL in the fields that support named ACLs, such as clients, mapped, and exclude.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-Dns64Synthesis Group	String	Yes			Example: Dns64SynthesisGroup
name	String	Yes	Name	name	Example: group1
prefix	IPv6 network	Yes	Prefix	prefix	Example: 64:FF9B::/96
comment	String	No	Comment	comment	
clients	Access control list	No	Name	clients	Valid values are IPv4 and IPv6 addresses and networks only. The default value is 'Any'. Example: 2000::/64/AllowNote that you can import the name of a named ACL in this field.
mapped	Access control list	No	Mapped IPv4 Address → Name	mapped	Valid values are IPv4 addresses and networks only. The default value is 'Any'. Example: 10.0.0.0/8/AllowNote that you can import the name of a named ACL in this field.
exclude	Access control list	No	Excluded IPv6 Address → Name	exclude	Valid values are IPv6 addresses and networks only. The default is 'None'. Example: 2000::/ AllowNote that you can import the name of a named ACL in this field.
disabled	Boolean	No	Disabled	disable	Example: FALSE

Examples

This section contains examples of how to create data files for DNS64 synthesis groups. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a DNS64 Synthesis Group

This example shows how to import a DNS64 Synthesis Group.

```
header-Dns64SynthesisGroup,name*,prefix*,mapped
Dns64SynthesisGroup,DNS64Group1,64:FF9B::/96,10.0.0.0/8/Allow
```

Overwriting DNS64 Synthesis Group Data

This example shows how to overwrite the mapped IPv4 address of a DNS64 synthesis group.

```
header-Dns64SynthesisGroup,name*,prefix*,mapped
Dns64SynthesisGroup,DNS64Group1,64:FF9B::/96,10.1.1.0/24/Allow
```

Adding Named ACL Data

This example shows how to add the name of a named ACL to the mapped address of a DNS64 synthesis group.

```
header-Dns64SynthesisGroup,name*,prefix*,mapped
Dns64SynthesisGroup,DNS64Group1,My_Named_ACL
```

Response Policy Zone

For a Response Policy Zone, CSV import supports all the values that are listed in *Authoritative Zone* along with the following values:

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
priority	Unsigned integer	No			Example: 1001
severity	String	No	Severity		Valid values are Critical, Major, Warning, and Informational
substitute_name	FQDN	No			Example: JKL.NET
rpz_policy	String	No	Policy Override		Valid values are GIVEN, NXDOMAIN, NODATA, PASSTHRU, SUBSTITUTE, and DISABLED
rpz_drop_ip_rule_enabled	Boolean	No	Ignore RPZ-IP triggers with too small prefix lengths		When this is set to **True,** DNS server ignores RPZ-IP rules with prefix lengths that are less than the specified prefix length limit. Example: TRUE
rpz_drop_ip_rule_min _prefix_length_ipv4	Unsigned Integer	No	Minimum IPv4 Prefix Length		Indicates the minimum IPv4 prefix length for RPZ-IP triggers. The default value is 29.
rpz_drop_ip_rule_min _prefix_length_ipv6	Unsigned Integer	No	Maximum IPv4 Prefix Length		Indicates the minimum IPv6 prefix length for RPZ-IP triggers. The default value is 112.

Response Policy A Record

For a Response Policy A Record, CSV import supports all the values that are listed in *A Record* along with the following values:

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
create_ptr	Boolean	No	Create associated PTR record		Example: TRUE
parent_zone	FQDN	No			Example: ABC.NET

Response Policy AAAA Record

For a Response Policy AAAA Record, CSV import supports all the values that are listed in *AAAA Record* along with the following value:

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
parent_zone	FQDN	No			Example: ABC.NET

Response Policy IP A Record

For a Response Policy IP A Record, CSV import supports all the values that are listed in *A Record* along with the following values:

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
create_ptr	Boolean	No			Example: TRUE
parent_zone	FQDN	No			Example: ABC.NET

Response Policy IP AAAA Record

For a Response Policy IP AAAA Record, CSV import supports all the values that are listed in *AAAA Record* along with the following value:

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
parent_zone	FQDN	No			Example: ABC.NET

Response Policy MX Record

For a Response Policy MX Record, CSV import supports all the values that are listed in *MX Record* along with the following value:

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
parent_zone	FQDN	No			Example: ABC.NET

Response Policy NAPTR Record

For a Response Policy NAPTR Record, CSV import supports all the values that are listed in *NAPTR Record* along with the following value:

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
parent_zone	FQDN	No			Example: ABC.NET

Response Policy PTR Record

For a Response Policy PTR Record, CSV import supports all the values that are listed in *PTR Record* along with the following value:

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
parent_zone	FQDN	No			Example: ABC.NET

Response Policy SRV Record

For a Response Policy SRV Record, CSV import supports all the values that are listed in *SRV Record* along with the following value:

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
parent_zone	FQDN	No			Example: ABC.NET

Response Policy TXT Record

For Response Policy TXT Record, CSV import supports all the values that are listed in *TXT Record* along with the following value:

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
parent_zone	FQDN	No			Example: ABC.NET

Response Policy CNAME Record

For Response Policy CNAME Record, CSV import supports all the values that are listed in *CNAME Record* along with the following value:

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
parent_zone	FQDN	No			Example: ABC.NET

Response Policy IP Address

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-ResponsePolicyIPAddress	String	Yes			Example: ResponsePolicyIPAddress
fqdn	FQDN	Yes	Name	name	Example: 10.1.2.3.ABC.NET
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used.
canonical_name	IP address	No	Canonical Name	canonical	Example: 10.1.2.3
parent_zone	FQDN	No			Example: ABC.NET
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable	disable	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 7200

Example

This example shows how to create data files for Response Policy IP Address. The example uses comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

```
header-ResponsePolicyIPAddress,fqdn*,canonical_name,disabled,parent_zone,view
ResponsePolicyIPAddress,10.1.2.3.ABC.NET,10.1.2.3,FALSE,ABC.NET,DEFAULT
```

Response Policy Client IP Address

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-ResponsePolicyClientIPAddress	String	Yes			Example: ResponsePolicyClientIPAddress
fqdn	FQDN	Yes	Name	name	Example: 10.1.2.1.ABC.NET
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
view	String	No	DNS View	views	If no view is specified, the Default view is used.
canonical_name	IP address	No	Canonical Name	canonical	Example: 10.1.2.1
parent_zone	FQDN	No			Example: ABC.NET
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable	disable	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 7200

Example

This example shows how to create data files for Response Policy Client IP Address. The example uses comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

```
header-
ResponsePolicyClientIPAddress,fqdn*,canonical_name,disabled,parent_zone,view
ResponsePolicyClientIPAddress,10.1.2.1.ABC.NET,10.1.2.1,FALSE,ABC.NET,DEFAULT
```

Response Policy IP Address CNAME

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-ResponsePolicyIPAddressCname	String	Yes			Example: ResponsePolicyIPAddressCname
fqdn	FQDN	Yes	Name	name	Example: 10.1.2.3.ABC.NET
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used.
canonical_name	IP address	No	Canonical Name	canonical	Example: 10.1.2.3
parent_zone	FQDN	No			Example: ABC.NET
comment	String	No	Comment	comment	

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
disabled	Boolean	No	Disable	disable	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 7200

Example

This example shows how to create data files for Response Policy IP Address CNAME. The example uses comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

```
header-
ResponsePolicyIPAddressCname,fqdn*,canonical_name,disabled,parent_zone,view
ResponsePolicyIPAddressCname,10.1.2.3.ABC.NET,10.1.2.3,FALSE,ABC.NET,DEFAULT
```

Response Policy Client IP Address CNAME

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-ResponsePolicyClientIPAddress	String	Yes			Example: ResponsePolicyClientIPAddress
fqdn	FQDN	Yes	Name	name	Example: 10.1.2.1.ABC.NET
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used.
canonical_name	IP address	No	Canonical Name	canonical	Example: 10.1.2.1
parent_zone	FQDN	No			Example: ABC.NET
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable	disable	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see . Example: 7200

Example

This example shows how to create data files for Response Policy Client IP Address CNAME. The example uses comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

```
header-
ResponsePolicyClientIPAddressCname,fqdn*,canonical_name,disabled,parent_zone,vi
ew
ResponsePolicyClientIPAddressCname,10.1.2.1.ABC.NET,10.1.2.1,FALSE,ABC.NET,DEFA
ULT
```

Network View

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-NetworkView	String	Yes			Identifies the first row as a header row for the network view objects. Example: NetworkView
name	String	Yes			Indicates the name of the network view. Example: net_view1
_new_name	String	No			Add this field to overwrite the **name** field when you select the **Overwrite** or **Merge** option.
comment	String	No	Comment	comment	Example: This is a network view.
EA-Site	String	No	Extensible attribute	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. Example: California.
EA-Users	String	No	Extensible attribute	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: John.
ADMGRP-XXXX	String	No	Permissions Admin Group/Role	permission	ADMGRP-JimSmith is an example of an admin permission of a specific admin group. Example: RW

DNS View

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guideline
Header-View	String	Yes			Identifies the first row as a header row for the DNS view objects. Example: View
name	String	Yes			Example: dns_view1

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guideline
_new_name	String	No			Add this field to overwrite the **name** field when you select the **Overwrite** or **Merge** option.
comment	String	No	Comment	comment	Example: This is a DNS view.
network_view	String	No	Network View	network_view	If no network view is specified, the default view is used. Example: Default
disable	Boolean	No	Disable	disable	Enable or disable view. Example: False
recursion	Boolean	No		allow_recursive_query	Flag to respond to recursive queries. Example: False
root_name_server_type	String	No			This is a single inheritance from GridDns. Example: Custom
match_clients	ACL	No			List of **address_tsig_ac** items. It can be an IP address, a network entry, **Any** or a **TSIG**-/permission. If the first value is not Any or TSIG-, it is assumed to be an IP address or a network entry. Example: 10.0.0.10/Allow, 11.0.0.0/16/Deny, TSIG-foo/xyz/Allow. It can also be a named ACL. Example: NACL1.
match_destinations	ACL	No			Indicates the match_destination list. It can be an IP address, a network, Any or a TSIG-/permission. If the first value is not **Any** or **TSIG-,** it is assumed to be an IP address or a network entry. Example: 10.0.0.10/Allow, 11.0.0.0/16/Deny, TSIG-foo/xyz/Allow. It can also be a named ACL. Example: NACL1.
custom_root_name_servers	Root nameserver list	No			List of custom root name servers. Example: rnm1.test.com/1.1.1.1/
lame_ttl	Unsigned integer	No			Indicates the lame TTL value in seconds. Example: 600
nxdomain_redirect	Boolean	No			Enable intercept and redirect nxdomain responses Example: False

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guideline
nxdomain_redirect_addresses	IP address list	No			Example: 1.1.1.1,2.2.2.2 Note that the field **nxdomain_redirect_addresses** is dependent on the **nxdomain_redirect** field. Infoblox recommends that you specify values for **nxdomain_redirect_addresses** a nd **nxdomain_redirect** fields and do not leave these fields blank while performing a CSV import operation.
nxdomain_redirect_ttl	Unsigned integer	No			Indicates the NXDOMAIN redirect ttl in seconds. Example: 60
nxdomain_log_query	Boolean	No			When you set this to **True**, NXDOMAIN redirections will be logged.Example: False
nxdomain_rulesets	List of domain names	No			List of Ruleset objects used for NXDOMAIN redirection. Example: nxd1.com, nxd2.com
enable_blacklist	Boolean	No		enable_blacklist	Enable or disable blacklisting at the Grid level. Example: False
blacklist_redirect_addresses	IP address list	No		blacklist_redirect_ addresses	Set or retrieve the list of IPv4 addresses to which the blacklisted queries are redirected.Example: 1.1.1.1,2.2.2.2
blacklist_action	String	No			Specify the action to be performed when a domain name matches the pattern defined in an assigned rule. Example: Redirect
blacklist_redirect_ttl	Unsigned integer	No			Set or retrieve the TTL value of synthetic DNS responses resulted by blacklisted queries. Example: 60
blacklist_log_query	Boolean	No		blacklist_log_query	Specify if blacklisted queries must be logged. Example: False
blacklist_rulesets	List of domain names	No		blacklist_rulesets	Specify or retrieve ruleset objects that are blacklisted at the Grid level. Example: list1.com, list2.com, ...
enable_dns64	Boolean	No			Enable or disable DNS64 synthesis. Example: False
dns64_groups	DNS64 group list	No			List of SynthesisGroup objects. Example: dns64_grp1, dns64_grp2
forwarders_only	Boolean	No	Use Forwarders Only	forward_only	Enable use of forwarders only. Example: False

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guideline
forwarders	IP address list	No		forwarders	List of forwarders for zone transfers. Example: "10.10.0.1,20.20.0.1,.."
filter_aaaa	String	No			Indicates the type of AAAA filtering for this Grid DNS object. The default value is **No**. Example: Yes
filter_aaaa_list	ACL	No			Indicates the list of IPv4 addresses and networks from which queries are received. Note that the AAAA filtering is applied to these addresses. Example: “12.0.0.12/ Deny,13.0.0.0/8/Allow,. .” or “NACL1”
max_cache_ttl	Unsigned integer	No			Indicates the maximum time (in seconds) for which the server will cache positive answers. The default value is 604800.
max_ncache_ttl	Unsigned integer	No			Indicates the maximum time (in seconds) for which the server will cache negative (NXDOMAIN) responses. The default value is 10800. The maximum allowed value is 604800.
EA-Site	String	No	Extensible attribute	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. Example: California.
EA-Users	String	No	Extensible attribute	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: John.
ADMGRP-XXXX	String	No	Permissions Admin Group/Role	permission	ADMGRP-JimSmith is an example of an admin permission of a specific admin group. Example: RW
rpz_drop_ip_rule_enabled	Boolean	No	Ignore RPZ-IP triggers with too small prefix lengths		When this is set to True, DNS server ignores RPZ-IP rules with prefix lengths that are less than the specified prefix length limit. Example: TRUE
rpz_drop_ip_rule_min_prefix_length_ipv4	Unsigned Integer	No	Minimum IPv4 Prefix Length		Indicates the minimum IPv4 prefix length for RPZ-IP triggers. The default value is 29.
rpz_drop_ip_rule_min_prefix_length_ipv6	Unsigned Integer	No	Maximum IPv4 Prefix Length		Indicates the minimum IPv6 prefix length for RPZ-IP triggers. The default value is 112

IPv4 Network Container

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guideline
Header- NetworkContainer	String	Yes			Identifies the first row as a header row for network container objects. Example: NetworkContainer
address	IP address	Yes	IP Address	ipv4addr	Indicates the IP address of the network container. Example: 192.138.1.1
netmask	Prefix	Yes	Netmask	network	Indicates the subnet mask of a network container in CIDR format. Example: 24
comment	String	No	Comment	comment	Example: This is an IPv4 network container.
lease_time	integer	No	Lease Time		Example: 1100
routers	IP address list	No	Routers		Example: "10.0.0.1,10.0.0.100,"
domain_name	FQDN	No	Domain Name		
domain_name_servers	IP address list	No	DNS Servers		Example: "10.2.3.4,11.2.3.4"
broadcast_address	IP address	No	Broadcast Address		Example: 10.0.0.1
OPTION-1	String	No	Custom DHCP Options	options	This is an example of a DHCP option. For Options information, see *Data Specific Guidelines*. Example: '255.0.0.0' name implies vendor_class='DHCP' (default)
OPTION-XXXX-200	Option information	No	Custom DHCP Options	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 'dfdfdfd' name implies vendor_class='XXXX', option code/ number 200
enable_ddns	Boolean	No	Enable DDNS Updates	enable_ddns	Example: FALSE
ddns_domainname	String	No	DDNS Domain Name	ddns_domainname	Example: ddns.corp100.com

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guideline
ddns_ttl	Unsigned integer	No	DDNS Update TTL	ddns_ttl	Indicates the DDNS TTL value in seconds. Example: 1200
ddns_generate_hostname	Boolean	No	Generate Hostname	ddns_generate_hostname	When you set this to **True,** DHCP server will generate a hostname for DNS updates if not sent by client. Example: TRUE
update_static_ leases	Boolean	No	Update Fixed Address	ddns_update_fixed_address	Example: FALSE
enable_option81	Boolean	No	Option 81 Support	ddns_use_option81	Example: TRUE
update_dns_on_ lease_renewal	Boolean	No	Lease Renewal Update	override_ update_dns_ on_lease_ renewal	Example: TRUE
enable_dhcp_ thresholds	Boolean	No	Enable DHCP Thresholds	enable_dhcp_ thresholds	When you set this field to TRUE, you must enter values in the range_high_water_mark and range_low_water_mark fields. You cannot leave those fields empty. Otherwise, the appliance generates an error.
enable_email_ warnings	Boolean	No		enable_email_warnings	Enable to send DHCP threshold warnings via email. Example: False
enable_snmp_ warnings	Boolean	No			Enable to send DHCP threshold warnings via SNMP. Example: False
threshold_email_ addresses	email address list	No	Email Addresses		Example: "'admin1@infoblox.com','admin2@somewhere.com'"
pxe_lease_time	Unsigned integer	No	PXE Lease Time	pxe_lease_time	Example: 1100
deny_bootp	Boolean	No	Deny BOOTP Requests	deny_bootp	Example: FALSE
boot_file	String	No	Boot File	bootfile	Example: bootfile1
boot_server	String	No	Boot Server	bootserver	Example: abc.corp100.com
next_server	String	No	Next Server	nextserver	Example: blue.domain.com

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guideline
option_logic_filters	List of IPv4 logic filter rules		Filter Type/ Action		Examples: .com.infoblox.dns.dhcp_mac_filter$mac_filter_name,.com.infoblox.dns.nac_filter$nac_filter_name, .com.infoblox.dns.dhcp_option_filters$opt_filter_name
lease_scavenge_time	Unsigned integer	No			Indicates the Grid level **lease_scavenge_time value**. If the value is -1, which means this lease scavenge will is disabled. The minimum value would be 7 * 24 * 60 * 60 (7 days).
is_authoritative	Boolean	No	Authoritative	authority	Example: FALSE
recycle_leases	Boolean	No	Lease Deletion	recycle_leases	This field is set to TRUE by default. Ensure that you use the overwrite option if you want to change the value to FALSE. Merging data from an import preserves the default value.
ignore_client_requested_options	Boolean	No	Ignore Optionlist	ignore_dhcp_option_list_request	Example: TRUE
network_view	String	No	Network View	network_view	If no network view is specified, the default view is used. Example: Default
rir_organization	String	No	Organization Name	rir_organization	Identifies the Regional Internet Registry (RIR) organization object. Use this only when the network is associated with an RIR organization. Example: corp100
rir_registration_status	String	No	Registration Status	rir_registration_status	Identifies the registration status of Regional Internet Registry (RIR). Use this only for an RIR network. When you enable the **Enable Updates Of RIR Registrations** checkbox at the Grid level and import a CSV file to add either an **IPv4 network container** or an **IPv6 network container** with the **rir_registration_status** set to Registered without values for any other RIR fields, the appliance completes the import operation and adds the IPv4 network container or the IPv6 network container to the Grid. The status of this IPv4 network container or the IPv6 network container is set as **Non-registered** network. Example: Non-registered
last_rir_registration_update_sent	String	No			Identifies the last registration update timestamp of Regional Internet Registry (RIR). This is a read-only attribute.
last_rir_registration_update_status	String	No			Identifies the last registration update status of Regional Internet Registry (RIR). This is a read-only attribute.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guideline
enable_discovery	Boolean	Yes	Enable Discovery	network	If this field is set to **True**, the **discovery_member** must also be defined.
discovery_member	String	Yes	Discovery Member	network	Indicates the discovery member name. Required if discovery is enabled for the network.
discovery_exclusion_range	Prefix	No			List of IP ranges to be excluded from the discovery process.
remove-subnets	Boolean	No			Specify **False** to keep the subnets or **True** to remove them. The default value is undefined, which is to remove all subnets. Use this only when you want to delete a network container. When you perform CSV export of a network container, the CSV file does not contain the **remove-subnets** column. You must add the **remove-subnets** column to the CSV export file if you want to perform a delete operation. When you delete a network container from the CSV file, you must set **remove-subnets** to **True** to delete both the parent and sub networks. When you set this column value to **False,** the CSV delete operation deletes only the parent network when you delete a network container.
EA-Site	String	No	Extensible attribute	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. Example: California.
EA-Users	String	No	Extensible attribute	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: John.
ADMGRP-XXXX	String	No	Permissions Admin Group/ Role	permission	ADMGRP-JimSmith is an example of an admin permission of a specific admin group. Example: RW

IPv4 Network

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-Network	String	Yes			Example: Network
rir_organization	String	No	Organization Name	rir_organization	Use this only when the network is associated with an RIR organization. Example: corp100

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
rir_registration_status	String	No	Registration Status	rir_registration_status	Use this only when this is an RIR network. Example: Registered
address	IP address	Yes	Address	network	Example: 10.0.0.11
netmask	Netmask	Yes	Netmask		Example: 255.255.0.0
network_view	String	No	Network View	network_view	If no view is specified, the Default view is used. Example: Default
enable_discovery	Boolean	Yes	Enable Discovery	enable_discovery	If this field is set to TRUE, the discovery_member must also be defined.
discovery_member	String	Yes	Discovery Member	discovery_member	Required if discovery is enabled for the network.
discovery_exclusion_range	IP Prefix	No	Network Editor → Discovery Exclusions	discovery_exclusion_range	List of IP ranges to be excluded from the discovery process.
comment	String	No	Comment	comment	
auto_create_reversezone	Boolean	No	Automatically create reverse mapping zone	auto_create_reverszone	Example: TRUE
is_authoritative	Boolean	No	Authoritative	authority	Example: FALSE
option_logic_filters	List of IPv4 logic filter rules	No	Filter Type/Action		Examples: .com.infoblox.dns.dhcp_mac_filter$mac_filter_name, .com.infoblox.dns.nac_filter$nac_filter_name, .com.infoblox.dns.dhcp_option_filters$opt_filter_name
boot_file	String	No	Boot File	bootfile	Example: bootfile1
boot_server	String	No	Boot Server	bootserver	Example: *abc.corp100.com*
ddns_domainname	String	No	DDNS Domain Name	ddns_domainname	Example: *ddns.corp100.com*
generate_hostname	Boolean	No	Generate Hostname	generate_hostname	When you set this to **True,** DHCP server will generate a hostname for DNS updates if not sent by client. Example: TRUE
always_update_dns	Boolean	No	DNS Zones Associations	ddns_server_always_updates	Example: FALSE

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
update_static_leases	Boolean	No	Fixed Address Updates	ddns_update_fixed_address	Example: FALSE
update_dns_on_lease_renewal	Boolean	No	Update DNS on DHCP Lease Renewal	override_update_dns_on_lease_renewal	Example: TRUE
ddns_ttl	Unsigned integer	No	DDNS Update TTL	ddns_ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 1200
enable_option81	Boolean	No	Option 81 Support	ddns_use_option81	Example: TRUE
deny_bootp	Boolean	No	Deny BOOTP Requests	deny_bootp	Example: FALSE
broadcast_address	String	No	Broadcast Address		
disabled	Boolean	No	Disabled	disable	Example: FALSE
enable_ddns	Boolean	No	Enable DDNS Updates	enable_ddns	Example: FALSE
enable_thresholds	Boolean	No	Enable DHCP Thresholds	enable_dhcp_thresholds	When you set this field to TRUE, you must enter values in the range_high_water_mark and range_low_water_mark fields. You cannot leave those fields empty. Otherwise, the appliance generates an error.
enable_threshold_email_warnings	Boolean	No	Enable Email Warnings	enable_email_warnings	When you use the merge function, the appliance preserves the existing value in this field. When you use the overwrite function, you must include a value (TRUE or FALSE). Otherwise, the appliance generates an error. Example: TRUE
enable_threshold_snmp_warnings	Boolean	No	Enable SNMP Warnings	enable_snmp_warnings	When you use the merge function, the appliance preserves the existing value in this field. When you use the overwrite function, you must include a value (TRUE or FALSE). Otherwise, the appliance generates an error. Example: TRUE
range_high_water_mark	Integer	No	High Water Mark	high_water_mark	When you set enable_thresholds to TRUE, you must enter values in this field and in the range_low_water_mark field. You cannot leave these fields empty. Otherwise, the appliance generates an error. Example: 80

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ignore_client_requested_options	Boolean	No	Ignore Optionlist	ignore_dhcp_option_list_request	Example: TRUE
range_low_water_mark	Integer	No	Low Water Mark	low_water_mark	When you set enable_thresholds to TRUE, you must enter values in this field and in the range_high_water_mark field. You cannot leave these fields empty. Otherwise, the appliance generates an error. Example: 10
next_server	String	No	Next Server	nextserver	Example: *blue.domain.com*
lease_time	Unsigned integer	No	Lease Time		Example: 1100
enable_pxe_lease_time	Boolean	No	Enable PXE lease time		Example: FALSE
pxe_lease_time	Unsigned integer	No	PXE Lease Time	pxe_lease_time	Example: 1100
recycle_leases	Boolean	No	Lease Deletion	recycle_leases	This field is set to TRUE by default. Ensure that you use the overwrite option if you want to change the value to FALSE. Merging data from an import preserves the default value.
threshold_email_addresses	email address list	No	Email Addresses		Example: "'admin1@infoblox.com','admin2@somewhere.com'"
dhcp_members	Grid member list	No	Members	members	Example: "*host1.infoblox.com*, *host2.infoblox.com*"
routers	IP address list	No	Routers		Example: "10.0.0.1,10.0.0.100,"
domain_name	FQDN	No	Domain Name		
domain_name_servers	IP address list	No	DNS Servers		Example: "10.2.3.4,11.2.3.4"
zone_associations	Zone list	No			Example: *test.com/TRUE*
VLANs	String	No	Assigned VLAN ID Assigned VLAN Name		VLAN View is a container object which can contain VLAN Range/VLAN objects. Example: default/1/4094/1

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
OPTION-1	String	No	Custom DHCP Options	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: '255.0.0.0' name implies vendor_class='DHCP' (default)
OPTION-XXXX-200	Option information	No	Custom DHCP Options	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 'dfdfdfd' name implies vendor_class='XXXX', option code/number 200
EA-Site	String	No	Extensible Attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-XXX	String	No	Extensible Attribute XXX value	inheritable	EA-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the value of an inheritable extensible attribute. For information about data format and examples, see *Data Specific Guidelines*.
EAInherited-XXX	String	No	Inheritance State of an Extensible Attribute XXX	inheritable	EAInherited-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the inheritance state of an inheritable extensible attribute. This column is displayed only if the extensible attribute is inheritable. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible Attribute User	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for networks. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an IPv4 Network

This example shows how to import network 10.1.0.0/16 in the network view External with auto create reverse zone enabled and a comment.

```
header-network,address*,netmask*,network_view,auto_create_reversezone,comment
network,10.1.0.0,255.255.0.0,External,TRUE,This is comment field
```

For a network that has discovery enabled:

```
header-network,address*,netmask*,network_view,auto_create_reversezone,
enable_discovery,discovery_member
 network,10.1.0.0,255.255.0.0,External,TRUE,TRUE,gridmember1.localdomain
```

For a network that has discovery enabled and including an IPv4 range that is excluded for discovery:

```
header-network,address*,netmask*,network_view,auto_create_reversezone,
enable_discovery,discovery_member,discovery_exclusion_range

network,10.1.0.0,255.255.0.0,External,TRUE,gridmember1.localdomain,10.1.8.0-10.1
.8.255
```

You cannot import a network container, but you can add an IPv4 network container through GUI.

Overwriting IPv4 Network Data

This example shows how to overwrite the following data in an existing network: enable the network to be "authoritative" and to add boot files bppt_file_001 and boot server 1.2.3.4.
header-network,address*,netmask*,is_authoritative,boot_file,boot_server
network,100.0.0.0,255.255.255.0,True,boot_file_001,1.2.3.4

Merging IPv4 Network Data

This example shows how to merge the following data to an existing network: DDNS domain name, enable generate hostname, and disable always update DNS.

```
header-
network,address*,netmask*,ddns_domainname,generate_hostname,always_update_dns
network,100.0.0.0,255.255.255.0,ddns.corp100.com,TRUE,FALSE
```

Adding IPv4 Networks with Zone Associations Enabled

This example shows how to add networks to a member in the default network view with zone association added as the default. The first row adds a network "20.0.1.0/24" that maps to member "*ib-10-34-43-2.infoblox.com*" in the "default" network view with zone association "*dnszone1.com*" added as the default zone association. The second row adds a network "20.0.2.0/24" that maps to member "*ib-10-34-43-2.infoblox.com*" in the "default" network view with zone associations "*dnszone1.com*" and "*dnszone2.com*" added, where zone "*dnszone2.com*" is configured as the default zone association.

```
network,address*,netmask*,dhcp_members,network_view,zone_associations

```

```
network,20.0.1.0,255.255.255.0,ib-10-34-43-2.infoblox.com,default,dnszone1.com/
True/default
```

```
network,20.0.2.0,255.255.255.0,ib-10-34-43-2.infoblox.com,default,dnszone1.com/
False/default, dnszone2.com/True/default
```

Overwriting IPv4 Network Data with Zone Associations Enabled

This example shows how to overwrite network data with zone association enabled. The first row modifies network "20.0.1.0/24" zone association from "*dnszone1.com*" to "*dnszone2.com*". The second row modifies network "20.0.2.0/24" default zone association from "*dnszone2.com*" to "*dnszone1.com*".

```
header-network,address*,netmask*,dhcp_members,network_view,zone_associations
```

```
network,20.0.1.0,255.255.255.0,ib-10-34-43-2.infoblox.com,default,dnszone2.com/
True/default
```

```
network,20.0.2.0,255.255.255.0,ib-10-34-43-2.infoblox.com,default,dnszone1.com/
True/default, dnszone2.com/False/default
```

IPv6 Network Container

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-IPv6NetworkContainer	String	Yes			Identifies the first row as a header row for IPv6 network container objects. Example: IPv6NetworkContainer.
address	IP Address	Yes	IP Address	ipv6addr	Indicates the IP address of the network container. Example: 2001::
cidr	Prefix	Yes	Netmask		Indicates the network container, in CIDR format, to which this network container belongs. Example: 64
network_view	String	No	Network View	network_view	If no network view is specified, the default view is used. Example: Default.
comment	String	No	Comment	comment	Example: This is an IPv6 network container.
zone_associations	Zone list	No	DNS Zone Associations	zone_associations	Example: test.com/TRUE

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
valid_lifetime	Integer	No	Valid Lifetime	valid_lifetime	Example: 43200
Preferred_lifetime	Integer	No	Preferred Lifetime	preferred_lifetime	Example: 604800
domain_name	String	No	Domain Name		Example: testdomain.com
domain_name_servers	IP address list	No	DNS Servers		Example: '2000::10,3000::10'
OPTION-7	Integer	No	Custom DHCP Options	override_options	This is an example of a DHCP option. For information, see *Data Specific Guidelines* on page 9. Example: '12' name implies option space = 'DHCPv6', option code/ number 7
OPTION-XXXX-200	Option informatio n	No	Custom DHCP Options	override_options	This is an example of a DHCP option. For information, see *Data Specific Guidelines* on page 9. Example: 'dfdfdfd' name implies vendor_class='XXXX', option code/number 200
recycle_leases	Boolean	No	Lease Deletion	recycle_leases	This field is set to TRUE by default. Ensure that you use the overwrite option if you want to change the value to FALSE. Merging data from an import preserves the default value.
enable_ddns	Boolean	No	Enable DDNS Updates	enable_ddns	Example: TRUE
ddns_domainname	String	No	DDNS Domain Name	ddns_domainname	Example: ddns.corp100.com
ddns_ttl	Unsigned integer	No	DDNS Update TTL	ddns_ttl	Indicates the DDNS TTL value in seconds. This is an inherited field. Example: 1200
generate_hostname	Boolean	No	Generate Hostname	override_ddns_generate _hostname	Example: TRUE

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
always_update_dns	Boolean	No	FQDN Support	ddns_server_always_updates	Example: TRUE
update_dns_on_lease_renewal	Boolean	No	Lease Renewal Update	override_update_dns_on _lease_renewal	Example: TRUE
rir_organization	String	No	Organization Name	rir_organization	Identifies the Regional Internet Registry (RIR) organization object. Use this only when the network is associated with an RIR organization. Example: corp100
rir_registration_status	String	No	Registration Status	rir_registration_status	Identifies the registration status of Regional Internet Registry (RIR). Use this only for an RIR network. When you enable the **Enable Updates Of RIR Registrations** checkbox at the Grid level and import a CSV file to add either an **IPv4 network container** or an **IPv6 network container** with the **rir_registration_status** set to Registered without values for any other RIR fields, the appliance completes the import operation and adds the IPv4 network container or the IPv6 network container to the Grid. The status of this IPv4 network container or the IPv6 network container is set as **Non-registered** network. Example: Non-registered
last_rir_registration_update_sent	String	No			Identifies the last registration update timestamp of Regional Internet Registry (RIR). This is a read-only attribute.
last_rir_registration_update_status	String	No			Identifies the last registration update status of Regional Internet Registry (RIR). This is a read-only attribute.
enable_discovery	Boolean	Yes	Enable Discovery	network	If this field is set to **True,** the **discovery_member** must also be defined.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
discovery_member	String	Yes	Discovery Member	network	This field is required if discovery is enabled for the network.
discovery_exclusion_range	IP Prefix	No	Network Editor → Discovery Exclusions	Network	List of IP ranges to be excluded from the discovery process.
EA-Site	String	No	Extensible attribute	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. Example: California.
EA-Users	String	No	Extensible attribute	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: John.
ADMGRP-XXXX	String	No		permission	ADMGRP-JimSmith is an example of an admin permission of a specific admin group. Example: RW

IPv6 Network

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-IPv6Network	String	Yes			Example: IPv6Network
rir_organization	String	No	Organization Name	rir_organization	Use this only when the network is associated with an RIR organization.Example: corp100
rir_registration_status	String	No	Registration Status	rir_registration_status	Use this only when this is an RIR network.Example: Registered
address	IPv6 address	Yes	Address	ipv6addrs	Example: 2001::
cidr	Prefix	Yes	Netmask		Example: 32

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
network_view	String	No	Network View	network_view	If no view is specified, the Default view is used. Example: Default
enable_discovery	Boolean	Yes	Enable Discovery	enable_discovery	If this field is set to TRUE, the discovery_member must also be defined.
discovery_member	String	Yes	Discovery Member	discovery_member	Required if discovery is enabled for the network.
discovery_exclusion_range	IP Prefix	No	Network Editor → Discovery Exclusions	discovery_exclusion_range	List of IP ranges to be excluded from the discovery process.
disabled	Boolean	No	Disabled	disable	Example: TRUE
comment	String	No	Comment	comment	
auto_create_reversezone	Boolean	No	Automatically create reverse mapping zone	auto_create_reverse zone	Example: TRUE
zone_associations	Zone list	No	DNS Zone Associations	zone_associations	Example: *test.com/TRUE*
dhcp_members	Grid member list	No	Members	members	Example: “*host1.infoblox.com*, *host2.infoblox.com*
domain_name	String	No	Domain Name		Example: *testdomain.com*
domain_name_servers	IP address list	No	DNS Servers		Example: ‘2000::10,3000::10’
valid_lifetime	Integer	No	Valid Lifetime	valid_lifetime	Example: 43200
Preferred_lifetime	Integer	No	Preferred Lifetime	preferred_lifetime	Example: 604800
recycle_leases	Boolean	No		recycle_leases	Example: FALSE
enable_ddns	Boolean	No	Enable DDNS Updates	enable_ddns	Example: TRUE

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
always_update_dns	Boolean	No	FQDN Support	ddns_server_always_updates	Example: TRUE
ddns_domain_name	String	No	DDNS Domain Name	ddns_domainname	Example: *ddnsdomain.com*
ddns_ttl	Unsigned integer	No	DDNS Update TTL	ddns_ttl	Example: 3600
generate_hostname	Boolean	No	Generate Hostname	override_ddns_generate_hostname	Example: TRUE
update_dns_on_lease_renewal	Boolean	No	Lease Renewal Update	override_update_dns_on_lease_renewal	Example: TRUE
VLANs	String	No	Assigned VLAN ID Assigned VLAN Name		VLAN View is a container object which can contain VLAN Range/VLAN objects. Example: default/1/4094/1
OPTION-7	Integer	No	Custom DHCP Options	override_options	This is an example of a DHCP option. For information, see *Data Specific Guidelines* .on page 9.Example: '12' name implies option space = 'DHCPv6', option code/number 7
OPTION-XXXX-200	Option information	No	Custom DHCP Options	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 'dfdfdfd' name implies vendor_class='XXXX', option code/number 200
EA-Site	String	No	Extensible Attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
EA-XXX	String	No	Extensible Attribute XXX value	inheritable	EA-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the value of an inheritable extensible attribute. For information about data format and examples, see *Data Specific Guidelines*.
EAInherited-XXX	String	No	Inheritance State of an Extensible Attribute XXX	inheritable	EAInherited-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the inheritance state of an inheritable extensible attribute. This column is displayed only if the extensible attribute is inheritable. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible Attribute Users	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for IPv6 networks. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an IPv6 Network

This example shows how to import an IPv6 network 3333::/64 in the Default DHCP view.

```
header-IPv6network,address*,cidr*,network_view,comment,auto_create_reversezone
IPv6network,2001:db8:6000:5000::,64,Default,This is a comment,TRUE
```

For a network that has discovery enabled:

```
header-
IPv6network,address*,cidr*,network_view,auto_create_reversezone,enable_discover
y,discovery_member
 IPv6network,2001:db8:6000:5000::,64,Default,TRUE,TRUE,gridmember1.localdomain
```

For a network that has discovery enabled and including an IPv6 range that is excluded for discovery:

```
header-network,address*,netmask*,network_view,auto_create_reversezone,
discovery_enabled,discovery_member,discovery_exclusion_range
 IPv6network,2001:db8:6000:5000::,64,Default,TRUE,TRUE,gridmember1.localdomain,
2001:db8:6000:5000::1-2001:db8:6000:5000::128
```

> You cannot import a network container, but you can add an IPv6 network container through GUI.

Overwriting IPv6 Network Data

This example shows how to overwrite the following data of an IPv6 network: address and cidr.

```
header-IPv6network,address*,_new_address,cidr*,_new_cidr
IPv6network,3333::,2222::,64,32
```

Merging IPv6 Network Data

This example shows how to merge the extensible attribute State and admin group USA_admins to an IPv6 network.

```
header-IPv6network.address*,cidr*,EA-State,ADMGRP-USA_admins
IPv6network,3333::,64,CA,RW
```

IPv4 Shared Network

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-SharedNetwork	String	Yes			Example: SharedNetwork
name	String	Yes	Name	name	Example: Site Network
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
networks	List	Yes			Example: "10.1.1.0/24,10.1.2.0/24," Note that you must first create the IPv4 networks 10.1.1.0/24 and 10.1.2.0/24 before designating them to the shared network.
network_view	String	No	Network View	network_view	If no view is specified, the Default view is used. Example: Default
is_authoritative	Boolean	No	Authoritative	authority	Example: FALSE
option_logic_filters	List of IPv4 logic filter rules		Filter Type/ Action		Examples: .com.infoblox.dns.dhcp_mac_filter$mac_filter_name, .com.infoblox.dns.nac_filter$nac_filter_name, .com.infoblox.dns.dhcp_option_filters$opt_filter_name
boot_file	String	No	Boot File	bootfile	Example: bootfile1
boot_server	String	No	Boot Server	bootserver	Example: abc.corp100.com
comment	String	No	Comment	comment	
generate_hostname	Boolean	No	Generate Hostname	ddns_generate_hostname	Example: TRUE
always_update_dns	Boolean	No	DNS Zones Associations	ddns_server_always_updates	Example: FALSE
update_static_leases	Boolean	No	Fixed Address Updates	ddns_update_fixed_address	Example: FALSE
update_dns_on_lease_renewal	Boolean	No	Update DNS on DHCP Lease Renewal	override_update_dns_on _lease_renewal	Example: TRUE
ddns_ttl	Integer	No	DDNS Update TTL	ddns_ttl	This is an inherited field. Example: 1200
enable_option81	Boolean	No	Option 81 Support		ddns_use_option Example: TRUE 81
deny_bootp	Boolean	No	Deny BOOTP Requests	deny_bootp	Example: FALSE
disabled	Boolean	No	Disable	disable	Example: FALSE

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
enable_ddns	Boolean	No	Enable DDNS Updates	enable_ddns	Example: FALSE
ignore_client_requested_options	Boolean	No	Ignore Optionlist	ignore_dhcp_option_list_request	Example: TRUE
next_server	String	No	Next Server	nextserver	Example: blue.domain.com
lease_time	Unsigned integer	No	Lease Time		Example: 1100
enable_pxe_lease_time	Boolean	No	Enable PXE time	lease	Example: FALSE
pxe_lease_time	Unsigned integer	No	PXE Lease Time	pxe_lease_time	Example: 1100
routers	IP address list	No	routers		Example: "10.0.0.1,10.0.0.100"
domain_name	FQDN	No	Domain Name	domain_name	
domain_name_servers	IP address list	No	Name Server		Example: "10.2.3.4,11.2.3.4"
OPTION-2	Integer	No	Custom DHCP Options	options	Example: 50
OPTION-1	String	No	Custom DHCP Options	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: '255.0.0.0' name implies vendor_class='DHCP' (default)
OPTION-XXXX-200	Option information	No	Extensible Attribute Site	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 'dfdfdfd' name implies vendor_class='XXXX', option code/number 200
EA-Site	String	No	Extensible Attribute Users	extensible attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Permissions Admin Group/Role	extensible attributes	extensible EA-Users is an example of a user defined

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for shared networks. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an IPv4 Shared Network

This example shows how to import a new shared Network in the Default DHCP view.

```
header-SharedNetwork,name*,networks*,network_view,comment,OPTION-2
SharedNetwork,Sharednetwork01,"10.0.0.0/24,20.0.0.0/24",Default,This is a
comment.,128
```

Overwriting IPv4 Shared Network Data

This example shows how to overwrite a shared network with additional networks.

```
header-SharedNetwork,name*,networks*
SharedNetwork,Sharednetwork01,"10.0.0.0/24,20.0.0.0/24,30.0.0.0/24"
```

Merging IPv4 Shared Network Data

This example shows how to merge the extensible attribute Site and a new admin group DHCP_admins with RW permission to an IPv4 shared network.

```
header-SharedNetwork,name*,networks*,EA-Site,ADMGRP-DHCP_admins
SharedNetwork,Sharednetwork01,"10.0.0.0/24,20.0.0.0/24",USA,RW
```

IPv6 Shared Network

> **Note**
>
> This object is supported in CSV export only.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-IPv6SharedNetwork	String	Yes			Example: IPv6SharedNetwork
name	String	Yes	Name	name	Example: IPv6Shared01

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.
networks	List	Yes			Example: “2000::/64,3000::/64". Note that you must first create the IPv6 networks 2000::/64 and 3000::/64 before designating them to the shared network.
network_view	String	No	Network View	network_view	If no view is specified, the Default view is used. Example: Default
comment	String	No	Comment	comment	
disabled	Boolean	No	Disabled	disable	Example: FALSE
domain_name	String	No	Domain Name		Example: testdomain.com
domain_name_servers	IP address list	No	Name Server		Example: “2000::10,3000::10”
valid_lifetime	Integer	No	Valid Lifetime	valid_lifetime	Example: 43200
Preferred_lifetime	Integer	No	Preferred Lifetime	preferred_lifetime	Example: 604800
enable_ddns	Boolean	No	Enable DDNS Updates	enable_ddns	Example: TRUE
always_update_dns	Boolean	No	DNS Zones Associations	ddns_server_always_updates	Example: TRUE
ddns_domain_name	String	No	DDNS Domain Name	ddns_domainname	Example: DDNSdomain
ddns_ttl	Integer	No	DDNS Update TTL	override_ddns_ttl	This is an inherited field. Example: 1200
generate_hostname	Boolean	No	Generate Hostname	ddns_generate_hostname	Example: Example: FALSE TRUE
update_dns_on_lease_renewal	Boolean	No	Update DNS on DHCP Lease Renewal	override_update_dns_on_lease_renewal	Example: TRUE

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
OPTION-7	Integer	No	Custom DHCP Options	override_options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: '12' name implies option space = 'DHCPv6', option code/number 7
OPTION-XXXX-200	Option information	No	Custom DHCP Options	override_options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 'dfdfdfd' name implies vendor_class='XXXX', option code/number 200
EA-Site	String	No	Extensible Attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible attribute Users	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

IPv4 DHCP Range

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-DhcpRange	String	Yes			Example: DhcpRange
start_address	IP address	Yes	Start		start_addr Example: 10.0.0.11
_new_start_address	IP address	No			Add this field to overwrite the start_address field when you select the overwrite or merge option. Example: 10.0.0.55
end_address	IP address	Yes	End	end_addr	Example: 10.0.0.22

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
_new_end_address	IP address	No			Add this field to overwrite the end_address field when you select the overwrite or merge option. Example: 10.0.0.66
network_view	String	No	Network View	network_view	If no view is specified, the Default view is used. Example: Default
name	String	No	Name	name	
comment	String	No	Comment	comment	
is_authoritative	Boolean	No	Authoritative	authority	Example: FALSE
boot_file	String	No	Boot File	bootfile	Example: bootfile1
boot_server	String	No	Boot Server	bootserver	Example: abc.corp100.com
ddns_domainname	String	No	DDNS Domain Name	ddns_domainname	Example: ddns.corp100.com
generate_hostname	Boolean	No	Generate Hostname	ddns_generate_hostname	Example: TRUE
deny_all_clients	Boolean	No		deny_all_clients	Example: FALSE
deny_bootp	Boolean	No	Deny BOOTP Requests	deny_bootp	Example: FALSE
disabled	Boolean	No	Disabled	disable	Example: FALSE
domain_name_servers	IP address list	No	Name Servers		Example: "10.2.3.4,11.2.3.4,"
enable_ddns	Boolean	No	Enable DDNS Updates	enable_ddns	Example: FALSE
enable_thresholds	Boolean	No	Enable DHCP Thresholds	enable_dhcp_thresholds	When you set this field to TRUE, you must enter values in the range_high_water_mark and range_low_water_mark fields. You cannot leave those fields empty. Otherwise, the appliance generates an error.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
enable_threshold_ email_ warnings	Boolean	No	Enable Email Warnings	enable_email_warnings	When you use the merge function, the appliance preserves the existing value in this field. When you use the overwrite function, you must include a value (TRUE or FALSE). Otherwise, the appliance generates an error. Example: TRUE
enable_threshold_ snmp_ warnings	Boolean	No	Enable SNMP Warnings	enable_snmp_ warnings	When you use the merge function, the appliance preserves the existing value in this field. When you use the overwrite function, you must include a value (TRUE or FALSE). Otherwise, the appliance generates an error. Example: TRUE
threshold_email_ addresses	email address list	No	Email Addresses		Example: "'admin1@infoblox.com','admin2@somewhere.com'"
range_high_water_ mark	Integer	No	High Water Mark	high_water_mark	When you set enable_thresholds to TRUE, you must enter values in this field and in the range_low_water_mark field. You cannot leave these fields empty. Otherwise, the appliance generates an error. Example: 80
ignore_client_requested_options	Boolean	No	Ignore Optionlist	ignore_dhcp_option_list_request	Example: TRUE
range_low_water_mark	Integer	No	Low Water Mark	low_water_mark	When you set enable_thresholds to TRUE, you must enter values in this field and in the range_high_water_mark field. You cannot leave these fields empty. Otherwise, the appliance generates an error. Example: 10
next_server	String	No	Next Server	nextserver	Example: blue.domain.com
lease_time	Unsigned integer	No	Lease Time		Example: 1100
enable_pxe_lease_ time	Boolean	No	Enable PXE lease time		Example: FALSE
pxe_lease_time	Unsigned integer	No	PXE Lease Time	pxe_lease_time	Example: 1100
unknown_clients_ option	String	No	Unknown Clients drop-down	unknown_client_ option	Example: Allow
known_clients_option	String	No	Known Clients drop-down	known_clients_ option	Example: Deny

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
recycle_leases	Boolean	No	Lease Deletion	recycle_leases	This field is set to TRUE by default. Ensure that you use the overwrite option if you want to change the value to FALSE. Merging data from an import preserves the default value.
update_dns_on_ lease_renewal	Boolean	No	Update DNS on DHCP Lease Renewal	override_update_ dns_on_lease_ renewal	Example: TRUE
always_update_dns	Boolean	No	DNS Zones Associations	always_update_ dns	Example: FALSE
exclusion_ranges	IP address range	No	Exclusion Ranges	exclude	This field indicates the start to end address range. You can also include a comment. The valid format is start address-end address/ comment. Example: “10.1.0.200-10.1.0.254/’The range for printers’,10.2.3.3-10.2.3.30/”
member	Grid member	No	Served by Grid Member	member	Example: member.infoblox.com
server_association_ type	Sting	No			Valid values are MEMBER, NONE, and FAILOVER
failover_association	Sting	No	Served by Failover Association	failover_assoc	
broadcast_address	IP address	No	Broadcast Address		Example: 10.0.0.1
routers	IP address list	No	Routers		Example: "10.0.0.1,10.0.0.100,"
domain_name	FQDN	No	Domain Name	domain_name	
option_logic_filters	List of IPv4 logic filter rules		Filter Type/ Action		Examples: com.infoblox.dns.dhcp_mac_filter$mac_filter_ name, .com.infoblox.dns.nac_filter$nac_filter_name, .com.infoblox.dns.dhcp_option_filters$opt_filte r_name
OPTION-2	Integer	No	Custom DHCP Options	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 50

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
OPTION-1	String	No	Custom DHCP Options	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: '255.0.0.0' name implies vendor_class='DHCP' (default)
OPTION-XXXX-200	Option information	No	Custom DHCP Options	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 'dfdfdfd' name implies vendor_class='XXXX', option code/number 200
EA-Site	String	No	Extensible Attribute Site	extensible attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-XXX	String	No	Extensible Attribute XXX value	inheritable	EA-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the value of an inheritable extensible attribute. For information about data format and examples, see *Data Specific Guidelines*.
EAInherited-XXX	String	No	Inheritance State of an Extensible Attribute XXX	inheritable	EAInherited-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the inheritance state of an inheritable extensible attribute. This column is displayed only if the extensible attribute is inheritable. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible Attribute Users	extensible attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for DHCP ranges. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a DHCP Range

This example shows how to import a new DHCP range, Range01, with starting IP of 100.0.0.1 and ending IP 100.0.0.254. The range is assigned to a member, master.corp100.com.

```
header-DhcpRange,start_address*,end_address*,name,comment,member
DhcpRange,100.0.0.1,100.0.0.254,Range01,This is a comment.,master.corp100.com
```

Overwriting DHCP Range Data

This example shows how to overwrite the starting address and the name of an existing DHCP range.

```
header-DhcpRange,start_address*,_new_start_address,end_address*,name
DhcpRange,100.0.0.100,100.0.0.150,100.0.0.254,Range02
```

Merging DHCP Range Data

This example shows how to merge an exclusion range 100.0.0.100 to 100.0.0.110 to an existing DHCP range, and to replace a member assignment with a failover association, Failover01.

```
header-
DhcpRange,start_address*,end_address*,exclusion_ranges,failover_association
DhcpRange,100.0.0.100,100.0.0.254,100.0.0.100-100.0.0.110,Fileaover01
```

IPv6 DHCP Range

> **Note**
> This object is supported in CSV export only.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-IPv6DhcpRange	String	Yes			Example: IPv6DhcpRange
address_type	Enumeration	No		address_type	Valid values are ADDRESS, PREFIX, and BOTH. If no value is specified, 'ADDRESS' (default) is used. Example: PREFIX
parent	String	No	Select Network	network	This field is required when address_type is 'PREFIX'. Example: 2000::/16
start_address	IP address	No	Address Start	start_addr	This field is required if address_type is 'ADDRESS' or 'BOTH'. Example: 2000::1
_new_start_address	IP address	No			Add this field to overwrite the start_address field when you select the overwrite or merge option.
end_address	IP address	No	Address End	end_addr	This field is required if address_type is 'ADDRESS' or 'BOTH'. Example: 2000::1

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
_new_end_address	IP address	No			Add this field to overwrite the end_address field when you select the overwrite or merge option.
ipv6_start_prefix	IPv6 address prefix	No	Prefix Delegated Start	ipv6_start_prefix	This field is required if address_type is ‘PREFIX’ or ‘BOTH’. Example: 2000:1111::
_new_ipv6_start_prefix	IPv6 address prefix	No			Add this field to overwrite the ipv6_start_address field when you select the overwrite or merge option.
ipv6_end_prefix	IPv6 address prefix	No	Prefix Delegated End	ipv6_end_prefix	This field is required if address_type is ‘PREFIX’ or ‘BOTH’. Example: 2000:1111::
_new_ipv6_end_prefix	IPv6 address prefix	No			Add this field to overwrite the ipv6_end_address field when you select the overwrite or merge option.
ipb6_prefix_bits	Integer	No		ipv6_prefix_bits	This field is required if address_type is ‘PREFIX’ or ‘BOTH’. Example: 32
network_view	String	No	Network View	network_view	If no view is specified, the Default view is used. Example: Default
name	String	No	Name	name	
comment	String	No	Comment	comment	Example: This is an IPv6 DHCP range.
disabled	Boolean	No	Disabled	disable	Example: FALSE
member	Grid member	No	Grid Member	member	Example: member.infoblox.com
server_association_type	String	No		server_association_type	Valid values are MEMBER and NONE. If no value is specified, None (default) is used.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
exclusion_ranges	IP address range	No	Exclusion Ranges	exclude	This field indicates the start to end address range. You can also include a comment. The valid format is: start address-end address/comment. Example: “2000::1-2000::5/’The range for printers’”
recycle_leases	Boolean	No	Lease Deletion	recycle_leases	This field is set to TRUE by default. Ensure that you use the overwrite option if you want to change the value to FALSE. Merging data from an import preserves the default value.
EA-Site	String	No	Extensible Attribute Site	extensible attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-XXX	String	No	Extensible Attribute XXX value	inheritable	EA-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the value of an inheritable extensible attribute. For information about data format and examples, see *Data Specific Guidelines*.
EAInherited-XXX	String	No	Inheritance State of an Extensible Attribute XXX	inheritable	EAInherited-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the inheritance state of an inheritable extensible attribute. This column is displayed only if the extensible attribute is inheritable. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible Attribute Users	extensible attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ADMGRP-JoeSmith	String	No	Permissions Admin Group/ Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

IPv4 Fixed Address/Reservation

> **Note**
>
> You can use the fixed address header to import reservations. When you import a reservation, you must specify 00:00:00:00:00:00 in the mac_address field.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-FixedAddress	String	Yes			Example: FixedAddress
ip_address	IP address	Yes	IP Address	ipv4addrss	Example: 10.0.0.11
ms_Server	IP address	Yes			Example: 100.102.30.180
_new_ip_address	IP address	No			Add this field to overwrite the ip_address field when you use the overwrite or merge option.
network_view	String	No	Network View	network_view	If no view is specified, the Default view is used. Example: Default
name	String	No	Name	name	
always_update_dns	Boolean	No	DNS Zones Associations	always_update_ dns	Example: FALSE
option_logic_filters	List of IPv4 logic filter rules	No	Filter Type/ Action		Examples: .com.infoblox.dns.dhcp_mac_filter$mac_filter_name, .com.infoblox.dns.nac_filter$nac_filter_name, .com.infoblox.dns.dhcp_option_filters$opt_filter_name
boot_file	String	No	Boot File	bootfile	Example: bootfile1
boot_server	String	No	Boot Server	bootserver	Example: abc.corp100.com
prepared_zero	Boolean	No			Example: FALSE
comment	String	No	Comment	comment	

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ddns_domainname	String	No	DDNS Domain Name	ddns_domainname	Example: ddns.corp100.com
deny_bootp	Boolean	No	Deny BOOTP Requests	deny_bootp	Example: FALSE
broadcast_address	IP address list	No	Broadcast Address		Example: 10.0.0.1
routers	IP address list	No	Routers		Example: "10.0.0.1,10.0.0.100,"
domain_name	FQDN	No	Domain Name		
domain_name_ servers	IP address list	No	Name Servers		Example: "10.2.3.4,11.2.3.4,"
dhcp_client_ identifier	String	No	Client Identifier	dhcp_client_ identifier	
disabled	Boolean	No	Disabled	disable	Example: FALSE
enable_ddns	Boolean	No	Enable DDNS Updates		Example: FALSE
ignore_client_ requested_ options	Boolean	No	Ignore Optionlist	ignore_dhcp_ option_list_request	Example: TRUE
circuit_id	String	No		agent_circuit_id	This field is required when match_option = CIRCUIT_ID. Example: 11
remote_id	String	No		agent_remote_id	This field is required when match_option = REMOTE_ID. Example: xyz
mac_address	MAC address	No Yes for reservation	MAC Address	mac	This field is required if match_option = MAC_ADDRESS, or if you are importing a reservation. For reservations, you must enter 00:00:00:00:00:00 in this field. Example: aa:bb:cc:dd:ee:ff
match_option	String	No		match_client	Data must be in the following format: ['MAC_ADDRESS','CLIENT_ID','CIRCUIT_ID','REMOTE_ID']
next_server	String	No	Next Server	nextserver	Example: blue.domain.com

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
lease_time	Unsigned integer	No	Lease Time		Example: 1100
enable_pxe_lease_time	Boolean	No	Enable PXE lease time		Example: FALSE
ddns_hostname	String	No		ddns_hostname	Example: host1.test.com
pxe_lease_time	Unsigned integer	No	PXE Lease Time	pxe_lease_time	Example: 1100
OPTION-2	Integer	No	Custom DHCP Options	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 50
OPTION-1	String	No	Custom DHCP Options	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. *Data Specific Guidelines*. Example: '255.0.0.0' name implies vendor_class='DHCP' (default)
OPTION-XXXX-200	Option information	No	Custom DHCP Options	options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 'dfdfdfd' name implies vendor_class='XXXX', option code/number 200
EA-Site	String	No	Extensible Attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-XXX	String	No	Extensible Attribute XXX value	inheritable	EA-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the value of an inheritable extensible attribute. For information about data format and examples, see *Data Specific Guidelines*.
EAInherited-XXX	String	No	Inheritance State of an Extensible Attribute XXX	inheritable	EAInherited-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the inheritance state of an inheritable extensible attribute. This column is displayed only if the extensible attribute is inheritable. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible Attribute User	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for IPv4 fixed addresses. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an IPv4 Fixed Address

This example shows how to import a new IPv4 fixed address.

```
header-
fixedaddress,ip_address*,network_view,mac_address*,match_option,ms_server,
remote_id,EA-
Sitefixedaddress,100.0.0.1,Default,aa:aa:aa:aa:aa:aa,Remote_ID,xyz,USA
```

To import MS sync data, specify ms_server field in the CSV format.

```
header-fixedaddress,ip_address*,ms_Server,EA-Location
fixedaddress,100.0.0.1,100.102.30.180,location-1
```

Overwriting IPv4 Fixed Address Data

This example shows how to overwrite the MAC address of an existing IPv4 fixed address from aa:aa:aa:aa:aa:aa to bb:aa:aa:aa:aa:aa.

```
header-fixedaddress,ip_address*,mac_address*
FixedAddress,100.0.0.1,bb:aa:aa:aa:aa:aa
```

This example shows how to overwrite the address of an existing IPv4 fixed address from 100.0.0.1 to 100.0.0.10.

```
header-fixedaddress,ip_address*,_new_ip_address,mac_address*
FixedAddress,100.0.0.1,100.0.0.10,bb:aa:aa:aa:aa:aa
```

Merging IPv4 Fixed Address Data

This example shows how to merge a new comment to an existing IPv4 fixed address.

```
header-fixedaddress,ip_address,mac_address*,comment
FixedAddress,100.0.0.10,bb:aa:aa:aa:aa:aa,A new comment here.
```

This example shows how to merge new routers addresses and the domain name to an existing IPv4 fixed address.

```
header-fixedaddress,ip_address*,mac_address*,routers,domain_name
fixedaddress,100.0.0.10,bb:aa:aa:aa:aa:aa,"2.2.2.2,4.4.4.4",ns1.corp100.com
```

Adding an IPv4 Reservation

This example shows how to import a new IPv4 reservation.

```
header-fixedaddress,ip_address*,network_view,mac_address*,EA-Site
fixedaddress,100.0.0.1,Default,00:00:00:00:00:00,USA
```

IPv6 Fixed Address

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-IPv6FixedAddress	String	Yes			Example: IPv6FixedAddress
address_type	Enumeration	No		address_type	Valid values are ADDRESS, PREFIX, and BOTH. If no value is specified, 'ADDRESS' (default) is used. Example: PREFIX
parent	String	Yes*	Select Network	network	This field is required when address_type is 'PREFIX'. Example: 2000::/16
ip_address	IP address	Yes*	Address	ipv6addrss	This field is required if address_type is 'ADDRESS' or 'BOTH'. Example: 2000::5
_new_ip_address	IP address	No			Add this field to overwrite the ip_address field when you select the overwrite or merge option.
ipv6_prefix	IPv6 address prefix	Yes*	Prefix Delegated	ipv6prefix	This field is required if address_type is 'PREFIX' or 'BOTH'. Example: 2000:1111::
_new_ipv6_prefix	IPv6 address prefix	No			Add this field to overwrite the ipv6_prefix field when you select the overwrite or merge option.
ipv6_prefix_bits	Integer	No		ipv6_prefix_bits	This field is required if address_type is 'PREFIX' or 'BOTH'. Example: 32
network_view	String	No	Network View	network_view	If no view is specified, the Default view is used. Example: Default
name	String	No	Name	name	Example: IPv6FixedAddr
comment	String	No	Comment	comment	
disabled	Boolean	No	Disabled	disable	Example: FALSE
match_option	String	No		match_client	Only 'DUID' is allowed. Example: DUID
duid	String	Yes	DUID	duid	Example: 0001

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
domain_name	FQDN	No	Domain Name		Example: ns1.corp100.com
domain_name_servers	IPv6 address list	No	Name Servers		Example: 2000::10,3000::10
valid_lifetime	Unsigned integer	No	Valid Lifetime	valid_lifename	Example: 43200
preferred_lifetime	Unsigned integer	No	Preferred Lifename	preferred_lifetime	Example: 604800
OPTION-7	Integer	No	Custom DHCP Options	override_options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: '12' name implies option space = 'DHCPv6', option code/ number 7
OPTION-XXXX-200	Option information	No	Custom DHCP Options	override_options	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 'dfdfdfd' name implies vendor_class='XXXX', option code/ number 200
EA-Site	String	No	Extensible Attribute Site	extensible attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-XXX	String	No	Extensible Attribute XXX value	inheritable	EA-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the value of an inheritable extensible attribute. For information about data format and examples, see *Data Specific Guidelines*.
EAInherited-XXX	String	No	Inheritance State of an Extensible Attribute XXX	inheritable	EAInherited-XXX is an example of an inheritable extensible attribute where XXX represents the attribute name. This column displays the inheritance state of an inheritable extensible attribute. This column is displayed only if the extensible attribute is inheritable. For information about data format and examples, see *Data Specific Guidelines*.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
EA-Users	String	No	Extensible Attribute Users	extensible attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/ Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Note

* Required in some cases, see detailed field description.

Examples

This section contains examples of how to create data files for IPv6 fixed addresses. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an IPv6 Fixed Address

This example shows how to import a new IPv6 fixed address.

```
header-IPv6FixedAddress,address_type,ip_address,network_view,match_option,EA-Site IPv6FixedAddress,ADDRESS,2000::5,default,DUID,USA
```

Overwriting IPv6 Fixed Address Data

This example shows how to overwrite an existing IPv6 fixed address from 2000::5 to 2000::1.

```
header-IPv6FixedAddress,address_type,ip_address,_new_ip_address IPv6FixedAddress,ADDRESS,2000::5,2000::1
```

Merging IPv6 Fixed Address Data

This example shows how to merge a new comment to an existing IPv6 fixed address.

```
header-IPv6FixedAddress,ip_address,comment IPv6FixedAddress,2000::1,A new comment.
```

This example shows how to merge a new domain name to an existing IPv6 fixed address.

```
header-IPv6FixedAddress,ip_address,domain_name IPv6FixedAddress,2000::1,ns1.corp100.com
```

DHCP Fingerprint

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-DHCPFingerprint	String	Yes			Example: DHCPFingerprint
name	String	Yes	Name	name	Example: Samsung Android
new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.
type	String	No			Device type. This can be 'Standard' or 'Custom.' The default is 'Custom.' Example: Custom
comment	String	No	Comment	comment	
disable	Boolean	No	Disabled	disable	Example: FALSE
vendor_id	String	No	Vendor ID	vendor_id	Example: MSFT 7.x
option_sequence	String	No	Option Number Sequence	option_sequence	DHCP options from 1 to 255 separated by commas (without spaces). Also enter the protocol (ipv4 or ipv6) at the end. Example: "['1,3,6,7,12,15,28,40,41,42,225,226,227,22/ipv4']"
device_class	String	No	Device Class	device_class	Device category to which the DHCP fingerprint belongs. This is used for filtering purposes. Example: Printers
protocol	String	Yes	protocol	protocol	Protocol type. This can be IPV4 or IPV6.
EA-Site	String	No	Extensible Attribute Site	extensible_ attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to custom DHCP fingerprints. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for DHCP fingerprints. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a Custom DHCP Fingerprint

This example shows how to import a new custom DHCP fingerprint.

```
header-DHCPFingerprint,name*,protocol*,comment,disable,option_sequence
DHCPFingerprint,SpecialPrinter,IPV4,Special printer for
QA,FALSE,"['1,3,6,7,12,15,28,40,41,42,225,226,227,228/ipv4']"
```

Overwriting DHCP Fingerprint Data

This example shows how to overwrite an existing custom DHCP fingerprint.

```
header-DHCPFingerprint,name*,new_name,comment
DHCPFingerprint,SpecialPrinter,QAPrinter,Changed from Special Printer to QA
Printer
```

Merging DHCP Fingerprint Data

This example shows how to merge a new comment to an existing DHCP fingerprint.

```
header-DHCPFingerprint,name*,comment DHCPFingerprint,Xbox,Blocked from network
```

DHCP MAC Filter

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-DhcpMacFilter	String	Yes			Example: DhcpMacFilter
name	String	Yes	Name	name	Example: MAC filter 1
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.
never_expires	Boolean	No	Never Expires		Example: TRUE
expiration_interval	Integer	No	Automatically expires in	default_mac_address_expiration	Example: 3624
enforce_expiration_time	Boolean	No	Enforce Expiration Times	enforce_expiration_times	Example: FALSE
comment	String	No	Comment	comment	

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
EA-Site	String	No	Extensible Attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible Attribute Users	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for DHCP MAC filters. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a DHCP MAC Filter

This example shows how to import a DHCP MAC filter.

```
header-dhcpmacfilter,name*,never_expires,expiration_interval,enforce_expiration_time,comment
 dhcpmacfilter,MacFilter01,FALSE,3600,TRUE,This is a comment.
```

Overwriting DHCP MAC Filter Data

This example shows how to overwrite the MAC filter name from MacFilter01 to MacFilter02.

```
header-dhcpmacfilter,name*,_new_name dhcpmacfilter,MacFilter01,MacFilter02
```

Merging DHCP MAC Filter Data

This example shows how to merge extensible attributes Site and Users, as well as admin group DHCP_admins with a RO permission.

```
header-dhcpmacfilter,name*,EA-Site,EA-Users,ADMGRPDHCP_admins
dhcpmacfilter,MacFilter02,USA,John Smith,RO
```

MAC Filter Address

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-MacFilterAddress	String	Yes			Example: MacFilterAddress
parent	String	Yes	MAC address filter	filter_name	Example: MAC filter 1
mac_address	MAC address	Yes	MAC address	mac_address	Example: aa:bb:cc:dd:ee:ff
_new_mac_address	MAC address	No			Add this field to overwrite the mac_address field when you select the overwrite or merge option.
is_registered_user	Boolean	No	Register as User		Example: TRUE
registered_user	String	No	Register as User		Example: John Doe
guest_first_name	String	No	Register as Guest: First Name		Example: John
guest_middle_name	String	No	Register as Guest: Middle Name		Example: Doe
guest_last_name	String	No	Register as Guest: Last Name		Example: Doe
guest_email	Email address	No	Register as Guest: Email Address		Example: jdoe@infoblox.com
guest_phone	String	No	Register as Guest: Phone Number		Example: 408-111-1111
guest_custom_field1	String	No	Register as Guest: Custom Field 1		
guest_custom_field2	String	No	Register as Guest: Custom Field 2		
guest_custom_field3	String	No	Register as Guest: Custom Field 3		

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
guest_custom_field4	String	No	Register as Guest: Custom Field 4		
never_expires	Boolean	No	Never Expires		Example: FALSE
expire_time	Date/Time	No	Expires On		Data must be in the following format: CCYY-MM-DDThh:mm:ss Example: 2009-02-29T10:30:00 The timestamp must be based on UTC time.
comment	String	No	Comment	comment	
EA-Site	String	No	Extensible Attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible Attribute Users	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	permission	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for DHCP MAC filters. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a DHCP MAC Filter

This example shows how to import MAC filter address, aa:aa:aa:aa:aa:aa, to MacFilter01.

```
header-macfilteraddress,parent*,mac_address*,is_registered_user,never_expires,comment
macfilteraddress,MacFilter01,aa:aa:aa:aa:aa:aa,FALSE,TRUE,This is a comment.
```

Overwriting DHCP MAC Filter

This example shows how to overwrite a MAC filter address with an expiration time.

```
header-macfilteraddress,parent*,mac_address*,never_expires,expire_time
macfilteraddress,MacFilter01,aa:aa:aa:aa:aa:aa,FALSE,2010-12-30T10:30:00Z
```

Merging DHCP MAC Filter

This example shows how to merge extensible attributes Site and Users to an existing MAC filter address.

```
header-macfilteraddress,parent*mac_address*,EA-Site,EA-Users
macfilteraddress,MacFilter01,aa:aa:aa:aa:aa:aa,USA,John Smith
```

Option Filter

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-OptionFilter	String	Yes			Example: OptionFilter
name	String	Yes	Name	name	Example: Option Filter 1
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.
comment	String	No	Comment	comment	
boot_file	String	No	Boot File	boot_file	Example: bootfile1
boot_server	String	No	Boot Server	boot_server	Example: abc.corp100.com
lease_time	Integer	No	Lease Time	lease_time	Example: 7200
pxe_lease_time	Unsigned integer	No	PXE Lease Time	pxe_lease_time	Example: 1100
next_server	String	No	Next Server	next_server	Example: blue.domain.com
option_space	String	No	Option Space	option_space	Example: Infoblox_DHCP
OPTION-2	Integer	No	Custom DHCP Options	option_list	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 50

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
OPTION-1	String	No	Custom DHCP Options	options_list	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: '255.0.0.0' name implies vendor_class='DHCP' (default)
OPTION-XXXX-200	Option information	No	Extensible Attribute Site	options_list	This is an example of a DHCP option. For information, see *Data Specific Guidelines*. Example: 'dfdfdfd' name implies vendor_class='XXXX', option code/number 200
EA-Site	String	No	Extensible Attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible Attribute Users	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for option filters. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an Option Filter

This example shows how to import an option filter with boot file, boot server, and lease time.

```
header-OptionFilter name*,comment,boot_file,boot_server,lease_time
OptionFilter,OptionFilter01,This is a comment.,bootfile01 1.2.3.4,12800
```

Overwriting Option Filter Datae

This example shows how to overwrite an option filter name and boot file name.

```
header-OptionFilter,name*,_new_name,boot_file
OptionFilter,OptionFilter01,OptionFilter02,bootfile02
```

Merging Option Filter Data

This example shows how to merge to an option filter the PXE lease time and next server domain name.

```
header-OptionFilter,name*,pxe_lease_time,next_server
OptionFilter,OptionFilter02,12800,next.corp100.com
```

Option Filter Match Rule

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-OptionFileterMatchRule	String	Yes			Example: OptionFilterMatchRule
parent	Option filter	Yes	Option Filter Name	filter	The name of the parent option filter. Example: Option filter 1
match_option	String	Yes	Match Option	num	Example: OPTION-1 (option space is DHCP)
match_value	String	Yes	Match Value	value	Example: 255.0.0.0
_new_match_value	String	No			Add this field to overwrite the match_value field when you select the overwrite or merge option.
comment	String	No	Comment	comment	
is_substring	Boolean	No	Value is a substring	is_substring	Example: FALSE
substring_offset	Integer	No	Substring Offset	substring_offset	Example: 2
substring_length	Unsigned integer	No	Substring Length	substring_length	Example: Doe

Examples

This section contains examples of how to create data files for option filter match rules. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an Option Filter Match Rule

This example shows how to import an option filter match rule.

```
header-
OptionFilterMatchRule,parent*,match_option*,match_value*,is_substring,substring
 _offset
 OptionFilterMatchRule,OptionFilter01,OPTION-1,2.2.2.2,FALSE,0
```

Overwriting Option Filter Match Rule Data

This example shows how to overwrite an existing match option with OPTION-2 and add a new match value of 3.3.3.3.
header-OptionFilterMatchRule,parent*,match_option*,match_value*,_new_match_value

```
OptionFilterMatchRule,OptionFilter01,OPTION-2,2.2.2.2,3.3.3.3
```

Merging Option Filter Match Rule Data

This example shows how to merge a substring length to an existing option filter match rule.

```
header-
OptionFilterMatchRule,parent*,match_option*,match_value*,substring_length
OptionFilterMatchRule,OptionFilter02,OPTION-2,3.3.3.3,256
```

Host Record

If only one IPv4 address is specified in the host record, you can add DHCP options to the host address.

> **Note**
>
> IDN is supported for object types: fqdn and aliases. You can use punycode or IDNs while importing these objects.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines Method
Header-HostRecord	String	Yes			Example: HostRecord
fqdn	FQDN	Yes	Name	name zone	This field combines the host record name and the zone name to form the FQDN. Example: h2.corp100.com
_new_fqdn	FQDN	No			Add this field to overwrite the fqdn field when you select the overwrite or merge option.
view	String	No	DNS View	views	If no view is specified, the Default view is used. Example: Default
network_view	String	No	Network View		If no network view is specified, the Default view is used. Example: Default

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines Method
addresses	IP address or IP address list	No	IP Addresses	ipv4addrs	You must specify a value in this field or in the ipv6_addresses field. Example: '1.2.3.4' or "1.2.3.4, 5.6.7.8". If there are multiple addresses in the host record, use HostAddress to specify the parameters for each address. For information, see *IPv4 Host Address* and *IPv6 Host Address*.
ipv6_addresses	IP address or IP address list	No	IP Addresses	ipv6addrs	You must specify a value in this field or in the addresses field. If there are multiple addresses in the host record, use HostAddress to specify the parameters for each address. For information, see *IPv4 Host Address* and *IPv6 Host Address*.
aliases	Alias list	No	Aliases	aliases	Example: www.infoblox.com
configure_for_dns	Boolean	No	Enable in DNS	configure_for_dns	Example: TRUE
_new_configure_for_dns	Boolean	No	Enable in DNS	configure_for_dns	Add this field to overwrite the configure_for_dns field when you select the overwrite or merge option.
comment	String	No	Comment	comment	
disabled	Boolean	No	Disable	disabled	Example: FALSE
ttl	Unsigned integer	No	TTL	ttl	This is an inherited field. For information, see *Data Specific Guidelines*. Example: 28800
mac_address	MAC address	No	MAC Address	mac_address	This field applies to the host address. This is required if the IP address is configured for DHCP. Example: aA:Bb:c2:DD:E1:FF
ddns_protected	Boolean	No	Protected	ddns_protected	If the record is marked as protected, DDNS updates are restricted to only the record. This applies to both static and dynamic records.
configure_for_dhcp	Boolean	No	DHCP checkbox	configure_for_dhcp	This field applies to the host address. Example: TRUE
deny_bootp	Boolean	No	Deny BOOTP Requests	deny_bootp	This field applies to the host address. Example: FALSE
broadcast_address	String	No	Broadcast Address		This field applies to the host address.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines Method
boot_file	String	No	Boot File	boot_file	This field applies to the host address.
boot_server	String	No	Boot Server	boot_server	This field applies to the host address.
next_server	String	No	Next Server	next_server	This field applies to the host address.
lease_time	Unsigned integer	No	Lease Time	lease_time	This field applies to the host address.
pxe_lease_time_enabled	Boolean	No	Enable PXE Lease Time		This field applies to the host address.
pxe_lease_time	Unsigned integer	No	PXE Lease Time	pxe_lease_time	This field applies to the host address.
domain_name	FQDN	No	Domain Name	domain_name	This field applies to the host address.
domain_name_servers	IP list	No	Name Server		This field applies to the host address. Example: "5.6.7.8,1.2.3.4"
routers	IP list	No	Router		This field applies to the host address. Example: "2.0.0.2,1.2.3.4"
match_option	String	No		match_client	This field applies to the host address. Data must be in the following format: MAC_ADDRESS/RESERVED
ignore_dhcp_param_request_list	Boolean	No	Ignore Optionalist	ignore-dhcp_option_list_request	This field applies to the host address.
OPTION-1	String	No	Custom DHCP Options	options	This field applies to the host address. Example: '255.0.0.0' name implies vendor_class='DHCP' (default)
OPTION-XXXX-200	Option Information	No	Custom DHCP Options	options	This field applies to the host address. Example: 'dfdfdfd' name implies vendor_class='XXXX', optioncode/ number 200
EA-Site	String	No	Extensible attribute Site	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines Method
ADMGRP-JoeSmith	String	No	Permissions Admin Group/Role	Permissions Admin Group/Role	ADMGRP-JoeSmith is an example of an admin permission of a specific admin group. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for host records. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a Host Record

This example shows how to add a new host record, host1, in zone corp100.com and DNS view Initial.

```
header-hostrecord,addresses,configure_for_dns*,fqdn*,view
hostrecord,100.0.0.101,TRUE,host1.corp100.com,Inital
```

This example shows how to add a new host record, host2, in zone corp100.com with aliases = www.corp100.com, comment = USA, and TTL = 3600 seconds.

```
header-hostrecord,addresses,configure_for_dns*,fqdn*,aliases,comment,ttl
hostrecord,100.0.0.102,TRUE,host2.corp100.com,www.corp100.com,USA,3600
```

Overwriting Host Record Data

This example shows how to overwrite the FQDN of an existing host record from host1.corp100.com to new_host1.corp100.com, and to change the TTL to 128 seconds.

```
header-hostrecord,addresses,configure_for_dns*,fqdn*,_new_fqdn,ttl
hostrecord,100.0.0.101,TRUE,host1.corp100.com,new_host1.corp100.com,1280
```

This example shows how to overwrite the aliases of a host record from www.corp100.com to www.corp200.com and comment from USA to Japan.

```
header-hostrecord,addresses*,configure_for_dns*,fqdn*,aliases,comment
hostrecord,100.0.0.102,TRUE,host2.corp100.com,www.corp200.com,Japan
```

Note that overwriting the host record data is not supported for non-DNS hosts.

Merging Host Record Data

This example shows how to disable an existing host record.

```
header-hostrecord,configure_for_dns*,addresses*,fqdn*,disabled
hostrecord,100.0.0.101,TRUE,new_host1.corp100.com,TRUE
```

This example shows how to add additional aliases to a host record.

```
header-hostrecord,configure_for_dns*,addresses*,fqdn*,aliases
hostrecord,100.0.0.102,TRUE,host2.corp100.com,"www.corp200.com,http.corp200.com"
```

Relay Agent Filter

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-RelayAgentFilter	String	Yes			Example: RelayAgentFilter
name	String	Yes	Name	name	Example: Relay Agent Filter 1
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.
comment	String	No	Comment	comment	
circuit_id_rule	String	No	Circuit ID: Match Value	is_circuit_id	Example: MATCHES_VALUE
circuit_id	String	No	Circuit ID	circuit_id_name	
remote_id_rule	String	No	Remote ID: Match Value	is_remote_id	Example: MATCHES_VALUE
remote_id	Integer	No	Remote ID	remote_id_name	Example: 50
EA-Site	String	No	Extensible Attribute Site	extensible_ attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible Attribute Users	extensible_ attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for relay agent filters. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a Relay Agent Filter

This example shows how to import a relay agent filter with a circuit ID and a remote ID.

```
header-
RelayAgentFilter,name*,circuit_id_rule,circuit_id,remote_id_rule,remote_id
RelayAgentFilter,relayagent1,MATCHES_VALUE,123456,MATCHES_VALUE,abcd
```

Overwriting Relay Agent Filter Data

This example shows how to overwrite the circuit ID and remote ID of an existing relay agent filter.

```
header-RelayAgentFilter,name*,circuit_id_rule,circuit_id,remote_id_rule
remote_id RelayAgentFilter,relayagent1,MATCHES_VALUE,336699,MATCHES_VALUE,xyz
```

Merging Relay Agent Filter Data

This example shows how to merge a comment and extensible attribute Site to an existing relay agent filter.

```
header-RelayAgentFilter,name*,comment,EA-Site RelayAgentFilter,relayagent1,This
is a comment.,USA
```

DHCP Fingerprint Filter

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-DHCPFingprintFilter	String	Yes			Example: DHCPFingerprintFilter
name	String	Yes	Name	name	Example: HP Printers
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.
fingerprint	String	Yes	DHCP Fingerprints	fingerprint	An array of DHCP fingerprints
_new_fingerprint	String	No			Add this field to overwrite the fingerprint field when you select the overwrite or merge option.
comment	String	No	Comment	comment	
EA-Site	String	No	Extensible Attribute Site	extensible_ attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for DHCP fingerprint filters. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a DHCP Fingerprint Filter

This example shows how to import a DHCP fingerprint filter.

```
header-DHCPFingerprintFilter,name*,fingerprint*,comment
DHCPFingerprintFilter,WindowsXP1,MSFT5.x,MSFT,Some Windows XP systems
```

Overwriting DHCP Fingerprint Filter Data

This example shows how to overwrite the filter name of an DHCP fingerprint filter.

```
header-DHCPFingerprintFilter,name*,_new_name
DHCPFingerprintFilter,WindowsXP1,WindowsXP5
```

Merging DHCP Fingerprint Filter Data

This example shows how to merge a comment to an DHCP fingerprint filter.

```
header-DHCPFingerprintFilter,name*,comment,EA-Site
DHCPFingerprintFilter,WindowsXP1,This is a comment
```

NAC Filter

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-NACFilter	String	Yes			Example: NACFilter
name	String	Yes	Name	name	Example: NAC Filter
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.
comment	String	No	Comment	comment	
expression	Option list	No	Match the following rule	expression	To include the option list in the **Matching the following rules** table in Grid Manager, you must enclose the expression in brackets. Example: (Sophos.ComplianceState="Compliant" AND RADIUS.ServerError="TRUE")
EA-Site	String	No	Extensible Attribute Site	extensible_ attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.
EA-Users	String	No	Extensible Attribute Users	extensible_ attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. For information about data format and examples, see *Data Specific Guidelines*.

Examples

This section contains examples of how to create data files for NAC filters. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a NAC Filter

This example shows how to import a new NAC filter.

```
header-NacFilter,name*,comment,expression,EA-Site NacFilter,nacfilter01,This is a comment.,option ServerError="true",USA
```

Overwriting NAC Filter Data

This example shows how to overwrite the name and comment of an existing NAC filter.

```
header-NacFilter,name*,_new_name,comment NacFilter,nacfilter01,nacfilter02,This is a new comment.
```

Merging NAC Filter Data

This example shows how to merge the extensible attribute Users to an existing NAC filter.

```
header-NacFilter,name*,EA-Users NacFilter,nacfilter02,John Smith
```

IPv4 Option Space

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-OptionSpace	String	Yes			Example: OptionSpace
name	String	Yes	Name	name	Example: ABC-co options
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.
comment	String	No	Comment	comment	

Examples

This section contains examples of how to create data files for option spaces. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an IPv4 Option Space

This example shows how to import a new IPv4 option space.

```
header-OptionSpace,name*,space_type OptionSpace,Optionspace01,VENDOR_SPACE
```

Overwriting IPv4 Option Space Data

This example shows how to overwrite the IPv4 option space name with Optionspace02.

```
header-OptionSpace,name*,_new_name OptionSpace,Optionspace01,Optionspace02
```

Merging IPv4 Option Space Data

This example shows how to merge a comment to the IPv4 option space Optionspace02.

```
header-OptionSpace,name*,comment OptionSpace,Optionspace02,This is a comment.
```

IPv6 Option Space

> **Note**
> This object is supported in CSV export only.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-IPv6OptionSpace	String	Yes			Example: IPv6OptionSpace
name	String	Yes	Name	name	Example: MySpace
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.
comment	String	No	Comment	comment	Example: Custom option space
ipv6_enterprise_number	String	No	Enterprise Number		This is the vendor's enterprise number that is registered with IANA. Example: 7779

IPv4 Option Definition

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-OptionDefinition	String	Yes			Example: OptionDefinition
space	String	Yes	Option Space	space	Example: ABC-co options
_new_space	String	No			Add this field to overwrite the space field when you select the overwrite or merge option.
name	String	Yes	Name	name	Example: Option one
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
code	String	Yes	Options: Code	code	
type	String	Yes	Options: Type	type	Use any of the following values: T_FLAG, T_STRING, T_TEXT, T_IP_ADDRESS, T_ARRAY_IP_ADDRESS, T_DOMAIN, T_ARRAY_DOMAIN, T_UINT8,T_UINT16, T_UINT32, T_INT8, T_INT16 Example: T_TEXT

Examples

This section contains examples of how to create data files for option definitions. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding an IPv4 Option Definition

This example shows how to import an option definition to the IPv4 option space Space01.

```
header-OptionDefinition,space*,name*,code*,type*
OptionDefinition,Space01,Option99,99,T_IP_ADDRESS
```

Overwriting IPv4 Option Definition Data

This example shows how to overwrite the IPv4 option definition type from T_IP_ADDRESS to T_FLAG.

```
header-OptionDefinition,space*,name*,code*,type*
OptionDefinition,Space01,Option99,99,T_FLAG
```

Merging IPv4 Option Definition Data

This example shows how to merge a new space and a new name to an existing IPv4 option definition.

```
header-OptionDefinition,space*,_new_space,name*,_new_name
OptionDefinition,Space01,New_Space01,Option99,New_Option99
```

IPv6 Option Definition

> **Note**
> This object is supported in CSV export only.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-IPv6OptionDefinition	String	Yes			Example: IPv6OptionDefinition

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
space	String	Yes	Option Space	space	Example: MySpace
_new_space	String	No			Add this field to overwrite the space field when you select the overwrite or merge option.
name	String	Yes	Name	name	Example: MyOption1
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.
code	String	Yes	Options: Code	code	Example: 10
type	String	Yes	Options: Type	type	Use any of the following values: 'T_ARRAY_DOMAIN', 'T_ARRAY_INT16', 'T_ARRAY_INT32', 'T_ARRAY_INT8', 'T_ARRAY_IP_ADDRESS', 'T_ARRAY_IP_ADDRESS_PAIR', 'T_ARRAY_UINT16', 'T_ARRAY_UINT32', 'T_ARRAY_UINT8', 'T_DOMAIN', 'T_FLAG', 'T_FLAG_IP_ADDRESS', 'T_FLAG_TEXT', 'T_INT16', 'T_INT32', 'T_INT8', 'T_IP_ADDRESS', 'T_STRING', 'T_TEXT', 'T_UINT16', 'T_UINT32', 'T_UINT8', 'T_UINT8_1_2_4_8' Example: T_INT8

Permissions for DNS Resources with Associated IP Addresses in Networks and Ranges

You can further control permissions for DNS resources that have associated IP addresses in a network container, network, or address range. These DNS resources include A records, AAAA records, PTR records, and DNS hosts. Permissions for these resources have been added so you now have more control over who can perform which tasks for these DNS resources without affecting permissions defined for the networks and ranges to which the resources belong. For more information about this feature, refer to the *Infoblox Administrator Guide*.
As a superuser, you can now grant permissions to admin groups for more granular access to the following resources:

- IPv4 and IPv6 DHCP fixed addresses and IPv4 reservations in a range
- IPv4 and IPv6 host addresses in a range
- A and AAAA records in a network container, network, or range
- IPv4 and IPv6 PTR records in a network container, network, or range Following are some examples:

Permissions for Host Address and Fixed Address in a DHCP Network:

```
header-network,address*,netmask*,ADMGRP-foogroup
network,10.100.0.0,255.255.0.0,"RW,HostAddress/RW,FixedAddress/DENY"
 header-IPv6network,address*,cidr*,ADMGRP-foogroup
IPv6network,2001::,64,"RW,IPv6FixedAddress/RW,IPv6HostAddress/DENY"
```

Permissions for Host Address and Fixed Address in a DHCP Range:

```
header-dhcprange,start_address*,end_address*,ADMGRP-foogroup
dhcprange,10.100.20.0,10.100.20.255,"DENY,FixedAddress/RO,HostAddress/RW"
```

Permissions for A and PTR Records in a DHCP Network:

```
header-network,address*,netmask*,ADMGRP-foogroup
network,30.30.0.0,255.255.0.0,"RW,ARecord/RW,PtrRecord/DENY"
```

> **Note**
> You cannot import network containers and IPv6 ranges using CSV import.

DHCP Failover Association

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-DhcpFailoverAssoc	String	Yes			Identifies the first row as a header row for the DHCP failover association. Example: DhcpFailoverAssoc.
name	String	Yes	Name	name	Indicates the name of the DHCP failover association. Example: dhcp_fo_assoc1.
_new_name	String	No			Add this field to overwrite the **name** field when you select the **Overwrite** or **Merge** option.
comment	String	No	Comment	comment	Example: DHCP Failover Association.
primary_server_type	String	Yes			Indicates whether the primary server of the name server group is set to Grid or External. Example: GRID
grid_primary	String	No	Grid Primary	primary	Indicates the name of the Grid primary. Example: infoblox.localdomain
external_primary	IP address	No	External Primary	primary	Indicates the IP address. Example: 10.10.10.1
secondary_server_type	String	Yes			Indicates whether the secondary server of the name server group is set to Grid or External. Example: External
grid_secondary	String	No	Grid Secondary	secondary	Indicates the name of the Grid secondary. Example: infoblox2.localdomain

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
external_secondary	IP address	No	External Secondary	secondary	Indicates the IP address. Example: 20.20.20.1
failover_port	Unsigned integer	No			Indicates the failover port number. The default value is 647. The port number must be between 1 and 63999.
max_response_delay	Unsigned integer	No		max_response_delay	Indicates the maximum response delay value of a DHCP failover object. Default value is 60 seconds and the minimum value is one second.
max_unacked_updates	Unsigned integer	No		max_unacked_updates	Indicates the maximum number of unacked updates value of a DHCP failover object. Default value is10 minutes and the minimum value is one second.
mclt	Unsigned integer	No		max_client_lead_time	Indicates the maximum client lead time value of a DHCP failover object. Specify the value of the maximum client lead time in a 32-bit integer format (range from 0 to 4294967295) that represents the duration in seconds. The default value is 3600.
max_load_balance_delay	Unsigned integer	No		max_load_balance_delay	Indicates the maximum load balancing delay value of a DHCP failover object. Specify the value of the maximum load balancing delay in a 32-bit integer format (range from 0 to 4294967295) that represents the duration in seconds. The default value is three seconds.
load_balance_split	Unsigned integer	No		load_balance_split	Indicates the load balancing split value of a DHCP failover object. Specify a value from zero to 255. The default value is 128.
recycle_leases	Boolean	No	Lease Deletion	recycle_leases	This field is set to **True** by default. When you set this to **True**, leases in a deleted range are kept until expiration. Ensure that you use the **Overwrite** option if you want to change the value to **False**. Merging data from an import preserves the default value.
EA-Site	String	No	Extensible attribute	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. Example: California.
EA-Users	String	No	Extensible attribute	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: John.

Grid Member

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-Member	String	Yes			Identifies the first row as a header row for the member objects. Example: Member

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
_new_name	FQDN	No			Add this field to overwrite the **name** field when you select the **Overwrite** or **Merge** option.
comment	String	No	Comment	comment	Example: This is a Grid member.
enable_ha	Boolean	No		enable_ha	Enable or disable HA. This is **True** if HA is enabled. Example: False
ha_nodes	String	No			Indicates the list of ha_status, or public_ip_address, or ipv6_public_ip_address, or ha_ip_address. Example: ACTIVE/10.0.0.11//10.0.0.12, PASSIVE/10.0.0.13//10.0.0.14
vpn_mtu	Unsigned integer	No		vpn_mtu	Indicates maximum transmission unit of the VPN. Example: 1450
ipv4addr	String	Yes (Insert)	IP Address	ipv4addr	Indicates IPv4 address.Example: 10.0.0.10. Note that you must specify this column in the CSV file when you perform a CSV Import Insert operation.
mask	String	Yes (Insert)		mask	Indicates the netmask. Example: 255.255.255.0. Note that you must specify this column in the CSV file when you perform a CSV Import Insert operation.
gateway	String	Yes (Insert)		gateway	Indicates the gateway address. Example: 10.0.0.1. Note that you must specify this column in the CSV file when you perform a CSV Import Insert operation.
vlan_id	Unsigned integer	No			VLAN Id for LAN1 and LAN2 address. Example: 10
ipv6addr	String	No	IP Address	ipv6addr	Indicates IPv6 address. Example: 2001::10
ipv6_cidr	Unsigned integer	No		ipv6_cidr	The CIDR of the Grid member. This is required only when ipv6addr is specified.Example: 64
ipv6_enable_auto_config	Boolean	No		ipv6_enable_ auto_config	Enable or disable IPv6 auto-configuration of the Grid member. Example: False

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ipv6_gateway	String	No		ipv6_gateway	The LAN IPv6 gateway of the Grid member. Example: 2001::1
ipv6_vlan_id	Unsigned integer	No			The IPv6 VLAN ID of a Grid member. Example: 10
nic_failover_enabled	Boolean	No		nic_failover_enabled	Set or deactivate the **nic_failover_enabled** flag of a Grid member. This is required only when the member is a single appliance. To enable this flag, you must set the **lan2_port** flag to **True**. Example: False
lan2_enabled	Boolean	No			Enable or disable LAN2.Example: False
lan2_ipv4addr	String	No		lan2_ipv4addr	The LAN IP address of the LAN2 port. To configure the LAN2 port, you must set the **lan2_port** flag to **True**. Example: 10.0.0.20
lan2_mask	String	No		lan2_mask	The netmask of the LAN2 port. To configure the LAN2 port, you must set the **lan2_port** flag to **True**. Example: 255.255.255.0
lan2_ipv6addr	String	No			The LAN IPv6 address of the LAN2 port. To configure the LAN2 port, you must set the **lan2_port** flag to **True**. Example: 2001::20
lan2_vlan_id	Unsigned integer	No			The VLAN ID of the IPv4 LAN2 port. To configure the LAN2 port, you must set the **lan2_port** flag to **True**. Example: 10
lan2_dscp	Unsigned integer	No			The DSCP value of the IPv4 LAN2 port. Valid values are integers between zero and 63. Example: 15
lan2_gateway	String	No		lan2_gateway	The gateway IP address of the LAN2 port. To configure the LAN2 port, you must set the **lan2_port** flag to **True**. Example: 10.0.0.1
lan2_ipv6_cidr	Unsigned integer	No		lan2_ipv6_cidr	The CIDR of the LAN2 port. To configure the LAN2 port, you must set the **lan2_port** flag to **True**. Example: 64

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
lan2_ipv6_dscp	Unsigned integer	No			The DSCP value of the IPv6 LAN2 port. Valid values are integers between zero and 63. Example: 15Example: 0
lan2_ipv6_enable	Boolean	No		lan2_ipv6_ enable	Enable or disable IPv6 configuration of the LAN2 interface. Example: False
lan2_ipv6_enable_auto_config	Boolean	No		lan2_ipv6_enable_auto_config	Enable or disable IPv6 auto-configuration of the LAN2 interface.Example: False
lan2_ipv6_gateway	String	No		lan2_ipv6_ gateway	The LAN IPv6 gateway of the LAN2 port. To configure the LAN2 port, you must set the **lan2_port** flag to **True**. Example: 2001::1
lan2_ipv6_vlan_id	Unsigned integer	No			The VLAN ID of the IPv6 LAN2 port. To configure the LAN2 port, you must set the **lan2_port** flag to **True**.Example: 20
nat_enabled	Boolean	No		nat_enabled	Specify **True** to enable the NAT compatibility setting or **False** to disable it. Example: False
nat_group	String	No		nat_group	The NAT group of a Grid member. This is required only when NAT compatibility is enabled. Example: group1/ comm1,group2/comm2
nat_ip_address	String	No			The NAT IP address of a Grid member. Required only when NAT compatibility is enabled. Example: 10.0.0.10
static_routes	List of IPv4 static routes	No		static_routes	This list contains the static routes of a Grid member. The valid format is: address/subnet_mask/ gateway. Example:10.10.1.10/255.255.0.0/ 10.10.1.1
ipv6_static_routes	List of IPv6 static routes	No		ipv6_static_ routes	This list contains the IPv6 static routes of a Grid member. The valid format is: address/cidr/ gateway. Example: 2001::10/64/2001::1

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
remote_console_access	Boolean	No		use_remote_ console_ access	Enable or disable remote console access. When you enable remote console access, a client can access the device using a Secure Shell (SSH) connection. Example: False
support_access	Boolean	No		use_support_ access	Specify **True** to set the r**emote_console_access** flag or **False** to deactivate it.Default value is **True**. Example: False
enable_query	Boolean	No			Example: False
query_comm_string	String	No			Indicates the SNMP (Simple Network Management Protocol) community string that management systems must send together with their queries to the Infoblox appliance. If this is set to **undef**, SNMP queries will be disabled.
enable_snmpv3_query	Boolean	No		enable_ snmpv3_query	Enable or disable SNMPv3 queries. Example: False
enable_traps	Boolean	No			Enable or disable traps. Example: False
trap_comm_string	String	No			The SNMP trap community string of the Grid member. Default value is **undef**.
enable_snmpv3_traps	Boolean	No			Enable or disable SNMPv3 traps. Example: False
snmp_admin	String	No			Set or retrieve the SNMP admin object. Example: sysname/ syscontact/syslocation/ sysdescr
snmpv3_query_users	String	No			Indicates the SNMPv3 user setting at the Grid level. Example: snmpv3User/comment
trap_receiver	String	No			Indicates the SNMP trap receivers of a Grid member. Example: 10.0.0.10/ snmpUseName/ comment

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
additional_ip_list	String	No		additional_ip_list	Indicates the additional IP list of a Grid member. This list contains additional interface information that can be used on the member level.The valid format is: interfaceType/networkSetting/ comment/ ospf/anycast/bgp Example for IPv4: address/subnet_mask/gateway/ vlan_id/primary/dscp/use_dscp Example for IPv6: virtual_ip/cidr_prefix/gateway/ vlan_id/ primary/dscp/use_dscp/ enabled/ auto_router_configure_enabled
enable_member_redirect	Boolean	No		enable_ member_redirect	Set or retrieve the flag that specifies if GUI redirection is enabled for members. Example: False
virtual_router_id	Integer	No			Indicates virtual router identifier. Example:110
dscp	Unassigned integer	No		dscp	Indicates the DSCP value. The default value is zero.
EA-Site	String	No	Extensible attribute	extensible_ attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. Example: California
EA-Users	String	No	Extensible attribute	extensible_ attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: John
ADMGRP-XXXX	String	No	Permissions Admin Group/Role	permission	ADMGRP-JimSmith is an example of an admin permission of a specific admin group. Example: RW

Upgrade Groups and Schedules

Consider the following when you import upgrade groups and their distribution and upgrade schedules:

- The appliance imports a new upgrade group only when both the distribution and upgrade schedules are inactive.
- You can modify members and the comment field of an existing upgrade group only when both the distribution and upgrade schedules are inactive.
- You can modify distribution related fields of an existing upgrade group only when the distribution schedule is inactive.
- You can modify upgrade related fields of an existing upgrade group only when the upgrade schedule is inactive.
- The Grid Master is the only member of the Grid Master group. You cannot move it to another upgrade group.
- You cannot change the members of the Reporting Member group nor move them to another upgrade group.
- When you remove a member from its original group, it will be placed in the Default group. You may notice additional members in the Default group if you remove members from any upgrade groups.

- When you specify both dependency and distribution or upgrade time for an upgrade group, dependency takes precedence.

> **Note**
>
> When you import an upgrade group and its distribution and upgrade schedules, you cannot control the activation and deactivation of the schedules. You can activate and deactivate the schedules through the GUI after the import.

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-upgrade_group	String	Yes		UpgradeGroup	Example: UpgradeGroup
name	String	Yes	Name		Example: UpgradeGp
comment	String	No	Comment	comment	Add this field to overwrite the comment you entered for the upgrade group.
members	Grid member list	No	Member Assignment Name	members	Enter a list of Grid members separated by commas. Use the FQDNs of the Grid members. Enclose the entire string in double quotes. Example: “corp100.mktg.com,corp100.dev.com”
time_zone	String	No	Time Zone	time_zone	The value in this field applies to both distribution_time and upgrade_time. If you do not specify a time zone, the Grid level time zone is used.
distribution_dependent_group	String	No	Name	distribution_ dependent_group	Enter the name of the preceding upgrade group that this group depends on during a distribution.
distribution_policy	String	No	Distribute to Members	distribution_policy	Valid values are: SIMULTANEOUSLY or SEQUENTIALLY.
distribution_time	Time	No	Start Distribution (Date/Time)	distribution_time	Enter the distribution start date and time in YYYY-MM-DDTHH:MM:SS format.
upgrade_dependent_group	String	No	Name	upgrade_dependent_group	Enter the name of the upgrade group that this group depends on during an upgrade.
upgrade_policy	String	No	Upgrade Members	upgrade_policy	Valid values are: SIMULTANEOUSLY or SEQUENTIALLY.

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
upgrade_time	Time	No	Start Upgrade	upgrade_time	Enter the upgrade start date and time in YYYY-MM-DDTHH:MM:SS format.

Named ACLs

Consider the following when you import named ACLs and ACEs for an existing named ACL:

- The appliance appends ACES to the end of the named ACL.
- Validate all imported named ACLs after a CSV import. The appliance does not automatically validate ACEs. To avoid conflicts and unexpected results, you must validate the named ACLs.
- To reorder an existing named ACL through CSV import, complete the following:
    a. Export the named ACL.
    b. Delete all ACEs in the named ACL. The appliance allows a named ACL without any ACEs.
    c. Reorder the ACEs in the .csv file.
    d. Re-import the updated file through CSV import.
- You can add a named ACL as a nested ACL to an existing named ACL.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-namedacl	String	Yes		NamedACL	Example: namedacl
name	String	Yes	Name	nacl	Example: nacl1
_new_name	String	No			Add this field to overwrite the name field when you select the overwrite or merge option.
comment	String	No	Comment	comment	Add this field to overwrite the comment you entered for the name ACL.

Examples

This section contains examples of how to create data files for named ACLs. All examples use comma as the separator. You can use other supported separators, such as semicolon, space, or tab.

Adding a new named ACL

This example shows how to import a new named ACL nacl1.

```
Header-namedacl,name*,comment namedacl,nacl1,"This is a new named ACL."
```

Overwriting the name of a named ACL

This example shows how to overwrite the name of an existing named ACL nacl1 to nacl2.

```
Header-namedacl,name*,_new_name namedacl,nacl1,nacl2
```

ACES in Named ACLs

You can add or overwrite ACEs in an existing named ACL. When you add or modify ACEs in a named ACL, you must have one of the following categories in each entry: IP address, TSIG key based ACE, or a nested named ACL. A combination of these in an entry will generate an error.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-namedaclitem	String	Yes		ACL item	Example: namedaclitem
parent	String	Yes	Named ACL	nacl	This is the existing named ACL. Example: nacl1
address	String	No	IPv4 Address IPv6 Address	ipv4addr ipv6addr	This field includes required information for IP address based ACEs. Use forward slashes as the delimiter to separate permission, address, and netmask. Example: “10.0.0.1/24/Allow”
_new_address	String	No			Add this field to overwrite the address field when you use the overwrite or merge option.
tsig_key	String	No	TSIG Key	TSIGKEY	This field includes required information or TSIG key based ACEs. Use forward slashes as the delimiter to separate tsig_key_name, tsig_key, tsig_key_alg, and use_2x_tsig_key. Example: “key_1/ny/bY2Da8Lj+2YZ4dYEJLQ==/HMAC-SHA256/false”
_new_tsig_key	String	No			Add this field to overwrite the tsig_key field when you use the overwrite or merge option.
defined_acl	String	No	Named ACL	nacl	This field adds a named ACL as a nested ACL to an existing named ACL. Example: nacl2
_new_named_acl	String	No			Add this field to overwrite the named_acl field when you use the overwrite or merge option.
comment	String	No	Comment	comment	Add this field to overwrite the comment you entered for the name ACL.

Adding an IP address based ACE to an existing named ACL

This example shows how to import an IP address based ACE to nacl1. You must include the following information in the address field: address/netmask/permission. The appliance append the ACE to the end of the ACL. Ensure that you validate the ACL after the import.

```
Header-namedaclitem,parent*,address namedaclitem,N1,10.0.38.230/ALLOW
namedaclitem,N1,172.0.0.0/8/ALLOW
```

Adding a TSIG key based ACE to an existing named ACL

This example shows how to import a TSIG key based ACE to nacl1. You must include the following information in the tsig_key field: tsig_key_name/tsig_key/tsig_key_alg/use_2x_tsig_key. The appliance append the ACE to the end of the ACL. Ensure that you validate the ACL after the import.

```
Header-namedaclitem,parent*,tsig_key nmaedaclitem,"nacl1","key_1/
bY2Da8Lj+2YZ4dYEJLQ==/HMAC-SHA256/false"
```

Adding a nested named ACL to an existing named ACL

This example shows how to import a nested named ACL nacl2 to the parent named ACL nacl1. The appliance append the nested ACL to the end of the ACL. Ensure that you validate the ACL after the import.

```
Header-nmaedaclitem,parent*,defined_acl namedaclitem,"nacl1","nacl2"
```

Adding and overwriting multiple ACEs

This example shows how to add new ACEs and modify existing ACEs. Ensure that you validate the ACL after the import.

```
Header-
namedaclitem,parent*,address,_new_address,tsig_key,_new_tsig_key,defined_acl,
 _new_acl naemdaclitem,"nacl1","Allow/10.0.0.1/24","Deny/10.0.0.1/24",,,,
 namedaclitem,"nacl1",,,"key_1/bY2Da8Lj+2YZ4dYEJLQ==/HMAC-SHA256/false",,,
namedaclitem,"nacl1",,,,,,"acl2"
```

Discovery Credentials

You can define a list of SNMP v1/v2c credentials or a list of SNMPv3 credentials to import through a CSV file. Sensitive authentication information may be part of an SNMP credential import, including SNMPv1 or SNMPv2c communities or SNMPv3 user/password tuples for privacy and authentication. This information is also stored in the NIOS database. CSV import of credentials contains community strings and passwords in plain text. Imported CSV files are uploaded with a POST in an HTTPS session and are deleted immediately after the import operation completes, whether or not the import is successful.

SNMPv1/SNMPv2c Credentials Format

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guideline
Header-discoverysnmpv1v2credentials	String	Yes		SNMPCredential	
comment	String	No	Comment	comment	Use this field to set or retrieve the comment on SNMPv1 and SNMPv2 users.
community_string	String	Yes	Read Community	community_string	
_new_community_string	String	No			Use this field to set or retrieve the public community string.
parent	String	Yes	SNMPv1/v2		This is the existing credential.

SNMPv3 Credentials Format

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guideline
Header-discoverysnmpv3credentials	String	Yes		SNMP3Credential	
user	String	Yes	Name	user	Use this field to set or retrieve the SNMPv3 user name.
_new_user	String	No	Name		Add this field to overwrite the user field when you use the overwrite or merge option.
authentication_password	String (if protocol is (MD5/SHA)	No	Auth Password	authentication_password	Use this field to set the authentication password if the authentication protocol is MD5 or SHA. This is a write-only attribute.
authentication_protocol	String (valid values are MD5/SHA/NONE/SHA-224/ SHA-256/ SHA-384/SHA-512)	No	Auth Protocol	authentication_protocol	Use this field to set or retrieve the authentication protocol.
_new_authentication_protocol	String	No			Add this field to overwrite the authentication_protocol field when you use the overwrite or merge option.

Field Name	Data Type	Required (Yes/ No)	Associated GUI Field	Associated PAPI Method	Usage and Guideline
comment	String	No	Comment		Add this field to overwrite the comment you entered for the credential.
parent	String	Yes	SNMPv3		
privacy_password	String (if protocol is AES/DES/3DES)	No	Privacy Password	privacy_password	Use this field to set the privacy password if the privacy protocol is 'AES', 'DES' or '3DES'. This is a write-only attribute.
privacy_protocol	String (valid values: AES-128/DES/3DES/NONE/ AES-192/AES-192C/AES-256/AES-256C)	No	Privacy Protocol	privacy_protocol	Use this field to set or retrieve the privacy protocol.
_new_privacy_protocol	String	No			Add this field to overwrite the privacy_protocol field when you use the overwrite or merge option.

DTC Header Items

This topic lists all the DTC objects whose names start with "dtc". These objects are displayed as DtcLbdn, DtcServer, and so on in the CSV export or import file. The object DtcCertificate supports only CSV export, whereas other objects support CSV import and export. For details, see the following sections:

- *DtcLbdn Header Items*
- *DtcServer Header Items*
- *DtcPool Header Items*
- *DtcMonitorHttp Header Items*
- *DtcMonitorSip Header Items*
- *DtcMonitorIcmp Header Items*
- *DtcMonitorPdp Header Items*
- *DtcMonitorTcp Header Items*
- *DtcMonitorSnmp Header Items*
- *DtcARecord Header Items*
- *DtcAaaaRecord Header Items*
- *DtcCnameRecord Header Items*
- *DtcNaptrRecord Header Items*
- *DtcCertificate Header Items*

DtcLbdn Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcLbdn	String	Yes	DtcLbdn		

Name	Type	Required	Example	Ibap Name	Comment
name*	String	Yes	load_bal		
_new_name	String	No		name	
lb_method*	String	Yes	GLOBAL_AVAILABILITY	lb_method	Valid values are 'GLOBAL_AVAILABILITY', 'RATIO', 'ROUND_ROBIN', 'TOPOLOGY' and 'SOURCE_IP_HASH'
patterns	List of strings	No	.domain.com, .test.com'	patterns	Valid value is an array of FQDN patterns in string format
disabled	Boolean	No	false	disabled	
comment	String	No	A DTC LBDN comment	comment	
persistence	Unsigned integer	No	5	persistence	Zero specifies no caching
topology	String	No	topology-1	topology	
ttl	Unsigned integer	No	10	ttl	
pools	LBDN linked list of pools	No	pool/ratio eg: "pool1/1,pool2/10...	pools	
auth_zones	LBDN linked list of auth zones	No	Must be in the zone_name/view_name format. For example: authzone1.com/view1, authzone2.com/view2...	auth_zones	List of DTC LBDN linked authoritative zones
types	String	No	NAPTR	types	Valid values are 'A', 'AAA', 'NAPTR', 'CNAME'
priority	Unsigned integer	No	3	priority	Valid values between 1 and 3. The default is 3.
EA-Site	String	No	San Jose		

DtcServer Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcServer	String	Yes	DtcServer		
name*	String	Yes	server1	name	
_new_name	String	No		name	

Name	Type	Required	Example	Ibap Name	Comment
host*	String	Yes	192.168.1.2	host	Address or FQDN of a DTC server
disabled	Boolean	No	false	disabled	
comment	String	No	A DTC server comment	comment	
auto_create_host_record	Boolean	No	false	comment	
sni_hostname	String	No	sni-host.infoblox.localdomain	sni_hostname	Host name for Server Network Indication to be used with the HTTPS monitor
monitors	List of DTC health monitors	No	Monitor name/Monitor type/Host For example: TCP-1/tcp/10.10.10.10,SIP-1/sip/20.20.20.20,ICMP-1/icmp/30.30.30.30,...	monitors	List of names of DTC server monitors
EA-Site	String	No	San Jose		

DtcPool Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcPool	String	Yes	DtcPool		
name*	String	Yes	pool1	name	
_new_name	String	No		name	
lb_preferred_method	String	No	RATIO	lb_preferred_method	Valid values are 'ALL_AVAILABLE', 'DYNAMIC_RATIO', 'GLOBAL_AVAILABILITY', 'RATIO', 'ROUND_ROBIN', 'TOPOLOGY', and 'SOURCE_IP_HASH'
disabled	Boolean	No	false	disabled	
comment	String	No	A DTC pool comment	comment	
lb_preferred_topology	Topology rules for preferred 'TOPOLOGY' load balancing method	No	custom-2	preferred_topology	

Name	Type	Required	Example	Ibap Name	Comment
lb_alternate_method	String	No	RATIO	alternate_method	Alternate load balancing method. Valid values are 'ALL_AVAILABLE', 'DYNAMIC_RATIO', 'NONE', 'GLOBAL_AVAILABILITY', 'RATIO', 'ROUND_ROBIN', 'TOPOLOGY' , and 'SOURCE_IP_HASH'.
lb_alternate_topology	Topology rules for alternate 'TOPOLOGY' load balancing method	No	custom-3	alternate_topology	
availability	String	No	any	availability	DTC pool resources availability status. Valid values are 'ALL', 'ANY', and 'QUORUM'.
quorum	Unsigned integer	No	20	quorum	The number of monitors that must report the resource as 'up' for 'QUORUM' availability mode to be available.
ttl	Unsigned integer	No	10	ttl	
servers	List of DTC servers	No	server/ratio For example: dtc-server1/1,dtc-server2/10...	servers	
monitors	List of health monitors	No	Monitor name/Monitor type For example: ICMP-1/icmp,HTTP-1/http,...	monitors	List of names and monitor types of DTC pool monitors
dynamic_ratio_preferred	Preferred dynamic ratio load balancing settings	No	method/monitor/monitor_metric/monitor_weighing/invert_monitor_metric For example: MONITOR/snmp/.1.3/RATIO/false	dynamic_ratio_preferred	When preferred_method="DYNAMIC_RATIO"
dynamic_ratio_alternate	Alternate dynamic ratio load balancing settings	No	method/monitor/monitor_metric/monitor_weighing/invert_monitor_metric For example: MONITOR/snmp/.1.3/PRIORITY/false	dynamic_ratio_alternate	When preferred_method="TOPOLOGY" and alternate_method="DYNAMIC_RATIO"
EA-Site	String	No	San Jose		

DtcMonitorHttp Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcMonitorHttp	String	Yes	DtcMonitorHttp		
name*	String	Yes	http_monitor1	name	
_new_name	String	No		name	
comment	String	No	A DTC HTTP monitor comment	comment	
interval	Unsigned integer	No	10	interval	
timeout	Unsigned integer	No	7	timeout	Valid values between 1 and 15
port	Unsigned integer	No	8080	port	Valid values between 1 and 65535
request	String	No	GET /	request	Maximum of 1024 characters
content_check	String	No	EXTRACT	content_check	Valid values are 'NONE'(default), 'MATCH', and 'EXTRACT'. If 'MATCH', then 'content_check_op' and 'content_check_regex' params are required; if 'EXTRACT' then ‘content_check_op’,’content_extract_type’, ‘content_extract_value’, and ’content_check_regex’ values are required.
content_check_input	String	No	BODY	content_check_input	Valid values are 'HEADERS', 'ALL'(default) and 'BODY'
content_check_regex	String	No	SQL Error	content_check_regex	
content_check_op	String	No	EQ	content_check_op	Valid values are 'EQ' and 'NEQ' for 'MATCH' content check, and 'EQ', 'NEQ', 'LEQ', and 'GEQ' for 'EXTRACT' content check type
content_extract_group	Unsigned integer	No	3	content_extract_group	Valid values between 0 and 8. The default is 0.
content_extract_type	String	No	INTEGER	content_extract_type	Valid values are 'INTEGER' and 'STRING'. The default is 'STRING'.
content_extract_value	String	No	1	content_extract_value	A desired extraction value in string format

Name	Type	Required	Example	Ibap Name	Comment
result	String	No	CODE_IS	result	Valid values are 'ANY', 'CODE_IS', and 'CODE_IS_NOT'
result_code	Unsigned integer	No	300	result_code	Valid values between 0 and 999
secure	Boolean	No	true	secure	Default is 'false'
client_cert	Client certificate	No	626596e ... 4362f80c (128 characters)	client_cert	Valid value is a DTC certificate object.
ciphers	String	No	DHE-RSA-AES256-SHA	ciphers	Valid value is array of ciphers in a string format
retry_up	Unsigned integer	No	3	retry_up	Valid values between 1 and 10
retry_down	Unsigned integer	No	3	retry_down	Valid values between 1 and 10
validate_cert	Boolean	No	false	validate_cert	Default is 'true'
enable_sni	Boolean	No	true	enable_sni	Default is 'false'
EA-Site	String	No	San Jose		

DtcMonitorSip Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcMonitorSip	String	Yes	DtcMonitorSip		
name*	String	Yes	sip_monitor1	name	
_new_name	String	No		name	
comment	String	No	A DTC SIP monitor comment	comment	
interval	Unsigned integer	No	10	interval	
timeout	Unsigned integer	No	7	timeout	Valid values between 1 and 15

Name	Type	Required	Example	Ibap Name	Comment
port	Unsigned integer	No	8080	port	Valid values between 1 and 65535
request	String	No	GET /	request	Maximum of 1024 characters
result	String	No	CODE_IS	result	Valid values are 'ANY', 'CODE_IS', and 'CODE_IS_NOT'
result_code	Unsigned integer	No	300	result_code	Valid values between 0 and 999
transport	String	No	UDP	transport	Valid values are 'TCP', 'UDP', 'SIPS', and 'TLS'
client_cert	Client certificate	No	626596e ... 4362f80c (128 characters)	client_cert	Valid value is a DTC certificate object
ciphers	String	No	DHE-RSA-AES256-SHA	ciphers	Valid value is array of ciphers in a string format
retry_up	Unsigned integer	No	3	retry_up	Valid values between 1 and 10
retry_down	Unsigned integer	No	3	retry_down	Valid values between 1 and 10
validate_cert	Boolean	No	false	validate_cert	Default is 'true'
EA-Site	String	No	San Jose		

DtcMonitorIcmp Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcMonitorIcmp	String	Yes	DtcMonitorIcmp		
name*	String	Yes	Icmp_monitor1	name	
_new_name	String	No		name	
comment	String	No	A DTC ICMP monitor comment	comment	
interval	Unsigned integer	No	10	interval	
timeout	Unsigned integer	No	7	timeout	Valid values between 1 and 15
retry_up	Unsigned integer	No	3	retry_up	Valid values between 1 and 10

Name	Type	Required	Example	Ibap Name	Comment
retry_down	Unsigned integer	No	3	retry_down	Valid values between 1 and 10
EA-Site	String	No	San Jose		

DtcMonitorPdp Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcMonitorPdp	String	Yes	DtcMonitorPdp		
name*	String	Yes	pdp_monitor1	name	
_new_name	String	No		name	
comment	String	No	A DTC PDP monitor comment	comment	
interval	Unsigned integer	No	10	interval	
timeout	Unsigned integer	No	7	timeout	Valid values between 1 and 15
retry_up	Unsigned integer	No	5	retry_up	Valid values between 1 and 10
retry_down	Unsigned integer	No	5	retry_down	Valid values between 1 and 10
port	Unsigned integer	No	6030	port	Valid values between 1 and 65535
EA-Site	String	No	San Jose		

DtcMonitorTcp Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcMonitorTcp	String	Yes	DtcMonitorTcp		
name*	String	Yes	tcp_monitor1	name	
port*	Unsigned integer		6030	port	Valid values between 1 and 65535

Name	Type	Required	Example	Ibap Name	Comment
_new_name	String	No		name	
comment	String	No	A DTC PDP monitor comment	comment	
interval	Unsigned integer	No	10	interval	
timeout	Unsigned integer	No	7	timeout	Valid values between 1 and 15
retry_up	Unsigned integer	No	3	retry_up	Valid values between 1 and 10
retry_down	Unsigned integer	No	3	retry_down	Valid values between 1 and 10
EA-Site	String	No	San Jose		

DtcMonitorSnmp Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcMonitorSnmp	String	Yes	DtcMonitorSnmp		
name*	String	Yes	snmp_monitor1	name	
port	Unsigned integer		6030	port	Valid values between 1 and 65535
_new_name	String	No		name	
comment	String	No	A DTC SNMP monitor comment	comment	
interval	Unsigned integer	No	10	interval	
timeout	Unsigned integer	No	7	timeout	Valid values between 1 and 15
retry_up	Unsigned integer	No	3	retry_up	Valid values between 1 and 10
retry_down	Unsigned integer	No	3	retry_down	Valid values between 1 and 10

Name	Type	Required	Example	Ibap Name	Comment
version	String	No	V1	version	Valid values are 'V1', 'V2C', and 'V3'
community	String	No	desired_community	community	SNMP community string for an SNMP authentication
oids	List of OIDs for SNMP monitoring	No	.1.3/Comment-1/INTEGER/RANGE/10/1000,.1.2/Comment-2/STRING/EXACT/abc/,...	oids	
user	String	No	user1	user	SNMPv3 user setting
context	String		desired_context	context	SNMPv3 context. Maximum of 1023 characters.
engine_id	String	No	desired_engine_id	engine_id	SNMPv3 engine identifier. Max of 1023 characters.
EA-Site	String	No	San Jose		

DtcARecord Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcARecord	String	Yes	DtcARecord		
ipv4addr*	IPv4 address	Yes	10.0.0.1	address	
_new_ipv4addr	IPv4 address	No		address	
dtc_server*	DTC server	Yes	server1	lbdns_server	DTC server the DTC A record is associated with
ttl	Unsigned integer	No	1024	ttl	
disabled	Boolean	No	false	disabled	
comment	String	No	Sample DTC A record	comment	

DtcAaaaRecord Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcAaaaRecord	String	Yes	DtcAaaaRecord		

Name	Type	Required	Example	Ibap Name	Comment
ipv6addr*	IPv6 address	Yes	2001:db8::1	address	
_new_ipv6addr	IPv6 address	No		address	
dtc_server	DTC server	Yes	server1	dtc_server	DTC Server the DTC AAAA record is associated with
ttl	Unsigned integer	No	1024	ttl	
disabled	Boolean	No	false	disabled	
comment	String	No	Sample DTC AAAA record	comment	

DtcCnameRecord Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcCnameRecord	String	Yes	DtcCnameRecord		
canonical*	String	Yes	dtc.localdomain	canonical_name	Canonical name of the resource
_new_canonical	String	No		canonical_name	
dtc_server*	DTC server	Yes	server1	dtc_server	DTC Server the DTC CNAME record is associated with
ttl	Unsigned integer	No	1024	ttl	
disabled	Boolean	No	false	disabled	
comment	String	No	Sample DTC CNAME record	comment	

DtcNaptrRecord Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-DtcNaptrRecord	String	Yes	DtcNaptrRecord		
dtc_server*	DTC server	Yes	server1	dtc_server	DTC server the DTC NAPTR record is associated with

Name	Type	Required	Example	Ibap Name	Comment
order*	Unsigned integer	Yes	100	order	
_new_order	Unsigned integer	No		order	
preference*	Unsigned integer	Yes	10	preference	
_new_preference	Unsigned integer	No		preference	
replacement*	String	Yes	domain2.com	replacement	The desired replacement value in a Fully-Qualified Domain Name (FQDN) format.
_new_replacement	String	No		replacement	
flags*	String	No	U	flags	Empty value is allowed. Supported values for the flags field are 'U', 'S', 'P', and 'A'.
_new_flags	String	No		flags	
services*	String	No	SIP+D2U	services	Empty value is allowed
_new_services	String	No		services	
regexp*	String	No	!http://my[.](.*)!1!i	regexp	Empty value is allowed
_new_regexp	String	No		services	
ttl	Unsigned integer	No	28800	ttl	
disabled	Boolean	No	false	disabled	
comment	String	No	Sample DTC NAPTR record	comment	

DtcCertificate Header Items

Name	Type	Required	Example	Ibap Name	Comment
Header-Dtccertificate	String	Yes	DtcCertificate		

Name	Type	Required	Example	Ibap Name	Comment
certificate	DTC certificate	No	Object Hash/Issuer/Valid from/Valid to/Subject For example: "702971b9b6bb34468f6006389f53849dff43c78ee415d256f771cdcb58782081025e28362c714d27c9c652967afa64f0edf0c17170b3ace72bd0b3c9eebad7ef/CN=""pannpn"",OU=""Engineering"",O=""Infoblox"",L=""NYC"",ST=""Kerala"",C=""IN""/2017-11-22 18:46:43/2018-11-22 18:46:43/CN=""pannpn"",OU=""Engineering"",O=""Infoblox"",L=""NYC"",ST=""Kerala"",C=""IN""	cert	Object hash is the SHA512 fingerprint of the certificate, that is to be used during the CSV import/ export of dtcMonitorHttp and dtcMonitorSip objects in the client_cert field

DHCP Lease

> **Note**
> Infoblox supports CSV export for DHCP lease, but does not support CSV import.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
header-lease	String	Yes			Example: Lease
agent_id	String				Determined based on the value of "option"
billing_class	String			billing_class	
binding_state	Enum{FREE, BACKUP, ACTIVE, EXPIRED, RELEASED, ABANDONED, RESET}			binding_state	
circuit_id	String	No		agent_circuit_id	This field is required when match_option = CIRCUIT_ID. Example: 11
duid	String	Yes	DUID	duid	Example: 0001
ends	DateTime			ends	Lease end time
fingerprint	String	Yes	DHCP Fingerprints	fingerprint	An array of DHCP fingerprints.
fingerprint-class	String	No	Next Server	next_server	Example: blue.domain.com

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ip_address	IP address	Yes	IP Address	ipv4addr	Example: 10.0.0.11
link_selection	IP address		IP address		Example: 10.0.0.0
mac_address	MAC address	No	MAC Address	mac	This field is required if match_option = MAC_ADDRESS, or if you are importing a reservation. Example: aa:d1:dd:10:ff:02
next_binding_state	Enum{FREE, BACKUP, ACTIVE, EXPIRED, RELEASED, ABANDONED, RESET}			next_binding_state	Example: FREE
protocol	String	Yes	protocol	protocol	Protocol type. This can be IPV4 or IPV6.
remote_id	Integer	No	Remote ID	remote_id_name	Example: 50
server_host_name	String	No			Indicates the name of the server host. Example: infoblox.localdomain
server_id_override	IP address		IP address		Example: 10.0.0.1
starts	DateTime				Lease start time
uid	String	Yes	UID	uid	
username	String		Username	username	

Subscriber Record

Field Name	Data Type	Required (Yes/No)	Usage and Guidelines	Example
ip_addr	IP address	Yes	Can be IPv4 or IPv6	2002::abcd or 20.20.20.20
prefix	Integer	Yes	• For IPv6, prefix must not be greater than 128 • For IPv4, prefix must not be greater than 32	• 32 if ip_addr is 20.20.20.20 • 128 if ip_addr is 2002::abcd

Field Name	Data Type	Required (Yes/No)	Usage and Guidelines	Example
localid	String	Yes	• Must be a valid hexadecimal string if it is MAC_Addr • Can be N/A if not available	a1b1c1d0e0f0 or N/A
ipsd	String	Yes	• Can be N/A if not available • Can be a port number in case of CGNAT support	BLR or NYK
flags	String	Yes	• S for static record • B for black and white list support • SB for both static and blacklist and whitelist support	S or B or SB
alt_ip_addr	IP address	No	• Must belong to a different type than ip_addr • Prefix can be a part of alt_ip_addr. Only 32 and 128 are supported as prefix values	• 2002::abcd if ip_addr is 20.20.20.20 • 20.20.20.20 if ip_addr is 2002::abcd • 2002::abcd/128 • 20.20.20.20/32
subscriber_id	String	No	Must be in the avp_name = avp_value format	• User_Name = Steve • IMEI = 123456 • IMSI = 78910
site	String	No	Site same must be the same as that configured on the **Subscribers Site** tab in Grid Manager	pc_site1
nas_contextual	String	No	• Must be in the avp_name = avp_value format • avp_name must be one among the list of Attribute Value Pairs displayed on the **NAS Contextual Information** list on the **Subscriber Services Properties** tab	• NAS-PORT = 25000 • NAS-IP-Address = 20.20.20.20

Field Name	Data Type	Required (Yes/No)	Usage and Guidelines	Example
ancillaries	String	No	• Must be in the avp_name = avp_value format • avp_name must be one among the list of Attribute Value Pairs displayed on the **Ancillary Fields** list on the **Subscriber Services Properties** tab	Subscriber-Secure-Policy=F0FB or Proxy-All=1
accounting_session_id	String	No	• Must be an alphanumeric string	Client-408123-8817 or Acct-Session-Id=408123-8817
subscriber_secure_policy	String	No	• Must be a valid hexadecimal string • Length must not be greater than 8 because it is a 32-bit binary value • Length of the hexadecimal string must be an even number	0x123456 or 0xABCD or 0x12EFB7 or FFEE4321 or ABCDEF12
parental_control_policy	String	No	• Must be a valid hexadecimal string • Length must not be greater than 32 because it is a 128-bit binary value • Length of the hexadecimal string must be an even number	123FAB78FA987654F000103A0B201245
wpc_category_policy	String	No	• Must be a valid hexadecimal string • Length must not be greater than 32 because it is a 128-bit binary value • Length of the hexadecimal string must be an even number	123FAB78FA987654F000103A0B201245
unknown_category_policy	Boolean	No	Must be either TRUE or FALSE	TRUE or FALSE
dynamic_category_policy	Boolean	No	Must be either TRUE or FALSE	TRUE or FALSE
bwflag	Boolean	No	Must be either TRUE or FALSE	TRUE or FALSE
proxy_all	Boolean	No	Must be either TRUE or FALSE	TRUE or FALSE

Field Name	Data Type	Required (Yes/No)	Usage and Guidelines	Example
black_list	String	No	• bwflag must be enabled to specify a value for this field • Must have a list of valid domain names separated by a comma	facebook.com or Facebook.com,bad.com,verybad.com
white_list	String	No	• bwflag must be enabled to specify a value for this field • Must have a list of valid domain names separated by a comma	google.com or google.com,good.com, verygood.com

Member DHCP Objects

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-MemberDhcp	String	Yes			Identifies the first row as a header row for the member DHCP objects. Example: MemberDhcp
broadcast_address	IP address	No	Broadcast Address		This field applies to the host address. Example: 10.1.0.
domain_name_servers	IP address list	No	Name server		List of domain name servers. Example: "10.2.3.4,11.2.3.4,"
ignore_client_requested_options	Boolean	No			Clears the value of option-55 when you set the value to True. Example: True
pxe_lease_time	Unsigned integer	No	PXE Lease Time	pxe_lease_time	Indicates the lease time for PXE clients in seconds. This field applies to the host address. Example: 43220.
lease_time	Unsigned integer	No	Lease Time	lease_time	Indicates the **lease_time** attribute of a DHCP NAC filter object. This field applies to the host address.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
domain_name	FQDN	No	Domain Name	domain_name	Indicates the domain name. This field applies to the host address.
routers	IP address list	No	Router		Indicates the router IP addresses. This field applies to the host address. Example: “2.0.0.2,1.2.3.4”
option_logic_filters	List of IPv4 logic filter rules		Filter Type/Action		Examples: .com.infoblox.dns.dhcp_mac_filter$mac_filter_name, .com.infoblox.dns.nac_filter$nac_filter_name, .com.infoblox.dns.dhcp_option_filters$opt_filter_name
enable_pxe_lease_time	Boolean	No	Enable PXE Lease Time		If this value is set to **True,** DHCP server uses different lease time for PXE clients. This field applies to the host address. Example: False
deny_bootp	Boolean	No	Deny BOOTP Requests	deny_bootp	When this is set to **True,** it denies BOOTP requests. This field applies to the host address. Example: FALSE
bootfile	String	No	Boot File	bootfile	Indicates the boot file name. Example: bootfile1
bootserver	String	No	Boot Server	bootserver	Indicates the boot server. Example: abc.corp100.com
nextserver	String	No	Next Server	nextserver	Indicates the next server. Example: blue.domain.com

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
enable_thresholds	Boolean	No	Enable DHCP Thresholds	enable_dhcp_thresholds	Enable DHCP thresholds. When you set this field to **True,** you must enter values in the **range_high_water_mark** and **range_low_water_mark** fields. You cannot leave these fields empty. Otherwise, the appliance displays an error message.
range_high_water_mark	Unsigned integer	No	High Water Mark	high_water_mark	Indicates the percentage value for DHCP range usage after which an alarm will be active. When you set **enable_thresholds** to **True,** you must enter values in this field and in the **range_low_water_mark** field. You cannot leave these fields empty. Otherwise, the appliance displays an error message. Example: 80
range_high_water_mark_reset	Unsigned integer	No			Indicates the percentage value for DHCP range usage after which an alarm will be reset. Example: 85
range_low_water_mark	Integer	No	Low Water Mark	low_water_mark	Indicates the percentage value for DHCP range usage below which an alarm will be active. When you set **enable_thresholds** to **True,** you must enter values in this field and in the **range_high_water_mark** field. You cannot leave these fields empty. Otherwise, the appliance displays an error message. Example: 10

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
range_low_water_mark_reset	Unsigned integer	No			Indicates the percentage value for DHCP range usage above which an alarm will be reset. Example: 10
enable_threshold_email_warnings	Boolean	No	Enable Email Warnings	enable_email_warnings	When you use **Merge,** the appliance preserves the existing value in this field. When you use **Overwrite,** you must include a value, either **True** or **False.** Otherwise, the appliance displays an error message. Example: **True**
enable_threshold_snmp_warnings	Boolean	No	Enable SNMP Warnings	enable_snmp_warnings	Send DHCP threshold warnings via SNMP. When you use **Merge,** the appliance preserves the existing value in this field. When you use **Overwrite,** you must include a value, either **True** or **False.** Otherwise, the appliance displays an error message. Example: TRUE
threshold_email_addresses	Email address list	No	Email Addresses	email_list	List of email addresses. Example: "'admin1@infoblox.com', 'admin2@somewhere.com'"
enable_ddns	Boolean	No	Enable DDNS Updates	enable_ddns	Enable or disable dynamic updates via DHCP to DNS server(s). Example: FALSE
enable_option81	Boolean	No	Option 81 Support	ddns_use_option81	Enable or disable option 81 support. Enables **always_update_dns field**. Example: TRUE
always_update_dns	Boolean	No	FQDN Support	ddns_server_always_updates	Updates DNS when the value is **True.** Example: TRUE

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
generate_hostname	Boolean	No	Generate Hostname	override_ddns_generate_ hostname	Generates host name only if not sent by client when the value is **True.** Does not generate host name when the value is **False.**
update_static_leases	Boolean	No	Fixed Address Updates	ddns_update_ fixed_address	When the value is set to **True, DHCP** server will update DNS for client with static IP address.
ddns_ttl	Unsigned integer	No	DDNS Update TTL	ddns_ttl	Indicates the DDNS TTL value in seconds. This is an inherited field. Example: 1200
update_dns_on_lease_renewal	Boolean	No	Lease Renewal Update	override_update_dns_on_lease_renewal	Indicates whether the DHCP server updates DNS when a DHCP lease is renewed. Specify **True** to enable it or **False** to disable it.
preferred_lifetime	Unsigned integer	No	Preferred Lifetime	preferred_lifetime	Indicates whether the **preferred_lifetime** value in the DHCP member is used, instead of the Grid default.Example: 604800
valid_lifetime	Unsigned integer	No	Valid Lifetime	valid_lifetime	Indicates whether the **valid_lifetime** value in the Grid Member DHCP is used, instead of the upper-level default. Example: 43200
name	Grid Member	Yes			The name of the Grid member. Example: member.infoblox.com
is_authoritative	Boolean	No	Authoritative	authority	Set this value to **True** to perform override operation. Example: FALSE

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
recycle_leases	Boolean	No	Lease Deletion	recycle_leases	This field is set to **True** by default. When you set this to **True,** leases in a deleted range are kept until expiration. Ensure that you use the **Overwrite** option if you want to change the value to **False.** Merging data from an import preserves the default value.
ping_count	Unsigned integer	No		ping_count	Indicates the number of DHCP pings. Example: 1
ping_timeout	Unsigned integer	No		ping_timeout	Indicates the timeout (in seconds) for DHCP pings. Example: 1000
enable_leasequery	Boolean	No			When you set this value to **True,** the appliance allows lease query. Example: False
retry_ddns_updates	Boolean	No		retry_ddns_updates	When you set this value to **True,** DHCP server will retry failed DNS updates. Example: False
ddns_retry_interval	Unsigned integer	No		ddns_retry_interval	Indicates the minimum time in minutes between DNS update retries. You must set **ddns_retry_updates** to **True** to modify the **ddns_retry_interval** value in the CSV file.
lease_scavenge_time	Unsigned integer	No			Indicates the Grid level **lease_scavenge_time** value. If the value is -1, which means this lease scavenge will is disabled. The minimum value would be 7 * 24 * 60 * 60 (7 days).

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
enable_fingerprint	Boolean	No			When you set this value to **True,** fingerprint matching for incoming lease requests will be enabled. Example: False.
ipv6_enable_ddns	Boolean	No			Set this value to **True** to override the value at the Grid level. Set the parameter to **False** to inherit the settings from the Grid. Example: False
ipv6_ddns_enable_option_fqdn	Boolean	No			Indicates whether the FQDN option sent by the client is to be used, or if the server can automatically generate the FQDN. Default value is half of lease time. Example: False
ipv6_generate_hostname	Boolean	No			When you set this value to **True,** the hostname is generated if it is not sent by the client. Example: False
ipv6_ddns_domainname	String	No			The DDNS domain name in FQDN format. Example: test_domain.com
ipv6_ddns_ttl	Unsigned integer	No			Indicates the member IPv6 DDNS TTL value in seconds. Example: 0
ipv6_domain_name_servers	IPv6 DNS server list	No			List of IPv6 domain name servers. Example: “2001::1, 2001::2,...”
ipv6_domain_name	String	No			To override the upper-level setting for **ipv6_domain_name**, you must set the value to **True.** Set the parameter to **False** to inherit the upper-level setting for ipv6_domain_name.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ipv6_recycle_leases	Boolean	No			When you set this to **True,** the leases are kept in recycle bin until one week after expiration. When you set this to **False,** the leases are irrecoverably deleted. Example: False
ipv6_server_duid	String	No			DUID (DHCPv6 unique identifier) of the Grid member in string format.
ipv6_enable_retry_updates	Boolean	No			When you set this flag to **True,** the DHCPv6 server retries failed dynamic DNS updates. The default value is **True.** Example: False
ipv6_retry_updates_interval	Unsigned integer	No			Set the retry interval when the member DHCPv6 server makes repeated attempts to send DDNS updates to a DNS server. The default retry interval is five minutes.
ipv6_update_dns_on_lease_ renewal	Boolean	No			Set or retrieve the **ipv6_update_dns_on_lease_renewal** flag. This attribute controls whether the DHCP server updates DNS when an IPv6 DHCP lease is renewed. Specify **True** to enable this feature or **False** to disable it. The default value is **False.**
ddns_domainname	String	No			The DDNS domain name in FQDN format. Example: test_domain.com

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
lease_per_client_settings	String	No			Defines how the server will release the client lease. This field is set to **RELEASE_MATCHING_ID** by default. Valid values are ONE_LEASE_PER_CLIENT, RELEASE_MATCHING_ID and NEVER_RELEASE.
ignore_client_identifier	Boolean	No			Indicates if the client identifier will be ignored for a DHCP shared network object. When you set this to **True,** the client identifier will be ignored. Example: False
OPTION-1	String	No	Custom DHCP Options	options	This field applies to the host address.Example: '255.0.0.0' name implies vendor_class='DHCP' (default)
OPTION-XXXX-200	Option information	No	Custom DHCP Options	options	This field applies to the host address.Example: 'dfdfdfd' name implies vendor_class='XXXX', optioncode/number 200
ADMGRP-XXXX	String	No	Permissions Admin Group/Role	permission	ADMGRP-JimSmith is an example of an admin permission of a specific admin group. Example: RW
v6_leases_scavenging_enabled	Boolean	No	Lease Scavenging	ipv6_enable_lease_scavenge	When you set this to **True,** the DHCPv6 server deletes free, expired, and released leases. The default value is **False. Example:** True

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
v6_leases_scavenging_grace_period	Unsigned Integer	No	Lease Scavenging	ipv6_lease_scavenge_time	Indicates the period (in seconds) for which free, expired, and released DHCPv6 leases remain in the database before they are automatically deleted. Example: 604800

e

Dynamic Update Group

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-ddnsprincipa lgroup	String	Yes			Example: ddnsprincipalgroup
name	String	Yes	Name	name	Example: corp.example.com
comment	String	No	Comment	comment	

Dynamic Update Cluster Group

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-ddnsprincipa lcluster	String	Yes			Example: ddnsprincipalcluster
name	String	Yes	Name	name	Example: cluster1
parent	String	Yes	Dynamic Update Group	clusters	Example: corp.example.com
principals	String	Yes	Principal	principals	Example: WIN-2008-CLUSTER1-NODE1$@CORP.EXAMPLE.COM
comment	String	No	Comment	comment	

Grid DHCP Objects

NIOS does not support add and delete operations.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-GridDhcp	String	Yes			Identifies the first row as a header row for the Grid DHCP objects. Example: GridDhcp
authority	Boolean	No			When you set this to **True,** DHCP server is authoritative for this domain. Example: False
domain_name	String	No			Indicates the domain name.
recycle_leases	Boolean	No	Lease Deletion	recycle_leases	This field is set to **True** by default. When you set this to **True,** leases in a deleted range are kept until expiration. Ensure that you use the **Overwrite** option if you want to change the value to **False.** Merging data from an import preserves the default value.
ignore_dhcp_option_list_request	Boolean	No		ignore_dhcp_option_list _request	When this is set to **True,** it clears the value of option-55. Example: False
enable_pxe_lease_time	Boolean	No	Enable PXE lease time		If this value is set to True, DHCP server uses different lease time for PXE clients. This field applies to the host address. Example: False
pxe_lease_time	Unsigned integer	No	PXE Lease Time	pxe_lease_time	Indicates the lease time for PXE clients in seconds. This field applies to the host address. Example: 43220.
bootfile	String	No	Boot File	bootfile	Indicates the boot file name. Example: bootfile1
bootserver	String	No	Boot Server	bootserver	Indicates the boot server. Example: abc.corp100.com

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
nextserver	String	No	Next Server	nextserver	Indicates the next server. Example: blue.domain.com
deny_bootp	Boolean	No	Deny BOOTP Requests	deny_bootp	When this is set to True, it denies BOOTP requests. This field applies to the host address. Example: FALSE
enable_ddns	Boolean	No	Enable DDNS Updates	enable_ddns	Enable or disable dynamic updates via DHCP to DNS server(s). Example: FALSE
ddns_use_option81	Boolean	No	Option 81 Support	ddns_use_option81	Enable or disable option 81 support. Enables **always_update_dns field**. Example: TRUE
ddns_server_always_updates	Boolean	No		ddns_server_always_updates	When you set this to True, DHCP server will always update DNS.
ddns_generate_hostname	Boolean	No	Generate Hostname	ddns_generate_hostname	When you set this to True, DHCP server will generate a hostname for DNS updates if not sent by client. Example: TRUE
ddns_ttl	Unsigned integer	No	DDNS Update TTL	ddns_ttl	Indicates the DDNS TTL value in seconds. This is an inherited field. Example: 1200
retry_ddns_updates	Boolean	No		retry_ddns_updates	When you set this value to True, DHCP server will retry failed DNS updates. Example: False
ddns_retry_interval	Unsigned integer	No		ddns_retry_interval	Indicates the minimum time in minutes between DNS update retries. You must set **ddns_retry_updates** to **True** to modify the **ddns_retry_interval** value in the CSV file.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
enable_dhcp_thresholds	Boolean	No	Enable DHCP Thresholds	enable_dhcp_thresholds	Enable DHCP thresholds. When you set this field to **True,** you must enter values in the **range_high_water_mark** and **range_low_water_mark** fields. You cannot leave those fields empty. Otherwise, the appliance generates an error.
high_water_mark	Unsigned integer	No	High Water Mark	high_water_mark	Indicates the percentage value for DHCP range usage after which an alarm will be active. When you set **enable_thresholds** to **True,** you must enter values in this field and in the **range_low_water_mark** field. You cannot leave these fields empty. Otherwise, the appliance displays an error message. Example: 80
high_water_mark_reset	Unsigned integer	No			Indicates the percentage value for DHCP range usage after which an alarm will be reset. Example: 85
low_water_mark	Integer	No	Low Water Mark	low_water_mark	Indicates the percentage value for DHCP range usage below which an alarm will be active. When you set **enable_thresholds** to **True,** you must enter values in this field and in the **range_high_water_mark** field. You cannot leave these fields empty. Otherwise, the appliance displays an error message. Example: 10
low_water_mark_reset	Unsigned integer	No			Indicates the percentage value for DHCP range usage above which an alarm will be reset. Example: 10

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
enable_email_warnings	Boolean	No		enable_email_warnings	Enable to send DHCP threshold warnings via email. Example: False
enable_snmp_warnings	Boolean	No			Enable to send DHCP threshold warnings via SNMP. Example: False
email_list	Email address list	No			List of email addresses. Example: "'admin1@infoblox.com', 'admin2@somewhere.com',"
ipv6_domain_name_servers	IPv6 DNS server list	No			List of IPv6 domain name servers. Example: “2001::1, 2001::2,...”
ping_count	Unsigned integer	No		ping_count	Indicates the number of DHCP pings. Example: 1
ping_timeout	Unsigned integer	No		ping_timeout	Indicates the timeout (in seconds) for DHCP pings. Example: 1000
capture_hostname	Boolean	No			When you set this value to **True,** the appliance captures host name and lease time when assigning fixed addresses.
enable_leasequery	Boolean	No			When you set this value to **True,** the appliance allows lease query. Example: False
update_dns_on_lease_renewal	Boolean	No	Lease Renewal Update	override_update_dns_on_lease_renewal	Indicates whether the DHCP server updates DNS when a DHCP lease is renewed. Specify True to enable it or False to disable it.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ipv6_update_dns_on_lease_renewal	Boolean	No			Set or retrieve the **ipv6_update_dns_on_lease_renewal** flag. This attribute controls whether the DHCP server updates DNS when an IPv6 DHCP lease is renewed. Specify **True** to enable this feature or **False** to disable it. The default value is **False.**
txt_record_handling	String	No			Specifies how DHCP should treat TXT records while performing DNS update. Example: ISC
lease_scavenge_time	Unsigned integer	No			Indicates the Grid level lease_scavenge_time value. If the value is -1, which means this lease scavenge will is disabled. The minimum value would be 7 * 24 * 60 * 60 (7 days).
failover_port	Unsigned integer	No			Indicates the failover port number. The default value is 647. The port number must be between 1 and 63999.
enable_fingerprint	Boolean	No			When you set this value to **True,** fingerprint matching for incoming lease requests will be enabled. Example: False
ipv6_enable_ddns	Boolean	No			Set this value to **True** to override the value at the Grid level. Set the parameter to **False** to inherit the settings from the Grid.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ipv6_ddns_enable_option_fqdn	Boolean	No			Indicates whether the FQDN option sent by the client is to be used, or if the server can automatically generate the FQDN. Default value is half of lease time. Example: False
ipv6_ddns_server_always_updates	Boolean	No			Specify True to enable this feature or False to disable it. The default value is False. You must set this to False to update DNS only if requested by the client.
ipv6_generate_hostname	Boolean	No			When you set this value to True, the hostname is generated if it is not sent by the client. Example: False
ipv6_ddns_domainname	String	No			The DDNS domain name in FQDN format. Example: test_domain.com
ipv6_ddns_ttl	Unsigned integer	No			Indicates the member IPv6 DDNS TTL value in seconds. Example: 0
Preferred_lifetime	Integer	No	Preferred Lifetime	preferred_lifetime	Indicates whether the preferred_lifetime value in the DHCP member is used, instead of the Grid default. Example: 6
valid_lifetime	Unsigned integer	No	Valid Lifetime	valid_lifetime	Indicates whether the valid_lifetime value in the Grid Member DHCP is used, instead of the upper-level default.Example: 43200
ipv6_domain_name	String	No			
ipv6_txt_record_handling	String	No			Example: ISC

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ipv6_capture_hostname	Boolean	No			Example: False
ipv6_recycle_leases	Boolean	No			When you set this to True, the leases are kept in recycle bin until one week after expiration. When you set this to False, the leases are irrecoverably deleted. Example: False
ipv6_enable_retry_updates	Boolean	No			When you set this flag to True, the DHCPv6 server retries failed dynamic DNS updates. The default value is True. Example: False
ipv6_retry_updates_interval	Unsigned integer	No			Set the retry interval when the member DHCPv6 server makes repeated attempts to send DDNS updates to a DNS server. The default retry interval is five minutes.
ddns_domainname	String	No	DDNS Domain Name	ddns_domainname	The DDNS domain name in FQDN format. Example: ddns.corp100.com
lease_per_client_settings	String	No			Defines how the server will release the client lease. This field is set to **RELEASE_MATCHING_ID** by default. Valid values are ONE_LEASE_PER_CLIENT, RELEASE_MATCHING_ID and NEVER_RELEASE.
ignore_client_identifier	Boolean	No			Indicates if the client identifier will be ignored for a DHCP shared network object. When you set this to **True,** the client identifier will be ignored. Example: False

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
disable_all_nac_filters	Boolean	No			When you set this value to **True,** NAC filters will be disabled on the Infoblox Grid. Example: False
format_log_option_82	String	No			Select the logging format to either hexadecimal or a decoded string which is human readable.
OPTION-1	String	No	Custom DHCP Options	options	This field applies to the host address. Example: '255.0.0.0' name implies vendor_class='DHCP' (default)
OPTION-XXXX-200	Option information	No	Custom DHCP Options	options	This field applies to the host address. Example: 'dfdfdfd' name implies vendor_class='XXXX', optioncode/number 200
v6_leases_scavenging_enabled	Boolean	No	Lease Scavenging	ipv6_enable_lease_scavenge	When you set this to **True,** the DHCPv6 server deletes free, expired, and released leases. The default value is **False.** Example: True
v6_leases_scavenging_grace_period	Unsigned integer	No	Lease Scavenging	ipv6_lease_scavenge_time	Indicates the period (in seconds) for which free, expired, and released DHCPv6 leases remain in the database before they are automatically deleted. Example: 604800

Member DNS Objects

NIOS does not support add and delete operations.

> ⚠ Note
>
> When you export member DNS properties, the CSV file might include the "unbound_logging_level" field with "OPERATIONS" as the value. Although this field is only applicable to the IB-4030-10GE appliance and might not apply to your Grid members, you can still perform CSV import using the CSV export file that contains this field without any issues.

Field Name	Data Type Required Associated (Yes/No) GUI Field	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-MemberDns	String	Yes			Identifies the first row as a header row for the member DNS objects. Example: MemberDns
parent	FQDN	Yes			Indicates the parent object. Example: member1.infoblox.com
dns_over_mgmt	Boolean	No			Enable or disable DNS services on the MGMT port. Example: False
dns_over_lan2	Boolean	No			Enable or disable DNS services on the LAN2 port. Example: False
minimal_response	Boolean	No			Enable or disable minimal response of the DNS server. Example: False
forwarders_only	Boolean	No	Use Forwarders Only		Enable use of forwarders only. Example: False
allow_forwarder	IP address list	No			Indicates the list of forwarders.
member_view_nats	integer	No			Indicates the list of views with NAT address used for creating glue records for the view. Example: dns_view1/ INTERFACE/10.10.10.
enable_notify_source_port	integer	No			Enable or disable **notify_source_port**. Example: False
notify_source_port	Unsigned integer	No			Indicates the notify source port number.
enable_query_source_port	Boolean	No			Enable or disable **query_source_port.** Example: False
query_source_port	Unsigned integer	No			Indicates the query source port number.
lame_ttl	Unsigned integer	No			Indicates the lame TTL value in seconds. Example: 600

Field Name	Data Type Required Associated (Yes/No) GUI Field	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
auto_sort_views	Boolean	No			Enable or disable DNS views auto-sort. Example: False
member_views	List of Member views	No			Indicates the list of member views. Example: dns_view1, dns_view2,..
allow_transfer	ACL	No	Allow zone transfers to	allow_transfer	List of **address_tsig_ac** items.Note that you can import the name of a named ACL in this field. Example: NACL1or "12.0.0.12/Deny,1234::/64/Allow".
excluded_servers	IP address list	No			List of excluded servers for zone transfers.
zone_transfer_format_option	String	No			Indicates the zone transfer format.
recursion_enabled	Boolean No				Indicates the flag to respond to recursive queries. Example: False
allow_query	ACL	No	Allow queries from	allow_query	List of **address_tsig_ac** items. It can be an IP address, a network entry, Any or a TSIG-/permission. If the first value is not **Any** or **TSIG**-, it is assumed to be an IP address or a network entry. Example: 10.0.0.10/Allow, 11.0.0.0/16/Deny, TSIG-foo/xyz/ Allow. It can also be a named ACL. Example: NACL1.
allow_recursive_query	ACL	No			List of **address_tsig_ac** items. It can be an IP address, a network entry, Any or a TSIG-/permission. If the first value is not **Any** or **TSIG**-, it is assumed to be an IP address or a network entry. Example:"10.0.0.10/ Allow,11.0.0.0/16/Deny,TSIG-foo/ xyz/Allow,.." or it can be a named ACL. Example: "NACL1"
limit_concurrent_recursive_clients	Boolean	No			Enable limit of concurrent recursive client number. Example: False
concurrent_recursive_clients	Unsigned integer	No			Indicates the number of clients allowed to perform concurrent queries. Example: 1000

Field Name	Data Type Required Associated (Yes/No) GUI Field	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
allow_update	ACL	No	Allow updates from	allow_update	List of **address_tsig_ac** items. It can be an IP address, a network entry, Any or a TSIG-/permission. If the first value is not **Any** or **TSIG**-, it is assumed to be an IP address or a network entry. Example: 10.0.0.10/Allow, 11.0.0.0/16/Deny, TSIG-foo/xyz/ Allow. It can also be a named ACL. Example: NACL1.
allow_gss_tsig_zone_updates	Boolean	No			Allow GSS-TSIG clients to perform zone updates. Example: False
allow_update_forwarding	Boolean	No	Allow updates from	forward_to	Enable update forwarding for secondary zones. Example: False
enable_custom_root_server	Boolean	No			Indicates the flag to enable custom root servers. Example: False
root_name_servers	Root nameserver list	No			Indicates the list of custom root servers. Example: rnm1.test.com/ 1.1.1.1/,. The appliance displays an error message if the **root_name_servers** column has an empty value when the **enable_custom_root_server** field is set to **True** in the imported CSV file.
enable_blackhole	Boolean	No			Enable blackhole setting. Example: False
blackhole	ACL	No			Indicates the list of banned addresses. Example: "NACL" or "12.0.0.12/Deny,1234::/64/ Allow ,.."
notify_delay	Unsigned integer	No		notify_delay	This field specifies the seconds of delay the notify messages are sent to the secondaries. The valid value is between 5 and 86400 seconds. Example: 5
enable_nxdomain_redirect	Boolean	No			Enable intercept and redirect nxdomain responses. Example: False
nxdomain_redirect_addresses	IP address list	No			Indicates the list of IPv4 addresses to redirect to for nxdomain responses. Example: "1.1.1.1,2.2.2.2,..."

Field Name	Data Type Required Associated (Yes/No) GUI Field	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
nxdomain_redirect_ttl	Unsigned integer	No			Indicates the NXDOMAIN redirect ttl in seconds. Example: 60
nxdomain_log_query	Boolean	No			If you set this to **True**, the appliance logs the NXDOMAIN redirections. Example: False
nxdomain_rulesets	Pattern list	No			Indicates the list of ruleset objects that are used for NXDOMAIN redirection. Example: pattern1/MODIFY, pattern2/PASS, ...
enable_blacklist	Boolean	No		enable_blacklist	Enable or disable blacklisting at the Grid level. Example: False
blacklist_redirect_addresses	IP address list	No		blacklist_redirect_addresses	Indicates the list of IPv4 addresses addresses to which the blacklisted queries are redirected. Example: 1.1.1.1,2.2.2.2
blacklist_action	String	No	Action	blacklist_action	Indicates the action to be performed when a domain name matches the pattern defined in an assigned rule. Example: Refuse
blacklist_redirect_ttl	Unsigned integer	No			Indicates the TTL value of synthetic DNS responses resulted by blacklisted queries. Example: 60
blacklist_log_query	Boolean	No		blacklist_log_query	Indicates if blacklisted queries must be logged. Example: False
blacklist_rulesets	List of domain names	No		blacklist_rulesets	Indicates the ruleset objects that are blacklisted at the Grid level. Example: list1.com, list2.com, ...
enable_dns64	Boolean	No			Enable DNS64 synthesis. Example: False
dns64_groups	List of Dns64 groups	No			List of SynthesisGroup objects. Example: dns64_groupA, dns64_groupB, ...

Field Name	Data Type Required Associated (Yes/No) GUI Field	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
max_cached_lifetime	Unsigned integer	No			Indicates the maximum time in seconds a DNS response can be stored in the hardware acceleration cache. You can specify unsigned integer between 60 and 86400. Default value is 86400.
dns_over_v6_mgmt	Boolean	No			Enable or disable DNS services on the IPv6 MGMT port. Example: False
dns_over_v6_lan2	Boolean	No			Enable or disable DNS services on the IPv6 LAN2 port. Example: False
filter_aaaa	String	No			Indicates the type of AAAA filtering for this Grid DNS object. The default value is **No**. Example: Yes
filter_aaaa_list	ACL	No			Indicates the list of IPv4 addresses and networks from which queries are received. Note that the AAAA filtering is applied to these addresses. Example: "12.0.0.12/Deny,13.0.0.0/8/ Allow,.." or "NACL1"
dns_over_v6_lan	Boolean	No			Example: False
copy_xfer_to_notify	Boolean	No			Enable or disable copying of the allowed IP addresses from zone transfer list into also-notify statement in named.conf. Example: False
transfers_in	Unsigned integer	No			Indicates the number of maximum concurrent transfers for the Grid. You can specify unsigned integers between 10 and 100. The default value is 10. Example: 10
transfers_out	Unsigned integer	No			Indicates the number of maximum outbound concurrent zone transfers for the Grid. You can specify unsigned integers between 10 and 100. The default value is 10. Example: 10

Field Name	Data Type Required Associated (Yes/No) GUI Field	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
transfers_per_ns	Unsigned integer	No			Indicates the number of maximum concurrent transfers per member for the Grid. You can specify unsigned integers between two and 100. The default value is two. Example: 2
serial_query_rate	Unsigned integer	No			Indicates the number of maximum concurrent SOA queries per second for the Grid. You can specify unsigned integers between 20 and 100. The default value is 20. Example: 20
max_cache_ttl	Unsigned integer	No			Indicates the maximum time (in seconds) for which the server will cache positive answers. The default value is 604800.
max_ncache_ttl	Unsigned integer	No			Indicates the maximum time (in seconds) for which the server will cache negative (NXDOMAIN) responses. The default value is 10800. The maximum allowed value is 604800.
disable_edns	Boolean	No			Enable or disable EDNS0 support for queries that require recursive resolution. The default value is **False.**
query_rewrite_enabled	Boolean	No			When this is set to **True,** query rewrite is enabled at the Grid level. Example: False
ADMGRP-XXXX	String	No	Permissions Admin Group/ Role	permission	ADMGRP-JimSmith is an example of an admin permission of a specific admin group. Example: RW
rpz_drop_ip_rule_enabled	Boolean	No	Ignore RPZ-IP triggers with too small prefix lengths		When this is set to **True,** DNS server ignores RPZ-IP rules with prefix lengths that are less than the specified prefix length limit. Example: TRUE
rpz_drop_ip_rule_min_prefix_ length_ipv4	Unsigned Integer	No	Minimum IPv4 Prefix Length		Indicates the minimum IPv4 prefix length for RPZ-IP triggers. The default value is 29.
rpz_drop_ip_rule_min_prefix_ length_ipv6	Unsigned Integer	No	Maximum IPv4 Prefix Length		Indicates the minimum IPv6 prefix length for RPZ-IP triggers. The default value is 112.

Field Name	Data Type Required Associated (Yes/No) GUI Field	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
atc_forwarding_enable	Boolean	No	Enable Recursive Queries Forwarding to BloxOne Threat Defense Cloud		Enable or disable the forwarding of DNS recursive queries to BloxOne Threat Defense Cloud.
atc_forwarding_access_key	String	No	Access Key		API Access Key for the current member.
atc_forwarding_resolver_address	IP Address	No	DFP Name Server		IP address of the local DNS resolver.
atc_forwarding_forward_first	Boolean	No	Fallback to a default resolver if ATC does not respond		Option to resolve the DNS query if there is any resolution failure in the BloxOne Threat Defense Cloud.

Stub Zone

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-StubZone	String	Yes			Identifies the first row as a header row for the stub zones. Example: StubZone
fqdn	FQDN	Yes	Name	zone	This field combines the AAAA record name and the zone name to form the FQDN. Example: *aaaa1.corp100.com*
view	String	No	DNS View	views	If no view is specified, the default view is used. Example: Default
zone_format	String	Yes	Type		Valid values are **FORWARD**, **IPV4**,and **IPV6**.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
prefix	String	No	RFC 2317 Prefix	prefix	Prefix is used for reverse-mapping RFC2317 zones only. If you include a prefix in a forward-mapping zone, the appliance ignores the prefix. No error message is generated.
disabled	Boolean	No	Disable	disable	Enable or disable the stub zone. Example: FALSE
comment	String	No	Comment	comment	Example: This is a stub zone.
disable_forwarding	Boolean	No	Do not use forwarders	disable_forwarding	Enable or disable forwarding. Example: False
stub_from	Master Nameserver list	Yes			List of external stub servers. Example: "*nm1.test.com/2.2.2.2,...*"
stub_members	Member server list	No			List of stub Grid members.
ns_group	String	No		ns_group	Stub member name server group name. Example: stub_ns_group1.
ns_group_external	String	No		external_ns_group	Forward/Stub server name server group name. Example: ext_ns_group1.
EA-Site	String	No	Extensible attribute	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. Example: California.
EA-Users	List	No	Extensible attribute	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: ['Annie', 'John'].

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
ADMGRP-XXXX	String	No	Permissions Admin Group/Role	permission	ADMGRP-JimSmith is an example of an admin permission of a specific admin group. Example: RW

Authoritative Name Server Group

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-NsGroup	String	Yes			Identifies the first row as a header row for the authoritative name server group objects. Example: AuthoritativeNsGroup.
group_name	String	Yes			Indicates the name of the authoritative name server group. Example: ns_group1
_new_group_name	String	No			You can overwrite the group name.
grid_primaries	Grid member list and stealth state	No	Grid Primary/ Stealth	primary stealth	List of primary servers of the name server group. The valid format is: "hostname/stealth" Example: "foo.localadmin/False,*corp1.com/True*,..."
external_primaries	Server list	No	External Primary	primary	List of external primary servers. The valid format is: name/ip/stealth/use_2x_tsig/use_tsig/tsig_name/tsig_key. Only name and IP address are required. If **stealth** is not specified, **use_2x_tsig** and **use_tsig** are used and the default value is set to **False** . Example: "*ext1.test.com/1.1.1.1/FALSE*,.."

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
external_secondaries	Server list	No	External Secondary	secondaries	List of external secondary servers. The valid format is: name/ip/stealth/ use_2x_tsig/use_tsig/ tsig_ name/tsig_key. Only name and IP address are required. Default values are assumed for **stealth**, **use_2x_tsig** and **use_tsig**. If either **use_2x_tsig** or **use_tsig** is **True**, then **tsig_name** and **tsig_key** are required. Example: "*sec1.com/1.1.1.1/ FALSE/FALSE/ FALSE/foo/* sdfsdf86ew,.."
grid_secondaries	Member server list	No	Grid Secondary	secondaries	List of Grid secondary servers. The valid format is: hostname/stealth/ lead/grid_replicate. Only hostname is required. The appliance assumes default value for **stealth.** Values are not specified for **lead** and **grid_replicate** fields. Example: "member1.localdomain/FALSE/TRUE/ FALSE,"
is_grid_default	Boolean	No			Set this to **True** to set this name server group as Grid default, set to **False** to unset this name server group as Grid default. Example: False
comment	String	No	Comment	comment	Example: This is a authoritative name server group.
EA-Site	String	No	Extensible attribute	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. Example: California.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
EA-Users	String	No	Extensible attribute	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: John.

Forward-Mapping Zone

Note that to delete a parent zone and the associated subzones, you must add **remove-subzones** column to the CSV export file and set the value to **True**. If you want to delete only the parent zone, then you must set this column value to **False**.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
Header-ForwardZone	String	Yes			Identifies the first row as a header row for the forward zones. Example: ForwardZone
fqdn	FQDN	Yes	Name	zone	This field combines the AAAA record name and the zone name to form the FQDN. Example: aaaa1.corp100.com
view	String	No	DNS View	views	If no view is specified, the default view is used. Example: Default
zone_format	String	Yes	Type		Valid values are **FORWARD**, **IPV4**,and **IPV6**.
prefix	String	No	RFC 2317 Prefix	prefix	Prefix is used for reverse-mapping RFC2317 zones only. If you include a prefix in a forward-mapping zone, the appliance ignores the prefix. No error message is generated.
disabled	Boolean	No	Disable	disable	Enable or disable the forward zone. Example: FALSE
comment	String	No	Comment	comment	Example: This is a Forward zone.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
forward_to	Zone forwarder list	Yes	Default Zone Forwarders		List of forwarders for a Forward type zone. Example: *fwd1.test.com/ 1.1.1.1/,...*
forwarding_servers	Forwarding members list	No	Members		List of forwarding servers. Example: "infoblox.localdomain ,..."
forwarders_only	Boolean	No	Use Forwarders Only		Enable use of forwarders only. Example: False
ns_group	String	No		ns_group	Forwarding member name server group name. Example: fwd_ns_group1.
ns_group_external	String	No		external_ns_group	Forward/Stub server name server group name. Example: ext_ns_group1.
EA-Site	String	No	Extensible attribute	extensible_attributes	EA-Site is an example of a predefined extensible attribute. You can add other predefined attributes to the data file. Example: California.
EA-Users	List	No	Extensible attribute	extensible_attributes	EA-Users is an example of a user defined attribute. You can add other user defined attributes to the data file. Example: ['Annie', 'John'].
ADMGRP-XXXX	String	No	Permissions Admin Group/Role	permission	ADMGRP-JimSmith is an example of an admin permission of a specific admin group. Example: RW
disable_ns_generation	Boolean	No	Disable auto-generation of NS records in parent authoritative zone		Determines whether auto-generation of NS records in the parent zone is disabled or not. When this is set to False, the auto-generation is enabled.

VLAN Objects

The list of VLAN objects are:

- *VLAN View*
- *VLAN Range*
- *VLAN Object*

> **Notes**
>
> - Scheduled operations (create/update/delete) are not supported for new VLAN objects. However, scheduled assignment of VLAN objects to IPv4/IPv6 Networks is supported.
> - CSV export operations for VLAN objects are supported only from Grid Manager and not from WAPI.

VLAN View

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
name	String	Yes	Name	name	Name of the VLAN view. Example: VLAN_view1
start_vlan_id	Unsigned Integer	Yes	Start VLAN ID	start_vlan_id	Start ID of the VLAN view. The default value is 1.
end_vlan_id	Unsigned Integer	Yes	End VLAN ID	end_vlan_id	End ID of the VLAN view. The default value is 4094.
comment	String	No	Comment	comment	A descriptive comment for the VLAN view.
allow_range_overlapping	Boolean	No	Allow Range Overlapping	allow_range_overlapping	When set to **true**, the VLAN ranges under the VLAN view can have overlapping IDs. By default, the value is set to **false**.

VLAN Range

VLAN view is an import dependency for VLAN range. Ensure that VLAN view data is available in the CSV file while importing data for VLAN range.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
vlan_view	Object Reference	Yes	VLAN View	vlan_view	Reference to the parent VLAN view to which the VLAN range belongs.
name	String	Yes	VLAN Range Name	name	Name of the VLAN range. Example: VLAN_range3
start_vlan_id	Unsigned Integer	Yes	Start VLAN ID	start_vlan_id	Start ID of the VLAN range.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
end_vlan_id	Unsigned Integer	Yes	End VLAN ID	end_vlan_id	End ID of the VLAN range.
comment	String	No	Comment	comment	A descriptive comment for the VLAN range.

VLAN Object

VLAN view and VLAN range are import dependencies for a VLAN object depending on whether the VLAN object has been added directly to the VLAN view or as part of a VLAN range. Ensure that the relevant VLAN view or VLAN range data is available in the CSV file while importing data for a VLAN object.

Field Name	Data Type	Required (Yes/No)	Associated GUI Field	Associated PAPI Method	Usage and Guidelines
parent	Object Reference	Yes	VLAN Parent	parent	Reference to the parent VLAN view or VLAN range to which the VLAN object belongs.
name	String	Yes	VLAN Name	name	Name of the VLAN object. Example: VLAN30
id	Unsigned Integer	Yes	VLAN ID	id	VLAN ID value.
comment	String	No	Comment	comment	A descriptive comment for the VLAN object.
reserved	Boolean	No	Reserved	reserved	When set to **true**, the VLAN object can only be assigned manually to the IPAM object. By default, it is set to **false**.
description	String	No	Description	description	A description for the VLAN object. The description may be used for longer VLAN names.
contact	String	No	Contact	contact	Contact information for the person or team managing or using the VLAN object.
department	String	No	Department	department	Department where the VLAN object is used.

Importing Multiple Action CSV file

When you import data, you can include multiple actions, such as add, modify, and delete, in one single CSV file. The multiple action CSV import file contains multiple types of objects with its headers and data rows listed in the order of their dependency hierarchy.

The CSV import option supports insert, merge/override and delete operations. To combine these operations together in a single CSV file, you must specify an optional **IMPORT-ACTION** column in the CSV import file. The column value for each data row describes the type of action that the appliance supports for the respective row. The action values include the following: **I** (Insert), **M** (Merge), **O** (Override), **IM** (Insert + Merge), **IO** (Insert + Override), **D** (Delete).

Note that you must specify appropriate values in the **IMPORT-ACTION** column for each row to perform a multiple action CSV import. The appliance performs the respective operation when you specify **I**, **M**, **O**, **D**, in the **IMPORT-ACTION** column. When you specify **IM** or **IO**, the appliance first checks if the corresponding object exists. If it exists, the appliance performs the merge or override operation accordingly. If the object does not exist, you must first perform the insert operation to add the data.

> **Note**
>
> When you choose the **Custom** option, the appliance verifies whether the **IMPORT-ACTION** column is present in the imported CSV file. If the **IMPORT-ACTION** column is empty for a data row, then that data row is considered invalid and the appliance displays an error message. If you choose **Continue on Error**, then the CSV import process continues.

In the list of *CSV Supported Objects for Export/Import*, the objects are listed in the order of their dependency. The least dependent objects are displayed at the top.

List of all CSV Supported Objects for Export/Import

Object Category	Export/import objects in the order of dependency	Actions that are not supported I - Insert; D - Delete
Global	NamedACL	
	NamedACL item	
	Network view	
	Upgrade group	
	DNS64 Synthesis Group	
	Rulesets	
	Blacklist Rule	
	NXDOMAIN Rule	
	DiscoverySnmpv3Credentials	
	DiscoverySnmpv1v2Credentials	
	DiscoveryCliCredentials	
	SubGridNetwork	D
	FtpUser	
	RirOrganization	
	IpBlockGroup	
	IpBlock	
	Member	I, D

Object Category	Export/import objects in the order of dependency	Actions that are not supported I - Insert; D - Delete
DNS Objects	GridDns	I, D
	View	
	MemberDns	I, D
	NS Group	
	Authoritative Zone	
	Delegated Zone	
	Bulk Host	
	IPv4 Host Address	
	Host Record	
	IPv6 Host Address	
	A Record	
	AAAA Record	
	CNAME Record	
	DNAME Record	
	MX Record	
	NAPTR Record	
	NS Record	
	PTR Record	
	TXT Record	
	SRV Record	
	Forward Zone	
	Stub Zone	

Object Category	Export/import objects in the order of dependency	Actions that are not supported I - Insert; D - Delete
	Response Policy Zone	
	Response Policy Arecord	
	Response Policy AAAArecord	
	Response Policy IP Arecord	
	Response Policy IP AAAArecord	
	Response Policy MXrecord	
	Response Policy NAPTRrecord	
	Response Policy PTRrecord	
	Response Policy SRVrecord	
	Response Policy TXTrecord	
	Response Policy CNAMErecord	
	Response Policy IP Address	
	Response Policy Client IP Address	
	Response Policy IP Address CNAME	
	Response Policy Client IP Address CNAME	
DHCP Objects	GridDhcp	I,D
	MemberDhcp	I,D
	Network Container	
	IPv4 Network	
	IPv6 Network Container	
	IPv6 Network	
	DHCP Failover Associations	

Object Category	Export/import objects in the order of dependency	Actions that are not supported I - Insert; D - Delete
	IPv4 Shared Network	
	IPv6 Shared Network	
	IPv4 Reserved Range	
	IPv6 Reserved Range	
	IPv4 Fixed Address/Reservation	
	IPv6 Fixed Address

	IPv4 Option Definition	
	IPv6 Option Space	
	IPv6 Option Definition	
	IPv4 DHCP Range	
	IPv6 DHCP Range	
	DHCP MAC Filter	
	MAC Filter Address Item	
	Option Filter	
	DHCP Fingerprint	
	DHCP Fingerprint Filter	
	Relay Agent Filter	
	NAC Filter	
	Lease	

Supported Expressions for Search Parameters

Regular expressions are text strings that you use to describe search patterns. You can use the following special characters to define regular expressions for search parameters.

Special character	Purpose	Example	Meaning
()	Defines the scope and precedence of the operator	gr(a|e)y	Matches “gray” or “grey”.
|	Matches either the regular expression before or after the vertical bar	a|c	Matches “a” or “c”
.	Matches any single character	.at	Matches any text string ending with “at”, such as “hat”, “cat”, and “bat”.
*	Matches the previous regular expression zero or more times	a*bc	Matches zero or multiple occurrences of “a” followed by “bc”, such as “bc”, “abc”, “aabc”, “aaabc”, and so on.
+	Matches the previous regular expression one or more times	a+bc	Matches one or more occurrences of “a”, followed by “bc”, such as “abc”, “aabc”, “aaabc”, and so on.
?	Matches the previous regular expression zero or one time	a?bc	Matches zero or one occurrence of “a”, followed by “bc”, such as “bc” or “abc”.
^	Matches the beginning of a text string	^c	Matches any string beginning with “c”, such as “cat”.
$	Matches the end of a text string	com$	Matches any string ending with “com”, such as “Infoblox.com”.
[ ]	Matches any character specified in the brackets	[03] [abcd] [15a-d]	Matches “0” or “3”. Matches “a”, “b”, “c”, or “d”. Matches “1”, “5”, “a”, “b”, “c”, or “d”.
[n-n]	Matches single characters contained in the specified range, including the start and end points	[0-3] [a-f]	Matches 0, 1, 2, and 3. Matches a, b, c, d, e, and f.
\{m,n\}	Matches the preceding expression at least m but not more than n times.	a\{3,5\}	Matches “aaa”, “aaaa”, and “aaaaa”.

Note

You can change a special character—such as the period (.), asterisk (*), plus sign (+), or question mark (?) —
into a literal character by prefixing it with a backslash (\ ). For example, to specify a literal period, asterisk, plus sign, or question mark, use the characters within the following parentheses: (\.) , (*), (\+), (\?), (\^), (\$).
